[illegible]: Under normal circumstances, a woman's uterus sheds a limited amount of blood during each menstrual period (around 80 ml). Bleeding that occurs erratically or excessive menstrual bleeding is called abnormal uterine bleeding (AUB). The causes of AUB are many and varied. Initial investigations include transvaginal ultrasound and histopathologic assessment of the endometrium. Objective of this study was to evaluation of endometrial thickness with trans-vaginal ultrasound and its correlation with histopathology by dilatation and curettage in abnormal uterine bleeding. To determine the efficacy of transvaginal ultrasound in evaluating the endometrial thickness. To correlate the endometrial thickness by transvaginal ultrasound with endometrial histopathology in women with AUB.

M[illegible]: It is a retrospective observational study. All reproductive and perimenopausal age group women who underwent dilatation and curettage for abnormal uterine bleeding during the period June 2014-June 2016 was taken and analyzed and correlated with their endometrial thickness measured with Transvaginal ultrasound.

[illegible]: Around 478 patients who underwent endometrial sampling over a period of two years were analyzed. Maximum number of patients were in the fourth decade and the overweight category 36.6%. Proliferative endometrium was the most common histopathologic picture (44.76%). Detection of precancerous lesions were-5.87% and endometrial cancer was 1.05%.

[illegible]: An ET of 8 mm and above gave 100% sensitivity and negative predictive value for precancerous and cancerous lesions.

[illegible]: Abnormal uterine bleeding, Dilatation and curettage, Endometrial hyperplasia and cancer, Endometrial thickness, Transvaginal ultrasound

[illegible]

Abnormal uterine bleeding is one of the most common gynecological problems in patients approaching the outpatient clinics in the country. These complaints definitely affect the quality of life of the patient. The etiology of AUB varies with the age group of the patient. There is the PALM COEIN classification for AUB by FIGO.[1] There are many diagnostic modalities for evaluating endometrial pathologies in women who have AUB. Transvaginal sonogram (TVS) has permitted the use of higher frequency ultrasound waves at greater proximity of the uterus. It is a relatively cheap and non-invasive diagnostic modality for studying the endometrial pattern and its thickness and at the same time to exclude organic pathology in case of AUB while dilatation and curettage gives us a definitive histopathologic picture. This study attempts to correlate the USG findings and histopathology in patients with AUB. The gold standard

for diagnosing AUB is hysteroscopy and directed biopsy but it is expensive when compared to the simple endometrial sampling. According to the PALM COIEN classification the causes of AUB can be divided into structural and non-structural cause which is given in detail in Table 1.

Aims and objectives of this study were

- Evaluation of endometrial thickness with trans-vaginal ultrasound and its correlation with histopathology by dilatation and curettage in abnormal uterine bleeding.
- To determine the efficacy of Transvaginal ultrasound in evaluating the endometrial thickness.
- To correlate the endometrial thickness by Transvaginal ultrasound with endometrial histopathology in women with AUB.

M□□□□□□

Retrospective observational study included all reproductive and perimenopausal age group women who underwent dilatation and curettage for abnormal uterine bleeding during the period June 2014 to June 2016.

Inclusion criteria

- AUB in all reproductive and perimenopausal women
- Only gynecological indications for dilatation and curettage.

Exclusion criteria

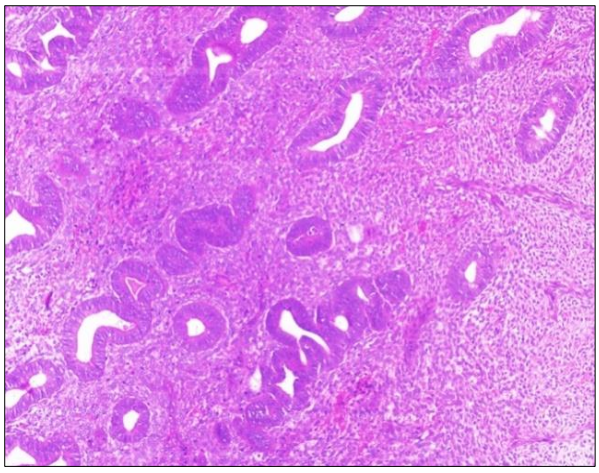
- Unmarried women
- Pregnancy and related causes of bleeding
- Postmenopausal bleeding
- Puberty menorrhagia.

From minor and major OT registers, list of all D and Cs which were done during 2014 June to 2016 June was taken. Cases which satisfied the inclusion and exclusion criteria was taken and analyzed

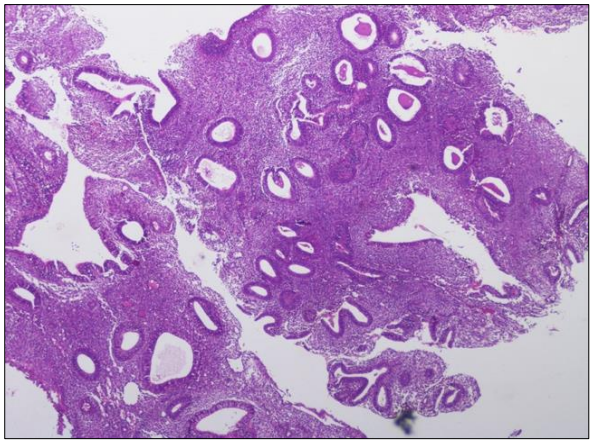
Statistical analysis

Chi square test was used for the statistical analysis.

□□□□□□□

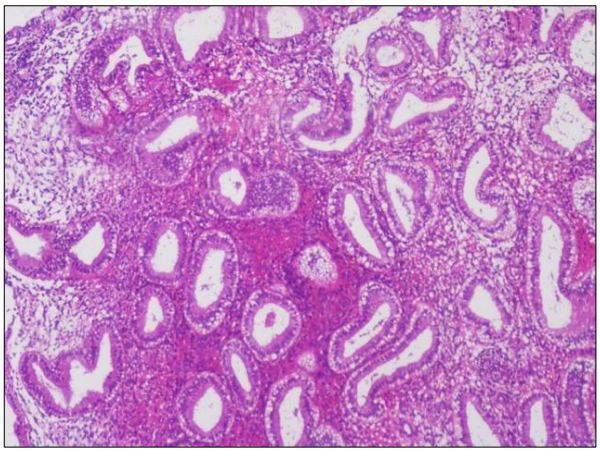


All the patients with abnormal uterine bleeding, fitting the inclusion criteria, who underwent endometrial sampling was taken for analysis. There were around 478 patients. All of them had a premenstrual ultrasound before the procedure. The age distribution, parity, BMI, presenting complaints, the histopathology and the endometrial thickness by TVS was evaluated. The results are given below:

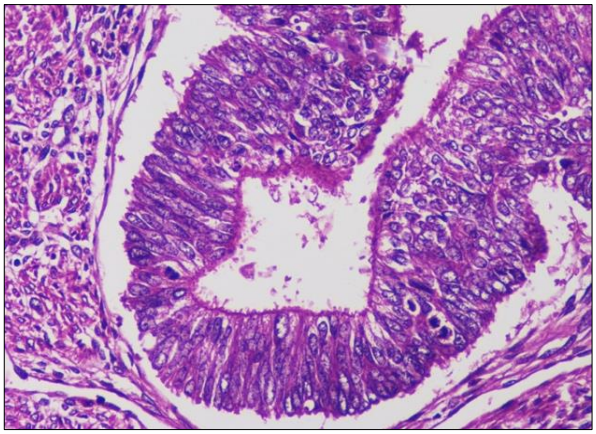


Of the 478 patients, the youngest patient was 22 years old and the oldest was 55 years, the mean age was 38.5 years. Maximum number of patients were in the 41-50 years age group which was 60.25% and the least in the 20-30 years group and was 4.6% (Table 2).

□□□□□2 □□□ □□d □□r □□□□□□□□□□□□□□□□□□□

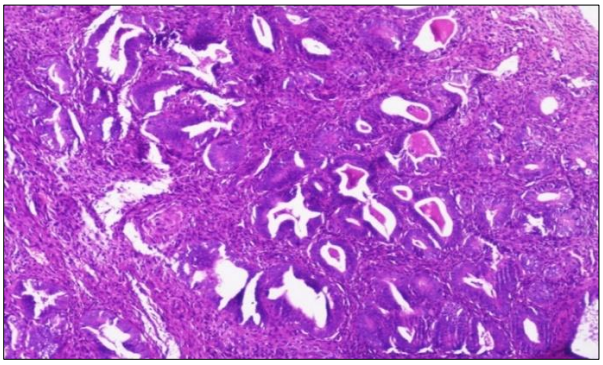


were having proliferative phases (Figure 1), of which 29.7% was disordered proliferative (Figure 2). 30.33% showed secretory changes (Figure 3) endometrial adenocarcinoma (Figure 4) was found in 1.05% of the cases and hyperplasia was seen in 5.86% (Table 5).



Disordered proliferative	142	29.7%	44.76%
Proliferative	72	15.06%	
Secretory	145	30.33%	
Endometrial hyperplasia	28	5.86%	
Endometrial carcinoma	5	1.05%	
Others	86	17.99%	
Total	478	100%	

Among the hyperplasia, 50% was simple hyperplasia without atypia. Atypical hyperplasia (Figure 5) was found in 12 cases. Complex hyperplasia was found in 13 out of the 28 cases of hyperplasia of which complex atypical was 11 cases (Table 6).



Simple hyperplasia without atypia	14	50%
Simple hyperplasia with atypia	1	3.57%
Complex hyperplasia without atypia	2	7.14%
Complex hyperplasia with atypia	11	39.29%
Total	28	100%

Endometrial thickness was 8mm and above up to 15 mm in majority of cases of AUB-54.81%. ET less than 8mm was found only in 19.3% of the study population.ET 15 mm and above was also less which was 25.5% (Table 7). ET less than 4mm in AUB was very less-only 1.67%. One ET was not measured due to diffuse adenomyosis. Out of the 477 patients whose endometrial thickness were measured, all the five cases of endometrial carcinoma was found with an ET ≥15 mm among the 28 cases of endometrial hyperplasia 12 cases of hyperplasia were also found with ET ≥15 mm and the rest 16 cases had ET ≥8-15 (Table 8). Surprisingly all the five cases of carcinoma was endometrioid adenocarcinoma.

It was found in this study that proliferative and secretory endometrium was maximum when the endometrial

thickness was ≥8-15 mm and least with an ET less than 4 mm (Table 9).

[illegible]

[illegible]

[illegible]

[illegible]	[illegible]	[illegible]
<4	8	1.67%
4-8	85	17.78%
≥8-15	262	54.81%
≥15	122	25.52%
Not measured	1	0.22%
Total	478	100%

If we take 8 mm as the cut off, we can see that in this study population all the cases of hyperplasia and malignancy had an ET ≥ 8 mm. Out of the 384 cases with ET ≥ 8 mm 28 cases had hyperplasia and five patients had endometrial carcinoma i.e. 8.59% (Table 10).

[illegible]

[illegible]	[illegible]	[illegible]	[illegible]	[illegible]	[illegible]
≥15	122	12	9.84%	5	4.46%
≥8-15	262	16	6.11%	0	0%
4-8	85	0	0%	0	0%
<4	8	0	0%	0	0%
Total	477	28	5.87%	5	4.46%

[illegible]

[illegible]	[illegible]	[illegible]	[illegible]	[illegible]	[illegible]
<4 mm	8	3	3	0	0	2
4 - <8	85	34	29	0	0	22
≥8-15	262	121	86	16	0	39
≥15	122	56	27	12	5	22
Total	477	214	145	28	5	85

[illegible]

[illegible]	[illegible]	[illegible]	[illegible]
≥8	384	33	8.59%
<8	94	0	0%

[illegible]

[illegible]	[illegible]	[illegible]	[illegible]
≥8	384	33 (a)	351 (b)
<8	94	0 (c)	94 (d)

Sensitivity, specificity, the positive and negative predictive value for an ET of ≥8 mm was calculated. 94 patients with ET less than 8 and 351 patients with ET ≥8 mm did not have carcinoma (Table 11).

- Sensitivity = a/a + c =33/33 = 100%
- Specificity= d/b + d = 94/445 = 21.12%
- Positive predictive value = a/a + b = 33/384 = 8.59%
- Negative predictive value = d/c + d = 94/94 = 100%

[illegible]

Abnormal uterine bleeding is a very common diagnosis in the op population. According to this study the maximum age groups of the patients were in the perimenopausal age of 41-50 years-around 60.25%. This is similar to the study by Shobitha et al -68.1% in the same age group while it was 38% in a study by Mahapatra M et al where the study group was less.[2,3]

The youngest patient was a 22-year-old primary infertility patient with heavy menstrual bleeding for which diagnostic curettage was done and had an ET of 6 mm and secretory endometrium.

In this study, 79.7% were multiparious while 2.93% were nulli, in almost all the studies this is similar. This is in accordance to the study by Nidhi et al, where 88% were multipara and 1.2% were nulliparous.[4] In a study by Betha K et al 81% were multipara.[5]

BMI was in the overweight category in 36.6% and obese in 24.3% in this study which is similar to the study in Iran by Kazamijalezah et al, where it was 33% and also with the study by Sahai A et al, where 56.2% were in overweight category and obese was 25%.[6,7]

There was heavy menstrual bleeding in 98% of patients.

Of these 478 patients only 39 had diabetes as risk factor and out of 39 one had endometrial carcinoma.

When we analyze the histopathologic findings of the 478 cases 44.5% was proliferative endometrium, of this disordered proliferative endometrium seems to be the commonest, in a study by Elavarasan et al, where disordered proliferative endometrium seems to be the commonest pattern observed i.e. 31.1%.[8] The term disordered proliferative endometrium refers to proliferative phase that does not seems to be appropriate for any one time in the menstrual cycle and mimics simple hyperplasia, but the process is focal rather than diffuse. Histologically there shows mild disorganization of architecture, with focal dilated glands, with normal gland to stromal ratio. In this study 30% was secretory endometrium; endometrial hyperplasia was found in 5.8% and endometrial cancer in 1%.

Transvaginal ultrasound was done to assess the endometrial thickness and it was done in the premenstrual phase, of the 478 cases 54.8% had an ET of ≥8-15, 25.5% had ET more than 15 mm. In a study by Jikki et al, 57% had et ≥8 mm which is similar to this study of 54%.[9]

In the study by Jikki et al, the endometrial hyperplasia was seen in 96.4% cases when ET was more than 8 mm and in this study 100% of the patients with endometrial hyperplasia had ET ≥8 mm.[9] In this study 100% cases of endometrial carcinoma occurred with ET ≥15 and all cases of hyperplasia had ET ≥8 mm.

Simple hyperplasia without atypia was 50% in this study which was comparable to 62% in a study by Tabata et al.[10]

Complex endometrial hyperplasia was 14.8% in a study conducted by Idris et al, while their atypical hyperplasia was only 2% whereas atypical hyperplasia was 42.4% in this study.[11] This may be because of the fact that most of the patients in the study group were in the fourth decade (60%) and in their study was in the third decade (80%).

Of the 384 cases with ET ≥8 mm, 33 had endometrial hyperplasia and carcinoma, and 351 did not have e/o hyperplasia and carcinoma, none of the cases below 8mm had any e/o hyperplasia or carcinoma. Sensitivity and negative predictive value was 100% for an ET of ≥8 mm. This is similar to studies by Chatpavit Getpook an ET of 8 mm showed optimal sensitivity and specificity -83.9% and 58.8% respectively and 90.4% negative predictive value for an abnormal endometrium.[12] They concluded that an ET of 8mm or less is less likely to be associated with malignant pathologies. In this study the negative predictive value was 100% and sensitivity was 100% but the specificity was only 21.1%. According to a study by Ozdemir S et al, there was negative predictive value of 95.6%, sensitivity and specificity of 83.6 and 56.4% respectively for an ET of 8 mm.[13]

Kurman et al, classified hyperplasia in to simple and complex and subcategory as atypical.[14] The 2014 revised WHO classification simply separates endometrial hyperplasia into 2 groups-hyperplasia without atypia and atypical hyperplasia.[15] According to the EIN classification all atypical endometrial hyperplasia is classified as endometrial intraepithelial neoplasia.[15] Progesterone was found to cause regression in 90% cases with hyperplasia.

The RCOG cutoff of ET is less than 7 mm below which there is no endometrial hyperplasia in a prospective study of 56 women with pcos.[11,16] In studies by Gianella et al, 11 mm was taken as the cut off.

The most common presenting symptoms of endometrial hyperplasia is abnormal uterine bleeding. According to studies, the risk of progression of simple hyperplasia to carcinoma is 1% and complex hyperplasia with atypia is 29%.[18]

□□□□□□□□□□

The clinical importance of endometrial hyperplasia is because of its progression to endometrial carcinoma. An ET of 8 mm in this study gives a 100% negative predictive value for hyperplasia and carcinoma and can be taken as a cut off for deciding the patients for dilatation and curettage especially in low risk patients.

One year retrospective analysis of PAP smears-from a tertiary hospital in Tamil Nadu

Dr. Chippy Tess Mathew, Dr. Uma Maheswari and Dr. Arthi Ramu

DOI: https://doi.org/10.33545/gynae.2019.v3.i4d.320

Abstract
Introduction: Cervical cancer is one of the leading causes of maternal mortality in India and worldwide, it usually takes 3–7 years for high-grade changes in cervical cells to become cancer. There are many effective screening tests for cervical cancer. PAP smear is one such test
Aim: To analyse the pap smears done in our hospital for a period of one year
Objectives: 1). To determine the percentage of abnormal smears detected 2). To analyse the myriad of findings in a PAP smear.
Materials and methods: It is a Retrospective Observational study, Data was collected from the PAP smears taken in the Gynaecology department outpatients and master health check-up of our hospital. Data was collected for a period of one year from January 2017 to December 2017.
Results: Around 2333 PAP smears were analyzed over a period of one year, of it 885 was from our OPD and 1448 was from the master health check-up, the detection of precancerous lesion was 1.2%, in addition to detecting pre-cancerous lesions, additional information showed a variety of infections like a Candida, Trichomonas, Actinomyces, etc.
Conclusion: Cytology based screening is one of the most cost effective and easy method of cervical cancer screening.

Keywords: Ca cervix, Pap smear, screening, pre malignant lesions

Introduction
Cervical cancer is one of the leading causes of morbidity and mortality in women worldwide. Cervical cancer is the fourth most frequent cancer in women with an estimated 570,000 new cases in 2018 representing 6.6% of all female cancers. The high mortality rate from cervical cancer globally could be reduced through a comprehensive approach that includes prevention, early diagnosis, effective screening and treatment programmes [1]. The screening methods range from VIA (visual inspection with acetic acid) and VILI (visual inspection with Lugol's Iodine in low resource setup where pathologist is not available, to the PAP smear and liquid base cytology with or without HPV testing and sophisticated colposcopy in high resource centres.

Materials and Methods
This is a retrospective study conducted in PSGIMSR. Data was collected from the PAP smears taken in the Gynaecology department outpatients and master health check-up.
Of our hospital. Data was collected for a period of one year from January 2017 to December 2017

Inclusion criteria
1) All PAP smears taken in our OP
2) All PAP smears taken as a part of master health check-up in our hospital

Exclusion criteria
1) Women without sexual exposure

Procedure
Cells from ectocervix and endocervix are collected simultaneously with the broom like spatula. The central bristles of the broom are inserted into the endocervical canal until the lateral bristles bend fully against the ectocervix. The sampling device is rotated 360º in the same direction five

times while maintaining gentle pressure. The broom is removed and with a single paint stroke motion the cellular sample is transferred along the long axis of the labelled surface of the slide. Minimum of two slides are taken except for vault smears where a single slide is taken. The slide is rapidly fixed by immersion in 95%ethanol and ether mix in a Koplik's jar and transferred to the cytology lab [2].

Slides are analysed by the pathologists and reported based on Bethesda classification.

Bethesda classification (2014) [3].

Discussion

PAP smears are analytical tools for screening of cervical cancer. It is a cost effective way for detecting the pre-invasive cervical lesions. In addition it also gives supplementary data on a variety of infections like Candidiasis, Bacterial vaginosis etc.

Of the 2333 pap smears taken over a period of one year, the maximum number of patients was of the age group 40-49 years accounting for 31.63%. The lowest age of the patient was 20 years –a married woman with severe itching and who's Pap smear showed inflammation. The oldest lady was 84 years old who came for a routine screening and the report was negative for IEL. According to a study by Kalyani *et al*. [4] the rate was 28.7%in the same age group and 32.5% in the 30-39year group which was maximum. According to Vijayalakshmi *et al.* [5], the maximum number of patients was in the age45-55 age group which was 34% The most common indication for Pap smear was for routine screening, accounting for 87.96% of the smears, Leucorrhea was the next common indication in those patients in the OPD- 4.59% with AUB being close behind - 4.37%. There were 0.4% of post Malignancy surgery follow up. Post ca endometrium being the commonest. The most common indication was leukorrhea accounting for 30% in a study by Vijayalakshmi *et al.* [5] while the routine screening was around 23%. The high rate of screening in our study might be due to increased awareness among the city population. Around 10.29% where vault smears.

Of the 2333 smears analyzed 2280 were negative for malignancy though they detected inflammation and infections. We had a detection rate of 1.03% (24 cases) of abnormal PAP smears. of the 24 cases there were 4 each of HSIL, LSIL, ASC-H AND AGUS and 8 of ASC-US, only 50% of these patients underwent colposcopy and directed biopsies and except two LSIL all the biopsy reports confirmed the lesions. This abnormal reports-1.03% in our study is close to the study conducted by Tamrakar *et al*. [6] which was 1.7%, but was less than the international and Indian studies done by Sherpa *et al.* [7]. (3.6%) and Sankaranarayanan *et al.* [8] (3.4%) respectively. There were around 1.24% of unsatisfactory smears were opinion was not possible which iscomparable to the study by Crasta *et al.* [5] which is 1.36%, The rate of unsatisfactory smear was high in the study by Kalyani *et al.*, [5] i.e., 17.8%.

Among the negative smears -Inflammmatory smears were found in 54.1% which was comparable to the study by Patel *et al.* [10] (51.5%).In our study, the various organisms detected where candida in 6.44% followed by bacterial vaginosis in 5.27%.in the study by Kalyani *et al.* [8] the inflammatory smears where 83.1%.. candida was found in 2.03% and bacterial vaginosis in 9.8%.while Candida was 3.71% in the study by Patel *et al.* [10]. In our analysis there were two cases of Actinomycosis also and 13cases of Trichomonas Vaginalis of which one patient had strawberry vagina. The comparison of the unsatisfactory and the pathological reports in the various studies are put in a tabular column below:

Table 6: The comparison of the unsatisfactory and the pathological reports in the various studies

Diagnosis	Kalyani *et al.* [5]	Crasta *et al.* [9]	Narasimha *et al.* [3]	Sankaranarayanan *et al.* [8]	Our study
Unsatisfactory	17.80%	1.36%	24.42%	4.10%	1.24%
ASCUS	1.46%	0.37%	4.14%	8.80%	0.34%
LSIL	0.24%	0.19%	2.70%	6.20%	0.17%
HSIL	0.41%	0.61%	2.50%	1.60%	0.17%

Conclusion

PAP smear examination is an economic method for screening forcervical pre-malignant lesions and help us to deal with the global scare of cervical cancer. Mass educational and awareness programs should be conducted to increase the detection rate and

Hair Loss in Paediatric and Adolescent Age Group: A Clinico-Pathological Analysis in a Tertiary Health Care Centre

UMAMAHESWARI GURUSAMY[1], CHAITRA VENKATASWAMY[2]

ABSTRACT

Introduction: Hair loss in children causes deep distress to both the child and the parent. The most common causes of paediatric alopecia are tinea capitis, alopecia areata, traction alopecia and trichotillomania. Timely diagnosis and treatment are indeed required to reverse these conditions.

Aim: To categorize paediatric alopecia into non-scarring, scarring and miscellaneous causes and to describe the histopathological features of each entity.

Materials and Methods: This retrospective study was carried out for duration of 10 years (July 2006 to July 2016) in the Department of Pathology. Scalp biopsies from patients aged 0-18 years with the history of hair loss were included in the study.

Results: There were 35 cases, which included non-scarring 22 (63%) cases, scarring 6 (17%) cases and miscellaneous causes 7 (20%) cases. Rare genetic causes such as Vitamin D resistant rickets associated with alopecia and epidermolysis bullosa were seen among the miscellaneous causes. Alopecia areata was the leading cause of hair loss in children followed by trichotillomania. The histopathological features of non-scarring and scarring alopecia were similar to that described in adults. KFSD, rarely seen in females, showed dilated infundibulum with follicular plugging, polytrichia, perifollicular lymphocytic infiltration and fibrosis on histology. Alopecia in patients with vitamin D resistant rickets showed reduction in number of hair follicles, irregular epithelial structures and epithelial cysts.

Conclusion: The commonest cause of paediatric alopecia seen in this study was alopecia areata. A holistic approach including history, clinical examination and histopathology will be essential for correct diagnosis.

Keywords: Alopecia areata, Non-scarring alopecia, Scarring alopecia

INTRODUCTION

Hair loss in children can cause immense psychological and emotional stress to the patients as well as the parents. While most adults with a history of alopecia are able to reconcile themselves to a bald head, the situation in children is different. In children it can be very traumatic and is a common cause of low self-esteem and difficult socio-cultural adjustments. Alopecia in children may be one of the manifestations of a systemic disease or a disease entity itself. Several classification schemes for hair loss in children have been proposed, but none of these are perfect [1,2]. Most forms of alopecia demonstrate clinical and histological overlap. This blurs the distinction between diseases and makes classification difficult. The best approach would be to group diseases according to their aetiology, but this is impossible since the causes of many forms of hair loss are unknown.

The most widely accepted classification divides paediatric alopecia into congenital and acquired [3,4]. Hair loss in children can be subclassified according to: 1) abnormality in initiation of hair growth (genetic); 2) hair shaft abnormalities presenting with hair breakage; 3) abnormal cycling (anagen/telogen loss); 4) focal/diffuse alopecia (scarring/non scarring) [5].

The commonly encountered causes of alopecia in children include, tinea capitis, alopecia areata, traction alopecia, telogen effluvium, trichotillomania and all these are reversible if diagnosed early [6,7]. A thorough clinical history with careful examination (local and systemic), microbiological studies, trichogram and scalp biopsy will be helpful for the evaluation of paediatric alopecia. This holistic approach will be rewarded with correct diagnosis.

There are many clinical studies on paediatric alopecia, but limited studies on histopathological features [6-8]. The present study was carried out to describe histopathological features of alopecia in paediatric and adolescent age groups and categorize them into non scarring, scarring alopecias and miscellaneous causes.

MATERIALS AND METHODS

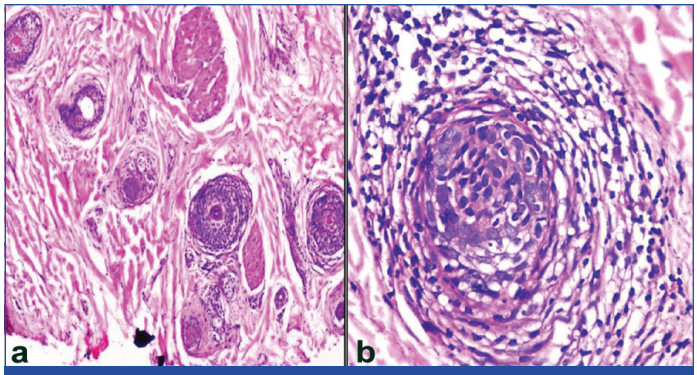
The retrospective study was carried out for duration of 10 years (July 2006 to July 2016) in the Department of Pathology, PSG Institute of Medical Sciences and Research. Scalp biopsies from children aged 0 to 18 yrs with history of hair loss were included. Biopsies less than 2 mm in size and poorly fixed tissues were excluded from the study. The punch biopsies were kept in 10% formalin and processed in an automatic tissue processor (LEICA TP 1020) prior to paraffin embedding. Both vertical and transverse sections were taken and stained with haematoxylin and eosin. Special stains such as Verhoeff van Gieson (VVG) and Alcian blue/periodic acid-Schiff (AB/PAS) were used as required. The former was used to analyse the loss of elastic fibres in cases of scarring alopecia. The AB/PAS stain was utilised to assess thickening of the basement membrane and increase in dermal and perifollicular mucin.

RESULTS

Over a period of 10 years, 130 scalp biopsies were received in the histopathology lab. A total of 35 children with hair loss (27%) from age group 0 months to 18 years were selected. Except for 2 biopsies that were 2 mm in diameter, the rest were 4 mm punch biopsies.

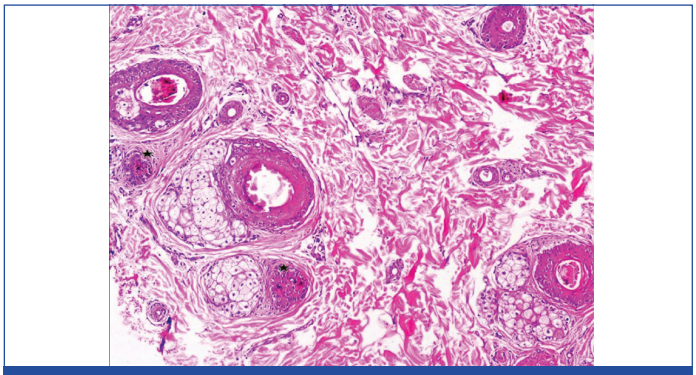
The distribution of these cases included 22 (63%) non-scarring alopecia, 6 (17%) scarring alopecia and 7 (20%) miscellaneous causes.

Details of non-scarring and scarring alopecia with histopathological features are summarized in [Table/Fig-1,2] respectively.



Among the non-scarring alopecia, there were 12 (54.5%) cases of alopecia areata [Table/Fig-3], 8 cases of trichotillomania [Table/Fig-4] and one each of traction alopecia and androgenetic alopecia.

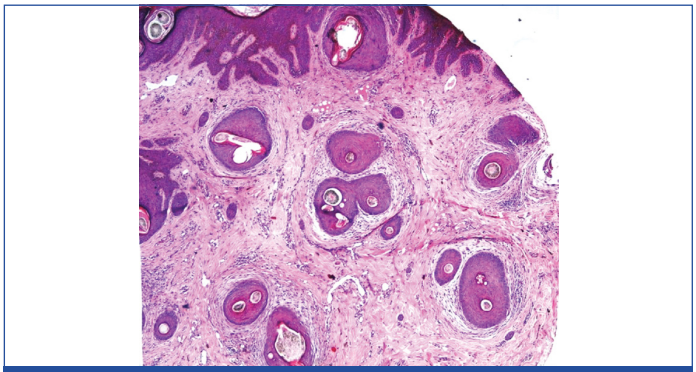
Diagnosis	Sex		Age range	Clinical features	Histopathologic features
	Female	Male			
Alopecia areata	10	2	10 month-18 year	Localized form-10 Alopecia universalis-2	Peribulbar lymphocytic infiltration, miniaturization, increased stelae, telogen follicles and nanogen follicles.
Trichotillomania	8	-	8-18year	No clinical history suggestive of mood and anxiety (obsessive compulsive) disorders	Distorted follicular anatomy with collapse of the inner root sheath, pigment casts, trichomalacia, variably increased telogen follicles and intra follicular haemorrhage.
Traction alopecia	1	-	15 year	Patchy hair loss with broken hairs and follicular prominence-since two yrs H/O traumatic hair styling	Increased number of telogen/ catagen hair follicles, stelae with no significant inflammation. An occasional hair follicle shows distorted anatomy and pigment cast.
Androgenetic alopecia	1	-	18 months	Diffuse hair loss of three months duration	Miniaturization, altered T:V and A:T ratios, slightly increased fibrous stelae and telogen hair follicles



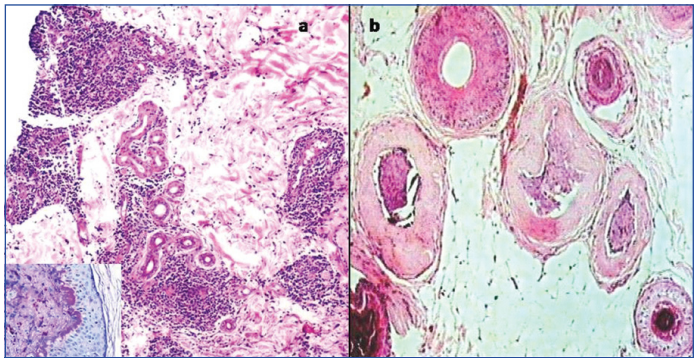
[Table/Fig-1]: Clinical and histopathological features of non-scarring alopecias.

Diagnosis	No of cases	Sex	Age	Clinical features	HP Features
KFSD#	2	female	8 and 13 years	Diffuse hair loss over the scalp, trunk and limbs with papular lesion Similar complaints were seen in female sibling of one case. No ocular lesions in both cases.	Follicular plugging dilated infundibulum, perifollicular inflammation and fibrosis. Polytrichia was noted in one case
Tinea capitis	1	female	14 years	Boggy swelling in the scalp with scaly patches of hair loss	Superficial and deep perifollicular, suppurative and granulomatous inflammation. Fungal spores (endothrix) within the hair follicle.
DLE†	1	female	16 year	Hair loss with pruritic pigmented lesions in frontal region and face	Perivascular, perifollicular and perieccrine lymphoplasmacytic infiltrate, BMZ‡ thickening, increased dermal mucin, full thickness scarring Direct immunofluorescence was positive
Scleroderma	1	female	18 years	Diagnosed case of connective tissue disorder with patchy hair loss over the scalp	Hair bulbs and follicles were surrounded by a thick sheath of hyalinized fibrous sheath, epidermal atrophy, homogenization of the upper dermis with loss of elastic fibres.
ESSA*	1	female	15 years	Presented with bald patches of five yrs duration	Marked reduction in the number of hair follicles with eccentric epithelial atrophy and increased stelae. Atrophic sebaceous glands and many blank spots were present.

[Table/Fig-2]: Clinical and histopathological features of scarring alopecia.
*ESSA-End stage scarring alopecia. #KFSD- Keratosis follicularis spinulosa decalvans
†DLE-Discoid lupus erythematosus. ‡BMZ – Basement membrane zone

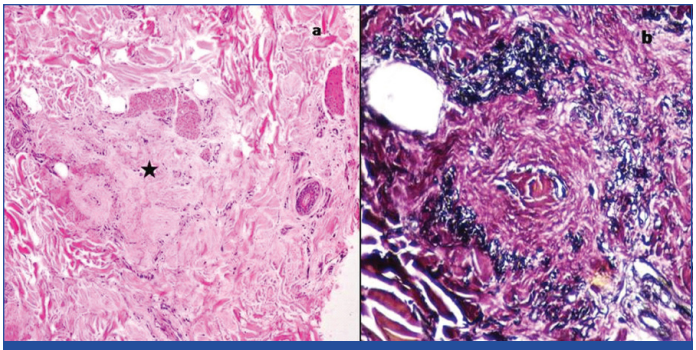


[Table/Fig-3]: Alopecia areata. Transverse section shows a) increase in telogen hair follicles with miniaturization (H&E, 10X). b) Peribulbar lymphocytic infiltration (H&E, 40X).



[Table/Fig-4]: Trichotillomania. Transverse section shows hair follicles with Pigment casts, collapse of inner root sheath and telogenization (*). (H&E, 10X).

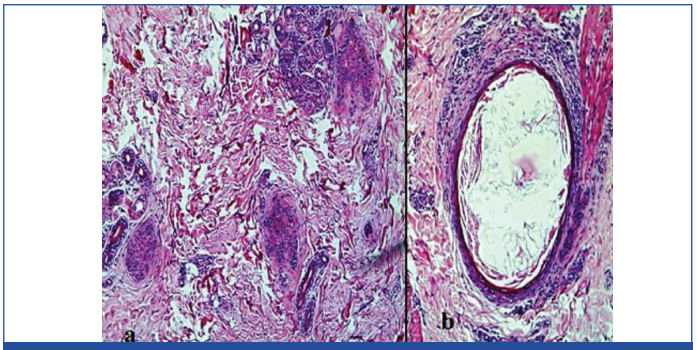
The group of scarring alopecia consisted of two cases of Keratosis Follicularis Spinulosa Decalvans (KFSD) [Table/Fig-5], and one case each of discoid lupus erythematosus (DLE) [Table/Fig-6a], scleroderma [Table/Fig-6b], tinea capitis and End Stage Scarring Alopecia (ESSA) [Table/Fig-7].



Genetic causes such as vitamin D resistant rickets associated alopecia (two cases), and epidermolysis bullosa (one case) were

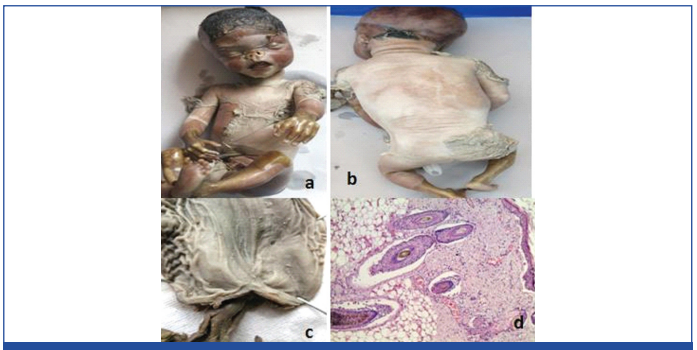
[Table/Fig-5]: KFSD. Transverse section shows polytrichia, perifollicular fibrosis and lymphocytic infiltration (H&E, 40X).

[Table/Fig-6]: a) Perieccrine and perifollicular lymphoplasmacytic infiltrate in a case of DLE (H&E, 10X). Inset shows thickened basement membrane (AB-PAS,40X); b) Transverse section shows thick hyalinized sheath around the hair follicles in scleroderma (H&E, 10X).



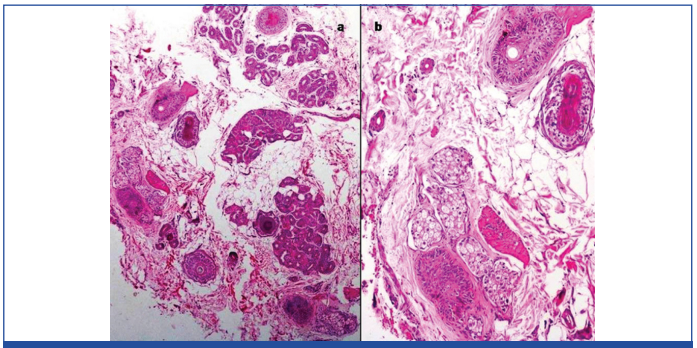
[Table/Fig-7]: End stage scarring alopecia; a) Scarred follicular unit: blank spot (*) (H&E, 10X); b) Loss of elastic fibres in areas of scar (VVG, 40X).

included. Apart from the above causes there were three cases of short anagen syndrome and one case of nevus sebaceus.



Clinical and histological features of miscellaneous causes are presented in [Table/Fig-8-11]. Epidermolysis bullosa: A neonate born to a 25-year-old G3P2L0 from third degree consanguineous marriage at 35 weeks of gestation presented with extensive bullous lesions and areas of skin peeling in most parts of the body. The child succumbed to death on day one and was submitted for autopsy examination. External examination showed extensive peeling of skin with diffuse hair loss over the occipital and temporal regions [Table/Fig-10a, b]. Internal examination revealed pyloric atresia, horse shoe kidney and urethral stenosis with dilated ureters and bladder [Table/Fig-10c]. Histopathological examination of scalp biopsy showed cleft at dermoepidermal junction and around hair follicles [Table/Fig-10d]. A diagnosis of Junctional Epidermolysis Bullosa (JEB) type was offered in view of severity of disease and involvement of internal organs. Previous two children had similar history and died on day one and three respectively. Genetic testing was suggested for parents to confirm the diagnosis and for selective embryo transfer in future pregnancy.

Diagnosis	Number of cases	sex	Age range	Clinical features	Histopathological features
Vitamin D resistant rickets associated alopecia	2	female	4 and 6 years	Clinically diagnosed Vitamin D resistant rickets presented with hair loss, which was patchy to start with, and progressed to become diffuse over a period of one year	Reduced number of hair follicles, irregular epithelial structures and infundibular type epithelial cyst
Epidermolysis bullosa	1	Male	Neonate	Extensive bullous lesions, skin peeling, diffuse hair loss, pyloric atresia, horse shoe kidney and urethral stenosis. Died on day one.	Cleft at dermo-epidermal junction and around the hair follicles
Short anagen syndrome	3	female	3 to 6 years	Sparse hair growth with short fine brown hairs	Increased telogen hair follicles with reversal of anagen: telogen ratio, miniaturization of hair follicles with irregular and angulated outlines.
Nevus sebaceus	1	male	4 years	Single hairless patch over vertex, noticed since six months of age. Slowly increasing in size	Hyperkeratosis with irregular acanthotic epidermis. Immature hair follicles with dilated infundibulum and abundant sebaceous glands



[Table/Fig-8]: Clinical and histopathological features of miscellaneous causes of alopecia.

[Table/Fig-9]: Alopecia associated with Vitamin D dependant rickets; a) Irregular epithelial structures of hair follicles (H&E, 4X); b) Keratinizing epithelial type of infundibular cyst (H&E, 10X).

[Table/Fig-10]: Epidermolysis bullosa: a,b) Generalized peeling off skin over face, chest, abdomen and back with diffuse loss of hair in occipital region; c) Specimen of stomach laid open showing pyloric atresia; d) sections from skin shows sub epidermal and perifollicular clefting. (H&E, 40X).

[Table/Fig-11]: Short anagen syndrome: a) Scanner; and b) low power view showing increased telogen hair follicles (H&E, 40X and 10X).

DISCUSSION

Alopecia is an unpleasant diagnosis at any age group. When it occurs in children, it is highly distressing to the parents, a challenge for the treating physician and has a negative psychosocial impact on the growing child. Elucidating accurate aetiology becomes a crucial step towards educating parents about available treatment options and prognosis.

Hair loss in paediatric age group could be congenital or acquired. Still it would be simpler to classify them into scarring and non scarring alopecia like in adults. There are a few conditions in children which cannot be categorized into either scarring or non scarring and these can be grouped under miscellaneous causes as done in the present study. Thorough clinical details, family history and histological findings are essential in making a right diagnosis. The common causes of paediatric alopecia are acquired and reversible. They include: alopecia areata, tinea capitis, trichotillomania, traction alopecia and androgenic alopecia.

In the present study, we have categorized causes of alopecia into non scarring, scarring and miscellaneous causes and will be discussed accordingly.

Non Scarring Alopecia

They accounted for majority of cases 22 (63%) cases. Among these causes, alopecia areata was the commonest followed by trichotillomania.

Alopecia areata (AA) was more frequently seen in female patients as in previous studies [7,8]. Female predominance can be explained because of its autoimmune basis, as autoimmune diseases are more prevalent in females. Laboratory evaluation of thyroid function, iron deficiency, blood sugar, HbA1c, serological markers of autoimmune diseases and testing for hyperandrogenemia are useful in the evaluation of patients presenting with alopecia. Though AA has bimodal age distribution (paediatric and adult) it is less likely to occur in children below 2 years of age [1,6,7]. In the present study, there were three patients (25%) below two years of age and the earliest onset of disease was in a 10 month old child. Diffuse AA, alopecia universalis and totalis are more frequent in children and in our study we diagnosed two children with alopecia totalis, accounting for 20% of cases of AA [6]. Histological features were similar to that of adult cases. Clinically, the localized form of AA can be confused with tinea capitis and trichotillomania and diffuse type with telogen effluvium and diffuse tinea capitis. This clinical challenge can be resolved by careful histopathological examination of the scalp biopsy [7].

Trichotillomania was the second most common cause of paediatric alopecia in our study and was noted to occur only in females. Trichotillomania is an impulse control disorder characterised by a long term urge that results in pulling out of one's own hair. It is often associated with anxiety and may co-occur with other disorders of the obsessive compulsive spectrum [1]. It is more frequent in females as in our study. The classic histological features include collapse of the inner root sheath, pigment casts, intrafollicular haemorrhage and these were noted in most of our cases [10].

Although, predominantly a disease of adults, children are less commonly affected by androgenetic alopecia. However, some studies have reported androgenic alopecia as the second most common cause of hair loss in children and leading cause in adolescent age group [11,12]. Its occurrence in an eight month old girl child was an unusual feature of our study. The youngest case described in the literature is that of a six year old child [13].

Scarring Alopecia

Keratosis Follicularis Spinulosa Decalvans is a rare genodermatosis with X-linked and autosomal dominant pattern of inheritance. It can also be sporadic in onset [14,15]. KFSD manifests as scarring alopecia mainly in male patients (females being carriers). In our study, two girls aged 8 and 13 years manifested with full blown disease, which has been reported in the literature [14,15].

Tinea capitis is common in children of tropical countries. It has varied clinical presentation such as hyperkeratosis of scalp, seborrhoea, alopecia and broken hair. Hair loss is non scarring type and reversible if treated early. When inflammation is severe, it can progress to scarring alopecia [16]. Though it is a common cause of hair loss, we had a single case of tinea capitis causing scarring alopecia. This is because most of the cases are clinically diagnosed with the help of Potassium Hydroxide (KOH) stained smears of hair shafts and are not biopsied. Other causes of scarring alopecia in the present study included connective tissue disorders such as Discoid Lupus Erythematosus (DLE) and scleroderma. When biopsy is taken from scarred area or in late stages of the disease the diagnosis cannot be ascertained as was seen in one of our cases (end stage scarring alopecia).

Miscellaneous Causes

Vitamin D is essential for bone mineralization. Few studies have shown various cutaneous manifestations of vitamin D deficiency like psoriasis, atopic dermatitis, vitiligo, ichthyosis, keloid and autoimmune diseases and its role in treating the above [17]. Few experiments have demonstrated its role in hair growth signalling. The histological features are similar to that seen in atrichia with papular lesion and include absence of hair shafts, irregular epithelial structures and epithelial cysts [18]. Similar findings were observed in two of our cases. A good clinico-pathological correlation is essential to arrive at correct diagnosis.

Epidermolysis bullosa (EB) causing alopecia is a rare manifestation and it was diagnosed in one of our case. EB is an inherited bullous disorder that can manifest as milder form to fatal disease. It is classified based on the level of separation within the cutaneous basement membrane zone into EB simplex, junctional EB and dystrophic EB. Blistering involving basement membrane zone of hair follicle is the cause of hair loss. Other manifestations include mild hair shaft abnormalities, cicatricial alopecia and alopecia universalis [19].

We had three cases of Short Anagen Syndrome (SAS). There are very few case reports of SAS in literature and one case was reported from India [20,21]. SAS is a recently described entity characterized by persistent short hair due to shorter anagen phase. It has characteristic clinical presentation i.e. short smooth hair since birth and diagnosed based on reversal of anagen: telogen ratio on trichogram, the normal ratio being 9:1. Scalp biopsy also shows increased telogen hair follicles with a mild perifollicular lymphocytic infiltrate and non-scarring type of alopecia [22]. A few reports from the literature revealed, SAS can have autosomal dominant pattern of inheritance and has a self-limiting course with spontaneous resolution at puberty [23,24].

There are some unique findings in present study: 1) unusual age at presentation (<1 year) in cases of alopecia areata and androgenetic alopecia 2) a full blown phenotypic expression of KFSD in females, who are generally carriers 3) rare causes of alopecias such as Vitamin D resistant rickets associated alopecia and short anagen syndrome were identified.

LIMITATION

The pitfall of the present study is the limited number of cases, though the study was carried out for 10 year duration. This is because not all cases of alopecia are biopsied routinely. Diagnosis is established based on its clinical presentation and ancillary techniques like KOH preparation, trichogram, and hair pull test. Biopsies are performed, when the diagnosis is not arrived on clinical grounds or the patient is not responding to treatment.

CONCLUSION

To conclude, alopecia areata is the commonest cause of hair loss in children. Good clinico-histopathological correlation is necessary to arrive at a correct diagnosis. Based on this, parents can be counselled about appropriate treatment options and prognosis.

Morphologic Spectrum of Undetermined Causes of Hemoptysis- A Pathologist's Role

Nidhya GANESAN, Umamaheswari GURUSAMY

Department of Pathology, PSGIMSR, TAMILNADU, INDIA

ABSTRACT

Objective: Hemoptysis is the expectoration of blood or blood-streaked sputum from the tracheobronchial tree. The etiology may derive from nonneoplastic conditions such as infections, chronic pulmonary diseases, and vasculitis or neoplastic causes. Sometimes a definitive cause for hemoptysis cannot be found after ample diagnostic workup. The role of biopsy in such cases is to help the clinician in arriving at the final diagnosis. Diffuse alveolar hemorrhage is the main histopathological finding in hemoptysis and it appears with diffuse chest infiltrates radiologically.

Material and Method: A retrospective study of 2 years duration was conducted to identify the morphological spectrum of diseases presenting with hemoptysis. A total of 243 lung biopsies obtained by various methods were retrieved in this study period and 20 cases with hemoptysis of undetermined etiology were detected.

Results: Based on imaging and histopathology findings, the etiological causes of hemoptysis were divided into hemoptysis with and without capillaritis or due to tumor/tumor-like lesions and due to miscellaneous conditions. The most common etiology was vasculitis followed by infections.

Conclusion: Histopathology helps to detect the etiology, particularly in cases of hemoptysis due to non-immunologic causes. In immunologic cases, histopathological findings may support the diagnosis in correlation with the clinical/imaging features.

Key Words: Hemoptysis, Immunologic, Diffuse alveolar hemorrhage, Capillaritis

INTRODUCTION

Hemoptysis is the expectoration of blood from the pulmonary parenchyma or the tracheobronchial tree below the level of the glottis. The expectoration of blood can vary from a small amount of blood-streaking sputum to massive bleeding with life-threatening consequences. The clinical diagnostic algorithm should aim to differentiate and identify the etiology of hemoptysis, since massive hemoptysis may result in a fatal outcome (1, 2).

The common causes of hemoptysis include pulmonary tuberculosis (TB), malignancy, bronchiectasis, chronic bronchitis, pneumonia, and fungal infections. The other rare causes are vasculitis due to collagen vascular diseases and hereditary hemorrhagic telangiectasia, essential cryoglobulinemia, Behcet's disease, acute lung transplantation rejection, drug-induced (e.g., chemotherapeutic agents, propylthiouracil), idiopathic pulmonary hemosiderosis, and toxin or inhalation injury (3).

About 30% of cases attending respiratory clinics and presenting with hemoptysis pose a problem in clinical diagnosis, and the histopathology plays a vital role in diagnosing these conditions. The condition can be localized or diffuse depending upon the underlying etiology (4). Intra alveolar hemorrhage, fibrin deposition, and hemosiderin-laden macrophages associated with or without capillaritis are the common findings observed in cases of diffuse alveolar hemorrhage (DAH) (5). Radiologically, DAH shows patchy/ diffuse bilateral areas of lung consolidation mainly involving the lower lobes and perihilar regions (6).

A literature search revealed only a few reports on using histopathological interpretation in diagnosing unknown causes of hemoptysis. This is vital to diagnose and treat the condition earlier, as it prevents disease progression, and constituted the reason for conducting the current study. This study aims to identify the various uncommon aetiologies of hemoptysis based on histopathological features and the pathologist's approach in diagnosing this condition.

MATERIAL and METHODS

All lung biopsies, including lobectomy specimens received in the department of pathology, between Jan 2018 to Jan 2020 (2 years duration) were retrospectively reviewed. Of the received 243 specimens, 20 cases had hemoptysis with undetermined causes. The obtained specimens were derived from various procedures and included 117 transbronchial lung biopsies (TBLB), 62 endo bronchial lung biopsies (EBLB), 28 guided (Ultra sonogram /CT) biopsies, 19 thoracoscopic/Video-assisted (VATS) biopsies, and 17 lobectomies. The cases with a history of hemoptysis associated with common causes such as tuberculosis (TB), carcinoma, bronchitis, bronchiectasis, and interstitial lung diseases (ILD) were excluded from the study. The clinical data obtained were age, sex, presenting complaints, clinical diagnosis/differential diagnosis, and significantly associated co-morbidities. Laboratory investigations such as autoimmune workup (ANCA, ANA, etc.), sputum for culture & acid-fast bacilli (AFB), bronchoalveolar lavage (BAL) for culture and cytology, and other relevant information were collected. The findings of imaging (high-resolution computerized tomography - HRCT) and bronchoscopic findings were recorded if available (not always performed).

Ethical approval for this study was obtained from PSG Institute of Medical Sciences & Research (Approval number: 20/117, Date: 27.05.2020).

RESULTS

Out of 243 lung biopsies received, a total of 20 cases with symptoms of hemoptysis due to undetermined etiology were included in our study.

Histopathological Findings

Based on imaging and histopathological findings, the etiology of hemoptysis was divided into localized and diffuse/bilateral pulmonary involvement (Table I). Depending upon the histological findings, the causes of hemoptysis were further divided into

- Hemoptysis with capillaritis (Table II)
- Hemoptysis without capillaritis (Table III)
- Unusual tumors and tumor-like lesions (Table IV)
- Miscellaneous uncommon causes

Miscellaneous uncommon causes are listed below:

Pulmonary Alveolar Micro Lithiasis (n=1)

HRCT of a 34-year-old male who presented with hemoptysis showed bilateral ground-glass densities with septal calcification -? Interstitial lung disease. TBLB sections showed distended alveoli containing concentric lamellated, calcific material with few hemosiderin-laden macrophages.

Pulmonary Endometriosis (n=1)

A 43-year-old man with a history of cirrhosis secondary to hepatitis 'C' had recurrent episodes of hemoptysis. Bronchoscopy revealed a mucosal white patch in the left lingular segment. The biopsied lesion showed lung tissue intimately admixed with a focus of endometrial glands and stroma. CD 10 immunostaining of the stroma, as well as estrogen and progesterone receptor staining of the glandular component, were both consistent with endometriosis (Figure 1A-D).

Table I: Etiological classification based on imaging & histopathological findings.

Causes of hemoptysis			
Localized	**Number of cases**	**Diffuse /bilateral**	**Number of cases**
Pulmonary hamartoma	1	GPA	3
Aspergillosis	1	Silicosis	3
Myelolipoma	1	EGPA	2
Mucor	1	Invasive aspergillosis	1
Pulmonary endometriosis	1	Invasive mucor+aspergillosis	1
Mucoepidermoid carcinoma	1	Multiple metastases from a leiomyosarcoma	1
Probably benign mesenchymal neoplasm	1	PAM	1
		Pulmonary intravascular hemangioma	1

GPA: Granulomatosis with Polyangiitis / Wegener's, **EGPA:** Eosinophilic granulomatosis with polyangiitis / Churg-Strauss syndrome, **PAM:** Pulmonary alveolar microlithiasis.

Table II: Causes of hemoptysis with capillaritis.

	Granulomatosis with Polyangiitis (GPA)			**Eosinophilic granulomatosis with polyangiitis (EGPA)**	
	Case - 1	**Case-2**	**Case-3**	**Case 1**	**Case 2**
Age, sex	40, M	46, F	51, F	43, M	42, M
Complaints	Cough, hemoptysis, and dyspnoea				
Serology	Anti-CCP, PR3-ANCA&RF: positive	PR3-ANCA positive	PR3-ANCA positive	RF: positive	PR3-ANCA: weakly positive
Imaging studies	Bilateral nodules	Ground glass changes, calcified nodule	Bilateral consolidation with few nodules	Bilateral nodules	Bilateral nodular and cavitating lesions.
Type of biopsy	EBLB	CT guided biopsy	CT guided biopsy	TBLB	VATS lung biopsy
HPE findings: **Vascular changes:**	• Capillaritis, venulitis • Fibrinoid necrosis (Figure 2A)	Vague outlines of thrombosed blood vessels	Vasculitis and Fibrin thrombi (Figure 2C- D)	Eosinophilic infiltration of the vessel wall	• Necrosis of the vessel walls with inflammatory cells infiltration (Figure 3A-C) • Organizing, recanalizing and fibrin thrombi
Parenchymal changes	• Granulomatous inflammation with MNG cells (Figure 2B) • Interstitial inflammation	• Necrosis, karyorrhexis, hematoxyphilic nuclear dust • Neutrophilic micro abscess	• Necrosis, karyorrhectic debris • Granulomatous response with MNG cells • Neutrophilic micro abscess	• Eosinophilic microabscess • Palisading granuloma	• Intraalveolar hemorrhage (Figure 3D) • Eosinophilic microabscess, parenchymal necrosis • Perl's stain highlights the hemosiderin-laden macrophages (Figure 4)

MNG cells: Multinucleate giant cells, **HPE:** Histopathological examination, **EBLB:** Endobronchial lung biopsy, **CT:** Computed tomography, **VATS:** Video-assisted thoracoscopic surgery, **TBLB:** Transbronchial lung biopsy.

Table III: Causes of hemoptysis without capillaritis.

	Silicosis			**Fungal infection**			
	Case -1	**Case-2**	**Case-3**	**Case-1**	**Case-2**	**Case-3**	**Case-4**
Age, sex	61, M	54, M	58, M	28, M	56, M	45, F	15, F
Complaints	Cough, hemoptysis and dyspnoea.			Cough, hemoptysis, and dyspnoea			
Another relevant history	Exposure to silicon dust +			Post Koch's sequelae	DM, CKD	Post TB, DM.	DM, DKA^{+}, Mild PAH
Imaging studies	Bilateral lung nodules&hilar nodes	Calcified nodes	B/L nodules, calcification	NA	Cavitatory consolidation	B/L subpleural nodules	B/L cavitating consolidations
Type of biopsy	TBLB			Right upper lobe segmentectomy	EBLB	Right lower lobectomy	TBLB
HPE Findings	• Nodules of epithelioid and pigment laden histiocytes, predominantly around the vascular channels (Figure 5A,B)			• Dilated bronchi forming a cavity containing the fungal ball • Tissue, angioinvasion & infarct • Fibrosis, chronic granulomatous inflammation • Oxalate crystals (Figure 6A,B)			
Special study	Polarizer: birefringent crystals (Figure 5B inset)			GMS & PAS stains: septate, acute-angled branching hyphae of aspergillus	PAS & GMS stains: broad, aseptate and wide-angle branching hyphae of mucor	PAS & GMS stains: Tangles of fungal elements, consistent with aspergillus and mucor	

DM: Diabetes Mellitus, **CKD:** Chronic kidney disease, **TB:** Tuberculosis, **NA:** Not available, **DKA:** Diabetic ketoacidosis, **PAH:** Pulmonary artery hypertension, **B/L:** Bilateral, **HPE:** Histopathological examination, **EBLB:** Endobronchial lung biopsy, **TBLB:** Transbronchial lung biopsy, **GMS:** Grocott Methenamine Silver Stain.

Table IV: Unusual tumors and tumor-like lesions of the lung.

Diagnosis	Pulmonary hamartoma (n=1)	High-grade Spindle cell sarcoma - metastatic LMS* (n=1)	Benign mesenchymal neoplasm (n=1)	Pulmonary myelolipoma (n=1)	Endobronchial mucoepidermoid carcinoma, high grade (n=1)
Age, sex	46, F	59, M	51, M	65, M	39, F
Complaints	Cough, hemoptysis, and dyspnoea				
Imaging studies	Solitary pulmonary nodule.	Nodular masses in both lungs - suggested metastases.	-	Endobronchial nodules -? TB/ sarcoidosis	-
Bronchoscopy	NA	NA	Irregularisation in left lingula? a blood clot? growth	-	Left main bronchus tumor with a possible endobronchial carcinoid.
Type of biopsy	Lobectomy	EBLB	EBLB	EBLB	Left Pneumonectomy
Gross	Glistening lobulated mass of 3x2.5 cm	-	-	-	Endobronchial ulcerated solid, yellow-white polypoidal mass
HPE findings	Circumscribed lesion of mature cartilage interspersed by adipose tissue, smooth muscle, and fibrovascular tissue. Foci of ossification, chondromyxoid area.	• Pleomorphic spindle cells • Coagulative necrosis. Positive for SMA$^{\pm}$and desmin.	• Polypoidal lesion • Fascicles of spindle cells • Cellular myxoid stroma. • Express Vimentin and SMA$^{\pm}$	• Circumscribed lesion of thin trabecular bone enclosing adipocytes and hematopoietic elements • MPO-highlighting the myeloid cells (Figure 7A-C).	• Infiltrating neoplasm, • Solid nests, cribriform pattern, and mucin filled acini. • Squamoid morules (Figure 8A,B). • Positive for Pan CK and P63

Pulmonary Intravascular Haemangioma (n=1)

HRCT of an elderly male showed multiple small nodules in both the lungs and a lobulated enhancing soft tissue lesion attached to the anterior wall of the right atrium-? Malignancy. TBLB sections showed lung parenchyma with medium to large-sized vessels containing an intraluminal, adherent lesion of tubular vascular spaces lined by endothelial cells. CD31 & CD34 immunostaining highlighted the endothelial cells. Since the right atrial mass could not be biopsied, the clinical/imaging findings were correlated and the final HPE diagnosis made was intravascular capillary haemangioma/?fragmented from cardiac haemangioma.

DISCUSSION

Haemoptysis is considered to be a serious medical condition and has a broad differential diagnosis. All cases with microscopic evidence of hemorrhage do not present with hemoptysis clinically. Similarly, all patients who presented with hemoptysis will not show alveolar hemorrhage histologically (4).

Haemoptysis with Capillaritis (Granulomatosis with Polyangiitis & Eosinophilic Granulomatosis with Polyangiitis)

Pulmonary vasculitis is characterized by inflammation of the small and medium-sized vessel wall, causing pulmonary hemorrhage. Imaging studies show multiple lung cavitary nodules/masses, which may mimic metastasis. Also in some conditions, the lung infiltrates are transitory making the diagnosis a challenging one (7).

Schnabel et al. stated that histopathological findings may vary depending upon the type of biopsy. They found out that the yield of guided lung biopsy is high when compared to TBLB since gross lesions are easily visible. Similarly, most of our cases had undergone guided biopsies and were adequate (8).

Travis et al. suggested that capillaritis is a morphologic marker of DAH in their study. They concluded that capillaritis and necrotizing granulomatous inflammation with mixed inflammatory cell infiltrate were pathognomonic features of GPA. Parenchymal necrosis, extravasated fibrin, and scattered multinucleate giant cells in a biopsy could suggest the diagnosis of a GPA even in the absence of granuloma. The destruction of the vessel wall can be highlighted by VVG elastic stains. However, correct sampling is essential for the maximum yield (9, 10).

The diagnosis of EGPA can be made if the biopsy shows granulomatous vasculitis with extravasated eosinophils and evidence of eosinophilic pneumonia (11). Correspondingly, three cases in our series showed capillaritis and the remaining two were diagnosed based on relevant clinical and imaging findings.

Haemoptysis without Capillaritis

Fungal Infection: Alveolar hemorrhage resulting from fungal infection is infrequent. The possible pathogenesis of hemoptysis in fungal infection could be 1) due to chronic inflammation as the granulation tissue lining the cavity is rich in capillaries, 2) these new vessels are rather fragile and can rupture easily, and 3) erosion of the blood vessels adjacent to the cavity (12). The presence of calcium oxalate crystals in a patient with a cavitary lesion will raise suspicion of a fungal infection and the pathologist should search for the same in the adjacent area (13). Likewise, our cases also had similar histology which would have led to hemoptysis.

Silicosis: An autopsy case study by Kyeong et al. revealed that unlike silicosis which affects mainly the lung parenchyma, silico - tuberculosis also affects the pulmonary vasculature causing hemoptysis (14). Our cases did not have evidence of tuberculosis. Streak-type hemoptysis seen in our cases could be explained by the destruction of small-sized blood vessels by fibrosis and chronic inflammation (15).

Unusual Tumors and Tumor-Like Lesions of the Lung

Primary Pulmonary Mesenchymal Tumors: Accounts for less than 1% of all lung malignancy. These tumors show lineage differentiation and can be diagnosed in the lung with similar histological and immunological criteria as in other sites (soft tissue) (16). Pulmonary hamartoma is the most common benign mesenchymal tumor of the lung, and is predominantly seen in older males**.** Geramizadeh et al. and Ahmed et al. in their study stated that the occurrence of hemoptysis in hamartoma is very rare and results from giant or endobronchial tumors causing erosion of the vessels (17, 18). In contrast to their findings, our patient was a middle-aged female with a small peripherally located pulmonary hamartoma.

According to Hashimoto et al., it is important to identify and differentiate metastatic mesenchymal tumors correctly, since most mesenchymal tumors presented as occult/unknown primary with pulmonary metastatic foci (19). Identically, one of our cases had metastatic LMS with a known diagnosis of primary LMS of the thigh.

Mucoepidermoid Carcinoma (MEC): MEC is a rare salivary gland type endobronchial tumor with mucous secreting cells, squamous cells, and intermediate cells. A definitive diagnosis requires bronchoscopy and representative biopsy as this tumor exhibits morphological heterogeneity. It can be misdiagnosed as primary non-small cell lung carcinoma if the biopsy is inadequate (20, 21). The diagnosis of this rare neoplasm was possible since ours was a pneumonectomy specimen.

Myelolipoma: Pulmonary myelolipoma is distinctly unusual and rarely presents with hemoptysis. Embolic origin, reticuloendothelial cell metaplasia, and proliferation of hematopoietic stem cells are possible mechanisms of histogenesis. Tumour arising adjacent to the bronchial cartilage may show bony trabeculae and this explains the possible histogenesis of the metaplastic theory (22). Our case also revealed a similar histology.

Miscellaneous Uncommon Causes

Pulmonary Endometriosis: Pulmonary endometriosis is a rare form of extra pelvic endometriosis, occasionally reported in men. Cases of male endometriosis have typically been linked to increased circulating estrogen levels. Peripheral conversion of androstenedione and testosterone to the circulating estrogens was noted in men with cirrhosis of the liver (23). Our patient had a history of cirrhosis, possibly leading to an altered hormonal state that interacted with a reactive/metaplastic process.

Pulmonary Alveolar Microlithiasis (PAM): PAM is a rare autosomal recessive lung disease characterized by the accumulation of concentrically laminated calcospherites within the alveolar spaces. Lauta in his study stated that there is a striking clinico-radiologic disparity in this condition (24). Since our patient did not have other system involvement, the possibility of PAM over secondary calcification was favored by correlating the clinical and imaging features.

Pulmonary Intravascular Haemangioma: The co-existence of cardiac and pulmonary haemangioma is very rare and very few reports of such an association have been described so far. Imaging studies may help in diagnosing cardiac haemangioma while histopathology is essential for confirmation. Complete excision is the treatment of choice in resectable cardiac haemangioma and solitary pulmonary haemangioma (25). Since the general condition of the patient was poor, resection was not possible in our case. Fragmented emboli from a cardiac haemangioma could also be considered as a differential.

In conclusion, in immunologic causes of hemoptysis, histopathological findings may support the diagnosis in correlation with the clinical/imaging features. However, in cases of non-immunologic causes of hemoptysis, a histopathologic examination is mandatory over clinical/imaging studies. The cases presented here are incredibly rare diseases with an uncommon presentation. The diagnosis is often missed or delayed, due to a low index of suspicion. Histopathological examination is imperative in unexplained cases of hemoptysis as it plays a vital role in therapy decisions.

[illegible]

[illegible] The purpose of this study was to evaluate gross umbilical cord abnormalities and to examine its relationship with placental pathological features and perinatal outcome.

M [illegible] We retrospectively collected 101 singleton placentas with gross umbilical cord abnormalities over 3-year period (delivered on or after 20 weeks of gestational age). Association between gross umbilical cord abnormalities such as hypercoiled cords, hypocoiled cords, thin cords, true knot, strictures, excessively long cord, and abnormal cord insertions were reviewed and evaluated for placental histology, clinical parameters and perinatal outcome.

[illegible] The most common umbilical cord abnormality (UCA) observed was coiling abnormality (hypercoiling, hypocoiling and strictures). Gross UCAs were associated with maternal factors (preeclampsia, oligohydramnios and gestational diabetes), foetal factors (intrauterine foetal death, SGA and intrapartum complications such as NRFHR tracing and low Apgar scores) and histologic placental features (maternal vascular malperfusion, foetal vascular malperfusion, villous capillary lesions and inflammation). Cords with multiple abnormalities were significantly correlated with histologic evidence of foetal vascular obstruction and intrauterine foetal death.

[illegible] Gross UCAs, especially when multiple were associated with clinically significant placental findings and adverse perinatal outcome. Therefore, our study reinforces that all placentas with gross UCAs should be submitted for examination with complete (full length of the) umbilical cord.

[illegible] Coiling abnormality perinatal outcome, Foetal vascular malperfusion, Maternal vascular malperfusion, Placental histology, Umbilical cord abnormalities

[illegible]

Umbilical cord (UC) is a vital structure which acts as a conduit between the developing foetus and placenta. It carries nutrients, oxygen and fluids necessary for the intrauterine life. This unique lifeline needs optimal protection which is provided by Wharton's jelly, amniotic fluid and coiling of the umbilical vessels.[1] The fully developed umbilical cord is pearly white, 50-60cms long with an average diameter of 1-2cm. It contains 2 arteries and a vein which course through the Wharton's jelly in a helical fashion with one coil/twist every 5 cms of cord. The cord normally inserts on the placental surface, more often near or at the center.[2]

Conditions such as abnormal cord length, abnormal coiling, knots, entanglements, constrictions, velamentous vessels, single umbilical artery (SUA) and thrombosis

may lead to cord compression and consequent reduction of blood flow in the umbilical vessels and have been associated with adverse foetal outcome and intrauterine foetal demise (IUFD).[3]

The purpose of this study was to evaluate gross patterns of umbilical cord abnormalities and determine correlations with placental histology and perinatal outcome.

M□□□□□□□

This retrospective study was carried out from January 2014 to December 2016 in the Departments of Obstetrics and Gynaecology and Department of Pathology.

101 Placentas with gross umbilical cord abnormalities delivered on or after 20 weeks of gestational age were taken for study consideration. Clinical indications for histological examination of the placenta were stillbirth, foetal growth restriction, preterm premature rupture of membranes, severe pre- eclampsia, diabetes, gross abnormalities of the placenta, clinical suspicion of infection or abruption and compromised neonatal outcome.

Umbilical cord abnormalities (UCA) included in the study were hypercoiled cord (>3 coils/10cm segment of umbilical cord), hypocoiled cord (< 1 coil per 10 cm), thin /narrow cord due to diminished Wharton's jelly (maximum cord diameter <0.8 cm), strictures (focal narrowing/thinning in relation to the remaining UC), true knot(TK), SUA, abnormal cord insertion-marginal (< 1cm from the true disc margin-MUC) / velamentous (membranous insertion-VEL) / furcate (umbilical vessels splitting and leaving Wharton's jelly prior to reaching the chorionic plate surface).[4] Excessively long umbilical cord (ELUC) was defined as those UCs measuring approximately 2 standard deviations (SD) above the mean or ≥ 70cms in length.[4,5]

Clinical details obtained along with the placental specimens were maternal age, gravidity and parity, gestational age, medical conditions complicating pregnancies, presence of IUFD, foetal growth restriction (FGR), non-reassuring foetal heart rate (NRFHR), meconium stained liquor, Apgar scores at 1 and 5 minutes and birth weight as recorded by the obstetricians. Infants with birth weight <10th percentile and >90th percentile of the gestational age were termed as small for gestational age (SGA) and large for gestational age (LGA) respectively. The rest were considered as appropriate for gestational age (AGA).[6]

Umbilical cord and placental assessment were based on gross and microscopic examinations. An entire placenta was available from all 101 patients and were fixed in 10% formalin. Placentas were weighed after the membranes and umbilical cord were trimmed off and compared with the reference weights for trimmed singleton placentas.[7]

Umbilical cord was examined for length, diameter, colour, insertion site, number of twists and vessels. Photography of the placentas were routinely taken after examining foetal, maternal surfaces and parenchyma. Relevant lesional sections were taken along with 2 sections of membrane roll, 2 or 3 sections from the UC at the stricture and non-strictured area and 3 full thickness sections of the normal parenchyma. All the histologic sections were stained with haematoxylin and eosin.

Umbilical cord abnormalities were correlated with gross, histologic placental characteristics and foetal outcome.

□□□□□□□□

Hundred and one cases were identified with gross UCAs. There were 48 cases of hypercoiling (Figure 1), 31 cases of hypocoiling (Figure 2) and 11 cases each of thin cords and strictures (Figure 3). Abnormal cord insertions were seen in 7 cases each of MUC, VEL (Figure 4) and 2 cases of furcate. Other less commonly seen abnormalities were 2 cases each of TK (Figure 5), ELUC and SUA. Of the 101 cases of analysed placentas 20 had more than one umbilical cord abnormality.

Isolated UCAs were each analyzed for association with clinical and histologic findings (Tables 1 and Table 2).

Clinical characteristics

The most common UCA identified was hypercoiling, followed by hypocoiling. Stillbirth was observed in 42 cases across all cord abnormalities but was by far most frequently associated with abnormal coiling.

Preeclampsia, oligohydramnios and gestational diabetes were the commonest maternal characteristics observed in UCAs. Infections, PPROM, polyhydramnios and autoimmune diseases were other maternal features identified in altered structure of UCs.

NRFHR, low Apgar and Meconium stained liquor were common in coiling abnormalities, more so in the group with hypercoiling. Fifty percent of hypercoiled and one third of hypocoiled cords had birth weights of < 10th percentile.

Placental findings

More than 50% of the placentas with UCAs were small for gestational age. Significant histologic features identified were maternal vascular malperfusion (MVM-35/101), foetal vascular malperfusion (FVM-26/101) and villous capillary lesions (19/101). The other microscopic features noted were distal villous immaturity (DVI), massive perivillous fibrin deposition (MPVFD), and inflammatory lesions.

Table 3: Clinical and histologic findings in cases with multiple UCAs

Parameter	Cases with multiple UCAs (n= 31)	IUFD (n=11)	Live born (n=20)	SGA (n=11)	AGA (n=20)	Hyper coiling (n=20)	Hypo coiling (n=20)	Strictures (n=20)	Thin cord (n=20)
Placental weight									
SGA	31	19	10	0	4	1	2	4	5	1
MVM	21	8	4	0	1	0	1	3	2	1
Infarcts	13	10	4	0	1	0	0	1	2	0
Retroplacental haematoma	3	5	1	0	0	0	0	0	1	0
Intervillous thrombus	9	8	2	0	0	0	0	1	1	1
MPVFD	1	1	0	0	2	1	0	0	0	0
FVM	8	10	5	0	6	0	2	3	1	0
Chorionic plate/stem villous vessel thrombus	5	7	2	-	6	0	2	3	1	0
Avascular villi	8	8	5	-	6	0	2	3	0	0
Villous Stromal Karyorrhexis	4	5	4	-	2	0	1	0	0	0
Nucleated RBCs	2	3	-	-	1	0	1	1	0	0
Inflammation	8	9	3	1	2	0	1	1	4	1
Acute chorioamnionitis	2	5	0	1	1	0	0	0	2	0
VUE	6	4	3	0	1	0	1	1	2	1
Villous capillary/vascular lesions	14	3	3	2	2	1	0	0	0	0
Chorangiosis	9	1	1	1	1	0	0	0	0	0
Chorangiomatosis	3	2	2	0	1	1	0	0	0	0
Villous congestion	2	0	0	1	0	0	0	0	0	0
DVI	5	4	1	0	0	0	0	2	1	0

Infarcts, intervillous thrombus, retroplacental haematoma and MPVFD (histologic markers of MVM) were observed in cases with gross UCAs. The other features noted were decidual vasculopathy, distal villous hypoplasia, increased syncytial knotting, cell islands, villous agglutination, and multinucleate trophoblastic giant cells.

The histologic features of chronic FVM such as chorionic plate /stem villous vessel thrombus, avascular villi, villous stromal karyorrhexis and nucleated red blood cells were significantly more common in cords with hyper, hypo coiling and strictures. Ectatic vessels were also noted in many of the chorionic plate /stem villous vessels of FVM.

Villous vascular lesions such as chorangiosis (increased number of capillaries - more than 10 capillaries/terminal villi, in 10 villi) in many areas of the placental parenchyma, patchy and occasional multifocal chorangiomatosis (excessive capillaries with surrounding pericytes in immature intermediate / stem villi) and villous congestion were found to be associated with hypercoiled cords.

Multiple UCAs

Placentas with multiple UCAs and their associations with clinical and histologic findings were also analysed. IUFD was significantly associated with the presence of multiple UCAs (13/20). In the remaining live born cases the clinical outcome was SGA (6/20) and AGA (1/20). The most common maternal obstetric complication was hypertension and the commonest placental histology was foetal vascular malperfusion (FVM) (Figure 6). These findings are summarized in (Table 3).

Discussion

The coiling pattern of the UC largely affects umbilical blood flow that is vital for sustaining foetal growth and development and its pathophysiological significance has been studied by many authors. UCAs often result in mechanical compression leading to venous stasis, endothelial damage and loss of perfusion to a large area of placental gas exchanging villi and ultimately resulting in foetal distress and hypoxia.[8-10] This study analyzed the UCAs such as hypercoiling, hypocoiling, strictures, thin cord, true knot, SUA, ELUC and abnormal insertions in

relation to gross, histologic placental changes as well as clinical parameters and foetal outcome.

Table 2: Correlation between umbilical cord coiling abnormalities and clinical parameters and foetal outcome

Parameters	Total number of cases	Total number of hypercoiled cords	Total number of hypocoiled cords	Total number of normal coiled cords	Total number of IUFD	Total number of FGR (<10th percentile)	Total number of NRFHR tracing	Total number of low Apgar score (<7 at 1 min)	Meconium stained liquor	Total number of preterm births (<37 weeks)
Gestational age										
<28 weeks	8	6	5	0	4	0	0	1	3	1
>28 weeks	40	25	6	2	7	2	2	6	4	1
Maternal factors										
HT	15	6	2	0	1	0	0	2	3	0
GDM	8	0	0	1	1	0	0	1	0	1
Rh Negative	1	0	0	0	0	0	0	1	0	0
Oligo	10	6	2	0	0	0	0	1	3	0
PPROM	3	6	2	0	0	0	0	0	1	0
Polyhydramnios	1	1	0	0	0	0	1	0	0	0
Auto immune	1	1	2	0	1	0	0	1	1	0
Infections	4	1	1	0	1	0	0	0	0	0
Foetal factors										
SGA	21	9	5	0	1	0	0	5	2	1
AGA	10	8	1	0	1	0	0	0	0	0
LGA	3	0	0	1	0	0	0	0	0	0
IUFD	14	14	5	1	9	2	2	2	5	1
NRFHR	15	2	1	0	1	0	0	2	1	1
Liquor										
<4 @1 mt	6	1	0	0	0	0	0	1	0	0
<7 @ 1 mt	7	2	1	0	1	0	0	1	0	0
Thick meconium stained liquor	4	1	0	0	0	0	0	0	0	0

Consistent with prior studies, our investigation showed that UCA has significant association with IUFD, SGA and intrapartum complications such as NRFHR tracing and low Apgar scores.[8-10] Meconium stained liquor was not a consistent finding in our study.

Umbilical cord coiling abnormality

Little is known about factors determining cord coiling. It is generally believed that coiling is established very early in gestation and is thought to be the result of foetal activity. Lack of coiling may then reflect foetal inactivity, which is supported by the fact that coiling is reduced in cases of restricted foetal movements due to various causes.1 The prenatal ultrasonographic evaluation of umbilical cord is usually limited to vessel number and umbilical artery Doppler. Predanic et al demonstrated a strong correlation between mid-trimester umbilical coiling index (UCI) and post-natal coiling index.[11]

Among 101 studied placentas, abnormal coiling was the commonest UCA, which accounted for 80%. The frequency and clinical correlations of hypercoiled cords were FGR (43%), IUFD (29%), NRFHR (31%). For hypocoiled cords, the frequencies of adverse outcomes were IUFD (45%) and FGR (29%). Our results were in contrast to the study by Machin et al who observed more IUFDs among hypercoiled cords. Our data support the finding that abnormal coiling may cause chronic umbilical cord obstruction and unfavourable foetal outcome.[12]

Among hypercoiled umbilical cords, specific gross patterns of coiling were recognized with histologic evidence of foetal vascular malperfusion and stillbirth.[8]

The placental weight was small for gestational age in more than two thirds of the studied cases. Placental histologic findings associated with UC coiling abnormalities include villous capillary congestion, chorangiosis, chorionic plate / stem villous vessel thrombi, avascular villi, MVM, inflammatory lesions and DVI. Placental infarcts and intervillous thrombus are the conspicuous lesions observed among coiling abnormality cases in our series.

They represent deficient maternal circulation (maternal vascular malperfusion) leading to parts of placental atrophy or infarction in areas of poor nutrition. However,

the association between MVM and cord coiling abnormalities appear speculative.

Hypercoiling+ Stricture	4	SGA	A) congestion around cord insertion	A) FVM	A) NIL	IUFD

We wondered whether the less placental reserve due to deficient intervillous circulation can affect foetal outcome if cord coiling abnormalities arise additionally.

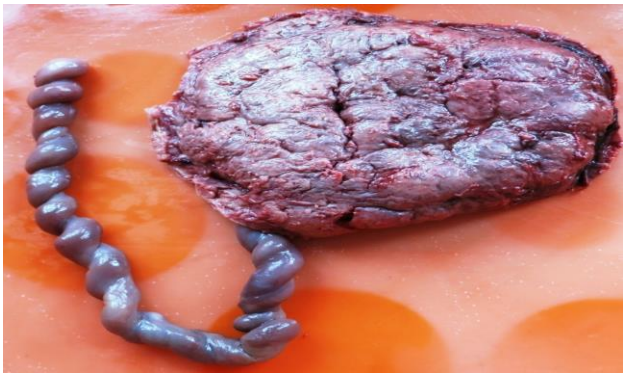

Figure 1: Hypercoiled cord

Presence of avascular villi, thrombosis of foetal vasculature, VSK and NRBCs reflect foetal blood flow obstruction and hypoxia. In our study 25% of the abnormal coiling cases tended to have FVM suggesting that these lesions would have caused chronic vascular obstruction.[10]

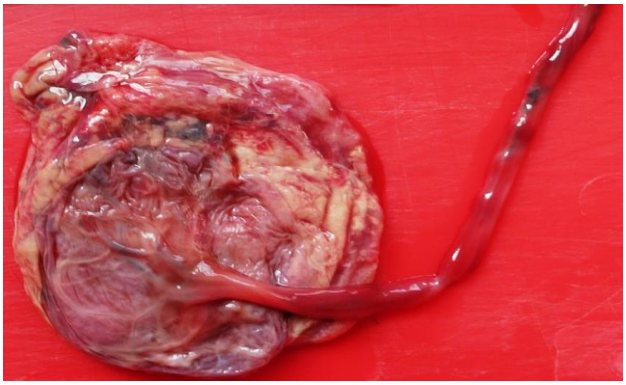

Figure 2: Hypocoiled cord

Figure 3: Hypocoiled cord

Chorangiosis, multifocal chorangiomatosis are overlapping villous capillary lesions believed to be related to hypoxia. Benirschke observed an association between chorangiosis and cord problems.[13] It is an adaptive mechanism to overcome hypoxia occurring in coiling abnormalities. Our observations were also similar.[14] Some of the cases also showed distal villous immaturity, one other lesion known to be associated with coiling abnormalities.

Figure 4: Hypercoiled cord with avascular villi and thrombosis

There was some correlation between inflammatory lesions such as VUE and, acute chorioamnionitis with individual UCA.

Figure 5: Hypercoiled cord with avascular villi and thrombosis

Cord strictures

Most investigators considered strictures and hypercoiling to be similar or related entities. In our study we observed a total of 11 cases with cord strictures. Four among the cases were associated with hypercoiling; one each with hypocoiling, velamentous cord insertion and ELUC. 4 cases had isolated stricture. This data suggested that cord stricture is a distinctive entity as agreed upon by Hong Qi Peng et al in their study.[15] We have also noted a high incidence (more than 80%) of foetal demise associated with cord stricture, coiling abnormalities or a

combination of both. Foetal vascular malperfusion was common when strictures and hypercoiling were coexistent. This implies that UC strictures and hypercoiling could decrease the blood flow with possible predisposition to development of thrombosis.

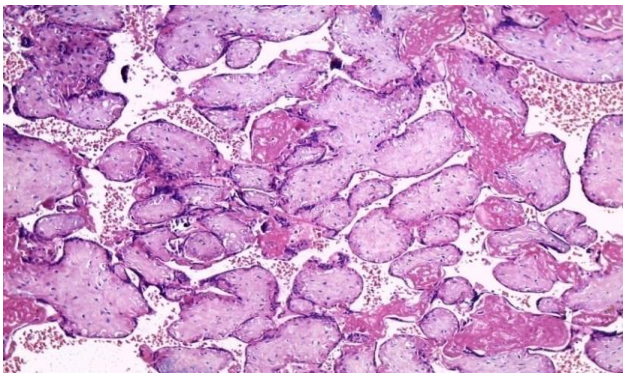

Figure 6: Photomicrograph of placental villi showing avascular hyalinised villi, villous stromal karyorrhexis and nucleated RBCs suggesting that these lesions would have caused prolonged obstruction (H&E, 10×)

Thin cord, SUA

It has been suggested that diameter of the umbilical cord is determined by the water content of Wharton's jelly. Previous studies have found an association of thin cord with FGR and other poor foetal outcome.[16,17]

A Wharton's jelly reductions have also been recognized as a possible cause of foetal death in the presence of single umbilical artery, which is the most common abnormality of the umbilical cord. These associations were confirmed in our study. According to Heifetz SA, non-malformed SUA infants can have an increased mortality rate, although SUA with associated malformations are the common cause of the high perinatal mortality.[18]

True knot, ELUC

Interestingly, both cases of true knot were associated with LGA. The case with a tight TK ended up in IUFD. Common associations like multi gravida and ELUC were also observed in our study. Like earlier studies we also found an association between ELUC and other multiple UCAs.[5] Both cases of ELUC were associated with multiple UCAs such as nuchal cord, TK and stricture and expectantly both resulted in IUFD.

Abnormal cord insertions

Marginal and velamentous insertions are suggested to result from disturbances of implantation and considered a marker of placental insufficiency.[19] We found that non-reassuring foetal status, SGA and IUFD were significantly associated with abnormal insertion which may reflect intrauterine hypoxia.

Multiple UCAs

Any UCA can sufficiently reduce placental function, when multiple predispose the foetus to placental circulatory stasis lesions and thrombosis, thus leading to vascular obstruction and unfavourable clinical sequelae.[3]

In our study the majority of multiple UCA cases tended to have extensive rather than focal FVM with admixture of avascular hyalinised villi, villous stromal karyorrhexis and nucleated RBCs suggesting that these lesions would have caused prolonged obstruction. Infants with multiple UCAs where FVM is extensive were found to have brain imaging abnormalities and/or abnormal neurological follow-up.

There were some limitations in our data. First, as a retrospective study, the clinical information was available only for the immediate neonatal period and further follow up could not be ascertained. Second, not all placentas and complete length of the UC (that remained attached to the neonate) were available for examination. Finally, different patterns of hypercoiling were not studied.

Conclusions

Gross UCAs, especially when multiple was associated with clinically significant placental findings and adverse perinatal outcome. Therefore, our study reinforces that all placentas with gross UCAs should be submitted for examination with complete (full length of the) umbilical cord. Coiling index with patterns of coiling should be a part of routine examination. A prospective study that also includes the follow up of these neonates could address the clinical effects of UCAs.

Abstract

Background: To evaluate the placental morphology and perinatal outcome in patients with gestational hyperglycemia on diet and medication.

Methods: Placental examinations performed at the Department of Pathology between August 2016 to August 2018 were retrospectively reviewed. Of the received 140 placentas, 35 of gestational diabetes (GDM) and pre gestational diabetes were identified and segregated into hyperglycemia on diet and on medication. The clinical details, placental findings and perinatal outcome of patients in both the groups (gestational hyperglycemia on diet and medication) were collected and analyzed.

Results: Among the 35 cases, there were 24 cases of mild gestational hyperglycemia controlled with diet and 11 cases of hyperglycemia on medication (oral hypoglycemic drugs ± insulin).

Most of the placentae in both the groups weighed less than tenth centile. The cord abnormalities such as hyper coiling, velamentous /marginal insertion and furcate cord were observed more in women with GDM on diet. There was no significant gross placental lesion in those on medication. Placental histological features most consistently associated with both the groups include, disturbances of villous maturation (DVM), Derangements in uteroplacental / foetoplacental circulation and villous capillary lesions. Small for gestational age and intrauterine foetal death were found in both the groups, but more commonly in patients with hyperglycemia on medication.

Conclusions: Villous maturation defects, uteroplacental / foetoplacental malperfusion are the essential placental changes which can result in adverse perinatal outcomes in women with hyperglycemia irrespective of the diabetic control.

Introduction

India has the second largest diabetic population in the world after China,with 8.7% of the total population in the age group 20-70 years being diabetic.[1] A cross sectional study among 15 states showed an estimated prevalence of 7.3%.[2] Diabetes in pregnancy is a growing health concern among the antenatal mothers in India. A recent meta-analysis shows the pooled estimate for mean prevalence of gestational diabetes to be 10.1% with a rising trend from 0.53% to 27.3%.[3-5]

Gestational diabetes is defined as glucose intolerance with onset or first recognition during pregnancy and is associated with a multitude of maternal and foetal complications.[6] There is a higher incidence of spontaneous miscarriages, congenital malformations, macrosomia, intrauterine death, operative deliveries, birth injuries, neonatal respiratory distress, neonatal hypoglycaemia in diabetic pregnancies and increased incidence of type 2 diabetes in offspring. Maternal complications include a higher incidence of preeclampsia, polyhydramnios, obstructed labour, caesarean sections, postpartum haemorrhage and infections.

Placenta is the organ which serves as a means of communication at the maternal foetal interface, meanwhile acting as a selective barrier between both the circulations. Changes in the glycemic status are known to affect the placenta and the resulting histopathological findings are categorised based on the time of onset of hyperglycemia.[7,8] Earlier onset of altered glycemic profile results in structural alterations whereas later onset causes functional impairment. Common changes observed include villous immaturity, villous fibrinoid necrosis, chorangiosis, and increased angiogenesis.

Hence the placenta may be regarded as a route map guiding us in our understanding of the pathological basis of the foetal complications encountered in diabetic pregnancies.

We sought to determine the placental morphological changes in diabetic pregnancies and to correlate them with neonatal outcome.

M□□□□□□

In this retrospective study, 35 singleton placentas from mothers with altered/abnormal glucose profile were studied. Institutional ethical committee approval was obtained. The study materials were archived from the departments of Pathology, Obstetrics and gynaecology and from medical record department. The study period was between August 2016 to August 2018 (2 years).

Inclusion criteria

- Placentas from patients with the clinical history of gestational diabetes / hyperglycemia on diet and medication irrespective of associated comorbidities

Exclusion criteria

- Unfixed/poorly fixed placental specimen and Placentas with no clinical details will be excluded

Clinical data collected were patient's age, gestational age, obstetric score, co-morbidities and types of glucose intolerance. All the antenatal women were routinely screened for gestational diabetes during 24 to 28 weeks of gestation by the DIPSI OGCT (75 grams glucose load in non-fasting state followed by a 2-hour plasma glucose).[9] Women with 2 hour plasma glucose more than 140mg/dl were categorized as gestational diabetes. They were categorized into 2 groups: Mild gestational hyperglycemia (on diet), diabetes on medication (pregestational /gestational).

Perinatal factors observed were mode of delivery, pregnancy outcome [intrauterine foetal death (IUD), neonatal death], birth weight, Apgar scores and NICU (neonatal intensive care unit) admission. According to the birth weight, the babies are classified as small for gestational age/ foetal growth restriction (SGA/FGR), appropriate for gestational age (AGA) and large for gestational age (LGA).

The placental tissues were fixed in 10% buffered formalin. The gross parameters observed were trimmed disc weight, measurements, cord (color, length, diameter, number of vessels, twists, insertion site, true/false knots), membranes (color, insertion and rupture site), foetal surface, maternal surface and parenchyma (color, sponginess, location & size of any lesion, calcification, etc.).[10]

After taking photographs of the foetal and maternal surfaces, 2 bits were taken each from the membrane roll and umbilical cord. The placental parenchyma was then cut into thin slices with the interval of 1.0cm (bread loaf method). Picture of the parenchyma was taken for all the placentas. 3 bits were taken from the normal looking central parenchyma and few more from the lesional area (if present grossly). Haematoxylin and eosin stained slides were reviewed, and significant changes were noted.

Since it was a descriptive study with limited numbers, statistical analysis for comparison was not attempted.

□□□□□□□

The 35 cases were identified with hyperglycemia in pregnancy. There were 24 cases of mild gestational hyperglycemia controlled with diet and 11 cases of hyperglycemia on medication, which included gestational and pre gestational diabetes.

Mild gestational hyperglycemia on diet (n=24)

Clinical characteristics

The age distribution of the patients whose placentae were examined ranged from 23 to 40 years with the mean age of 30.83 years. The earliest gestational age was 25 weeks and the maximum was 40 weeks. Fourteen patients were primigravida and ten were multigravida. Half of the placentas were from preterm pregnancies and half from term pregnancies. Associated maternal conditions were analysed with few cases showing comorbidities such as oligohydramnios (n=3),hypertension /preeclampsia (n=2),

antiphospholipid antibody (n=2), anemia (n=2), abruption (n=2) and one each of familial hypercholesterolemia, placenta previa, polyhydramnios and hypothyroidism.

Foetal outcome

The birth weights of nine (37.5%) of the neonates were appropriate for gestational age (AGA). Among the remaining, 8 (33%) were small for gestational age (SGA), 3 (12.5%) were large for gestational age (LGA) and 4 (16.6%) of the pregnancies resulted in intrauterine foetal demise (IUFD). Table 1 highlights the perinatal outcome in both the groups.

Placental findings

Weight: Of the 24 studied placentas, 11 weighed less than the 10th centile (11/24). This is in correlation with the growth restriction in 6 foetuses (6/11) and IUD in 1 case (1/11). The remaining small placentas (4/11) were of foetuses with normal weights.

The weights of nine of the placentas(9/24) were in the normal range

Gestational and pre gestational diabetes on medication (n=11)

Clinical characteristics

The age distribution of the patients whose placentae were examined ranged from 25 to 42 years with the mean age of 32.9 years.

The earliest gestational age was 30 weeks and the maximum was 39 weeks. Four patients were primigravida and seven were multigravida. Three of the placentas were from term pregnancies and eight from preterm pregnancies. Associated maternal conditions included were three cases each of gestational hypertension/preeclampsia and hypothyroidism and one each of anemia and immune thrombocytopenic purpura.

Foetal outcome

Five (45%) of the neonates were SGA, 2(18%) were AGA and 1(9%) was LGA. The remaining 3 (27%) were IUFD (Table 1).

Table 1: Perinatal outcome in GDM on medication and GDM on diet

Perinatal outcome	SGA	AGA	LGA	IUFD
GDM on diet (n=24)	8	3	9	4
GDM on medication (n=11)	5	1	2	3

Placental findings

Weight: 7/11 placentas weighed less than 10th centile. Four of them were associated with small foetuses and 2 each were associated with AGA and IUD respectively.

Gross features

Table 2 highlights the gross placental findings including umbilical cord.

Microscopic findings

Table 3 displays the microscopic features of placenta in both the groups.

Apart from the tabulated findings, calcification, perivillous fibrin deposition, increased NRBCs, subchorionic cysts and mild focal villitis were also observed.

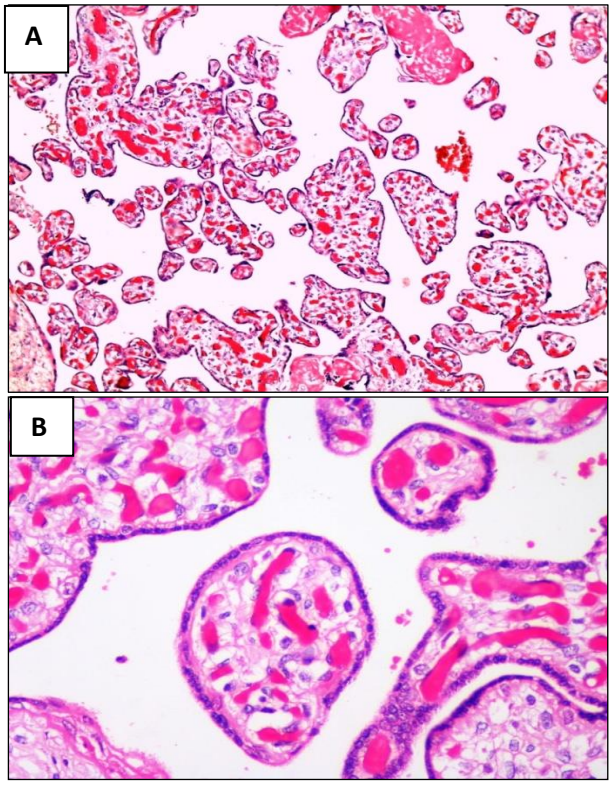

Table 2: Gross placental findings in GDM on medication and GDM on diet

Gross placental findings	GDM on diet (n=24)				GDM on medication (n=11)			
	SGA (n=8)	AGA (n=3)	LGA (n=9)	IUFD (n=4)	SGA (n=5)	AGA (n=1)	LGA (n=2)	IUFD (n=3)

[illegible]

[illegible]

In the present study, we analyzed the placental morphology and clinical outcome in pregnant women with mild hyperglycemia on diet and Gestational and pre-gestational diabetes on medication.

[illegible]

[illegible] 10 [illegible]

There have been studies on placentas of diabetic women which have reported large babies and higher placental weights.[11-15] In contrast to that, we encountered more number of small placentas which belonged to small to normally grown babies and was comparable with Edu et al.[16]

Risk of foetal loss is increased in diabetic pregnancy irrespective of glycemic control.[17] Similarly, incidence of intrauterine death was higher in women in both the groups.

There was no significant increase in gross placental lesions among GDM on medication.[18] The cord abnormalities such as hypercoiling, velamentous/marginal insertion and furcate cord were observed more in women with GDM on diet.[19] Single umbilical artery is generally associated with gestational diabetes, but there were no such instances in our study.

Placental histologic changes

Disturbances of villous maturation (DVM)

DVM also known as distal villous immaturity were found in more than half of the cases in both groups. In contrast to the findings of Huynh et al, we did not find any differences between the two groups.[20]

Generally, in the last trimester of pregnancy, there is accelerated differentiation into terminal villi with increase in vasculosyncytial membrane formation. However, in pregnancies complicated by diabetes, this terminal differentiation is inhibited due to growth factor like activity of foetal insulin. Additionally, this is amplified by coexistent hypercoiling of the cord as seen in our study.[21]

As a result of defective villous maturation, there is reduced placental reserve leading to poor tolerance to acute hypoxia resulting in late intra uterine foetal loss. Since, this entity has a 10% risk of recurrence in subsequent pregnancies, it has been recommended to rescue the foetus by early delivery.[22]

Derangements in uteroplacental circulation/Maternal vascular malperfusion (MVM)

In our study, we observed greater incidence of features of MVM such as, infarcts, intervillous thrombus and increased syncytial knotting in both the groups. As described in literature, decidual vasculopathy was the prominent finding in women with coexistent preeclampsia/APLA as compared to isolated GDM.[23] Retroplacental hematoma with blood dissecting into the intraparenchymal villous space and subsequent haemorrhagic necrosis was also noted in few cases of GDM on diet.

Derangements in foetoplacental circulation/foetal vascular malperfusion (FVM)

FVM frequently goes undetected antenatally and is commonly diagnosed with pathologic examination of placenta. Among the multitude of factors associated with FVM, maternal hyperglycemia plays a significant role.[24]

Pregnancy per se is a thrombogenic state. When it is combined with maternal hyperglycemia (prothrombotic tendency) and hypercoiling of the cord (thereby causing vascular stasis and ischemia), it results in thrombosis in the foetal vascular tree, leading to foetal growth restriction and increased perinatal mortality and morbidity.[25,26]

The following findings were seen as part of FVM in our study population: chorionic plate/ stem villous vessel thrombi, vascular ectasia, groups of avascular, fibrotic to hyalinized villi and villous stromal karyorrhexis.

Villous capillary lesions

A gamut of villous capillary lesions encompassing chorangiosis, chorangiomatosis and chorangiomas believed to be caused by preplacental hypoxia.[27]

GDM in pregnancy is commonly associated with chorangiosis, which is hypothesized to be caused by insulin/IGF-1 receptor mediated angiogenesis.[25]

In our series, we predominantly encountered chorangiosis and an occasional case of microscopic chorangioma, but none of the cases showed chorangiomatosis.

Inflammatory lesions

Acute chorioamnionitis was detected in a few cases of maternal hyperglycemia, of which more than half were complicated by preterm labour /preterm rupture of membranes. Severe maternal inflammatory response and early foetal inflammatory response were noted.[28]

Mild chronic villitis and chronic histiocytic intervillositis (CHIV) were also observed in some cases. Both the lesions have strong association with maternal autoimmune diseases.

Chronic histiocytic intervillositis is an uncommon placental lesion, characterized by a dense lymphohistiocytic infiltrate confined to the intervillous space. CHIV has a tendency for causing recurrent pregnancy loss due to the presence of persistent increase in memory T cells in subsequent pregnancies.[29,30]

Subchorionic pseudocysts, increased cell islands, foetal nucleated red blood cells and vascular ectasia are a known histologic sign of hypoxic lesions and found more in cases of GDM on diet.[31]

The strengths of our study include that all the women were booked at our hospital, the investigations, follow up and delivery was in the same institution and there was no loss to follow up and hence no attrition of data.

The limitations of our study include, smaller sample size and retrospective nature. Not all placentas with GDM were sent for pathological examination. Only those cases with maternal clinical conditions warranting special attention and those with adverse perinatal outcomes were sent for examination.

To summarize, Villous maturation defects, uteroplacental / fetoplacental malperfusion and villous capillary lesions are the essential placental changes which can result in adverse perinatal outcomes in women with hyperglycemia irrespective of the diabetic control.Further prospective studies with large sample size including all GDM placentas with exclusion of confounding factors would help in better characterization of placental lesions in different levels of glycemic control. Understanding the placental pathogenesis will help to develop protocols for prevention and treatment strategies to improve perinatal outcomes.

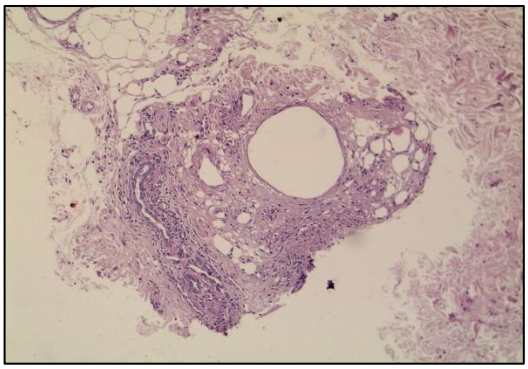
[illegible]

Sir,



Idiopathic localized involutional lipoatrophy (ILIL) is a rare form of localized lipoatrophy that arises spontaneously without inflammation.

A 6 year old boy presented with depressed skin lesion involving trunk since 3 years. No history of previous trauma, drug intake, injections or prior inflammatory conditions. On examination, well demarcated, non-tender, non-indurated, depressed pigmented plaque seen over centre of abdomen of size 10x7 cm, right side of chest of size 5x4 cm (Figure 1) and over back of size 6x4 cm. A differential diagnosis of morphea and lipoatrophy was made. Routine hematological, biochemical investigations, fasting blood sugar, serum triglycerides, serum TSH and ANA were normal. Ultrasonography of depressed skin lesions showed thinning of subcutaneous plane with increased echoes in right posterior thorax.

[illegible]

Biopsy from the depressed lesion showed epidermis exhibiting basket weave keratin, mild papillomatosis and acanthosis. Papillary and upper dermis showed mild perivascular lymphocytic infiltrate with occasional eosinophils. Dermal collagen fibres are normal, pilo sebaceous gland appear small with other adnexal structures. There is loss of subcutis with shrunken fat globules, within the lobule, adipocytes appear reduced in size, number, with some dilated fat spaces and many tiny adipocytes. Fibrosis, mild infiltrate of lymphocytes, histiocytes, foamy macrophages observed around fat (Figure 2). As there was no history suggestive of preceeding inflammatory process, normal laboratory findings and classical histopathological involutional changes, a final diagnosis of idiopathic localized involutional lipoatrophy was made.

[illegible]

ILIL is characterized by selective loss of subcutaneous fat without exudative reaction or fibrosis. It is more common in young females, usually solitary and very few childhood cases have been reported. Pathogenesis is unclear and literature suggests impairment of adipocyte differentiation, adipocyte apoptosis, and mitochondrial dysfunction.[1] Activated macrophages trigger immunologic disorders by secreting variety of cytokines such as fibroblast growth factor-2, platelet-derived growth factor, interleukin-1, tumor necrosis factor-α, and transforming growth factor-β, resulting in involution of subcutaneous fat tissue.[2]

Clinically localized involutional lipoatrophy, presents as an asymptomatic, well demarcated, localized, non-inflamed atrophic depression affecting only one site and commonly involve arms, buttocks, thighs and abdomen. In our case multiple sites were involved. Histologically as seen in our case, ILIL lesions show well developed involutional changes, exhibiting shrunken fat lobules with retraction of whole fat lobules from surrounding collagenous septa. Within each affected fat lobule, lipocytes are shrunken and retracted resembling embryonic fat tissue.[3,4] ILIL was differentiated from morphea which exhibits pronounced inflammatory infiltrate in subcutaneous fat, and the trabeculae dividing the subcutaneous fat are thickened because of inflammation and deposition of new Collagen.[4] Majority

of cases resolve spontaneously. Anti-inflammatory agents such as steroids, calcineurin inhibitors, and antimalarials can be used in the initial phase when the lesion is expanding.[5] In long-standing lesions, localized fat transplantation may be performed.

We report this case for its rarity, as the child presented with ILIL involving multiple sites. Although skin lesions can resolve spontaneously without treatment, currently in our case the lesions persisted without progression.

Cystic adrenal lymphangioma

Kiran Yagain[1], Vinod Kumar[1], Sanjeev Bhaskaran[2]

Departments of [1]Pathology and [2]Surgery, Kasturba Medical College, Manipal, India

An 18 year old female presented with vaginal bleeding at 2 months of gestation. Ultrasonography revealed a large retroperitoneal cyst. Histopathological examination of the excised cyst showed features suggestive of a cystic adrenal lymphangioma. This case is reported because of its rarity and detection during pregnancy.

Keywords: Retroperitoneal cyst, adrenal cystic lymphangioma

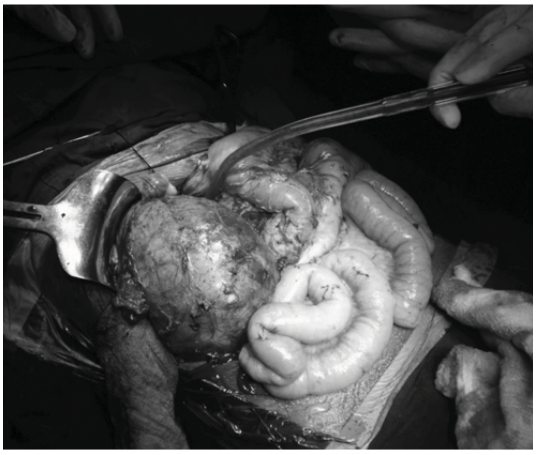
Correspondence: Dr. Kiran Yagain, Department of Pathology, Kasturba Medical College, Manipal, 576104, Karnataka State, India, Email: kiranyagain@rediffmail.com

Date received: 15/1/2010 Date accepted (after revision): 7/4/2010

Introduction

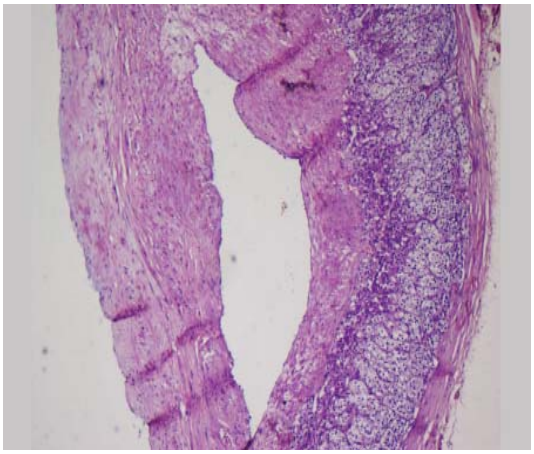
Adrenal lymphangioma is a rare and benign lesion most often found incidentally during abdominal imaging, surgery or autopsy.

Case report



An 18-year old female presented with vaginal bleeding at 2 months of gestation (i.e. at 8 weeks of pregnancy). Abdominal ultrasonography was done to check for the status of embryo. The uterine cavity was empty suggesting a diagnosis of missed abortion. However a retroperitoneal cyst was found incidentally while doing ultrasonography. Computed tomography confirmed the presence of retroperitoneal cyst, which measured 16 x 10 x 10 cms and was seen displacing the right kidney. Surgical excision of the cyst was done 3 months after initial evaluation of the retroperitoneal mass by USG and CT examination.

On exploratory laparotomy, the cyst was identified in the retroperitoneal location and was found to contain straw colored fluid (Figure 1). The cyst was excised and sent for histopathological examination.



Gross examination showed a grey-white cystic mass weighing 15 grams with yellowish areas admixed with congested areas. The cut surface showed focally thickened areas with nodular yellow tissue. Histologically the cyst was partially lined by endothelial cells overlying fibro-collagenous tissue with areas of hyalinization, large dilated lymphatic channels, with smooth muscle hyperplasia, foci of ceroid laden macrophages and islands of compressed adrenal tissue in the wall (Figure 2). The endothelial cells were immunoreactive for CD34. A diagnosis of adrenal cystic lymphangioma was made.

Discussion

Adrenal cysts are usually asymptomatic and are discovered incidentally at autopsy[1]. Currently, due to increased use of imaging, increased numbers of adrenal cysts are reported[1]. They occur at all ages, with a peak in the 3rd to 6th decades, a definite female preponderance, and bilaterality in 10% of cases[1].

□□□□□ **1**□ Intra-operative picture: cystic mass mobilized below liver.

□□□□□**2**□ Photomicrograph of cyst lined by endothelium and wall showing compressed adrenal tissue (H&E stain, 40X magnification).

Small adrenal cysts are clinically silent. Large ones may cause abdominal discomfort, loin pain, gastro-intestinal disturbances or acute abdomen due to intracystic hemorrhage, rupture or infection. Peripheral and curvilinear calcification is present in 15% of adrenal cysts[1].

Adrenal cysts are histologically classified as parasitic, epithelial, endothelial or pseudocysts; with endothelial cysts being the most common[1]. They can be lymphangiomatous or angiomatous in origin.

Adrenal lymphangioma is a benign cystic tumor composed of dilated lymphatic vessels with a lymphoid stroma and a smooth endothelial lining[2]. It results from faulty development or ectasia of lymphatic vessels[2]. The cyst may contain serous or chylous fluid.

In our case, the patient presented with vaginal bleeding and the cyst was large. The diagnosis of cystic lymphangioma was made only after histopathological examination of the cyst.

The treatment of adrenal cysts depends on symptoms, size and complications. Malignant transformation is extremely rare[3]. The prognosis is generally good after removal of the cyst[3].

Case report

Intradiploic epidermoid cyst - a pearl within the skull

V Lakshmi[1], KS Thirumurthy[2], S Rabia[1], V Chaitra[1]

Introduction

Epidermoid cysts are quite uncommon in the craniofacial region and more so in the intradiploic region within the skull. They are benign and slow-growing. Some attain great size, producing major neurological signs. A high index of suspicion with an accurate radiological assessment followed by complete removal of the tumour and its capsule are essential for good long-term prognosis. We report an interesting case of an epidermoid cyst occurring in the skull of a young male patient with a short review of the relevant literature.

Case report

A 31-year-old male patient presented to the outpatient unit of the neurosurgery department with complaints of giddiness. The symptoms were present intermittently and no relevant past medical history or family history could be elicited.

On examination, the patient had a GCS (Glasgow Coma Scale) of 15/15 and his vital signs were stable. Computed tomographic scan (CT Scan) showed an intradiploic expansile cystic lesion with a sclerotic rim in the left temporo-parietal region. The patient underwent craniotomy for excision of the cyst. A small piece of the lesion was sent for frozen section study, which showed anucleate squames and keratin debris. The cyst was excised and the residual bone defect was covered with a titanium mesh, fixed with titanium screws. Bone cement was applied to solidify. Post-operatively, the patient remained stable. A course of antibiotics and anticonvulsants were prescribed.

The specimen was sent to the histopathology laboratory in 10% neutral buffered formalin. An elliptical piece of bone with the inner surface showing a fleshy mass was received. Cut surface of the growth appeared friable with gritty areas. (Fig. 1)

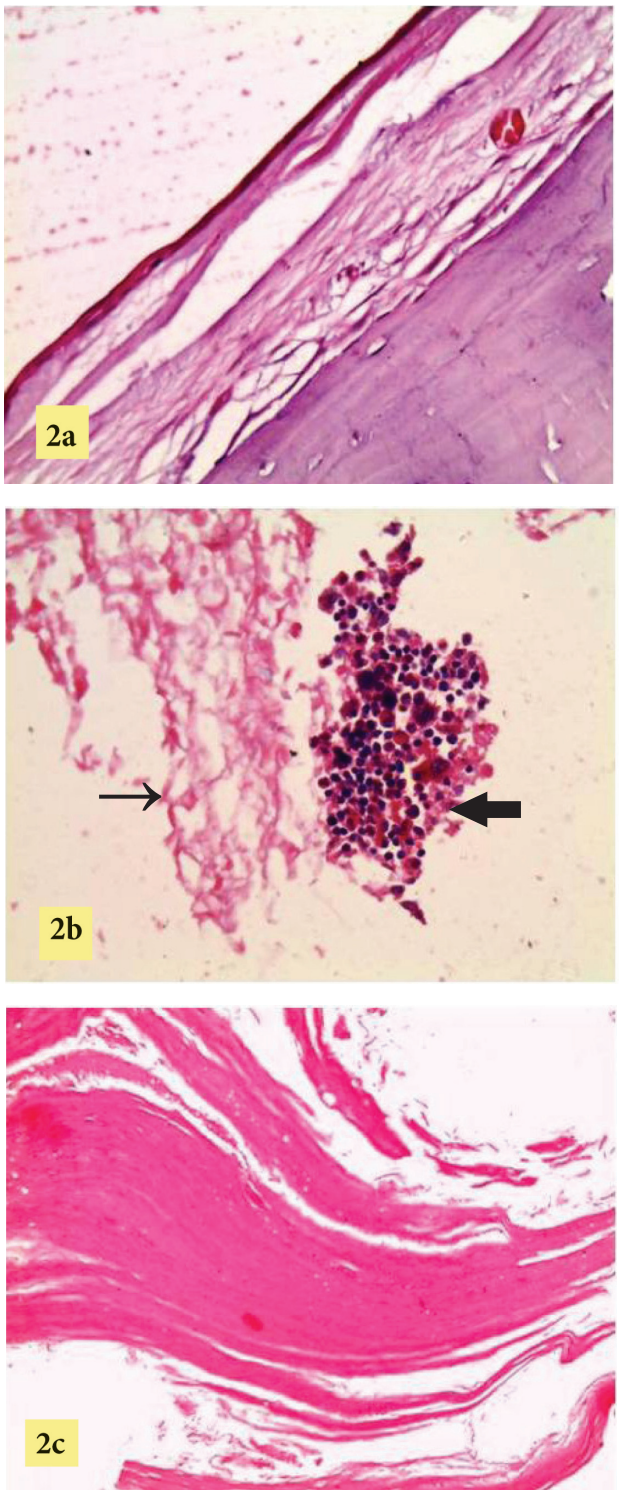

Fig.2. 2a Degenerated bony spicules with a cyst lined by stratified squamous epithelium H&Ex400. 2b. Anucleate squames (arrow) and hematopoietic elements (block arrow). 2c. Keratin flakes; H&E x400.

On histological examination, degenerated fragments of bone were seen with a lesion composed of a lining stratified squamous epithelium overlying lamellated flakes of keratin, keratinous debris and occasional anucleate squames. (Fig.2) Other adenexal structures were not seen. On follow up the patient showed a significant improvement of his symptoms.

Discussion

Epidermoid cysts are common in routine histological practice and they are usually located in hair-bearing areas of the skin. Location within the cranial cavity are rare. They represent 0.04 to 0.7% of intracranial neoplasms (1). Intradiploic dermoid cyst was first described by Cushing in 1922.

During neural tube formation, sequestration of ectodermal elements can be seen within the cranial cavity due to defective separation of the neuroectoderm (2). This results in the formation of epidermoid cysts which can remain asymptomatic even after attaining a large size. The presence of cheesy, keratinous debris within the cyst lumina imparts a "pearly" appearance and hence these tumours have also been referred to as "pearly tumours" in literature (3). The intradiploic location is far less common than the intradural location (4).

CT imaging (5) is of greater value than plain radiography as CT allows better assessment of both skull involvement as well as intracranial extension. Intraparenchymal extension of intradiploic epidermoids is known to occur. Imaging appearance depends on the ratio of keratin to cholesterol in the lesion. Typically epidermoids are hypodense on CT.

Although they remain asymptomatic for long periods, erosion of the bone and involvement of the brain parenchyma can occur. Rupture of the cyst with release of contents can occur into the subarachanoid space. Chronic granulomatous arachnoiditis can result from irritation of the meninges due to released keratin.

Epidermoid cysts are mostly seen in the third and fourth decades of life with a male predominance. The lesions may extend and present as a subcutaneous swelling of the scalp. In contrast, dermoid cysts are typically associated with the suture lines, commonly occur in orbital region and in the midline and usually present in childhood. (6). Histology of an epidermoid cysts shows a keratin-filled cyst lined by stratified squamous epithelium (7). The cyst wall characteristically lacks dermal elements.

Other differential diagnoses of epidermoid intradiploic cysts include bone-destroying lesions affecting the orbit, eosinophilic granulomas, giant cell granulomas, cholesterol granulomas, cavernous hemangioma, and osteolytic intradiploic metastases (8,9).

Giant extradural epidermoids with profound deformation of the brain and extensive lytic skull lesions may allow a normal life without any significant restrictions (10). Individual risk-benefit assesment is mandatory in the discussion of a specific treatment. In our case, the surgical excision was done because the patient was symptomatic and the size of the lesion was significant, causing compressive symptoms.

We report this case because of its characteristic radiological and histopathological appearance and stress the importance of considering this entity in the differential diagnosis of skull lesions.

Key words:
Body mass index.

ABSTRACT

Objectives: To study the role of Body Mass Index as an independent risk factor and prognostic factor in breast cancer.

Methods: A hospital based epidemiological study was conducted in a tertiary care hospital in India involving 50 patients with a diagnosis of breast cancer who visited the Medical Oncology outpatient department for a period of 3 months. 50 age matched controls who had no detectable breast cancers were selected as controls. Their body mass index was calculated. Data including stage of breast cancer, lymph node status and presence of metastasis, histological type, grade of the tumour and hormone receptor status. (ER, PR and Her 2 neu) were tabulated. Additional information regarding menstrual, menopausal status, co-morbidities like Diabetes mellitus, hypertension and epilepsy was also gathered.

Results: The mean age of patients was 53.8 years and that of controls was 49.08 years. 56 % of cases and 44% of controls were post menopausal. 20 patients and 10 controls were diabetic; 14 patients and 9 controls were hypertensive and 2 patients and 2 controls had hypothyroidism. The odds ratio which quantifies the risk of association of breast cancer and obesity is 0.339 in premenopausal women and 0.045 in post menopausal women. The number of triple negative breast cancers was more in I and II classes of body mass index. Obesity grade 2 and 3 were also associated with advanced disease, including larger tumor size, positive lymph nodes, regional and/or distant stage and deaths after breast cancer.

Conclusion: There is a statistically significant association between obesity and breast cancer in post menopausal women but the same is not applicable in pre menopausal women.

INTRODUCTION

Obesity is increasingly becoming a major public health problem in developing countries. It is defined as an accumulation of adipose tissue that is of sufficient magnitude to impair health. Excess weight is best assessed by body mass index or BMI, which is a surrogate marker for underlying obesity. The normal BMI range is 18.5 to 25 kg/m^2 (Torre *et al*., 2015). According to World Health Organization (WHO) people can be divided into the following categories based on BMI. Approximately 7% of cancers in women are associated with obesity (van den Brandt *et al*., 2000). In women, a BMI greater than 25kg/m^2 correlated strongly with an increased incidence of carcinomas of esophagus, endometrium, gall bladder, breast and kidneys. A proposed hypothesis for such an association is explained by the presence of hyperinsulinemia and peripheral insulin resistance in obese individuals (Roberts *et al*., 2010). Insulin at high concentrations has multiple effects on cell growth.

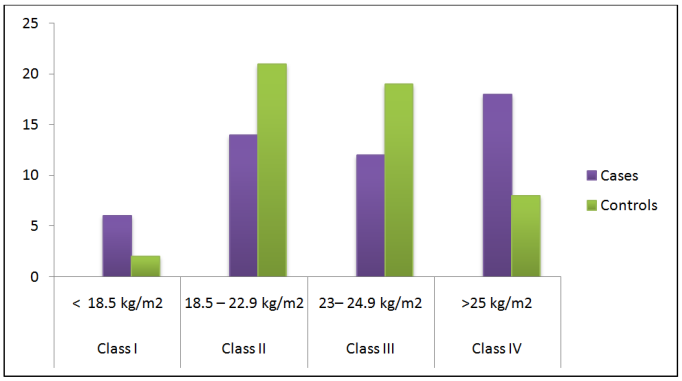
i. Activation of phosphatidyl inositol 3 kinase, β catenin and RAS
ii. Hyperinsulinemia causes increase in insulin like growth factor 1, which is a mitogenic and anti apoptotic agent, which activates many of the cell growth pathways.
iii. Obesity increases the synthesis of estrogen from androgen precursors through an effect on adipose tissue aromatases.
iv. Insulin increases androgen synthesis in ovaries and enhances estrogen availability in obese persons by inhibiting production of sex hormone binding globulin in liver.

BMI	Classification
< 18.5	underweight
18.5–24.9	normal weight
25.0–29.9	overweight
30.0–34.9	class I obesity
35.0–39.9	class II obesity
≥ 40.0	class III obesity

Corresponding author:* **Vidhya Lakshmi,
PSG Institute of Medical Science & Research, India.

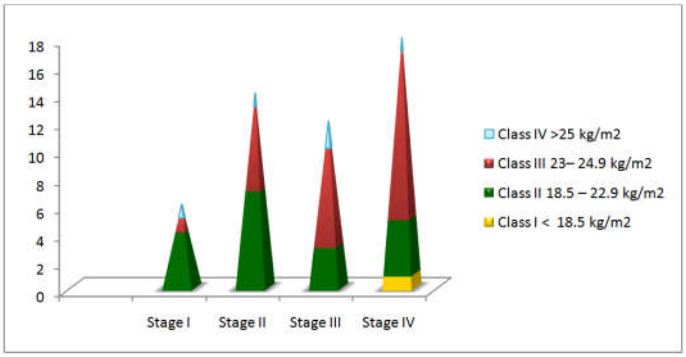
Obese women under the age of 40 have a decreased risk as a result of anovulatory cycles and lower progesterone levels. In contrast, post menopausal obese women have an increased risk, which is attributed to the synthesis of estrogen in fat deposits (Schmidt *et al*., 2015).

MATERIALS AND METHODS



A case control study was carried out at our tertiary care hospital. This was a single institution study drawn from patients who attended the medical oncology outpatient department over a period of three months. The women accompanying the patients and a few voluntary women who had no detectable breast cancers were selected as controls. The study protocol was approved by the Institutional Human Ethics Committee. Informed consent was obtained from every patient and control and the patients were asked to enter the details provided in a questionnaire. Results of their heights and weights were entered. As a relative indicator of body weight, Body Mass Index was calculated as weight in kilograms divided by square of height in meters. The patients and controls were categorized into 4 classes based on BMI.

Class I – BMI < 18.5 kg/m^2
Class II – BMI 18.5 – 22.9 kg/m^2
Class III – BMI 23 – 24.9 kg/m^2
Class IV – BMI > 25 kg/m^2



Data including stage of breast cancer, lymph node status and presence of metastasis was obtained from the case records of the patient. The histopathology reports were analyzed for recording the histological type, grade of the tumour and hormone receptor status (ER, PR and Her 2 neu).

Additional information regarding menstrual, menopausal status, co-morbidities like Diabetes mellitus, hypertension and epilepsy was also gathered. The results were tabulated and analyzed using SPSS (Statistical Package for the Social Sciences). The relationship between body mass index and risk of breast cancer was evaluated using odds ratio and the p value was calculated.

Cases	17 (60.7%)	11 (39.3%)			
Controls	19 (86.4%)	3 (13.6%)	0.045	0.058-1.024	.045

Histogram showing estrogen receptor expression in various classes of BMI

The odds ratio which quantifies the risk of association of breast cancer and obesity is .339 in premenopausal women and .045 in post menopausal women.

DISCUSSION

Overweight and obesity are current escalating public health issues. The prevalence of obesity in females has accelerated over the past decade in many developing countries. Obesity is an established risk factor for cancer and cancer related deaths, including that of breast cancers. Several studies show that a significantly stronger association is obvious between increased body mass index (BMI) and higher breast cancer incidence. Increased levels of estrogens due to excessive aromatization activity of the adipose tissue, over expression of pro-inflammatory cytokines, insulin resistance and hyper activation of insulin-like growth factors (IGFs) pathways, adipocyte-derived adipokines, hypercholesterolemia and excessive oxidative stress contribute to the development of breast cancer in obese women. Lopez *et al*. (2017) conducted a cross-sectional study of 849 women diagnosed with breast cancer in Columbian patients. Participant's body weight, height, and body mass index were collected at the time of diagnosis. Patients were classified following the Center for Disease control's (CDC) criteria: underweight (BMI $<$ 18.5 kg/m2), normal (18.5 $\leq$ BMI $<$ 25 kg/m2), overweight (25 $\leq$ BMI $<$ 30 kg/m2), and obese (BMI $\geq$ 30 kg/m2). Their data revealed that an association between BMI and menopausal status was not statistically significant in the study population. In the current study, the odds ratio of association was .339 with a p value of 0.23 in premenopausal women, which is not significant. However, the odds ratio in post menopausal women was .045 with a p value of .045 which is significant. Obese breast cancer patients are often associated with advanced stage disease, larger tumors, and axillary lymph node-positive status, partly due to delayed diagnoses and technical difficulties in palpation of the tumors. In a study conducted by Turkos *et al*. (2013), obese patients compared with normal-weight women were older at diagnosis and more often had high grade tumor with lymphovascular invasion. According to the molecular subtypes, overall survival and disease free survival were significantly shorter in obese patients with triple negative breast cancer. Obesity and lymphovascular invasion were found to be independent prognostic factors for TNBC mortality. In our study also we found that more number of obese breast cancer patients presented with stage III or IV disease, although the association was not statistically significant.

The study done by Sahin *et al*. (2017) BMI was an independent factor in patients with BC, with an association indicating a decreased incidence for luminal-like subtype and increased incidence for triple-negative subtype among premenopausal patients. However, this significance was not found in postmenopausal patients. Accordingly, a plausible etiological heterogeneity in BC might play a role among immunohistochemical subtypes in every life stage of women. Makama *et al*. (2017) published an association study of established breast cancer reproductive and lifestyle risk factors with tumour subtype defined by the prognostic 70-gene expression signature. Using prognostic gene expression profiles, they found that specific reproductive factors like higher parity was associated with low-risk (good prognosis) tumours. Also, longer duration of breastfeeding was associated with high-risk (poor prognosis) tumours. Neuhouser *et al*. (2015) performed a randomized control study and detected that A BMI of 25.0 or higher was strongly associated with risk for estrogen receptor-positive and progesterone receptor-positive breast cancers but was not associated with estrogen receptor-negative cancers. In our study we found that there was no significant difference in the distribution of estrogen receptor positive tumours and Her 2 neu positive tumours in obese and non obese patients. However, the number of triple negative breast cancers was more in I and II classes of body mass index. Obesity grade 2 and 3 were also associated with advanced disease, including larger tumor size, positive lymph nodes, regional and/or distant stage and deaths after breast cancer. An article by Schmitz *et al*. (2013) proposes that obesity and related co morbid conditions pose an increased risk for common adverse treatment effects, including breast cancer–related lymphedema, fatigue, poor health–related quality of life, and worse functional health. But we did not notice any significant difference in the post treatment morbidity among obese and non obese individuals.

Limitations of our study

The sample size of our study is limited to derive a statistically significant association of obesity and malignancy. The follow up was for a period of 6 months to one year and so the response of obese and non obese patients to the various treatment strategies could not be compared.

Conclusion

There is a valid association between obesity and breast cancer in post menopausal women but the same is not applicable in pre menopausal women. There is no significant difference in the size, histological type and immunohistochemical profile of breast cancers in obese and non obese patients, although the incidence of triple negative cancers was high in class I and class II BMI individuals. However obese patients presented with more advanced stages, possibly due to delay in detection.

ABSTRACTS

Gelatinous marrow transformation (GMT) is a rare disorder of bone marrow characterized by deposition of extra cellular gelatinous material. There is atrophy of the marrow adipocytes and loss of hematopoietic elements. It is also called as osseous atrophy of the bone marrow. It is not a specific disease but it is seen associated with chronic illness like malnutrition, anorexia nervosa, HIV infection and administration of cytotoxic drugs. Here, we report a case of gelatinous transformation of bone marrow in a 17 year old female presented with severe weight loss and anemia.

KEYWORDS: Gelatinous Marrow Transformation, Bone Marrow Biopsy

INTRODUCTION

Gelatinous transformation of the bone marrow was first reported in 1898. The condition is defined by hypo cellularity of bone marrow and deposition of extra cellular gelatinous material (hyaluronic acid). This is associated with various diseases and malnutrition is assumed to be the basic causative factor. We report a patient with unexplained weight loss who had GMT.

CASE REPORT

A 17-year-old female came to the gastroenterology department with history of significant weight loss and amenorrhea for the past one year and vomiting, since 6 months. She had no fever, abdominal pain, diarrhea, jaundice or hematamesis. There was no co morbid illness. Physical examination revealed that she was very emaciated with loss of buccal pad of fat. She had Marfanoid habitus with positive wrist and thumb sign, arachnodactyly and high arched palate. Secondary hair and skin changes, Seborrheic dermatitis and Gottron's papules were present. Her height was 167cm and weight was 27kgs (BMI- 9.68).

Her blood glucose levels, serum urea, creatinine, Bilirubin and liver enzymes were all within normal limits. Serum electrolytes including calcium and magnesium levels were normal.

Urine examination revealed no significant pathology. Her hemoglobin was 13gm/dl with Mean corpuscular volume (MCV) of 98.9fl and packed cell volume of 37.2%. The Erythrocyte sedimentation rate was 5mm/hr. The total WBC count and differential count were within normal limits.

Peripheral smear showed a normocytic to mild macrocytic, normochromic blood picture with no significant findings in leucocytes and platelets

Serology testing for HIV, Hepatitis B and C and VDRL testing did not yield any positive results. Mantoux test was negative. Serum IgG was 1.63g/L, IgA was 6.01g/L and IgM was 1.29 g/L. Stool examination did not reveal any ova or cyst.

Serum Lactate dehydrogenase (LDH) was 212 units/L. Serum B12 level was 469pg/ml and serum folate was > 20.0ng/ml. Serum C3 level was 52mg/dl and C4 level was

17mg/dl. Serum prolactin and TSH levels were within normal limits.

Ultrasound abdomen was normal. Ultra sonogram of the pelvis revealed a small size uterus and the ovaries could not be visualized. Upper GI endoscopy revealed severe esophageal candidiasis, severe antral gastritis with flattened duodenal folds. A dermatology consultation was sought for and their diagnosis was Seborrheic dermatitis with Icthyosis keratosis pilaris, suggestive of nutritional deficiency.

The working clinical diagnosis of a connective tissue disorder was made. Further workup was done to exclude a collagen vascular disease. Antinuclear antibody (ANA) profile including anti SS, Smith, Anti mitochondrial antibody, PCNA, dsDNA, Ro52 nRNP/Sm, Rib were all negative.

Bone marrow aspiration and imprint study showed mild megaloblastic changes with deposition of a proteinaceous material in the background. The bone marrow trephine biopsy sections showed hypo cellular marrow particles with erythroid hyperplasia and scattered megaloblasts. The myeloid and the megakaryocytic lineages showed normal maturation. There was deposition of an eosinophilic material which stained positively with Alcian Blue at pH 2.5 and Periodic Acid Schiff (PAS). The findings were consistent with gelatinous transformation of the bone marrow.

The patient was referred to psychiatry department with the diagnosis of anorexia nervosa. She was discharged with the prescription of Tab.Fluconazole, T.Olanzepine and T.Folic acid. On follow up after 2 weeks, she reported improvement of appetite and showed a weight gain of 1.5 kg.

DISCUSSION

Gelatinous transformation of bone marrow, also called serous atrophy is defined as loss of hematopoietic cells with atrophy of fat cells and deposition of extra cellular gelatinous material in the bone marrow.

The gelatinous material in the marrow space consists of acid mucopolysacharides, mainly of hyaluronic acid staining positively with Alcian Blue at pH of 2.5. According to previous case reports in literature [1], the incidence of Gelatinous marrow transformation (GMT) is more common in males around 20 to 30 years of age.

Bohm [2] and his colleagues state that the spectrum of underlying diseases in gelatinous transformation varies with age. In young adults (<40 years of age), anorexia nervosa in women and AIDS in men were associated with GMT, whereas in the age group of 40 to 50 years alcoholism and age group more than 60 years, lymphomas, carcinomas and chronic heart failure were the most common causes. However it is well documented that chronic malnutrition is the source of gelatinous marrow transformation as in anorexia and starvation. A recent study from South India. [3], published that the underlying clinical diagnosis was HIV positivity in 5 cases, 2 with coexistent disseminated tuberculosis (TB), 1 with cryptococcal meningitis, and 1 with oral candidiasis; disseminated TB in 1 case; pyrexia of unknown origin (PUO) in 2 cases; Hodgkin's lymphoma (HD) in 1 case; acute lymphoblastic lymphoma (ALL) with maintenance chemotherapy in 1 case; and alcoholic pancreatitis in 1 case.

Severe metabolic diseases like diabetes mellitus and hypothyroidism and severe infectious diseases like AIDS also may induce gelatinous transformation. Amos et al in 1990 reported that GMT also occurs in patients in intensive care units. In a study involving 33[4] patients, GMT was almost always seen in men and associated with weight loss and anemia.

The deposited gelatinous material was found to consist of randomly aggregated non-amyloid fibrillar and granular material. Cotta [5] suggested that hyaluronic acid replaces fat cells in the marrow once they are lost.

Hutter [6] et al observed that changes of the peripheral blood cell count in patients with Anorexia Nervosa are a frequent observation but the peripheral blood cell count cannot predict the severity of bone marrow atrophy.

Abella [7] et al concluded that changes in stereo logic bone marrow parameters of adipocytes might appear soon in anorexia nervosa.

A large study was conducted in 2002, which involved the analysis of bone marrow changes in 44 consecutive patients diagnosed with Anorexia Nervosa. The marrow was classified as normal in 11%, hypo plastic or aplastic in 39%, with partial or focal gelatinous degeneration in 30%, or with complete gelatinous degeneration of the bone marrow (GDBM) in 20%.

Starvation of carbohydrate and calories cause hypoplasia and reduction of adipose tissue in the marrow [8], which adversely affects hematopoiesis. This is not a fibrotic process and is found to be reversible with the reestablishment of adequate nutritional intake.[9]The spectrum of peripheral blood changes and bone marrow correlates with the amount of weight loss rather than the clinical findings [10]

In our case, the patient is a young female with Marfanoid habitus presenting with severe weight loss and vomiting. She was immunocompetent with no co-morbid illness. Elaborate investigations did not reveal any evidence of a connective tissue disorder. Despite severe gelatinous transformation of the marrow, her peripheral blood picture and the bone marrow aspiration study were relatively normal.

CONCLUSION

This case is reported because of the rarity of association of gelatinous transformation of marrow in anorexia nervosa occurring in a young female with Marfanoid habitus. Bone marrow trephine biopsy should be carried out in any patient

with unexplained weight loss to rule out a gelatinous transformation.

ABSTRACT

Isospora belli is an opportunistic protozoan causing wasting diarrhea especially in patients with an immunocompromised status. Diagnosis is usually established by demonstrating the oocyst of the organism on stool examination, which however can often be inconclusive. Serological tests for isosporiasis are currently not available. In such a scenario, biopsy often provides evidence for a confirmatory diagnosis. We describe two such cases, in which intestinal biopsy was the only diagnostic evidence of isosporiasis as the cause for chronic diarrhea.

1. Introduction

An increasing number of zoonotic infections in humans are found to be associated with a declining immunocompetent status of patients. Isosporiasis is a diarrheal illness seen in immunocompromised individuals in the tropics. It was first described by Virchow in 1860. The causative agent *Isospora belli* (*I. belli*) is closely related to *Cryptosporidium* species. Transmission is by ingestion of oocyst contaminated food and person to person contact.

2. Case report

Case 1: A 41-year-old man presented with complaints of watery diarrhea for a duration of 8 months. Peripheral smear showed mild eosinophilia. Ultrasound abdomen, upper gastrointestinal endoscopy and colonscopy were normal. Stool examination was negative for ova and cysts. The patient was subsequently found to be retropositive. Duodenal biopsy was performed to ascertain the cause of diarrhea.

Case 2: A postrenal transplant, diabetic patient on immunosuppressive therapy, presented with diarrhea of 1 year duration. Stool examination was negative for any ova or cysts. On follow up, upper gastrointestinal endoscopy was normal. Colonoscopy showed an erythematous cecal patch. Biopsies were taken from multiple sites in the cecum, ileum, duodenum.

2.1. Histopathological findings and follow up

Light microscopic evaluation of haematoxylin and eosin stained sections of duodenum in the first case and the ileum in the second case, showed relatively normal small intestinal mucosa with focal villous flattening and crypt distortion. Some of the enterocytes on the villous surface epithelium, showed elongated, fusiform organisms suggestive of *Isospora* merozoites in maturing schizonts (Figure 1). The lamina propria showed lymphoplasmacytic infiltrate and congested vessels. The duodenal and cecal biopsies of the second patient did not show any organism. The first patient responded well to trimethoprim-sulfamethoxazole therapy.

On follow up, the second patient's diarrhea had subsided without any treatment. On enquiry, he was found to have been noncompliant with immunosuppressive therapy during that period, perhaps explaining his recovery. Subsequent intestinal biopsies did not reveal any parasite.

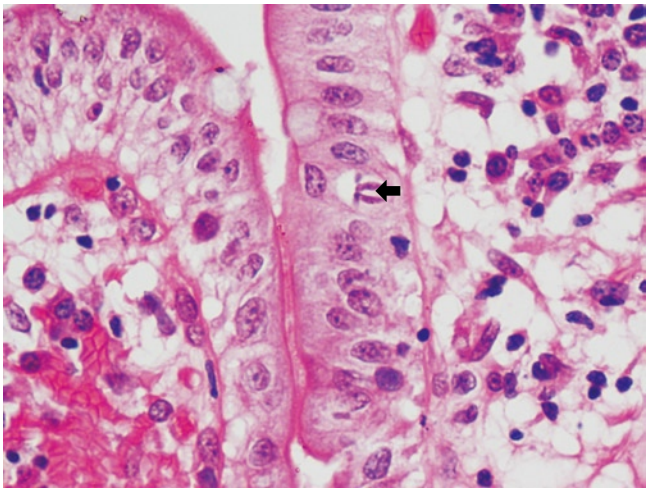

Figure 1. Microphotograph of *I. belli* organism in enterocyte (arrow). H & E × 400.

3. Discussion

I. belli is an obligate intracellular coccidian, spore forming parasite with a prevelance of 0.3%-0.5% in healthy individuals[1]. Human Isosporiasis is caused by *I. belli*, though rarely, it can be caused by *Isospora natalensis*. It may cause acute, self limiting diarrhea in immunocompetent individuals or severe, chronic diarrhea in the immunocompromised[2,3]. Stool examination may be unrewarding, as was noted in both cases. Diagnosis based on stool examination for oocysts is difficult, as these are scanty even in the presence of severe diarrhea. Incubation of the fecal specimen for 2 days with zinc flotation techniques often proves useful[4].

I. belli, like cryptosporidium occurs in the small intestine. Cryptosporidium, however, appears to multiply only in the brush borders of the intestinal epithelial cells whereas *Isospora* invades them. Brandborg *et al*[4] have elucidated, at length, the characteristic morphologic features of these organisms on light microscopy. Identification of any of the several sexual forms, gametocytes and merozoites in the subnuclear cytoplasm of the superficial epithelium and not in the crypts of the small intestine, is diagnostic of the disease. The organisms are rounded to banana shaped, pale staining[1]. The sporozoite first colonizes the epithelial cell, and becomes a rounded trophozoite. These enlarge to mature into schizonts with numerous merozoites. Merozoites infest the adjoining epithelial cell and either become schizonts or sexual gametocyte. The macrogametocyte when fertilized, becomes the oocyst which is passed in the feces. It can also exist as unizoite tissue cysts with uninucleated zoites located in the centre with a vacuole around it[4]. Non diagnostic minimal histological alterations including mild shortening of villi, crypt hyperplasia, increased inflammatory cells especially eosinophils in the lamina propria of the infected intestinal mucosa may be observed. Hence, diligent search for these organisms under high power objective in an hematoxylin and eosin stained slide can prove to be rewarding. Special stains used to identify other organisms like Giardia, cryptosporidia and microsporidia may not be particularly useful in identifying *Isospora*. Besides the intestine, the organism has also been reported in lymph nodes and spleen in disseminated cases[2]. The structure of the sporulated oocyst helps in deciding the species.

Sho Ogata and colleagues diagnosed an isolated case of intestinal cryptosporidiosis by endoscopic biopsy and have stressed the utility of histopathology in diagnosing such cases[5]. No such reports however, have come to light of isosporiasis being diagnosed primarily on the basis of a biopsy. The diagnosis of isosporiasis is important, as patients respond promptly to treatment.

In conclusion, light microscopic examination of intestinal biopsy plays a crucial role in diagnosing intestinal parasitic infestation and can be instrumental in initiating prompt and specific treatment. Medical professionals treating immunosuppressed individuals should be aware of the role of biopsy in diagnosing this curable cause of diarrhea, especially in cases where fecal examination and endoscopy are inconclusive.

Conflict of interest statement

We declare that we have no conflict of interest.

Histomorphological Spectrum of Mediastinal Masses with Special Emphasis on Rare Lesions

SAKTHISANKARI SHANMUGA SUNDARAM[1], S VIDHYALAKSHMI[2]

(cc) BY-NC-ND

ABSTRACT

Introduction: Mediastinal lesions are not frequently observed in routine clinical practice. A wide variety of disease process can occur within the mediastinum. Tissue from needle biopsies forms the major diagnostic material. There is need for detailed studies to make pathologists aware of the wide histological spectrum and to know the unusual lesions that can be encountered during diagnosis.

Aim: To describe the histomorphological spectrum of various mediastinal lesions and to highlight the rare lesions that posed a diagnostic challenge.

Materials and Methods: This was a retrospective study done on all mediastinal masses over a period of two years from January 2016 to December 2018. The clinical data and imaging findings were collected from the test request forms and patients' files for all the cases. Haematoxylin and eosin stained slides of all cases and immunohistochemistry markers and cytochemical stains wherever done were reviewed and analysed. Mean, median and percentage were used for statistical analysis.

Results: Thirty-four cases of mediastinal lesions were included in the study. Of these, 28 cases (82.4%) presented as anterior mediastinal masses, three cases (8.8%) each in the middle and posterior mediastinum. Thymoma (n=15) followed by lymphoma (n=4) were the most frequent neoplasms reported. There were five lesions which were rare in the mediastinum with unusual presentation that posed diagnostic difficulties. These lesions included Primitive neuroectodermal tumour in an adult, Primary Mediastinal B Cell Lymphoma (PMBCL), Malignant Peripheral Nerve Sheath Tumour (MPNST) with nodal metastasis, Seminoma deposits in mediastinal node occurring as late relapse and dedifferentiation of thyroid carcinoma in mediastinal node metastasis without an obvious primary.

Conclusion: Primary mediastinal tumours were more frequent than metastasis. Although thymomas and lymphomas are dealt extensively in literature, this article highlights the fact that pathologists must be aware of those lesions that don't display the classical histological and/or clinical features as observed in our study.

Keywords: Malignant peripheral nerve sheath tumour, Mediastinum, Mediastinal B cell lymphoma, Morphological spectrum, Primitive neuroectodermal tumour

INTRODUCTION

Primary mediastinal tumours are rare. Anterior mediastinal masses constitute >50% of mediastinal lesions and majority of them involve thymus. Middle mediastinal lesions include congenital cyst, (pericardial and bronchogenic cyst) while neurogenic tumours form the majority of posterior mediastinal masses [1-3]. Lymphomas can arise in any of these three compartments [4]. Aggarwal R et al., in their study of mediastinal lesions have reported 70% of lesions confined to anterior mediastinum, of which thymic lesions were the most frequent, constituting to 45.7% [1]. Posterior, superior and middle mediastinal lesions were reported to be 19, 6 and 4%, respectively. Lymphomas were the second most common tumour (11.2%) after thymoma. Sarcoma was seen in 6.9% cases and showed random compartment localisation. In their study, primary lesions were more common when compared to secondary deposits.

Dixit R et al., in their evaluation of 144 cases of mediastinal lesions have reported metastasis to be the most common, contributing to 37.4% of malignant lesions followed by lymphoma [5]. The clinical findings with radiological findings can narrow the differential diagnosis. However, advent of new techniques has made it easier to obtain tissue material from this site [5,6]. Hence, it is important for a pathologist to be familiar with the wide variety of lesions in the mediastinum since an accurate early tissue diagnosis directs therapy. There are variations in the existing literature regarding the frequency of individual lesions encountered in mediastinum. Hence the study was undertaken to analyse the histopathological spectrum of mediastinal lesions in our population and to highlight the rare lesions.

MATERIALS AND METHODS

This was a retrospective study done on all mediastinal masses over a period of two years from January 2016 to December 2018. The data was retrieved from the archives of Pathology department of PSG Institute of Medical Sciences and Research. Institutional Human ethics committee clearance was obtained before conducting the study (vide letter 20/108).

Needle biopsies and surgical resections were included in the study. A total of 36 cases were received during the study period. Of these cases, two cases showed only necrosis and hence were excluded from the study. The remaining 34 cases were included.

Relevant demographic and clinical data including the presenting symptoms, past history relevant to the lesions and examination findings was collected from patient files in all the cases. Laboratory investigations such as serum markers like carcinoembryonic antigen, CA125, alpha fetoprotein wherever available were obtained from test request forms and hospital information system. Computed Tomography findings including the location, size and solid or cystic nature of the lesion were recorded. Haematoxylin and eosin stained slides of all cases and Immunohistochemistry (IHC) markers and cytochemical stains like periodic acid, Ziehl Neelsen wherever done were reviewed and analysed. Immunohistochemical markers included cytokeratin (Mouse, polyclonal, AE1/AE3), CD99 (Mouse, 12E7) S100 (rabbit, polyclonal, 504),Thyroid transcription factor (Mouse, 056), napsin (EP205), CD45 (Mouse, EP273), CD3 (rabbit, polyclonal, 503), CD20 (Mouse, L26), CD15 (Mouse, 273), CD30 (Mouse, BER-H2), CD117 (IB 077) and PLAP (mouse, 376). IHC was done on paraffin embedded tissue sections using heat induced antigen

retrieval. Diaminobenzidene was the chromogen used. The cases which posed diagnostic challenge or had an unusual presentation were extensively studied. Mean, median and percentage were used for statistical analysis. The analysis was done using SPSS software version 20.0.

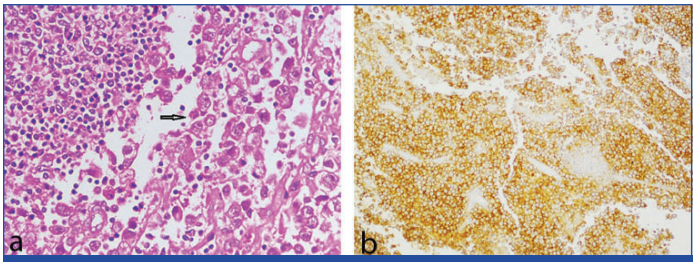
RESULTS

Thirty four cases of mediastinal lesions were included in the study. Age of the patients ranged from 14 to 75 years. Majority of the lesions were in females with male to female ratio being 1:1.5. The presenting symptoms included chest pain, cough and breathlessness in 26 cases. A total of 24 cases were the Primary mediastinal tumours while metastatic lesions were two in number. About Twenty eight (82.4%) cases presented as anterior mediastinal masses, and three cases each in the middle and posterior mediastinum. The majority of lesions were involving the thymus (n=21) constituting to 67.8% [Table/Fig-1]. The frequency of malignancy was higher in females (6 cases).

S. No.	Diagnostic category	Anterior 82.4% (n=28)	Middle 8.8% (n=3)	Posterior 8.8% (n=3)	Total % (n)
1	Non-neoplastic				
	Retrosternal goitre	1		1	23.5 (8)
	Sarcoidosis	1	1		
	Thymic cyst	2			
	Thymolipoma	2			
2	Neoplastic, Benign				
	Thymoma	15			47 (16)
	Teratoma		1		
3	Neoplastic, Malignant				
	Thymic carcinoma	2			
	Lymphoma	3	1		23.5 (8)
	Primitive neuroectodermal tumour			1	
	Malignant peripheral nerve sheath tumour			1	
4	Neoplastic, metastatic	2			6 (2)

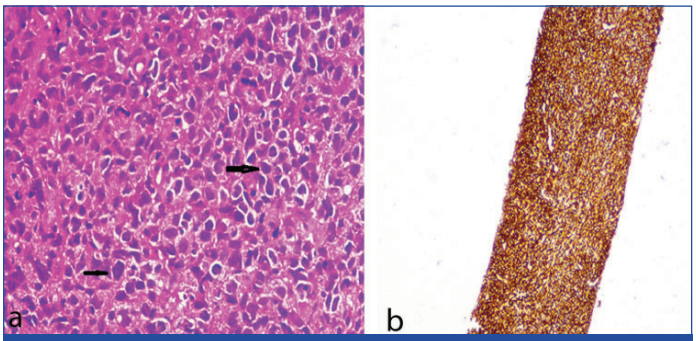
[Table/Fig-1]: Distribution of mediastinal lesions.

The variants of thymoma included four cases each of type A, B1 and B2 and three cases of type AB thymoma. Both the cases of thymic carcinoma occurred in females, one of which occurred in a young female (age 28 years).



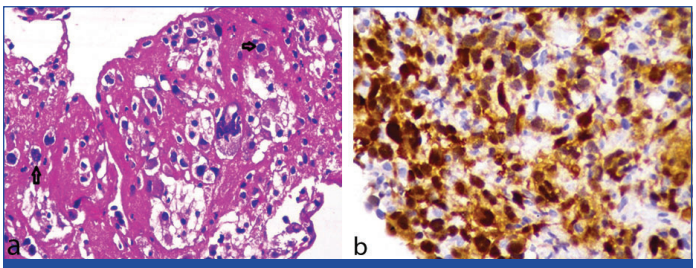
The two cases of Non-Hodgkin Lymphoma (NHL) reported were precursor T-lymphoblastic lymphoma in adolescent patients. The other NHL was Primary Mediastinal B Cell Lymphoma (PMBCL). The two cases of Hodgkin Lymphoma (HL) included one case each of Nodular Sclerosis and Mixed cellularity HL.

Of the 34 cases, 13 (38.2%) were diagnosed on guided biopsies and 21 (61.8%) on excision biopsies. In all the guided biopsies, a confirmatory diagnosis was made only after immunohistochemistry.

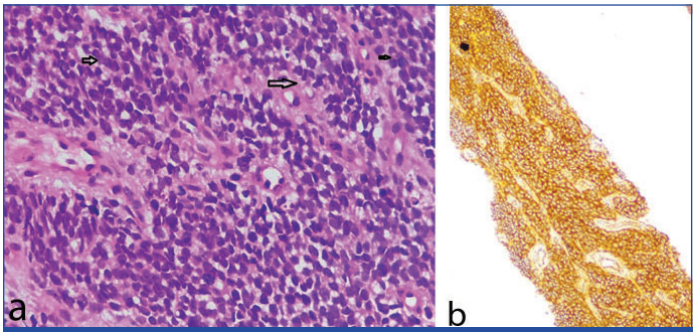


The rare tumours encountered are described below [Table/Fig-2]. Case 1 presented with multiple lymph nodes involvement suggesting the possibility of lymphoma. Seminoma relapse was not initially considered for this case. The diagnosis of seminoma metastasizing to lymph node was made only with the help of immunohistochemistry [Table/Fig-3]. Case 2 (PMBCL) was a rare lesion occurring in a young male, but had the typical presentation. Differential diagnosis entertained in this case were PNET and thymoma based on the morphology [Table/Fig-4]. Case 3 (MPNST) occurred in a patient with Neurofibromatosis. Cytology of pleural fluid also showed atypical cells. Based on the morphology, a provisional diagnosis of high-grade sarcoma was made. The diagnosis of MPNST with nodal metastasis was made with immunohistochemistry (S100 positive and Ki67 90%) [Table/Fig-5]. Case 4 (PNET/Ewing's sarcoma) occurred in an adult female (65 years) which is rare [Table/Fig-6]. Case 5 (dedifferentiated thyroid carcinoma in mediastinal nodes) occurred in an adult female who did not have any history of thyroidectomy. Histopathological examination showed an anaplastic tumour suggesting the possibility of sarcoma/carcinoma. Extensive sampling revealed tiny foci of conventional papillary thyroid carcinoma which was supported by IHC markers (Thyroid transcription factor positive, Napsin negative, Cytokeratin positive in anaplastic areas). Lung carcinoma was ruled out by napsin negativity [Table/Fig-7]. Normal thyroid parenchyma was not identified in the tissue and thus the possibility of aberrant

Case No.	Clinical details	Imaging findings (CT Scan)	Histology and IHC	Diagnosis and unusual finding
1	48/M, operated for testicular seminoma 5 years back and had defaulted surveillance	Hypodense, soft tissue mass of size 5.5×2.9 cm in anterior mediastinum. Mediastinal lymphadenopathy +. Beta HCG-420 mIU/mL LDH-1820IU/L	Lymph node with sheets of large cells having pleomorphic vesicular nuclei and prominent nucleoli separated by fibrous septa rich in lymphocytes. There was no other germ cell tumour elements. CD117 and PLAP positive.	Seminoma metastasing to mediastinal lymph nodes. Late relapse presenting with generalised lymphadenopathy
2.	21/M, anorexia, night sweats, significant loss of weight for two months. No organomegaly or superficial lymphadenopathy	large anterior mediastinal mass of size 6×7 cm invading superior vena cava.	Monomorphous population of blue round cells separated by thick fibrous septa. CD20 and CD45 positive Neuron Specific enolase, Cytokeratin negative	Primary Mediastinal B Cell Lymphoma (PMBCL). Rare lesion (incidence-2 to 3% of NHL) [1]
3.	35/M, known case of Neurofibromatosis presented with a complaint of dry cough associated with breathlessness	Multiple nodules in both lungs and pleura. Multiple enlarged mediastinal, para-aortic, celiac lymph nodes suggesting metastasis	Oval to spindle neoplastic cells exhibiting marked pleomorphism arranged in sheets. Vimentin, S100 positive. Ki67 index-90% Desmin and CD34 negative	MPNST with nodal metastasis. Rare presentation
4	65/F, chest pain, breathlessness and fever	intrathoracic mass measuring 15×12 cm extending into posterior mediastinum, encasing and lifting aorta, inferior vena cava and causing diaphragmatic inversion.	Small round cells with scant cytoplasm, uniform hyperchromatic nuclei with perivascular accentuation and surrounded by fibrous septa. Differential diagnoses entertained were lymphoma, Ewing's sarcoma and rhabdomyosarcoma. CD99 positive, CD45, Tdt and Myogenin negative	PNET/Extraskeletal Ewing's sarcoma in adult. (incidence -1.8%) [27]
5	69/F, chest pain, breathlessness and intermittent fever and inspiratory stridor	Large heterogeneously enhancing mass measuring 5×4×5 cm in the right upper posterior mediastinum encasing the esophagus in the left lateral aspect. Few small nodules in the right lung suggestive of metastasis were seen. A small nodule was noted in the thyroid. Thyroidectomy could not be done in this patient.	An anaplastic tumour composed of multinucleated giant cells and highly pleomorphic cells with extensive areas of coagulative necrosis. Tiny foci of conventional papillary thyroid carcinoma. No normal thyroid tissue identified. (strong nuclear expression of TTF1 in conventional papillary thyroid carcinoma. The anaplastic component was positive for Cytokeratin and lacked TTF 1 expression. Napsin-negative (rules out lung carcinoma)	Dedifferentiated thyroid carcinoma metastasis with no obvious lesion in thyroid.



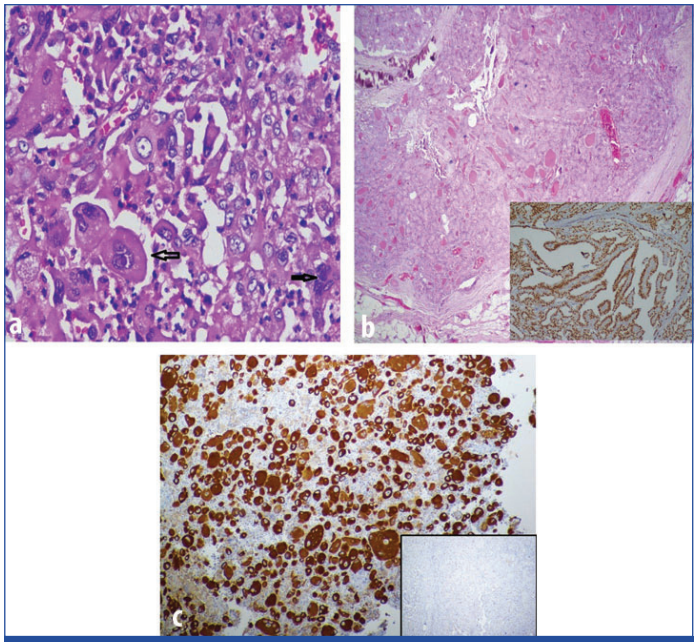
[Table/Fig-2]: Unusual features of the reported rare cases.
MPNST: Malignant peripheral nerve sheath tumour; PNET: Primitive neuroectodermal tumour



[Table/Fig-3]: a) Large neoplastic cells separated by fibrous septa rich in lymphocytes, Seminoma (H&E,40X). b) Neoplastic cells with strong membranous expression of PLAP (IHC-40X).

[Table/Fig-4]: a) Discohesive pleomorphic large round cells (arrow), PMBCL (H&E, 40X).b) Neoplastic cells with strong membranous CD20 expression (IHC, 10X).

[Table/Fig-5]: a) Pleomorphic tumour cells, MPNST (H&E, 40X). b) Tumour cells expressing S100 (IHC 40X).



[Table/Fig-6]: a) Small round cell tumour, PNET (H&E, 10X). b) Tumour cells expressing membranous staining for CD99 (IHC 10X).

thyroid and retrosternal extension were ruled out. Small nodule identified in thyroid by Computed Tomography of neck could not be evaluated since thyroidectomy could not be done on this patient.

DISCUSSION

In the present study, the majority of the tumours were primary in origin (88.2%) except for two cases. Literature review also showed that primary mediastinal lesions are more common than metastatic malignancies [3,4,6-9]. There was a female predominance in the current study which contrasts with the previous studies [5-9].

In keeping with other studies [3-10], most of the lesions were in the anterior compartment (82.4%) and benign lesions (47%) were more frequent than malignant tumours (23.5%). However, there are studies reporting malignant lesions to be more commoner constituting about 60% of lesions [11,12].

[Table/Fig-7]: a) Sheets of pleomorphic cells with multinuleation and hyperchromatic nuclei (H&E- 40X).b) Conventional papillary carcinoma component. (IHC-10X). Inset TTF1 expression (IHC 10X). c) Anaplastic carcinoma with CK expression (IHC-40X). Inset TTF 1 negative (IHC 10X).

Thymoma was the most frequent neoplasm in the present study which is similar to other studies [3-9]. However, Vaziri M et al., in their study had reported lymphomas to be more common than thymoma in a series of 105 cases [11]. In the current study, thymic lesions constituted 61.7% of anterior mediastinal masses which is higher when compared to the studies by Aggarwal R et al., and Dasgupta S et al., [1,3].

Thymic carcinomas are reported to be rare malignancies occurring in the age group of 30 to 60 years. Suster S, in his study have reported a slight male predilection (1.5:1) [13]. In the present study both the cases of thymic carcinoma occurred in females.

Retrosternal goitres are usually located anteriorly, in the superior or anterior mediastinum. Posterior mediastinum is rarely involved. Their incidence in the general population is about 1:5000 [14]. The case described in the study also occurred in posterior mediastinum. In the present study, there were five cases which were either rare or had unusual presentations that posed diagnostic difficulties [Table/Fig-2].

Primary mediastinal Seminomas originating from extragonadal germ cells are rare [15]. In general, the relapse occurs within 2 to 3 years. It has been reported in inguinal lymph nodes, contralateral testis, retroperitoneum, mediastinum and lung [16-18]. The case described here presented with seminoma deposits in mediastinal lymph nodes along with multiple abdominal lymphadenopathy 5 years after orchidectomy. Hence, the possibility of any mediastinal germ cell tumour representing a metastasis from testicular primary should always be investigated. Considering the above facts, this case is unusual since it presented as a late relapse.

PMBCL is a subtype of Diffuse Large B Cell Lymphoma (DLBCL) of thymic B cell origin affecting adolescents and young adults and having a slight female preponderance. Of the cases reported, 75% present with bulky anterior mediastinal mass greater than 10 cm that grows rapidly and nearly always present with superior vena cava obstruction [19]. Bone marrow involvement is reported to be extremely rare. It shares the biological and clinical characteristics with Nodular Sclerosis type of Hodgkin Lymphoma (NSHL) [19]. The characteristic histologic findings include clearing of cytoplasm of cells and alveolar fibrosis. Because of the presence of compartmentalisation of

cells divided by fibrous septa, it mimics thymoma, NSHL and germ cell tumours. Hence, immunohistochemistry becomes an essential aid in diagnosis. All the cases of PMBCL express CD20 and a proportion of cases express CD30. PMBCL has been reported to have better prognosis when compared to DLBCL with secondary mediastinal lymph node involvement [19,20]. The case presented here had the typical presentation of PMBCL with superior vena cava obstruction and absence of superficial lymphadenopathy and organomegaly but its occurrence in a young male is rare.

Intrathoracic presentation of MPNST is rare. There are nearly 20 such cases reported in literature, majority of them in the posterior mediastinum [21]. A 20 -30% of MPNST occur in the setting of Neurofibromatosis. Those cases show an increased recurrence and risk of distant metastasis [22,23]. Lung, bone and pleura are the most common sites of metastasis. Metastasis to lymph nodes is reported in less than 10% of patients and is usually seen as a part of widespread metastasis. In the case presented here, there was mediastinal lymph node metastasis from MPNST. Since these tumours show a weak expression of S100 in majority of cases, it becomes difficult in cases of unusual presentation like nodal metastasis, especially in small biopsies to diagnose [24]. The challenge faced in this case was that the presence of neurofibromatosis in this patient was not available at the time of diagnosis.

PNET is a rare and aggressive tumour of neuroectodermal origin most frequently occurring in children and young adults. There are only a few published series of PNET in adults [25]. Primary mediastinal PNET is very rare constituting 1.8% of mediastinal tumours. In a study by Applebaum MA et al., it was found that Extraskeletal Ewing sarcoma had a higher mean age when compared to those with skeletal tumours [26,27]. Metastasis was frequent in the cases with extraskelatal Ewings sarcoma/ PNET [25,28]. The case presented here also occurred in an adult female (65 years).

PTCs are known for anaplastic transformation at the metastatic sites [29] and have been reported in retroperitoneum, liver and lungs. This has been proven even with papillary microcarcinoma [29,30]. The cases reported previously were postsurgery for papillary carcinoma which occurred as a recurrence, many years after treatment for papillary carcinoma [29]. The case presented here did not have any history of proven PTC nor did the patient present with thyroid mass. This could probably represent an occult papillary microcarcinoma in thyroid with mediastinal metastasis of papillary thyroid carcinoma that has undergone dedifferentiation. The diagnosis of dedifferentiated thyroid carcinoma was not made on the initial sections. This case re-emphasises the need for extensive sampling in a case of anaplastic tumour to look for a well differentiated tumour to accurately diagnose even a remote possibility.

Limitation(s)

The smaller sample size in this study precludes generalisation of study results considering the frequency and distribution of mediastinal tumours. Further studies including larger sample size and studies aiming at analysing correlation with clinical and radiological findings are needed to estimate the subtype distribution of mediastinal lesions.

CONCLUSION(S)

To summarise, benign tumours were more common than malignant ones. Primary mediastinal tumours were more frequent than metastasis. Although thymomas and lymphomas are dealt extensively in literature, this article highlights the fact that pathologists must be aware of those lesions that don't display the classical histological and/or clinical features as observed in our study.

Second-trimester fetal autopsy: A morphological study with prenatal USG correlations and clinical implications

Chaitra Venkataswamy, Umamaheswari Gurusamy, S. Vidhya Lakshmi

Abstract:

OBJECTIVES: The objective of this study is to analyze the second-trimester fetal autopsies and to reemphasize the role of autopsy by comparing autopsy findings with prenatal ultrasound observations.

MATERIALS AND METHODS: Retrospective analysis of second-trimester fetal autopsies over a period of 7.5 years (January 2009–June 2016). A standard protocol of autopsy procedure was followed, which included external examination with photography, X-ray, internal examination, and histopathological examination. In fetuses with congenital malformations (CMs), the findings of prenatal ultrasonogram and autopsy examination were compared.

RESULTS: We analyzed a total of 66 fetuses, which includes 17 intrauterine fetal death, 49 terminations for CM, and increased risk for chromosomal abnormality. In fetuses with CM, multiple anomalies were more common than a single anomaly. The most common anomalies were seen involving central nervous system (neural tube defect) followed by the genitourinary system. Autopsy confirmed prenatal ultrasound findings in all cases except three. Complete agreement between USG findings and autopsy were seen in 17 cases (39.7%). Additional findings on autopsy were noted in 25 cases (62.2%). Among these, 15 cases had a significant change of recurrence risk due to altered initial ultrasound diagnosis.

CONCLUSION: Fetal autopsy plays an important role in arriving at the final diagnosis and detecting the cause of death. This information is very essential for the clinicians, in genetic counseling of the parents, and management of future pregnancies.

Keywords:

Congenital malformations, fetal autopsy, multiple anomalies, prenatal ultrasound

Introduction

The common indications for second-trimester fetal autopsies are termination of pregnancy (TOP) for congenital anomalies, intrauterine fetal death (IUFD), and inevitable abortion.[1] TOP for congenital anomalies accounts for the majority of cases of second-trimester fetal autopsies as most of the anomalies are detected during 18–20 weeks of gestation by anomaly scan which is an integral part of antenatal screening. These remain the common cause of perinatal deaths both in developed and developing countries and account for 25%–30% and 10%–15%, respectively.[2] The occurrence of these anomalies in subsequent pregnancy varies from negligibly low to 25%, and it depends on the etiology of diagnosis. Hence, it is important to make an accurate diagnosis.

In the present era, Ultrasonographic (USG) examination can accurately diagnose many lesions but has its own limitation in detecting soft-tissue lesions such as malrotation

of intestines, asplenia/polysplenia, and pulmonary hypoplasia, and the success rates of ultrasound also depend on the equipment used and expertise of the sonologist. Perinatal autopsy either confirms or refute the ultrasound diagnosis and complements USG examination in making a precise diagnosis.

The objectives of the present study are to evaluate the reasons for second-trimester fetal autopsies, to categorize the congenital malformations (CMs) into various systems, syndromes, and complexes, and to compare the autopsy findings with prenatal USG examination.

Materials and Methods

The retrospective analysis of all second-trimester fetal autopsies from January 2009 to June 2016 (7.5 years) was done in the Department of Pathology. Fetuses with gestational age 14–28 weeks were included in the study. Fetuses with gestational age <14 weeks and >28 weeks were excluded from the study. Informed written consent for performing autopsy examination was obtained from either of the parents before the autopsy. All the fetuses were examined on preset protocol based on the recommendation given in guidelines in autopsy practice by Royal College Of the Pathologists,[3] which included photography, fetogram (whole body radiography), and external and internal examination.

Evisceration is performed by starting with a linear skin incision extending from symphysis menti to midline of chest, abdomen, passing to the left side of the umbilicus, and extending up to the symphysis pubis. *In situ* assessment of the intestines was done to rule out malrotation and they were removed from jejunum up to the rectum. Rest of the organs was taken out as "*en bloc*" by freeing the tongue from the floor of the mouth and releasing the attachments of the neck structures. The pelvic organs were cut as low as possible. External genitalia and urethra were dissected in case of suspected urorectal septum malformation. The individual system was thoroughly inspected and dissected for anomalies.

The brain is removed by incising the scalp behind one ear extending to vertex and to the other ear. Skin flaps are reflected anteriorly up to the eyebrows and posteriorly up to the nape of the neck. Skull bones are opened along the suture lines. The brain is delivered by placing the head at a lower level than the body, by releasing the nerve attachments, and falx cerebri, tentorium cerebelli and the upper cervical spinal cord is incised. The removed brain is then fixed by hanging in formalin using gauze.

All the organs are weighed. Histopathological examination of the brain, thyroid, thymus, heart, lung, liver, pancreas, spleen, kidney, adrenal, gonads, and placenta was carried out. Additional sections from the skin, muscle, bladder, pylorus, etc., were also studied when required.

In cases of fetuses terminated for CMs, the findings on autopsy and prenatal ultrasound examination were compared.

Approval was obtained from the institutional Ethical Clearance Committee.

Results

There were 87 fetal autopsies in 7.5 years of which 66 cases (75.8%) were second-trimester fetuses. Causes of second-trimester fetal autopsies are summarized in Figure 1.

In cases of IUFD and abortions, mean maternal age was 27 years (range19–35) and mean gestational age was 22 weeks (range 16–27). An autopsy provided a final diagnosis in 15 (88.2%) out of 17 cases. The causes are summarized in Table 1. In two cases, there was no detectable anomaly in the fetuses and the placental causes could not be excluded as placenta was not available for examination.

Cases terminated for increased risk for chromosomal abnormality include two cases of Down syndrome. One case presented with hydrops fetalis, cystic hygroma neck, common atrioventricular canal defect with persistent left superior vena cava, and hypoplasia of thymus. Other case showed nuchal edema, hydrocephalus, and abnormal left hand, feet, and legs. There was one case of Turner syndrome with partial deletion of short arm of X chromosome. This case showed telangiectatic vascular nevi, hypoplastic nails, widely spaced nipples, clitoromegaly, septate vagina, and aortic arch isthmus hypoplasia. In one case, amniocentesis and FISH showed deletion of short arm of chromosome

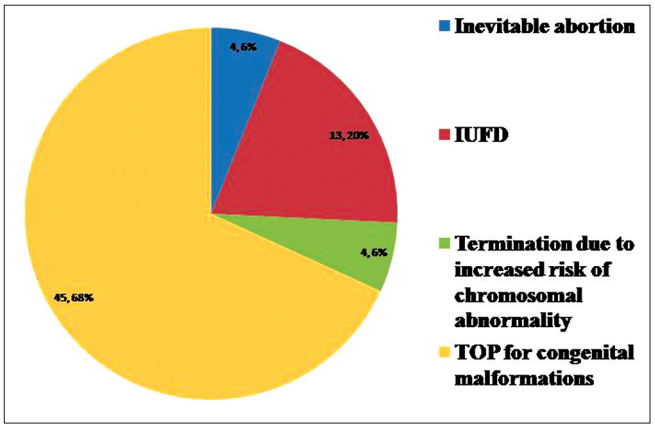

Figure 1: The pie diagram shows causes of fetal autopsies requested

Table 1: Causes of intrauterine fetal death in the second trimester

Causes	Number of cases (*n*=17)
1. Placental causes	10
Cord stricture	6
Hyper coiled cord with fetal vascular obstruction	1
Massive perivillous fibrin deposition	1
Infectious villitis with hydrops fetalis	1
Isolated hydrocephalous with central placenta previa in mother and cord stricture (spontaneous abortion)	1
2. Fetal causes	4
Hypoplastic left heart syndrome with visceral heterotaxy	1
Healed myocardial infarction	1
Hydrops fetalis due to premature ductus closure	1
Bladder outlet obstruction due to distal urethral stenosis (spontaneous abortion)	1
3. Maternal cause	
Maternal thrombophilia	1
4. Diagnosis not possible	2

15. USG examination of fetus showed bilateral mild ventriculomegaly, hypoplastic cerebellum, increased nuchal pad thickness, postaxial polydactyly in both feet, and multiple anomalies. An autopsy confirmed the USG findings and in addition showed focal cerebellar dysplasia. Parental karyotyping was suggested to confirm Prader–Willi/Angelman syndrome.

In fetuses terminated for congenital anomalies, the mean maternal age was 24 years (range: 18–32). The mean gestational age at the time of diagnosis was 21 weeks (13–27). A majority of them showed multiple malformations which are summarized in Tables 2 and 3. Central nervous system (CNS) anomalies were the most common followed by genitourinary malformations. The frequently encountered CNS anomaly was Arnold–Chiari II malformation with myelomeningocele. Two cases of rhombencephalosynapsis characterized by fusion of cerebellar hemisphere with absent cerebellar vermis were seen. There were four cases of hydrops fetalis and the underlying cause was detected in all. In a case of DiGeorge syndrome (DGS), there was hypoplastic thymus in the cervical region which was not detected on ultrasound [Figure 3]. A case of sirenomelia showed single median lower limb. Fetogram revealed single femur, two tibias, and no fibula [Figure 4].

Prenatal USG examination was available in all fetuses terminated due to prenatally diagnosed anomalies. There were a total of 121 anomalies in 45 cases. About 50 (41.3%) out of 121 anomalies were diagnosed only on autopsy. Three anomalies identified on USG were not confirmed on autopsy examination and includes two Dandy–Walker complex (DW) and aqueduct stenosis. One of the cases of DW complex showed additional findings on autopsy, and a diagnosis of Fryns syndrome was offered. Anomalies detected exclusively on autopsy examination include 13 (26%) gastrointestinal (malrotation of intestine), 13 (26%) genitourinary, 5 (10%) cardiovascular, 5 (10%) facial abnormality (cleft palate and micrognathia), four cases of CNS lesions, two cases each of polysplenia, skeletal abnormalities, and ductal plate malformation liver, and one case each of congenital diaphragmatic hernia, omphalocele, choanal atresia, microphthalmia, and nesidioblastosis.

Complete agreement between the USG findings and autopsy results were seen in 17 cases (39.7%). An additional finding in autopsy was noted in 25 (62.2%) out of 45 cases. In 15 cases (34.8%), the additional findings on autopsy changed the initial ultrasound diagnosis [Table 4]. In nine out of 15 cases, the revision of diagnosis led to significant change in recurrence risk (3%–25%) in subsequent pregnancy.

Discussion

With the advent of newer imaging techniques with higher resolution, the rate of autopsy is declining steadily. This is true even in cases of perinatal autopsies.[4] Perinatal autopsy still remains the gold standard in detecting the cause of death in IUFD and confirming the anomalies detected on ultrasound.[1] The present study focuses on second-trimester fetal autopsies and in reemphasizing its value in detecting congenital anomalies.

In the present study, major indication for second-trimester fetal autopsy was TOP for congenital anomalies. In cases of IUFD, fetal malformations were noted in 23.5% of cases, this is slightly higher as compared to the study done by Joó *et al*. where fetal malformation was seen in 13.05% in second-trimester miscarriages.[5] A study done by Peng *et al*. showed that 18.7% cases of IUFD were associated with umbilical cord stricture, hypercoiling or combination of both, most of these demises occurred in the second trimester.[6] The current study showed cord stricture and hypercoiling as a cause of IUFD in 41.1% of cases, significantly high. This highlights the importance of examination of the placenta and umbilical cord in cases with absence of congenital anomalies.

In fetus with deletion in chromosome 15, there were multiple anomalies including cerebellar hypoplasia. Deletion in chromosome 15 is known for phenotypic heterogeneity, with well documented, diverse clinical syndromes. The best known of these are Prader–Willi syndrome and Angelman syndrome, both of which are not associated with generalized cerebellar hypoplasia

Table 2: Postmortem diagnosis in fetuses terminated for congenital malformations (limited to 1 or 2 systems)

Congenital anomalies	Associated anomalies	Number of cases (*n*=27)
1. Central nervous system malformations		9
Arnold–Chiari malformation II with meningomyelocele	Agenesis of the right kidney and fused adrenals (1 case)	3
Hydrocephalous with aqueduct stenosis		1
Rhombencephalosynapsis	Lobar holoprosencephaly, aqueductal stenosis, interhemispheric cyst, TEV (1)	2
	Craniofacial dysmorphism (1)	
Hydrocephalus	Double aortic arch	1
Lumbar meningomyelocele	Kyphoscoliosis spine, ruptured omphalocele	1
Mild ventriculomegaly	Hypoxic ischemic encephalopathy	1
2. Urogenital malformations		8
AR polycystic kidney disease	Ductal plate malformation	2
Bladder outlet obstruction due to the posterior urethral valve	Hydrops fetalis (2 cases)	3
	TEV (1 case)	
Persistent cloaca with persistent Mullerian duct syndrome	Male pseudohermaphroditism (2), Occipital encephalocele, TEV, agenesis right kidney, imperforate anus, and malrotation intestine (1)	2
Persistent Mullerian duct syndrome	Ambiguous genitalia, male pseudohermaphroditism, anorectal atresia, bladder outlet obstruction with bilateral hydronephrosis, and renal obstructive dysplasia SUA	1
3. Cardiovascular system malformation		3
D-transposition of great arteries	Omphalocele (1 case)	2
Congenitally corrected transposition of great arteries		1
4. Respiratory system		2
Congenital high-airway obstruction syndrome	Hydrops fetalis	1
Alveolar capillary dysplasia with misalignment of pulmonary veins		1
5. Congenital diaphragmatic hernia [Figure 2]	Choroid plexus cyst (1 case)	3
	Meckel's diverticulum, bicuspid aortic and pulmonary valves, bicornuate uterus (1 case)	
6. Talipes equinovarus	Accessory tragi	1
7. Hydrops fetalis	Placental mesenchymal dysplasia	1

SUA = Single umbilical artery, TEV = Talipes equinovarus

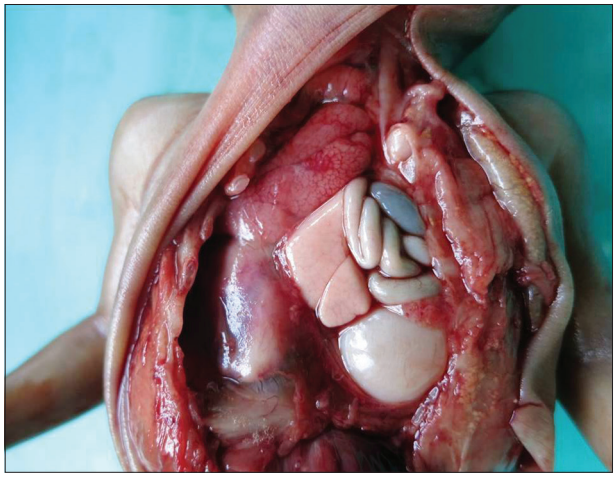

Figure 2: Congenital diaphragmatic hernia. The left hemithorax contains loops of small intestine and stomach pushing the heart and left lung to the right side

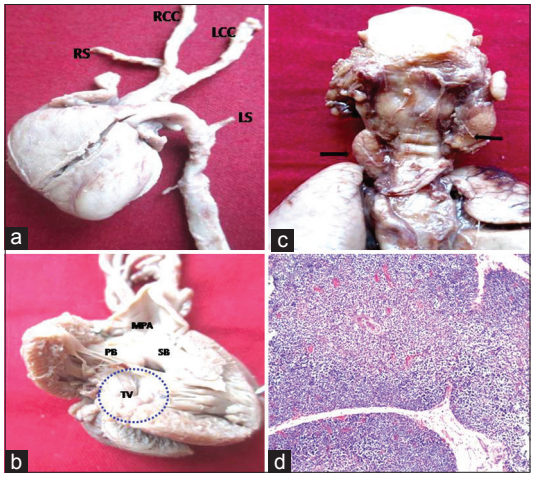

Figure 3: DiGeorge syndrome; (a) Interrupted aortic arch Type-B, (b) ventricular septal defect, perimembranous type, (c) cervical hypoplastic thymus, (d) lobules of thymic tissue composed cortex, medulla with Hassall's corpuscles (H and E, ×100)

as seen in present case. To the best of our knowledge, this association has not been described in literature. It is possible that this might belong to the expanding spectrum of chromosome 15q deletions.[7-9]

In 45 fetuses terminated for congenital anomalies, multiple malformations were seen in 75% of cases which is relatively high when compared to previous studies.[2,10]

CNS malformations were the most common followed by genitourinary anomalies. This is in concordance with the previous studies.[2,9-12] Arnold–Chiari malformation is characterized by downward displacement of cerebellum and brainstem into the spinal cord and is divided into three types. Type II is the most common form; this was true even in our series.[13]

Table 3: Postmortem diagnosis in fetuses terminated for congenital malformations (involving multisystem)

Diagnosis multiple malformations	Number of cases (*n*=17)
1. Syndromes/complexes/association	13
Fraser syndrome	1
Meckel–Gruber syndrome	2
Fryns syndrome	1
DiGeorge syndrome (SUA)	1
DiGeorge/velocardiofacial syndrome	1
Amniotic band syndrome	1
Charge syndrome	1
Zellweger syndrome/Smith–Lemli–Opitz syndrome	1
Sirenomelia with pseudo tail (SUA)	1
VACTERL or VATER Association (SUA)	2
Tuberous sclerosis complex	1
Multiple malformations – no definite syndrome	4
Renal hepatic pancreatic dysplasia with duodenal atresia	
Situs inverses with polysplenia and conotruncal malformation	
Meningocele, Arnold–Chiari malformation, tricuspid atresia, and double-outlet right ventricle	
Neural tube defect, Arnold–Chiari malformation, hydrocephalus with aqueductal stenosis, agenesis of corpus callosum, cerebellar hypoplasia, renal dysplasia, malrotation of small intestine, and polysplenia	

SUA = Single umbilical artery

Figure 4: Mermaid fetus; (a) single median lower limb with pseudo tail in the lumbosacral region, (b) fetogram shows fused pelvic bones, single femur, and absent fibula, (c) hypoplastic descending abdominal aorta continuing as single umbilical artery, (d) meconium filled, blind-ended colon

DGS also known as del22q11.2 is the most common microdeletion. Phenotypic features include heart defects, thymic hypoplasia/agenesis, facial dysmorphism, and developmental delay.[14] Two cases of DGS were diagnosed on prenatal ultrasound examination in view of congenital heart defects and absent thymus. Autopsy examination revealed hypoplastic cervical thymus in one case. Ectopic thymus was noted in 1% of children in a study of 3236 children at autopsy, of these 71% had features of DGS.[15] This might explain the variable immune status in the patients with DGS. Radiologist should be familiar with the locations of ectopic thymus and try to look for them when it is not found in the anterior mediastinum.

There was a case of sirenomelia with atypical skeletal framework. Sirenomelia is a rare CM characterized by varying degree of fusion of the lower limbs, single umbilical artery, and internal malformations related to genitourinary and gastrointestinal systems.[16] Stocker and Heifetz have classified sirenomelia into seven types based on skeletal framework in the lower limbs.[17] The bone pattern in the present case does not fit into any of the subtypes described in the literature. The exact etiological cause for sirenomelia remains unclear, but widely accepted hypothesis include defective blastogenesis and vascular steal hypothesis.[16]

In the present study, fetal autopsy provided definitive diagnosis in 95% of cases and confirmed ultrasound findings in 93% of cases, which is comparable to the previous studies.[2,12,18] An autopsy could not confirm DW complex in two cases. The previous studies have shown a poor correlation between ultrasound and autopsy findings in cases of DW complex with concordance being achieved in 55%, even after standardized reevaluation of sonographic and pathology images.[19] The poor correlation could be attributed either due to the membranous quality of the cyst wall with loss of fluid during anatomical dissection or due to the overdiagnosis of DW complex on ultrasound. Hence, the diagnosis should be reserved to cases which show all the classical findings on ultrasound. In doubtful cases, repeat ultrasound or magnetic resonance imaging (MRI) should be suggested to confirm the diagnosis.[19]

On comparing autopsy and ultrasound findings, our study showed complete agreement in 37.7% (17/45), partial agreement in 22.2% (10/45), and discordance in 33.3% (15/45). Thus, overall agreement was seen in 59.9%. This is in concordance with study done by Yeo *et al*.[20] Table 5 shows comparison of autopsy and ultrasound findings in various studies.[2,10,12,20,21]

Anomalies that were missed on USG examination were related to gastrointestinal, genitourinary, cardiovascular

Table 4: Comparison of ultrasound findings with autopsy findings in cases of discrepancy

Serial number	USG finding with diagnosis	Autopsy findings with diagnosis
1	Sacral meningomyelocele, bifid spine with the hypoplastic right ventricle of the heart	Arnold–Chiari malformation and tricuspid atresia with double-outlet right ventricle
2	Anhydramnios, B/L renal agenesis	Cryptophthalmos, ventriculomegaly, bifid nasal tip, clitoromegaly, B/L renal agenesis, absent vagina, uterus, and proximal fallopian tubes - Fraser syndrome
3	Anhydramnios, cystic dilatation of biliary radicles and common bile duct, a cyst in pancreas, bilateral multicystic dysplastic kidneys, microcephaly and shot bowed tibia - Ivemark syndrome	Bilateral cleft lip, cleft palate, lingual abnormalities and dysplastic epiglottis. Occipital encephalocele, Arnold–Chiari malformation Type III. Holoprosencephaly. Diffuse cystic renal dysplasia congenital hepatic fibrosis (ductal plate malformation), choledochal cyst Todani Type IV. Persistent left SVC, mild atrioventricular valve dysplasia. Ambiguous external genitalia, bilateral testes. Postaxial polydactyly, bow legs Meckel–Gruber syndrome
4	Situs ambiguous, isolated levocardia, VSD, and truncus arteriosus	Situs inversus, isolated levocardia with polysplenia, and conotruncal malformation
5	Cerebellum V-shaped with large cisterna magna. ? partial agenesis of inferior cerebellar vermis- possibility of DW complex	CDH, malrotation of the intestine, B/L cleft palate, ankyloglossia, bifid tongue, and uterus didelphys-Fryns syndrome
6	Short femur, humerus, narrow chest- Possibly achondroplasia	Syndactyly, postaxial polydactyly of hands and feet, dysplasia of epiglottis, nonrotation of intestine, ductal plate malformation of liver, renal dysplasia, X-ray - B/L shortening of long bones of the upper and lower limbs - Meckel–Gruber syndrome-variant
7	Oligohydramnios, B/L echogenic kidneys to R/O CMV	AR PCKD with congenital hepatic fibrosis
8	Increased nuchal translucency, generalized subcutaneous edema, hypertelorism, midline facial cleft, small omphalocele, cardiac outflow tract anomaly. Suggested invasive test to rule out aneuploidy. Patient not willing for amniocentesis	Craniofacial defects with a membranous tag at the head - cranioschisis, absent ears, and nose, bilateral cleft lip and palate, Conotruncal cardiac anomaly? Transposition of great arteries with pulmonary atresia? Double outlet right ventricle with pulmonary atresia, abdominoschisis, renal cystic dysplasia - suggestive of amniotic band syndrome
9	Lumbosacral spina bifida and Arnold–Chiari malformation	Lumbar meningomyelocele, ruptured omphalocele
10	Bilateral presacral kidneys with bilateral hydronephrosis due to pelviureteric junction obstruction, parenchyma of left kidney is dysplastic	Ambiguous genitalia, male pseudohermaphroditism, persistent mullerian ducts Anorectal atresia, bladder outlet obstruction with bilateral hydronephrosis, and renal obstructive dysplasia. SUA
11	SUA, TOF, ectopic hydronephrotic left kidney, left clubfoot with absent 2nd to 5th digits	TOF with the right aortic arch and left-sided patent ductus arteriosus, atresia of distal sigmoid, rectum and anus, fused crossed renal ectopia with hydronephrosis, left clubfoot with a single digit Fetogram-hemivertebra, absent metatarsal l bones-vacterl association
12	Pierre syndrome, left hydronephrosis due to pelviureteric obstruction	Bilateral posterior choanal atresia, lop ears, Micrognathia, Microphthalmia, persistent cloaca, left hydronephrosis - CHARGE syndrome
13	Two echogenic masses suggestive of cardiac rhabdomyoma	Heart: Multiple rhabdomyomas Brain: Subependymal nodules of dystrophic neurons and astrocytes - tuberous sclerosis complex [Figure 5]
14	Complete AVSD Bilateral cleft lip and palate, echogenic focus left ventricle	Congenitally corrected transposition of great arteries Alveolar capillary dysplasia with misalignment of pulmonary veins, bilateral cleft lip and palate, mild pyloric stenosis, bladder outlet obstruction? Vascular dysplasia kidneys and brain

TOF = Tetralogy of Fallot, CDH = Congenital diaphragmatic hernia, SUA = Single umbilical artery, SVC = Superior vena cava, USG = Ultrasonography, CMV = Cytomegalovirus, B/L = Bilateral, DW = Dandy-walker complex, AVSD = Atrio ventricular septal defect, VSD = Ventricular septal defect, R/O = Rule out, AR PCKD= Autosomal recessive polycystic kidney disease

systems, and facial defects. Antenatal detection of these CMs depends on the expertise of sonologist, quality of equipment, maternal habitus, and reduction in liquor volume.[22] In addition, some cardiac, gastrointestinal, and renal abnormalities are not evident at 20 weeks. Few are histopathological diagnosis (e.g.: tuberous sclerosis, PCKD). Oligo- and anhydramnios were noted in some of our cases. All the above factors could explain the shortcomings of routine antenatal USG examination. Other prenatal diagnostic modalities such as three-dimensional ultrasound and MRI will provide better resolution for CNS and soft-tissue abnormalities. Detailed analysis of fetus using these advanced imaging modalities may help in achieving higher rates of complete agreement. Implementing them in routine antenatal screening may not be feasible due to higher cost, lack of expertise, and limited availability in developing countries.

When the parents are reluctant to give consent for full autopsy due to religious reasons, limited, or minimally invasive autopsy may be of value. Minimally

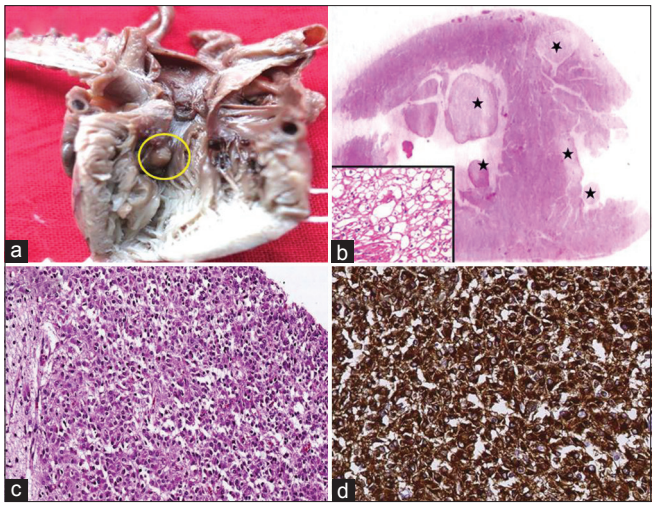

Figure 5: Tuberous sclerosis complex: (a) fleshy, pale brown mass in the left ventricular outflow tract, (b) transverse section of the heart shows multiple paler nodules(*) in subendocardial and intramural location. Inset shows high-power view of the nodule consisting of large vacuolated cells-rhabdomyoma (H and E, ×400), (c) section from medulla shows large subependymal plaque consisting of a cellular admixture of glial cells (H and E, ×100) and (d) these cells strongly express GFAP (IHC, ×400)

Table 5: Comparison of autopsy and ultrasound findings in various studies

USG = Ultrasonography

invasive autopsy includes external examination with photography, placental examination, genetic analysis, and histopathological assessment of open or targeted biopsy of specific internal organs. Imaging studies, such as X-ray, postmortem MRI or micro-computed tomography, and assessment of body cavity fluids may be helpful to a certain extent.

Postmortem MRI can provide the details of structural malformation; however, it is not useful in cases of suspected infection, skeletal dysplasia, and in fetuses with severe maceration. It is not cost-effective and cannot provide details at histopathological levels.

Although minimally invasive autopsy can provide additional information in some cases, clinicians should explain to the concerned parents that complete perinatal autopsy remains the gold standard method for identifying the causes of fetal autopsy and its risk of recurrence.

Conclusions

The abnormalities detected by the fetal autopsy can be minor, major, or additional findings that modify the recurrence risk in subsequent pregnancy from 1%–3% to 25%. Thus, autopsy plays an essential role in accurate diagnosis and appropriate genetic counselling. The present study reemphasizes the need for fetal autopsy even in the era of advanced imaging techniques

Declaration of patient consent

The authors certify that they have obtained all appropriate patient consent forms. In the form the patient(s) has/have given his/her/their consent for his/her/their images and other clinical information to be reported in the journal. The patients understand that their names and initials will not be published and due efforts will be made to conceal their identity, but anonymity cannot be guaranteed.

Acknowledgment

The authors express their profound gratitude to Dr. Ammu Sivaraman, emeritus professor, Department of Pathology, PSGIMSR, under whose guidance all the autopsies were meticulously performed.

Financial support and sponsorship

Abstract

The development of whole-body inhalational chambers for acute toxicity risk assessment of aerosols in rodents is of key importance in clinical and occupational hazard evaluations. The key aim of study is the design, development, optimization, and validation of an inhalational chamber using water aerosol, vehicle, and Aroclor 1232. The second goal has been to apply this chamber in the risk assessment of Aroclor 1232. Broncho-alveolar Lavage fluid cytology and chromatography, and lung histopathology were used to supplement the validation process. PCB concentrations were uniformly distributed across different places inside the chamber and a MMAD generation of 4.3 µm ± 1.7 µm GSD was suggestive of lower airway atomization of PCB particles. The chamber environmental parameters were within acceptable limits for rodents during the experimental procedures. Mouse behavioral alterations were minimal during water aerosolization. Acute exposure to Aroclor 1232 showed reproducibility of behavioral scores. Benchmark dose for further studies using Aroclor 1232 was derived at 4 mg/cu.m. Its toxicities could be verified by correlating the behavioral scores, neurobehavioral functions with concentrations in plasma and BAL fluid samples from Swiss albino mice. The rodent chamber can be utilized for risk assessment of occupational hazards such as complex pollutant mixtures and particulate matter aerosols. The inhalational chamber possesses the versatility to enable assessment of toxicological mixtures across sub-acute toxicity timelines.

Keywords Inhalation toxicity · Acute toxicity test · Whole-body chamber · Rodent toxicology · Behavioral toxicology · Respiratory system · Aerosol toxicity · Aroclor 1232 · Biphenyl · Polychlorinated biphenyl · Broncho-alveolar Lavage

Introduction

The first line of defense in any organism exposed to such intoxicants can be the skin (dermal exposures) or the gastrointestinal tract (oral exposures). But an especially important route of exposure is inhalation which should bypass the respiratory tract to produce toxicity in the organism. The dosing of inhaled toxicants and pathophysiologic responses to inhaled toxicants and mechanisms behind their toxicities are key determinants of current and future human health, due to various reasons. Currently pollution rates and pollutants levels in the environment including the atmosphere are increasing. Also, the increasing incidence and prevalence of respiratory disorders including occupational diseases and substance abuse through inhalation route could be considered as important justifications to carry out research in inhalation toxicology. The results of inhalation toxicity studies can then be used to extrapolate to further improve health and quality of life of patients. Clinical and pre-clinical studies of this nature make use of inhalation chamber models

to evaluate the toxicology of complex inhaled intoxicants. Based on the design and the exposure protocols, inhalation chambers can be used to evaluate the toxic effects of general exposures like whole-body chambers, or more specific exposures, e.g., nose-only or head-only chambers. They can also be utilized to assess health effects after even more localized exposures like whole-lung or partial lung chambers in animal models or human participants (Pauluhn and Mohr 2000; Colli Neto et al. 2014). Being the oldest models described in inhalation toxicology, whole body chambers are widely used, much like the utility of nose-only chambers.

The utility of inhalation chambers for pharmacological and toxicological risk evaluations cannot be undermined at the cost of their limitations, like difficulty in experimental extrapolations to real-life situations, ethical issues in exposure methods, and the presence of concurrent routes of exposures and other confounders apart from the inhalation route. Though few research evaluations have utilized exposure chambers in modeling inhalation toxicities in the past, their applications are of importance in regulatory policy making (Pauluhn 2003; Raju et al. 2014).

Standard environment exposure systems exist for inhalation exposures of animals like the BuxCo® system used to evaluate the effects of printer emitted particles (Pirela et al. 2014) and the Madison whole body chamber in fungal inhalant evaluations (Springer et al. 2013), though they may not be suited to deliver semi-volatile chemical and bioactive mixtures with potent but undetermined toxicities. Secondly, these chemical mixtures and congeners are complex and persistent, which makes it prudent to afford for safe elimination after the experiment without much provision to cause pollution and accumulation.

Aroclor 1232 is a semi-volatile PCB mixture which contains many individual Polychlorinated biphenyl, PCB congeners. Of the representative PCB congeners, we selected PCB 77, a tetrachlorobiphenyl, and PCB 180, a heptachlorobiphenyl, both being of toxicological significance (ATSDR, 2000). PCB 77 is a dioxin-like PCB, whereas PCB 180 is a highly lipophillic, biomagnifiable PCB congener.

There are only a handful of studies reporting the successful development and design of inhalation chambers in avian and rodent models of exposure (Kumamoto et al. 2013; Shaheen et al. 2016).

We describe the design and development of a whole-body rodent inhalation chamber for sub-acute inhalational toxicity testing, from its conception to its utility in evaluation of neurobehavioral parameters in mouse models. Since nose-only chambers usually do not simulate the occupational exposure better than whole-body chambers, we have applied the latter in toxicity assessment of a PCB mixture in rodents (Swiss albino mice). We have used water, water plus methanol, and Aroclor 1232 (PCB mixture) aerosols for validation of the chamber. We have also quantified PCB 77 and PCB 180 concentrations in plasma and BAL fluid of mice, after dosing Aroclor 1232 at dose increments, and evaluated using behavioral responses. Lung histopathology was used to supplement these results. The research was carried out at PSG Center for Molecular Medicine & Therapeutics laboratory, from March 2015 to July 2018.

Materials and methods

Chemicals and reagents

The PCB mixture, Aroclor 1232 was obtained from Sigma-Aldrich Inc., India. PCB 77, PCB 180 HPLC-grade standards were obtained from Sigma-Aldrich Inc., India. Acetonitrile of HPLC grade was purchased from Sigma-Aldrich, India. HPLC grade of methanol (carbinol) and Methyl tert-butyl Ether were purchased from Hi-Media, India. Ultrapure water (18.2 mΩ cm) was obtained from Millipore (Milford, USA) using MilliQ water purification system. Disodium EDTA calcium hydrate crystals and Sodium Hydroxide crystals were purchased from Sigma-Aldrich Inc., India.

Animals

Swiss albino mice were procured and quarantined at the PSG Animal Facility. They were housed under ambient light–dark cycle and optimum environmental conditions with water *ad-libitum*. Prior Institutional Animal Ethics Committee (IAEC) approval was obtained for study execution. All mice were of age 8–12 weeks with body weights ranging from 17 to 28 g at initiation of experiments. The Animal Facility is accredited by the local Regulatory Authority, the Committee for the Purpose of Control and Supervision of Experiments on Animals (CPCSEA 2003).

Structural design of the inhalation chamber

The inhalation chamber is a whole-body exposure chamber meant for small laboratory animals including laboratory rodents. The development process of the chamber has been undertaken in two stages viz., design-and-development, and characterization-cum-optimization.

Design and development

The whole-body inhalation exposure chamber consists of three different mechanical units. The units have been divided based on their utility and role in the function of the chamber—the inlet system, the central chamber system, and the outlet system. Additionally, the environment of the chamber system, and the connections of the systems are also included in the chamber construction (Fig. 1a).

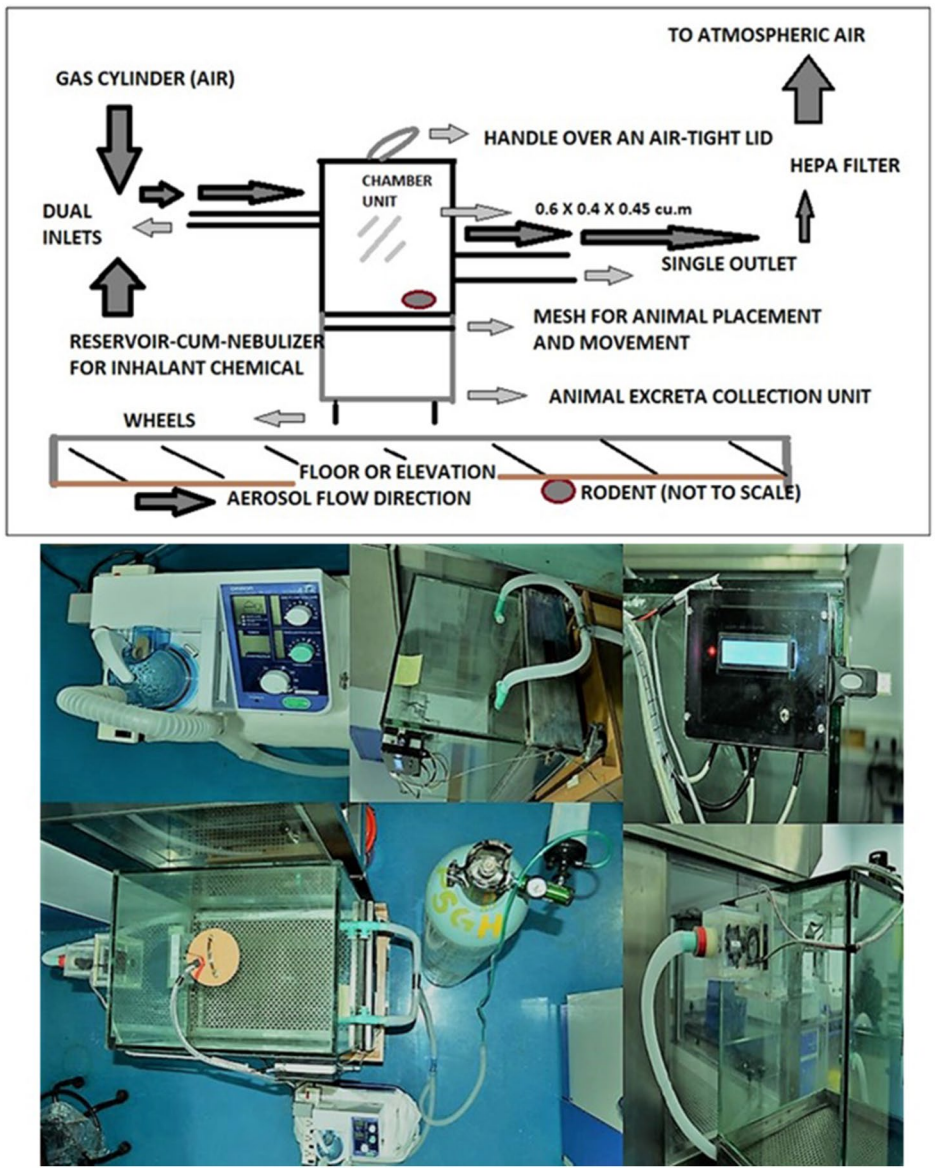

Fig. 1 Chamber Design—Line blueprint depicting chamber design (**a**) and photograph (**b**) depicting the key elements for inhalant exposures

Before initiation of the experimental procedure, the chemical mixture is prepared as per the dilution and dosing protocol of the experiment, for delivery of the test substance as aerosol particles. In order to achieve the desired flow rates of the aerosol particles by nebulization, air is used to forcibly propel the chemical mixture into the chamber after generation from the gas source (Air cylinder with control gauge and valve). The chemical pumping system (Ultrasonic nebulizer, Omron Inc.) is used to deliver the chemical aerosol of the test substance into the inhalation chamber. The central chamber core system is a glass transparent cuboid measuring 600 mm × 400 mm × 450 mm in dimensions. The base of this chamber comprises of another subunit made of stainless-steel mesh grid, below which a compartment is located to collect and dispose of the animal wastes. The roof of the chamber has a 10-cm diameter hole which can be sealed off or opened to place or retrieve the experimental animals. The wall along a breadth side has two inlet openings, each with a diameter of 10 cm, located about 10 cm from the base of the wall, which are connected to the aerosol pumping-cum-delivery system. The base compartment can be removed like the lid covering the roof hole, both of which are air-tight, then sealed to avoid gas or aerosol particles from escaping into the external environment. The internal environment of the chamber is controlled by five different sensors connected to a display panel through wires and a printed circuit board (pressure, temperature, relative humidity, oxygen level, and flow rate). This panel is then connected to a computer software (Serial Input–Output interface, SIOW) console for recording and storing the readings of different atmospheric variables. The outlet is meant for maintaining a uniform circulation and pressure of the aerosol particles in the chamber

atmosphere by continuously removing the exhaled gases and particles from the chamber. To achieve this purpose, the outlet system, consisting of a single circular hole, is located on the contralateral wall of the chamber about 40 cm from the base of that wall, with a diameter of 10 cm. A fan is encased behind the outlet opening for providing continuous ventilation to animals and rotates with a mean speed of 3400 rpm to achieve uniformity of flow rates inside the chamber. The terminal end of the outlet opens onto a Class II Type A_1 Biohazard workplace system with HEPA filters to eliminate the aerosols after circulation and recirculation inside the chamber system.

Five different sensors were pre-calibrated and fitted onto the chamber. These sensors were installed to continuously detect relative humidity, pressure, temperature, oxygen concentration and flow rate inside the chamber. We measured Mass Median Aerodynamic Diameter (MMAD) in the room wherein the chamber was housed during the experiment on three occasions using an impact cascade method. The Geometric Standard Deviation (GSD) of MMAD was calculated using the following formula:

$$\mathrm{GSD} = \frac{84.1\%\ \text{mark}}{50\%\ \text{mark}}$$

Allowed limits for the chamber environment parameters must not exceed 20%, and oxygen concentration must not fall below 19% in the chamber. The time to chamber equilibrium, $t\text{-}_{95\%}$ was calculated using the following formula:

$$t - 95\% = 3 \times \frac{\text{Chamber Volume}}{\text{Air flow rate in chamber}}$$

Periodical and regular variations in the chamber environmental conditions were recorded and visualized onto a display panel and computer console using Serial Input and Output software (SIOW, software v 1.2, hardware v 1.1, CCS, Inc.).

Characterization and optimization

Experiment 1 We checked for hourly variations in chamber atmosphere (Pressure, temperature, Relative humidity, flow rate and oxygen content) in response to water nebulization. The experiment was carried out water aerosol (350 mL daily dosing volume) for 4 h/day for two weeks (five days / week).

Experiment 2 The procedure consisted of standardization of methanol and water ratio using 54 animals inside for assessing any behavioral effects on animals. For the initial tests, a dose ranging from 0.1 to 1000 ppm of water aerosol in methanol was used in different combinations with dosing durations (1 s, 3 min, 5 min, 10 min, 30 min). Any acute signs of intoxication or mortality were noted later at each of these dose levels using 6 mice, with equal sex ratio. Animals were randomized using a Latin square design to various combinations of dose levels and dosing durations based on a c x t protocol. The behavior was measured periodically using Irwin scale (Table 1, Irwin, 1968).

Experiment 3 To assess the uniformity of aerosol distribution inside the chamber, PCB concentrations were measured after 4 mg/cu.m of Aroclor 1232 for 6 h-duration was introduced into the chamber without animals inside. The floor of the chamber interior was divided into 3×3 equal spatial circles. In each of these circular divisions, a 5 mL glass beaker was placed with 2 mL of 1:1 methanol: water inside. The analytes (PCB 77 and PCB 180) were quantified by Ultra-high performance liquid chromatography with Diode array detection (UPLC-DAD) after 6 h of exposures in each of the beakers (Ramanujam et al. 2017).

Risk assessment of PCB mixture (single duration exposure)

Experiment 4: Aroclor 1232 (1 mg/cu.m) in methanol–water aerosol at 1 ppm was used to ensure reproducibility of chamber conditions with animals. This was performed on three different days for assessment of replicability of acute 4-h behavioral toxicity. The behavior was measured periodically, and the respiratory physiological parameters were calculated, using the following formulae:

$$\text{volume of dissolved oxygen}\left(\frac{\text{ml}}{\text{dl}}\right) = 0.003 \times P02$$

Experiment 5 Three male and three female Swiss albino mice were exposed to 1 mg/cu.m of Aroclor 1232 for 6 h to assess gender-differences in behavioral scores. Irwin scale was used to assess behavioral scores across all eleven subdomains, and forty-seven functions from six physiological systems in Swiss albino mice.

Broncho-alveolar lavage (BAL) analysis

Experiment 6 Twelve female Swiss albino mice (12–14 weeks age) were assigned to four cages (three mice per cage), weighed and acclimatized. Isotonic (0.65%) sterile BAL ringer was prepared 6.5 g NaCl in 700 ml double distilled water with citric acid as buffer, till p H is adjusted to 7.0–7.2 at temperature of 4 °C. Methanol 1 ppm was used for exposure in the vehicle control group. Aroclor 1232 at 2, 4, and 16 mg/cu.m was used for test group exposures, with

three mice per group. Exposures were carried out for 6 h per group, and tracheostomy was performed after termination of exposure under Ketamine (75 mg/kg I.P) – Xylazine (3 mg/kg I.P) using 25 G needle. After tracheostomy was performed, a 40 n. thread was inserted under trachea, 21 G needle with long (25 cm) tube inserted to its other end, and using 1 m L syringe, 500 mcL of BAL fluid was pushed through plunger and aspirated thrice, finally being collected onto 2.5 mcL microcentrifuge tubes (Tarsons Inc.) for centrifuge at 300 g for 5 min till storage at 4 °C, and further analysis after freeze-thawing. Analysis was carried out for cytology (Giemsa stain for Total and differential counts), and UPLC-DAD estimation of PCB 77 and PCB 180; the analysis was carried out using a pre-defined protocol (Ramanujam et al. 2017).

Lung histopathology

Experiment 7 Ice cold PBS perfusate was prepared overnight and after tracheostomy was performed, the trachea and lungs were irrigated with the perfusate. This was followed by dissection of the carinae and / or lung parenchyma for storage in 8% Formalin solution for histopathological analysis at 40× in H&E stain.

Applicability to behavioral toxicology risk assessment: acute toxicity

Experiment 8 An acute Aroclor 1232 toxicity study was used to determine the sex differences and reproducibility

of behavioral scores on three days in response to 4 mg/cu.m exposure dose level for 6 h. For this objective, three male and three female mice behavior were compared for their variability. To ascertain the constancy of animal concentrations from different spatial co-ordinates inside the chamber, all animals were anesthetized for retro-orbital sampling of plasma. PCB 77 and PCB 180 were then quantified in these plasma samples using UPLC-DAD method in these six mice (three males and three females) after 6 h of exposure to 4 mg/cu.m of Aroclor 1232 (Ramanujam et al. 2017).

Benchmark dose derivation

Experiment 9 Acute toxicity study with control, 1, and, 4 mg/cu.m of Aroclor 1232 in 8 female Swiss albino mice each with a pre-defined Bench Mark Response Rate (BMR) from control of ± 50% change in basal behavioral scores and subsequent benchmark dose modeling in the BMDS version 2.4 (BMD Software, US-EPA) using polynomial model (Fig. 2):

$$y\,(\text{dose}) = \text{control} + \text{slope} * \text{dose}^{\text{power}}$$

Applicability to behavioral toxicology risk assessment: repeated dose neurotoxicity

Experiment 10 The optimization was further enhanced by addition of operant or instrumental assessments of mice exposed to Aroclor 1232 aerosols (4 mg/cu.m) for two-week occupational protocol. Briefly the mice were exposed to water aerosols (control group) via inhalational route, followed by washing of chamber thrice with 20% Isopropyl alcohol in methanol. This was followed by exposure to Aroclor 1232 at benchmark dose in similar manner. Occupational exposure was defined as 6 h a day (9 am to 3 pm), 5 days per week for two weekly exposures for this dosing group. Assessments were performed for neuro-cognitive endpoints a baseline, after one week and at termination for each dose level, on Y-maze, elevated plus maze and open field box in both groups. (Narayanan et al. 2017).

Results and discussion

Chamber (Fig. 1b) characterization, validation and optimization protocols were successful in yielding uniform and reproducible results in animal behavior and survival, within acceptable variability limits.

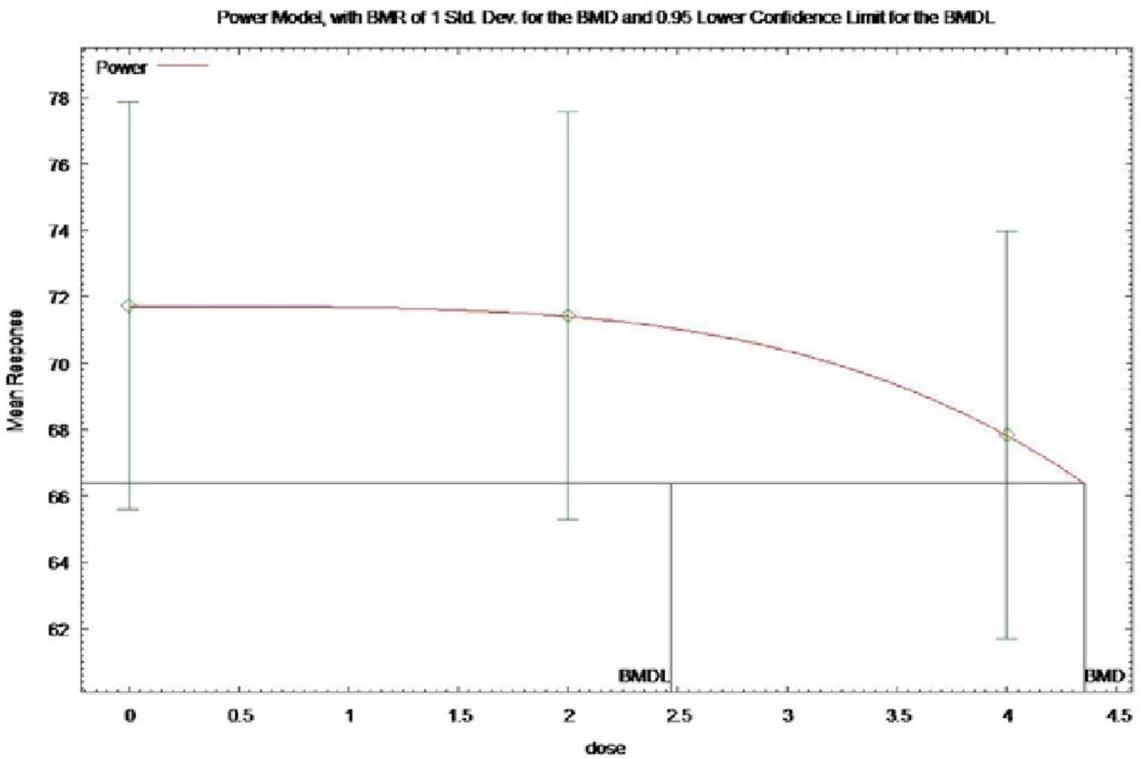

Fig. 2 Dose Response graph depicting the Bench-Mark Dose (BMD) with 95% Limit (BMDL) from the US-EPA BMDS Version 2.6, using Power modeling

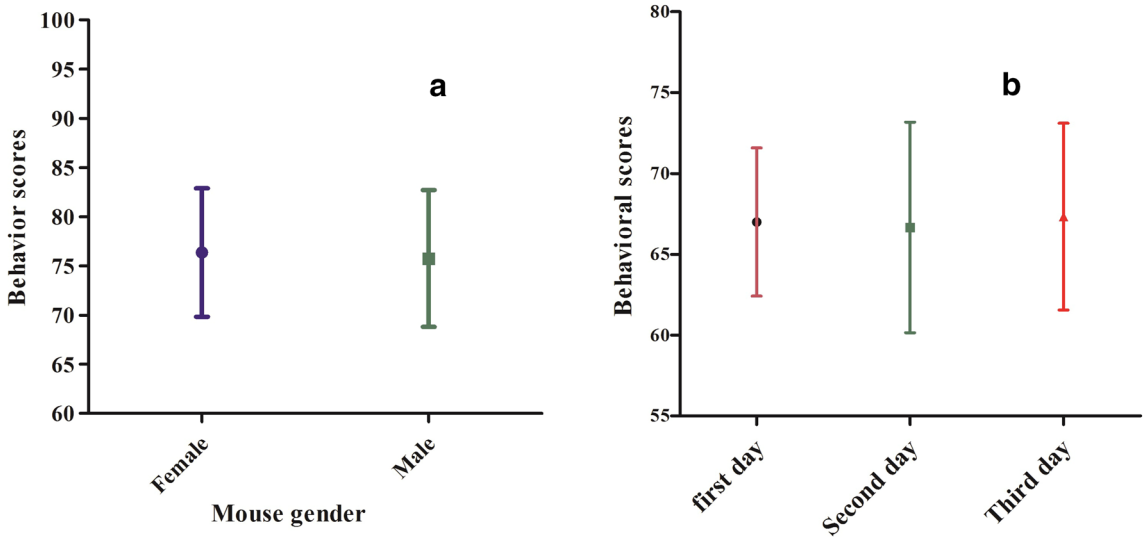

Fig. 3 **a** Chamber optimization for behavioral toxicity. **b** The effects are reproducible acutely. 3-male and 3-female mice were used for all three tests, at 1 ppm dose of water aerosol

Development

The chamber dimensions are well within the CPCSEA-regulatory limit of cage size for laboratory mouse (CPCSEA 2003). We optimized the air flow and PCB flow patterns inside the chamber in-silico using different permutations of inlet and outlet and the physicochemical properties of PCBs. Based on the simulation experiments, the best inlet–outlet configuration was determined to be with two-inlet and single-outlet chamber design (Fig. 3). The inlets were placed below the plane of the contralateral outlet, for optimum flow and uniform particle distribution in the chamber (Table 2). As per the Committee for the Purpose of Control and Supervision of Experiments on Animals (CPCSEA) guidelines, the minimum requirement for one mouse, each weighing up to 25 g, is 77.4 sq. cm per mouse with a height of 12 cm (cage) (CPCSEA 2003). Using a cascade impactor, we estimated the MMAD to be well within the Organization for Economic Co-operation and Development (OECD) toxicity guidelines (OECD 2009). The MMAD with GSD of the particle sizes was 4.3 µm ± 1.7 µm (Table 3). The time to 95% equilibrium ($T\text{-}_{95}$) in the aerosol under the chamber conditions was found to be 7.27×10^{-1} s. Then after the apparent completion of $T\text{-}_{95}$ as theoretically calculated, the inhalation exposure to test aerosol was initiated at pre-calibrated flow rates and other nebulization parameters.

Characterization

We have analyzed the environmental conditions in the chamber using five different sensors connected to a panel and a software console. Similarly, hourly atmospheric variations did not exceed 20%, which was preserved in our limit test and the sighting study over two-week exposures (Table 4). Oxygen saturation in the chamber was well at 21%.

The optimum ratio of methanol–water was 1:1 with optimum dosing duration of ≥ 90 min, based on minimal behavioral disruptions achieved for this protocol, compared to other methanol to water ratio x dosing duration permutations. The exposure duration for optimization of vehicle-solvent (methanol: water) ratio was below the 4 h as per OECD requirements

Table 2 Table depicting chamber optimization parameters: chamber environment variables assessed using pre-calibrated sensors

Environment variable	Mean ± SD
Flow rate (L/min)	16 ± 1

for acute inhalation toxicity. Based on this experiment, the behavioral scores did not vary much across different dosing combinations of methanol to water (77 ± 6). However, the variation was minimum with a 1:1 ratio of methanol to water for all durations tested in this phase.

Optimization

After 6-h exposure to 4 mg/cu.m of Aroclor 1232, the entire nine beakers (3 × 3 equal spatial circles) containing samples were quantified for PCB 77 and 180 using UPLC-DAD. PCB 77 and PCB 180 concentrations in the all the beakers were found to be 1795.65 ± 6.41 and 1964.42 ± 18.24 ng/mL. Hence, this indicates uniform distribution of test aerosols across the chamber floor and its vicinity.

No significant change in behavioral scores between male and female mice was observed after exposure to 4 mg/cu.m × 6 h of Aroclor 1232 (Fig. 4).The results of behavioral assessment of Aroclor 1232 acute exposures on three similar occasions with the exposure duration of four hours as shown in Fig. 4. The mean behavioral scores for water aerosol-treated animals were 65 ± 15.

The mean plasma PCB 77 and PCB 180 concentrations were 144.00 ± 16.51 ng/mL and 323.03 ± 34.95 ng/mL, respectively, at 6 h of exposure to 4 mg/cu.m in six (1:1: Male: Female) Swiss albino mice. The minimum variability of concentrations between animals in the group may be due to their movement across different parts of the inhalational chamber and the resultant uniform distribution of the PCB mixture at the bottom of the chamber during the exposures, as shown by the simulation results.

BAL fluid analysis and lung histopathology

The cytological analysis of BAL fluid samples showed dose-dependent leukocytosis with lymphocytes occupying majority of the WBCs in low power under Giemsa stain (Fig. 5a). The control (Methanol) group exhibited minimal signs of alveolar edema in the lung parenchymal specimen (Fig. 5a). There was dose-dependent increase in alveolar inflammation, mild interstitial fibrosis, alveolar edema, tracheitis and eosinophilic and mast cell infiltrates in the treatment groups (Fig. 5b–d). HPLC-FLD analysis of BAL-fluid showed dose-dependent increase in PCB 77 and PCB 180 concentrations (Fig. 5b).

Benchmark dose

The median scores of behavior in control (water aerosol), 2 mg/cu.m, and 4 mg/cu.m Aroclor 1232 dose levels were nearly 72, 71, and 68, respectively, at 2–4 h of single 6 h exposures, respectively (Fig. 4). The change in scores was more than 50% (behavioral depression) in the 2 mg/cu.m versus 4 mg/cu. group, as compared to control versus 2 mg/cu.m group comparison. Using a polynomial model,

Table 4 Normative values for neuro-cognitive indices assessed during the validation of the chamber using water aerosolization for 2 weeks at 1 ppb dose

calculations on the BMD (Bench Mark Dose) Software yielded a BMD of nearly 4.35 mg/cu.m [BMDL = 2.46 mg/cu.m, 95% Confidence Interval for risk of deviation of control values from SD of test dose values, log-likelihood test, $p < 0.003$] for single 6 h exposures.

Sub-acute risk assessment

The neuro-cognitive indices across three time points over two-week water exposure at 1 ppm of water aerosol show preservation of the normative ranges, as shown by the two-way ANOVA (Table 4), for temporal interactions of each mean value. Hence, the chamber can be used for neurobehavioral efficacy or toxicity testing of chemicals by aerosols with minimum temporal variations. Also, the mean behavioral scores showed minimal inter-day and intra-group variations, which correlated well the neuro-cognitive indices of mice.

Discussion

We describe the successful designing, development, and characterization of a whole-body inhalation chamber for exposing mouse to aerosols and pollutant mixtures (Fig. 1b). Inhalation chambers can be used in animals and less commonly in human participants to deliver physical, chemical, or even biological agents to the animal model via the inhalation route. For example, inhalation of smoke from e-cigarettes have shown to decrease phagocytosis and other host defenses in mice following infection with respiratory bacteria and viruses in a whole-body chamber (Sussan et al. 2015). Similarly, using an inhalation chamber, pregnant mice exposed to diesel exhaust particles on daily basis exhibited developmental abnormalities in the off spring as determined by altered brain DNA methylation markers independent of -CpG- islands. Chemical agents like Acrolein have also been delivered to the respiratory tract and detected in the circulatory systems of animal models using inhalation chambers and gas cylinder systems (Tully et al. 2014). Fungal agents

like *Aspergillus conidia* have also been delivered to the respiratory tract of mice as a part of model development using inhalation chambers (Buskirk et al. 2014). Likewise, to evaluate the teratogenic effects of alcohol and alcohol spectrum disorders in mice, vapor chambers were designed and used successfully to deliver alcohol vapors(Morton et al. 2014). Studies assessing inhalation risk with vapor measurements in the upper respiratory tract and silicon dioxide, design of Aluminum chambers for rodent exposures(O'Shaughnessy et al. 2003), histopathological assessment after exposures to quartz exist in publication databases, with provision for risk assessment of diverse xenobiotic exposures.

Although the nose-only exposure chambers for rodents utilize or allow less durations of exposures (Duch et al. 2014) than whole-body chambers because of the differences in the portal of entry of aerosols, the chamber we developed was successfully tested at lower durations also. Unlike earlier semi-open inhalation chambers which were used for chronic dosing at high concentrations, the chamber we have developed is versatile and could be used for dosing low to high concentration aerosols and vapors from acute to chronic protocols. However, we also agree that our chamber can be used only for small laboratory animals including laboratory rodents (OECD 2009). It cannot be used for large animals like rabbits and monkeys which are more closely related to humans than rodents, making extrapolations of research data to humans more reliable in the latter.

Acute or even repeated dose toxicity studies in short term (sub-acute and sub chronic durations) do not affect the histology of lung of mice adversely as reported recently (Umezawa et al. 2013), which was taken as a rationale for acute testing of mice in ours study in the inhalation chamber. Although lung-only or nose-only exposure systems (Weber et al. 2010) would directly deliver the inhalant to the lungs than a whole-body inhalation chamber, they either do not reach lower airways, or do more damage if at all they reach the lower airways, and are better suited for vapors than aerosols. Since the conditions in the chamber were normobaric with Pressures ranging from 731–737 mm Hg, we are certain that the flow rates used will not affect the mouse respiratory physiology adversely.

Though the inhalation chamber was developed to evaluate the effects of pollutant aerosols with complex chemistry as described previously by others (Mainelis et al. 2013; McIntosh-Kastrinsky et al. 2013), the chamber can also be applied for a range of utilities ranging from cardio-respiratory assessments to chronic respiratory and occupational toxicological evaluations of pollutant mixtures. Indeed, it took nearly 0.7 s for the chamber's internal environment to equilibrate, which is very quick; preventing cross-contamination. Recently such assessments have been reported elsewhere using simple exposure systems (Weber et al. 2010; Gatzioufas et al. 2013). Many of these address the designing of nose-only inhalational chamber meant for short-term exposure durations of drug aerosols (Kaur et al. 2020). Nanotoxicology research inputs have also been used previously in the characterization of inhalation chambers (Taquahashi et al. 2013; Yi et al. 2013). Usually, respirable fraction via dry powder inhaler for rodents ranges from 47–54% and that via nebulizer ranges from 34–73% in previous studies(Sinha and Mukherjee 2012). Although nose-only inhalation is preferred to whole-body exposures to deliver drugs to target tissue specifically, whole body chambers simulate occupational exposures more naturally in rodents than nose-only chambers though the deposition of particles in lungs may be similar by both types of inhalation chambers (Pauluhn 2006; Oyabu et al. 2016). Hence, though nose-only inhalation usually achieves greater respirable concentrations and is specific for delivery of aerosol mixtures into the alveoli than whole-body chambers, the mode of aerosol generation which is reflected upon by time to equilibrium ($T\text{-}_{95\%}$) is more important determinant of total body concentrations of test mixtures than the method of aerosol exposure.

Although physical parameters in the chamber like humidity and oxygen saturation are key confounding determinants of the health of animal housed and exposed (Springer et al. 2013; Reis et al. 2013), we have maintained the chamber environment under strict allowed limits to ensure safety of the animals exposed in our study and avoid variations in the study results.

We conclude with certain limitations of our study such as the requirement of aerosol particles to be within the limits set by regulatory authorities may be difficult to meet with due to the complex chemical and unknown physical properties of the inhaled intoxicants and the non-generic nature of our chamber in that it can house small rodents only. We, however, have simulated the chamber conditions and ensured the safety of the housed animals with the uniformity of the results as incorporated in actual chamber development and testing (Olsgard and Smits 2008).

A novel technique of a whole-body inhalation chamber optimization has been reported and this type of biologically-accountable chamber can be used for inhalation neurological or neurotoxicity studies, climatic simulation experiments with animals and pharmacology and physiology studies after dosing drugs via inhalational route, with strict compliance to standard regulatory guidelines. In conclusion, the inhalational chamber developed in the above-mentioned manner is versatile and robust; it could cause minimum neuro-cognitive and behavioral alterations during the sub-acute exposure timelines, in small rodents. This inhalation chamber can be applied in regulatory pharmacology studies (e.g. aerosol/drug nebulization studies), toxicology studies (e.g., pollutants' inhalational risk assessment in rodents), and in biohazard studies (e.g., suspended viral hazards—risk assessments in rodents). It

can be specifically curated to neuropharmacology and neurotoxicity efficacy and toxicity studies in rodents via inhalational route.

Conclusion

The whole-body inhalation chamber has been constructed, developed, optimized, and validated for use in rodents to assimilate the Aroclor 1232 toxicity data at acute and subacute timelines. To achieve this objective and outcome, the in-vitro validation was confirmed with uniformity studies of PCB concentration across different chamber floor quadrants, followed by in vivo penetrability and neurobehavioral risk assessment of PCBs. To this end, Irwin scale and interoceptive memory and higher functional battery of tests were used to evaluate the risk hazard of Aroclor 1232 as an indoor and industrial occupational hazard as per regulatory guidelines for neurotoxicity studies in mice. The environmental and analytical optimization parameters hence developed can be applied to higher rodent models including rats and guinea pigs as per standard animal housing guidance available world-wide. The final output, i.e. the inhalational chamber hence developed could be utilized for risk assessment of complex chemical mixtures, including Aroclors, and related dioxins, via inhalational route, in regulatory toxicology studies assessing persistent environmental pollutants as occupational hazards. However, despite limitations like non-applicability of this inhalational chamber for risk assessment of non-volatile, non-hydrophilic, and non-air pollutant chemicals in rodents, these applications can be further explored, in addition to the currently broad scope of this chamber. Further, the BAL assessments and MMAD measurements confirm lower airway penetrability of PCBs, as a novel regulatory platform, confirming the chamber's robustness and working mechanism.

Journal of Evolution of Medical and Dental Sciences 2014; Vol. 3, Issue 69, December 11; Page: 14225-14234,
DOI: 10.14260/jemds/2014/3991

ABSTRACT: Carcinoma breast is the commonest malignancy of females all over the world and second leading cause of death due to cancer among females. The incidence of breast carcinoma in India is on the rise. The prognosis of tumors depends upon the size of the tumour at presentation, histological type, grade, marginal clearance and lymph node status. The prevalence of hormone receptor-positive breast cancer in Asian countries has been found to be lower than the western world where more than 50% tumours express hormone receptors. The study aims at determining the incidence and prevalence of hormonal receptors and Her-2-neu in various subtypes of breast carcinoma and the distribution of expression among the epidemiological subgroups of patients of different age groups, parity, reproductive status etc. All cases of breast cancers attending the oncology OPD in a tertiary care hospital in South India during a 2 year period (2012-2013) were taken up for our study. The criteria of selection of patients included availability of histopathological diagnosis, hormone receptor studies, Her-2-neu expression status and follow up till the study period. Breast carcinomas tend to occur more frequently in older and post-menopausal females. However the incidence of breast carcinoma in females below 40 is on the rise. Greater awareness regarding self-examination of breast, screening tests like mammogram and ultrasound and fine needle aspiration cytology should be advocated for an early diagnosis and better prognosis. Risk factors of developing carcinoma breast include obesity, diabetes, estrogen exposure and nulliparity. Most tumors belong to Grade III, probably because patients present to the hospital a late stage of cancer. The prevalence of estrogen receptor positivity is 43.3%, progesterone receptor is 30% and Her 2 neu over expression is 56.6%. Hormone receptor status depends on size, histological type and grade of the tumour. In our study we found that there is no significant association between hormone receptor status and age, menopausal status or number of axillary lymph nodes showing tumor deposits.

KEYWORDS: Breast cancers, tumour grading, hormone receptors.

INTRODUCTION: Carcinoma breast is the commonest malignancy of females all over the world and second leading cause of death due to cancer among females. The incidence of breast carcinoma in India is on the rise. The risk factors of breast carcinoma include long estrogen exposure, nulliparity, obesity and family history of breast cancer. The incidence of breast carcinoma differs in various age groups of patients. Most cancers are diagnosed when patients find a lump during self-examination of their breasts. Mammograms are done as a screening test in many centers and the finding of micro calcifications in a breast lump alerts the treating physician that there is a high index of suspicion of malignancy.

DOI: 10.14260/jemds/2014/3991

Fine needle aspiration of the tumour can be done as an out-patient procedure to confirm malignancy. Neo adjuvant chemotherapies before surgeries have improved the over-all prognosis of operable breast cancers. The surgeries for a malignant breast swelling range from lumpectomy to modified radical mastectomy. Nevertheless, breast conservation surgery followed by chemotherapy and hormonal therapy produce almost equal results as radical surgery, thereby ensuring better quality of life after surgery.

The prognosis of tumors depends upon the size of the tumour at presentation, histological type, grade, marginal clearance and lymph node status. Immunohistochemical evaluation of estrogen receptor (ER) and progesterone receptor (PR) status of breast carcinoma has become a routine investigation to predict the response to adjuvant endocrine therapy. The prevalence of hormone receptor-positive breast cancer in Asian countries has been found to be lower than the western world where more than 50% tumours express hormone receptors.

HER-2/neu is the human homologue of the neu gene, called HER-2 or c-erbB-2, which shares extensive homology with epidermal growth factor receptor (EGFR). It is considered one of the poor prognostic factors in breast cancer. The introduction of Herceptin {Trastuzumab}, which is a monoclonal antibody which binds to Her 2 neu receptor has brought significant changes in the prognosis and survival of breast cancer patients.

The study aims at determining the incidence and prevalence of hormonal receptors and Her-2-neu in various subtypes of breast carcinoma and the distribution of expression among the epidemiological subgroups of patients of different age groups, parity, reproductive status etc. The hormonal status has definite prognostic implications and so enables the clinicians to initiate various ancillary modalities of therapy.

AIMS AND OBJECTIVES:

To identify the risk factors of breast Carcinomas:

1. To classify breast carcinomas based on histopathological features
2. To document the estrogen and progesterone receptor (ER & PR) status and Her-2-neu expression of breast cancers
3. To correlate the steroid receptor status of breast cancer with all relevant patient and tumour characteristics.

MATERIALS AND METHODS: All cases of breast cancers attending the oncology OPD in a tertiary care hospital in South India during a 2 year period (2012-2013) were taken up for our study. The criteria of selection of patients included availability of histopathological diagnosis, hormone receptor studies, Her-2-neu expression status and follow up till the study period. The clinical data regarding age, family history, reproductive status, exogenous hormone administration and parity were gathered from the hospital case records. Special care was taken to note the presence of Diabetes mellitus, hypertension, History of tobacco, alcohol and use of oral contraceptives. An approval from the Institutional Human Ethics Committee was obtained prior to our study.

The clinical presentation of the tumour, the size of the swelling, axillary lymph node status, the presence of sub cutaneous lymphatic involvement, ulceration and adherence to the chest wall etc were noted.

DOI: 10.14260/jemds/2014/3991

A detailed record of all pre-operative investigations like mammogram, ultrasound, Fine needle aspiration cytology and true cut biopsies was made. Some patients had received pre-operative neo adjuvant chemotherapy and the complete record of it was made too.

The details of surgery performed like radical mastectomies, breast conservation surgeries or toilet mastectomies and presence of any post-operative complications were noted.

The gross specimen reports were reviewed to note the size of the tumour, marginal clearance, involvement of the nipple and areola and presence of ulceration. The number of axillary lymph nodes dissected was recorded in each case.

The histopathological slides were reviewed and the tumour was classified into the following histological types namely infiltrating ductal carcinoma, lobular carcinoma, colloid or mucinous carcinoma, medullary carcinoma, tubular carcinoma and other rarer type of tumors like sarcomas.

The tumours were graded according to the Nottingham modification of Scarff Bloom Richardson (SBR) grading system into Grade I, II and III based on tubule formation, mitotic activity and nuclear pleomorphism.

The margin clearance status, necrosis and lymphovascular invasion were observed. The exact number of axillary nodes showing tumor deposits was recorded.

The paraffin blocks were taken up for immunohistochemical studies using the Avidin Biotin immunoassay method. The markers for Estrogen and Progesterone receptors and Her-2-neu over expression were used. Evaluation of the staining and assigning a score was performed. The staining was evaluated on the invasive component only. Best-preserved and best-stained areas of the sections were assessed. Nuclear staining was assessed for ER and PR while membrane staining was assessed for Her 2.

A score for the proportion of stained cells (0 = no nuclear staining, 1 = <1% nuclear staining, 2 = 1-10% nuclear staining, 3 = 11-33% nuclear staining, 4 = 34-66% nuclear staining and 5 = 67-100% nuclear staining) and the intensity of staining (0 = no staining, 1 = weak staining, 2 = moderate staining, 3 = strong staining) were assigned to each tumour. Tumors that showed strong complete membrane staining in >10% of the tumour cells were considered positive.

The observations in each of these were tabulated and critically analyzed. Graphs and charts were made to study the expression of the hormone receptors and Her-2-neu among different histological types, high & low grade tumors. These results were compared with other high risk epidemiological factors.

OBSERVATIONS AND RESULTS: 30 patients were included in our study. The age of the patients varied from 27 to 78. The median age was 54. The distribution of the tumour in various age groups is given below.

7 patients were pre-menopausal and 23 of them were post-menopausal. 2 patients gave a positive history of breast cancer in mother and maternal aunt respectively.

The average parity of the patients was 2.8. Only one patient was nulliparous and she had a grade III tumour with metastatic deposits in the liver. All the 30 patients denied use of tobacco or alcohol. 5 patients had been sterilized and none of them had taken oral contraceptives.

The tumours were classified based on size into 3 groups; < 5cm, 5 to 10 cm and > 30cm. There were 11, 13 and 6 cases in each of these sub groups respectively.

The size of the tumour did not correlate with the grade or receptor status.

DOI: 10.14260/jemds/2014/3991

There were 24 cases of infiltrating ductal carcinoma, 2 cases of invasive lobular carcinoma, 1 case of tubulolobular carcinoma, 2 cases of colloid/mucinous carcinoma and 1 case of ductal carcinoma in situ.

Grading of the tumours was done using the Nottingham modification of Scarff Bloom Richardson grading system and tumours were grouped in to 3 categories based on tubule formation, mitotic rates and nuclear pleomorphism. 5 tumours were graded as Grade I, 11 as grade II and 14 as grade III.

Grade of the tumour	Total cases	ER +	PR +	Her 2 neu +
I	5	5	3	4
II	11	4	2	7
III	14	4	4	6

The number of axillary nodes showing metastasis ranged from 0 to 8.

13 patients received neoadjuvant chemotherapy prior to surgery. 20 of them received chemotherapy after surgery also. The patients with estrogen receptor positive tumours received Tamoxifen.

The details of follow up of all these 30 patients were obtained from the hospital case files. 3 patients developed metastases in the liver within a period of 1 year. 1 patient had a cystic metastasis in the brain. 3 of these patients had a primary grade III tumour whereas one had grade II tumour.

3 patients developed a contra lateral tumour in the opposite breast. Interestingly, a patient with ductal carcinoma in situ had carcinomatous deposits in all 20 lymph nodes detected and in due course she developed invasive tumour in the opposite breast.

DISCUSSION: In India there is concern about the rising incidence of breast cancers in younger women. Premenopausal women comprised 50% of the cohort in an urban study conducted by Raina et al.[1] The median age at presentation in their study was 47 years. In our study only 7 patients were premenopausal. The median age of presentation in our study was 54. However 3 patients were below the age of 35. Primary breast carcinomas arising before the age of 40 are far more aggressive and the likelihood of metastasis is higher than those arising in older patients regardless of the hormone status. These issues raise the concern about the lifestyle, use of exogenous hormone administration and the need to implement screening mammograms at an early age.

As mammographic facilities are not widely available here and there is no nation-wide breast-screening program, the commonest mode of presentation remains a lump in the breast, 96% of the patients in the present series presented with a breast lump.

In our study we found that modified radical mastectomy was the most preferred surgery followed by lumpectomy. Raina et al[1] proposed that patient preference for mastectomy is an important reason for the under-utilization of breast conservation therapy. The advanced stage and lack of facility for radiotherapy provoke the treating physicians to opt for radical surgeries. The majority of patients included in the present study had high-grade tumors, which explains the low prevalence of hormone receptor expression. It is often observed that high-grade tumors tend to be negative for hormone receptor expression.

DOI: 10.14260/jemds/2014/3991

Thriveni et al[2] proposed that grade of the tumour was directly proportional to the number of axillary lymph nodes. But in our study, there was no significant association between the grade of the tumor and number of lymph nodes.

Estrogen receptor is a well-established predictive and prognostic factor in breast cancer. In the recent International consensus on the treatment of early breast cancer, the panel affirmed that the first consideration was endocrine responsiveness of the tumour and suggested categorization of the tumours into endocrine responsive, endocrine non-responsive and tumours of uncertain endocrine responsiveness. Therefore testing for estrogen and progesterone receptors status is critical to plan optimal treatment in breast cancers.

According to Desai et al[3] the receptor positivity rates are lower in Indian population than in Western countries. This is probably due to the high prevalence of high-grade tumors among the study population. The Nottingham grade and the mitotic count have a significant inverse correlation with the Quick Score of hormone receptor expression. They reported ER and PR positivity rates of 32.6% and 46.1% respectively. Additionally, not all patients in India undergo hormone testing due to financial constraints. In our study ER positivity was found in 43.3% of the cases and PR positivity in 30% of the cases.

Chlebowski et al[4] published a data indicating a different pattern of association for most factors with ER-positive disease than with ER-negative disease. For ER-negative cancers, odds ratios for age, family history, age at menopause, greater parity, smoking, and alcohol use were all close to 1.0. The association between breast cancer risk and chronologic age, race or ethnicity, and age at menopause differed statistically significantly across ER disease subtypes. Age at menarche was not statistically significantly associated with either ER-positive or ER-negative breast cancer.

Our study is in concordance with the above data.

PR^- breast cancers, even if they are ER^+, are more aggressive than the PR^+ phenotype and are more likely to be of high grade than PR^+ tumours. ER and PR were inversely related to HER-2/neu over expression, whereas tumour grade was positively associated with HER-2/neu over expression according to the study undertaken by Huang et al.[5] In our study also, the PR^- tumours were all grade III and 2 of them showed muscle invasion and lymphovascular invasion. Unlike ER, there was only a low tendency for PR to be associated with smaller carcinomas and with older patients, but this tendency was not statistically significant.

Almasri et al[6] said that ER expressing breast carcinomas were, on average, 1.6 cm smaller than carcinomas lacking ER expression. Similarly, 57% of T2 tumors were ER positive as opposed to only 30% of T3 tumors. Our study did not show any significant relationship between ER expression and size of the tumour.

The presence of necrosis and lymphovascular invasion showed an inverse relationship with ER and PR reactivity according to Desai et al.[3] In our study, 2 tumors showed perineural/ lymphovascular invasion and both of these were negative for ER and PR but showed strong membrane positivity for Her 2 neu.

Swain et al[7] declared that whether contralateral breast cancer represents a second primary versus recurrent or metastatic disease clearly has implications for treatment. For example, if contralateral breast cancer represents a second, biologically distinct primary cancer, treatment with Tamoxifen may be beneficial for women with an ER-negative primary cancer who are at risk for

DOI: 10.14260/jemds/2014/3991

developing contralateral disease. In our project, only one of the tumours which metastasized to the opposite breast was ER positive and she was treated with Tamoxifen.

Naeem et al[8] reported that Her 2 neu over expression tends to decrease with age. But in our study there was no significant difference in Her 2 neu over expression among patients of different age groups.

Various studies have shown that Her 2 neu over expression is significantly associated with ER and PR negativity. In our study, Her 2 neu was positive in 13.3% cases with positive ER receptor status.

Almasri et al[6] observed that Her 2 neu over expression is directly proportional to the size of the tumour and the number of positive axillary lymph nodes. But in our study we found that there was no relation between the Her 2 neu expression status and the number of positive axillary lymph nodes. Also Her 2 neu over expression was more prevalent in grade II tumours.

In the present study, the overall grade of the tumour correlated well not only with the proportion of cells stained but also the intensity of staining, the two components of the Quick Score that justify the assessment of the intensity of staining in giving a score in an article that was published by Lakmini et al.[9]

Onody et al[10] suggested The HER-2/neu gene status may be useful not only as a prognostic factor in determining clinical outcome, but also as a predictive factor in projecting the response to adjuvant therapies. In our study, most of the Her 2 neu positive cases were given neo adjuvant chemotherapy and were disease free during our follow up period.

Dujaily et al[11] reported that most of the ductal carcinoma cases were purely invasive ductal carcinomas of nonspecific type (74.4%) that showed significant HER-2/neu over expression (65.6%). This provides more evidence of the hypothesis that aggressive tumors seem to show significant HER-2/neu over expression and demonstrates the association between the nature of the biological expression of HER-2/neu by the tumor and its degree of malignancy since it has been argued that nonspecific type ductal carcinomas are the most aggressive variants of breast cancer. The current study demonstrated that 58.3% of invasive ductal carcinoma cases exhibited HER-2/neu expression whereas 100% of invasive lobular carcinomas were Her2 neu positive.

The present study found no significant association between HER-2/neu over expression and age of the patients, which is in concordance with the publication of Dujaily et al.[11]

Li et al[12] proved that lobular and ductal/lobular tumours tended to be diagnosed at a more advanced stage and to be both >5.0 cm and node positive, but they were also much more likely to be hormone receptor positive. In contrast, come do and medullary carcinomas were less likely to have an advanced stage at diagnosis and to be node positive, but more likely to be hormone receptor negative and to have a high grade. Our study reproduced similar inferences.

Guarneri et al[13] proposed that the molecular classification of breast cancer represents the foundation of treatment selection for early and advanced disease. The more clinically useful classification recognizes three subtypes: HR positive (ER and/or PR ≥10%), HER-2 positive (IHC 3+, irrespective of HR expression), and triple-negative tumors (ER, PR, and HER-2 negative). Endocrine manipulation and anti–HER-2 agents represent the foundation of treatment in cases of HR-positive and HER-2–positive tumors, respectively, while, so far, chemotherapy is the only available option in triple-negative tumors. The practice of obtaining biopsies of metastatic lesions varies considerably across centers; therefore, the clinical management of the majority of patients is still based on the

initial assessment. In our study all the 3 tumours which metastasized to the liver were triple negative, whereas the tumour that produced a cystic metastasis in the brain was strongly positive for ER and PR.

Hawkins et al[14] suggested that tumour type, soluble protein content, type of surgery, tumour stage, type of systemic therapy and tumour size (clinical/pathological)] appeared to relate to risk of any recurrence. Eight of these factors also appeared to relate by univariate analysis to risk of distant metastases. And seven (ER concentration, node status, tumour grade, clinical and pathological tumour size, type of surgery and soluble protein content) appeared to relate to risk of death. For risk of local recurrence, however, only tumour grade and ER concentration appeared important. The tumors which metastasized to liver and brain in our study were all grade II/III, size above 5cm and triple negative (except one). But there was no difference in the type of therapy or surgery given to these patients. This was similar to the study done by Sambasivaiah et al [15] in 2007.

CONCLUSION: Breast carcinomas tend to occur more frequently in older and post-menopausal females. However the incidence of breast carcinoma in females below 40 is on the rise. Greater awareness regarding self-examination of breast, screening tests like mammogram and ultrasound and fine needle aspiration cytology should be advocated for an early diagnosis and better prognosis. Risk factors of developing carcinoma breast include obesity, diabetes, estrogen exposure and nulliparity:

- Infiltrating ductal carcinoma is the commonest histological type of breast carcinoma.
- Most tumors belong to Grade III, probably because patients present to the hospital a late stage of cancer.
- The prevalence of estrogen receptor positivity is 43.3%, progesterone receptor is 30% and Her 2 neu over expression is 56.6%
- Hormone receptor status depends on size, histological type and grade of the tumour. In our study we found that there is no significant association between hormone receptor status and age, menopausal status or number of axillary lymph nodes showing tumor deposits.
- Her 2 neu over expression status is inversely proportional to hormone receptor positivity. Poorly differentiated tumours, larger tumours and tumours with a more aggressive histological type express stronger Her 2 neu membrane staining.
- There is no significant association between Her 2 neu over expression and parameters like age, menopausal status and number of axillary lymph nodes.
- Widely metastasizing tumours are usually negative for hormone receptors and Her 2 neu genes.
- The introduction of neo adjuvant chemotherapy has brought about significant improvement in the prognosis of operable breast cancers.
- A regular follow up and better patient awareness will bring about drastic reduction in mortality due to breast carcinoma.

Abstract-

Introduction: Treatment for breast cancer is based on the expression of the immunomarkers such as ER, PR, and HER2/neu. Cases which are negative to all the three immunomarkers are called Triple Negative Breast Cancers (TNBC) and they have a poor prognosis. Recent studies have shown that some of the TNBCs express cytokeratins CK 5/6 (subcategorizing them as basal-like breast cancers) and these respond well to anthracycline-based chemotherapy.

Aim and Objectives: To study the expression of basal cytokeratins CK 5/6 in breast carcinomas reported in our center and to correlate with histological type, grade, size, clinical features and ER, PR and HER2/neu status.

Methods: Tissues of 44 cases of breast carcinoma diagnosed between June 2009 and May 2014 were retrieved. Immunohistochemical staining for CK 5/6 was done and it was correlated with parameters such as histopathological type, grade, size, invasion and ER, PR and HER2/neu status.

Results: Eight of the breast carcinomas (18%) were categorized as Triple Negative Breast Cancers (TNBC) as they were negative for ER, PR, and HER2/neu. Four of the TNBCs (50%), were positive for CK 5/6. The significant statistical correlation was observed between the size of a tumor and positive CK 5/6 expression. All CK 5/6 positive cases were of high grade.

Conclusion: The routine use of CK 5/6 is recommended in all cases of TNBCs, as 50% of them are positive for these markers. Patients in this subcategory could benefit from anthracycline-based chemotherapy.

Keywords- Triple Negative Breast Cancers, Cytokeratin 5/6, basal-like breast carcinoma

Introduction

Breast cancers are a diverse group of diseases that vary remarkably in terms of clinical presentation, histology, behavior and genetic characteristics [1]. There has been a steady increase in the incidence of breast

Downloaded from
Medico Research Chronicles

cancers worldwide and especially in the developing countries, mainly attributable to globalization causing adaptation of western lifestyle and improved access to diagnostic modalities. As per the International agency for research on cancer, the number of new cases of female breast cancers in India in the year 2012 was 144,937. [2] The mortality rate in the Indian cohort was 50% compared to that in the USA, where only one woman out 5-6 patients die of breast cancer.

Breast cancers that express Estrogen and Progesterone receptors can be treated by hormonal manipulation [3]. Targeted therapy towards HER2 neu has great success and Trastuzumab has been introduced as an adjuvant drug in those showing overexpression of Her 2 neu [4]. A subset of breast cancers has been found to show no expression of any of the above-mentioned markers. These have been labeled as Triple Negative Breast Cancers (TNBCs). Though hormonal manipulation is of no use in this subset, they have found to show expression of other markers such as basal Cytokeratins and EGFR. They have greater sensitivity to anthracycline-based chemotherapy despite poor pathologic complete response [5].

This study focuses on identifying the cases of breast cancer at our center, performing immunohistochemical studies of the basal Cytokeratin CK5/6 in them and studying their expression and correlation with various clinicopathological parameters.

Materials and Methods

Cases of breast carcinomas diagnosed between the years 2009 and 2014 were included in our study. The study was performed after getting approved by the Institutional Human Ethics Committee (IHEC). A few of the cases were rejected owing to the absence of sufficient clinical information, ER/PR studies or if blocks were unavailable. The requisition form sent by the operating surgeon was used for deriving information such as age, size, nodal status, and other gross findings. Hematoxylin and eosin stained slides from representative sections of the breast tumors were used for grading and assessing the histological type of a tumor, evidence of lymphovascular invasion, perineural invasion and skin involvement. Immunohistochemical staining for Estrogen Receptor, Progesterone Receptor, Her2neu and CK5/6 was performed on these sections after antigen retrieval in pressure cooker followed by EDTA buffer at an alkaline pH (pH of 9).

The antibody reagent clones were Clone EP1 by DAKO, Clone PgR 636 by DAKO, Anti-v-erbB-2 Clone CB11 by Biogenix and FLEX Monoclonal Mouse Anti-human Cytokeratin5/6 (Clone D5/16B4) for ER, PR, Her2neu and CK5/6 respectively. A two-stage process involving binding of the primary antibody to the targeted epitope; second step by identifying a secondary antibody bound to a dextran polymer with the help of horseradish peroxidase enzyme attached to a chromogen.

The various parameters analyzed were age, histological type, size of a tumor, grade, skin, lymphovascular and perineural invasions, number of axillary lymph nodes showing metastasis and staining properties of ER, PR, Her2neu, and CK5/6.

Based on studies conducted by Rakha et al [1], Laakso et al [6] an arbitrary scoring system was drawn up for quantifying the expression of CK5/6. (Table: 1)

Score	Description
0	Less than 1 % positivity
1 +	1-10% tumour cells are positive

Downloaded from
Medico Research Chronicles

2 +	10-50% tumour cells are positive
3 +	More than 50% of tumor cells are positive

Results

44 cases of female breast cancer were under study. The ages ranged between 33 and 67 years. The age group that had the most number of cases was 41 to 50 years. The commonest histological grade in our study was Grade 2, with 24 cases and 9 cases were grade 3(Fig:1).

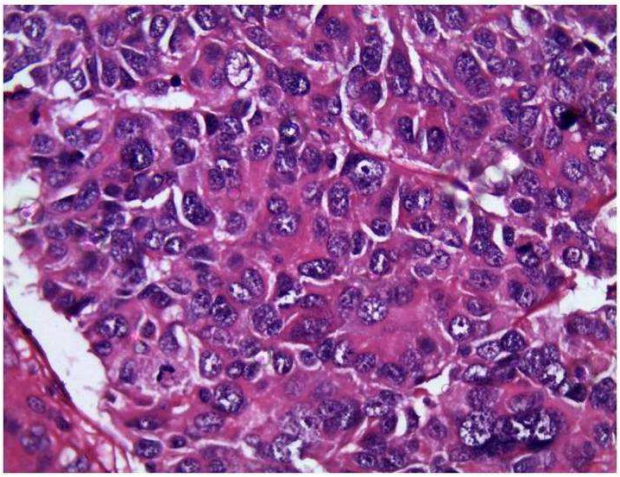

Fig 1 - Invasive ductal carcinoma NOS, H&E 400x

88% of the tumors were of the infiltrating ductal carcinoma, not otherwise specified (NOS). Two cases of micropapillary carcinoma, a case of metaplastic carcinoma and papillary carcinoma were included. Most cases (22) were of sizes between 2cm-5 cm. Lymphovascular invasion was seen in 20 out of 44 cases, with most cases belonging to Grade 2. Perineural invasion (Fig: 2) was seen in only two cases.

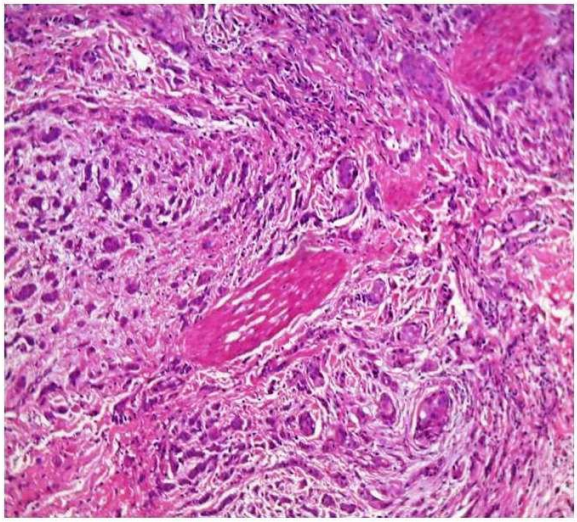

Fig 2 - Invasive ductal carcinoma with perineural invasion, 400x

Downloaded from
Medico Research Chronicles
"The expression of basal cytokeratins in breast cancers."
Estrogen receptor expression was seen in around 45% of cases and 52% of the cases showed Her 2 neu overexpression. (Fig 3)

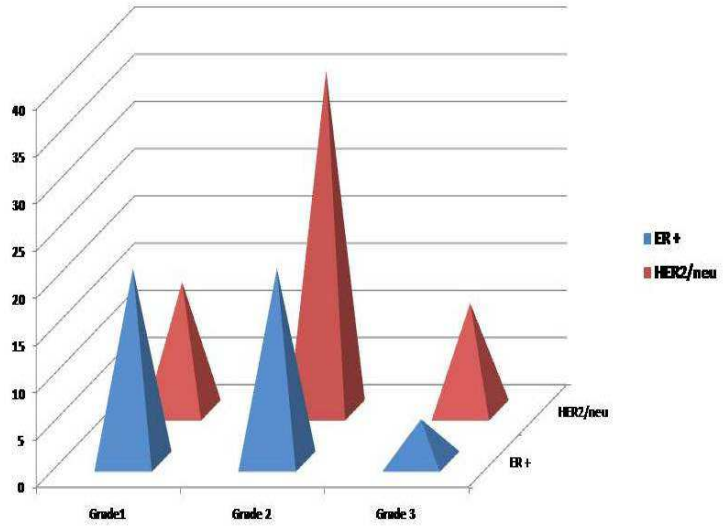

Fig 3 - Histogram showing the distribution of ER/Her 2 neu & grade
K 5/6 positivity. Larger tumors had a greater incidence of CK 5/6 positivity with the largest t Size of a tumor statistically correlated with C a tumour being 13.5 cm in size. (Fig 4)

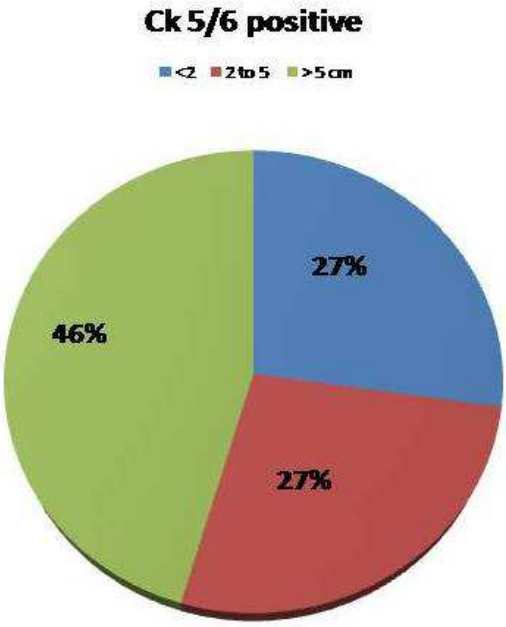

Fig 4 – Pie chart showing CK5/6 positive cases and size of tumors

Correlation between CK 5/6 with invasive and prognostic features was performed and we observed that the tumors with higher grade, lymphovascular, perineural invasion, and extensive lymph node metastases showed greater CK5/6 expression than their respective counterparts. (Fig 5).

Discussion

Breast carcinomas have emerged as the most common malignancy in Indian women. Not only is their incidence high, but the fatality rate of these cases exceeds those of the western population [6]. The cure rates, quality, and length of life have improved in these women after the development of targeted therapy. Glass et al [7] observed quantitative and qualitative trends in breast cancer incidence. There has been a tremendous increase, particularly in ER-positive tumors. The reason for the exponential rise has been attributed to the use of post-menopausal hormone replacement therapy and widespread utilization of mammography.

Breast cancers have been subclassified into 4 molecular subtypes.

1. **Luminal A** – a high expression of luminal cytokeratins and hormone receptors. ER/PR-positive.HER2/neu- negative.
2. **Luminal B** - Expression of luminal cytokeratins are seen. ER/PR-positive.HER2/neu expression-variably positive. Higher grade and proliferation than Luminal A
3. **HER2/neu** - a Low expression of ER. High expression of HER2/neu and 17q12. ER/PR negative. HER2/neu positive. High grade, TP53 mutations present and a higher likelihood of nodal metastasis
4. **Basal-like** - A High expression of basal cytokeratins and epithelial genes. Low expression of hormone receptors. Triple-negative (ER, PR, HER2/neu). TP53, BRCA1 mutations seen.

Treatment response to endocrine therapy is good in 'Luminal type A tumors. The response in 'Luminal B' tumors is not as satisfactory as in Luminal A tumors. Her 2 neu class of tumors responds to Trastuzumab. The basal-like tumors do not respond to endocrine therapy or Trastuzumab

The subsets of breast carcinoma which are not susceptible to conventional therapy, have a paradigm shift in molecular genetics and immunohistochemical expression. These are the Basal-like breast carcinomas and the Triple Negative Breast Cancers.

The overall percentage of ER-positive cases in our study was 45%, lesser when compared with western literature. (Fig 6). This is consistent with findings in a study conducted by Ambroise et al [8], which concluded by saying that hormonal expression is lesser in the south Indian population. We noted that 54% of ER-positive tumors were node positive and most ER positive neoplasms [9] were less than 2 cm in size.

Downloaded from
Medico Research Chronicles
"The expression of basal cytokeratins in breast cancers."

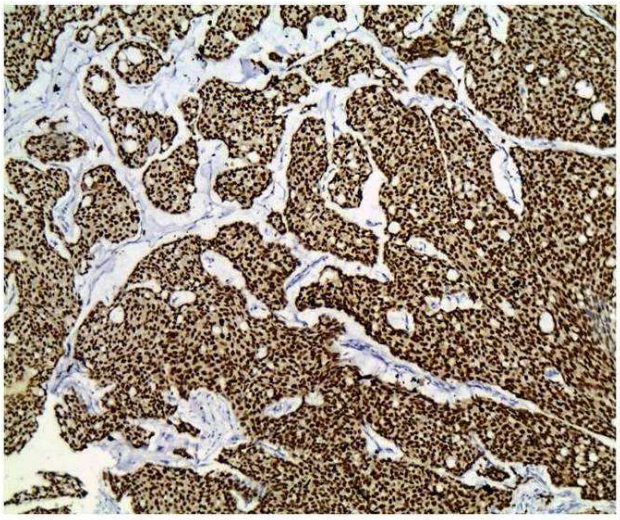

Fig 6 - 100% cells showing strong nuclear staining for Estrogen Receptor

We inferred that due to the large size of the tumors in our study, there was increased nodal metastasis. Almost all the women with ER-positive cases belonged to the 35 to 65 year age group.

Normalization technique was introduced for standardization of results and to avoid discordance between immunohistochemistry and FISH results. There is improved accuracy of HER2 studies using a subtraction scoring system in which a signal score of non-neoplastic breast epithelium is subtracted from that of a tumor [10]. Using this system, the proportion of HER2 positive tumors in our study is 63%. (Fig 7). This stresses the need to look into other markers and their routine use in South Indian cohorts.

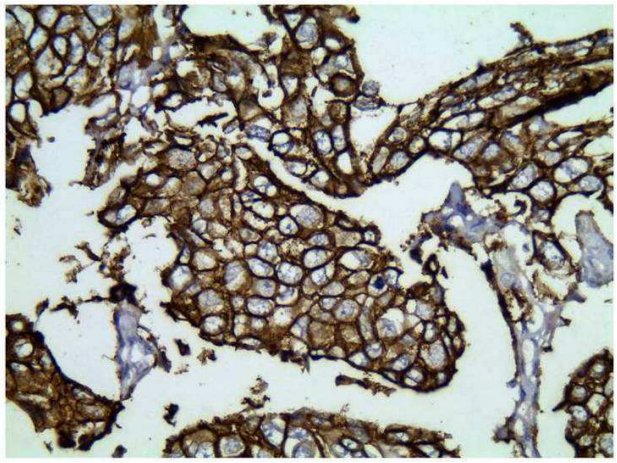

Fig 7 - Cells showing strong and complete membrane staining for Her2neu

Dolle et al [11] inferred that Triple Negative Breast Cancers (TNBCs) are breast cancer subtypes associated with high mortality rate and resistance to hormonal manipulation and Herceptin. Since these tumors are negative for ER, PR, and HER2, newer markers are to be identified for this subtype. These tumors have been seen with increased incidence in younger women (aged 45 years or younger). Our study

Downloaded from
Medico Research Chronicles
"The expression of basal cytokeratins in breast cancers."

showed close correlation, with the mean age of women with TNBCs being 46 years and nearly a third of the women were 40 or younger.

The purpose of our study was to identify a newer basal marker and observe the expression and clinic-pathological in cases of breast cancer at our center. The basal marker that we selected for our study was CK 5/6[12]. Clark et al suggested that CK5 is positive in breast progenitor cells, which are believed to be the cell of origin in basal-like breast cancers (Rakha) [1]. In our study, 25% of the cases were basal-like, with all of these tumors falling into either Grade 2 or Grade 3. Thus CK 5/6 was positive in 50 % of TNBCs (Fig: 8). The only case of the metaplastic tumor was negative for basal markers.

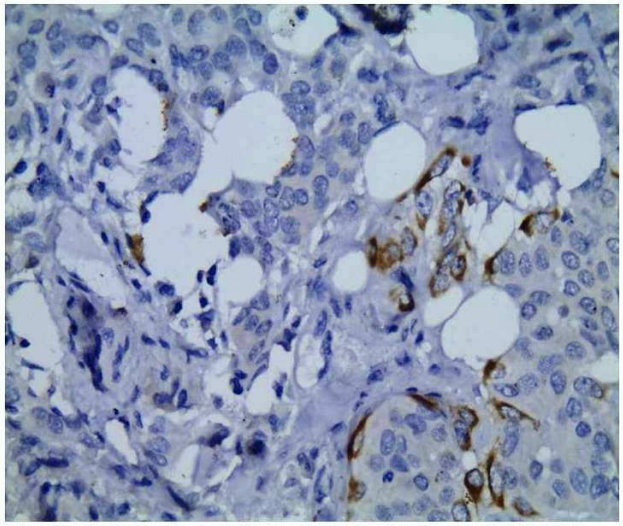

Fig 8 - < 10% cells showing staining with CK5/6 IHC marker, IHC 100 x

Nodal positivity in basal Cytokeratin positive cases in our study was nearly 80%. Vascular emboli were also prominent in these tumors, consistent with their highly invasive nature (Fig: 9). These malignancies are associated with poor prognosis and have a distinctive response to chemotherapy.

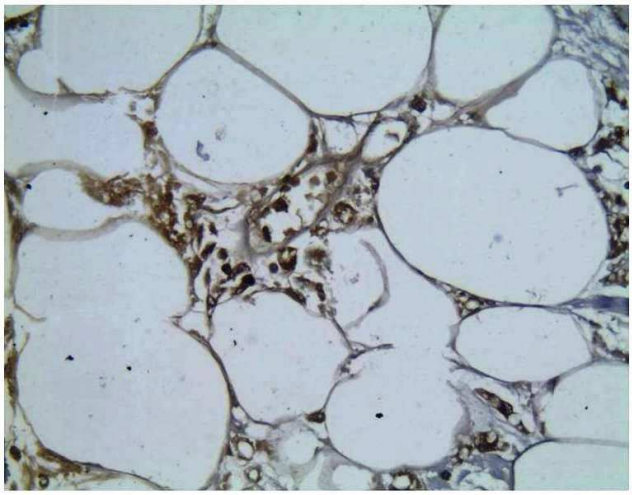

Fig 9 - > 50% cells showing staining with CK5/6 IHC marker, IHC 100 x

Downloaded from
Medico Research Chronicles
"The expression of basal cytokeratins in breast cancers."

Nielson et al [13] observed that a panel consisting of ER, HER2 and CK 5/6 to identify the basal-like subset was useful as this immunohistochemical combination had a 76% sensitivity and 100% specificity rate when compared with genetic microarray analysis.

The conclusions drawn from our study is that CK5/6 positivity was seen in tumors of larger size and higher grades.

Histological Evaluation Of Articular Cartilage Damage Following Radiofrequency Chondroplasty

Vidhya Lakshmi, Rufus V Raj, and Santosh Sahanand

***Abstract*— *Background*: Radiofrequency probes have been used extensively in various arthroscopic procedures. Measurable cartilage damage occurs after radiofrequency probe application. However, the histological changes of cartilage damage following radiofrequency chondroplasty have not been extensively studied.**

***Materials & Methods*: Articular cartilage specimens were obtained from patients undergoing total knee replacement surgeries. Radiofrequency probes were applied at 1, 3 and 5 seconds and samples were sent to histopathology laboratory. The histological changes of cartilage damage were analyzed using the International Cartilage Repair Society (ICRS) assessment scale. Safranin O staining was done to assess the proteoglycan content.**

***Results*: Histologically measurable articular cartilage damage occurs after radiofrequency probes**

***Conclusions*: The time of application of radiofrequency probes should be optimized so as to minimize cartilage damage.**

***Index Terms*— Articular cartilage, damage, Radiofrequency Chondroplasty,**

I. Introduction

In Chondroplasty, Radiofrequency energy (RFE) creates a smooth cartilage surface at the expense of collagen denaturation & dose dependent chondrocyte death especially in the superficial layer. Despite the popularity and promising short term outcomes, histological damage to articular cartilage after Radiofrequency (RF) technology has not yet been extensively studied. The safety profile of RF energy and long term prognosis after treatment with this technology remains a concern for both surgeons and patients. The proposed hypothesis is that at minimal settings, radiofrequency probes cause cell death in measurable areas when applied to human articular cartilage. This article aims at studying the degree of articular cartilage damage using radiofrequency chondroplasty in humans by histological evaluation.

II. Materials and Methods

A controlled laboratory study was performed on articular cartilage specimen samples that were obtained from patients undergoing total knee replacement surgeries after obtaining due informed consent. The study was carried out after clearance from Institutional Ethics Committee.

Cartilage was classified into 4 grades:

- Grade I - softening of the cartilage
- Grade II - partial-thickness fibrillation and fragmentation of the cartilage
- Grades III and IV - extensive fibrillation down to the bone with much of the cartilage worn away.

Only fresh, healthy appearing Grade ≤ II cartilage from the distal posterior femoral condyle was included in this study. To simulate an arthroscopic procedure, samples were placed in normal saline maintained at 37°C in a large metal container. RF probe placed on the cartilage at 1, 3 and 5 seconds at different places.

A total of 90 samples of cartilage (30 cases – 1, 3 and 5 seconds after radiofrequency probes) were received in the department of Pathology. Representative bits were taken from these samples and were subjected to decalcification using nitric acid for 1 day(short DC). The specimens were processed using Leica automatic tissue processor and 3 micron sections were cut using the microtome. The slides were stained using routine Hematoxylin and Eosin stains. All these sections were also stained with Safranin O.

Safranin O is a basic dye that stains growth plate cartilage and articular cartilage (proteoglycans, chondrocytes and type II collagen) in varying shades of red. The intensity of Safranin O stain is proportional to the proteoglycan content in the cartilage tissue. Fast green was used for counter staining to provide contrast. Full thickness, diffuse strong staining is optimal and considered as 100%.

International Cartilage Repair Society (ICRS II) developed a scoring system to evaluate the quality of the repair tissue. ICRS visual assessment scale assesses 6 components – matrix, cell distribution, Subchondral bone & surface, cell population viability and cartilage mineralization.

Overall assessment – Fibrous tissue is indicative of poor quality of the repaired tissue. Articular cartilage is indicative of ideal repair/ regeneration. Fibro cartilage should be graded in the midrange of the scale (average).

III. Results

A. Histological Assessment Of Human Cartilage Repair

Histological assessment may provide an indication of the quality of structural repair because the organization of the tissue as well as of the components present is being evaluated. Articular cartilage is a tissue with specific organization for low friction, efficient load bearing and distribution. The major constituents are chondrocytes embedded in an extra cellular matrix along with collagen fibers and proteoglycans. Changes in structure and

composition of cartilage lead to abnormal function. The lack of blood vessels and lymphatic supply and the presence of extra cellular matrix restrict the natural repair of cartilage. There is a clear need for a reliable, sensitive, objective and reproducible method to assess the quality of repair tissue.

In 2003, International Cartilage Repair Society (ICRS II) developed a scoring system to evaluate the quality of the repair tissue. ICRS visual assessment scale assesses 6 components – matrix, cell distribution, Subchondral bone & surface, cell population viability and cartilage mineralization.

The following 14 parameters were analyzed based on the scoring criteria proposed by ICRS

1. Tissue morphology – hyaline, fibrous or mixed. Hyaline is glass like without any collagen fibers and hence indicates good quality repair. Fibrous indicates presence of collagen fibers which means poor healing.
2. Matrix staining – the metachromasia indicates the proteoglycan content, i.e. load bearing qualities of the cartilage. Absence of metachromatic staining using Safranin O is considered poor. Full thickness diffuse strong staining is optimal
3. Cell morphology – cells associated with hyaline cartilage are oval with pericellular lacuna. Cells associated with fibro cartilage are elongated and spindle shaped.
4. Chondrocytes clustering – chondrocyte cluster is defined as a group of at least 4 cells. Presence of chondrocyte clustering may indicate remodeling of cartilage during healing.
5. Surface architecture – Smooth surface is indicative of ideal repair/ regeneration. Delamination, loosening and disruptions indicate poor repair.
6. Basal Integration – Integration to subjacent bone is an important feature of cartilage repair.
7. Formation of tide mark – "Tidemark" separates the lower radial zone of cartilage from the underlying zone of calcified cartilage. A single tidemark is a feature of normal healthy cartilage The lack of a visible interface between radial zone and calcified cartilage indicates poor quality
8. Subchondral bone abnormalities/marrow fibrosis – presence of an advanced/irregular Subchondral plate with or without infiltration by fibroblasts/ vascularity (marrow fibrosis) into the subchondral bone marrow is considered as poor tissue repair. Abnormal subchondral bone interface is seen in fractures, sclerosis, disruption and intense remodeling causing fibro vascular infiltration into the marrow space.
9. Inflammation – presence of lymphocytes or plasma cells in repaired cartilage is a negative feature.
10. Abnormal calcification/ ossification within the cartilage repair tissue – indicative of functional impairment
11. Vascularization (within the repair tissue) – No blood vessels in normal articular cartilage. Vascularization seen in fibrous tissue is considered as a negative feature in cartilage repair
12. Surface/ superficial assessment – upper 3rd of cartilage tissue should be intact with elongated cells and collagen fibers parallel to the surface in the most superficial zone. Severely disrupted cartilage with no obvious collagen fiber organization suggest poor healing
13. Mid/Deep zone assessment – lower 2/3rd of tissue – hyaline cartilage should be rich in proteoglycans with no detectable collagen fibers.
14. Overall assessment – Fibrous tissue is indicative of poor quality of the repaired tissue. Articular cartilage is indicative of ideal repair/ regeneration. Fibro cartilage should be graded in the midrange of the scale (average).
15. Safranin O staining – full thickness , diffuse strong staining is optimal and considered as 100%.

These histological parameters and Safranin O staining (intensity and percentage of cells) after radiofrequency probe application for 1, 3 and 5 seconds in the 30 cartilage samples are given below in Table I.

TABLE I: HISTOLOGICAL PARAMETERS AND SAFRANIN O STAINING AFTER RADIOFREQUENCY PROBE APPLICATION

Parameter	**A** **RF- 1sec**	**B** **RF- 3secs**	**C** **RF- 5secs**
Fibrosis of cartilage	2/30	4/30	13/30
Chondrocyte clustering	0/30	7/30	16/30
Basal integration	18/30	11/30	7/30
Lack of interface	2/30	12/30	12/30
Abnormal calcification/vascularity	0/30	2/30	6/30
Safranin O staining < 50%	2/30	5/30	20/30

IV. Discussion

Radiofrequency probe is increasingly used for arthroscopic procedures. The harmful effects of this probe on cartilage need to be studied to avoid any iatrogenic cartilage damage. Intact articular cartilage provides a smooth, lubricated gliding surface that distributes the loads of articulation in a joint. Injury and disease can alter the mechanical and biochemical properties of articular cartilage. Cartilage injury response varies depending on the extent and type of injury. The assessment of cartilage damage was based only on clinical response of the patients in earlier studies. The present study is unique in that the histological parameters of the cartilage damage were assessed using a scoring system and Safranin O staining of proteoglycan content. The damage to articular cartilage in the form of chondrocyte clustering, lack of interface and abnormal calcification increases with increasing time of application of RF probes. Also there is decrease in Safranin O positive proteoglycan content as time of probe application increases.

V. Conclusion

Histologically measurable articular cartilage damage occurs after radiofrequency probes. Considering the effects of iatrogenic damage to the cartilage, the time of application of RF probes has to be optimized.

For the SIHAM Candidemia Network.

Take home message: This multicentric study from India on ICU-acquired candidemia highlights the unique epidemiology of this country with its vast spectrum of *Candida* species and high rate of *C. tropicalis* isolation. The disease occurred comparatively early after ICU admission, even in patients with less severe physiology scores.

Abstract *Purpose:* A systematic epidemiological study on intensive care unit (ICU)-acquired candidemia across India. *Method:* A prospective, nationwide, multicentric, observational study was conducted at 27 Indian ICUs. Consecutive patients who acquired candidemia after ICU admission were enrolled during April 2011 through September 2012. Clinical and laboratory variables of these patients were recorded. The present study is an analysis of data specific for adult patients. *Results:* Among 1,400 ICU-acquired candidemia cases (overall incidence of 6.51 cases/1,000 ICU admission), 65.2 % were adult. Though the study confirmed the already known risk factors for candidemia, the acquisition occurred early after admission to ICU (median 8 days; interquartile range 4–15 days), even infecting patients with lower APACHE II score at admission (median 17.0; mean ± SD 17.2 ± 5.9; interquartile range 14–20). The important finding of the study was the vast spectrum of agents (31 *Candida* species) causing candidemia and a high rate of isolation of *Candida tropicalis* (41.6 %). Azole and multidrug resistance were seen in 11.8 and 1.9 % of isolates. Public sector hospitals reported a significantly higher presence of the relatively resistant *C. auris* (8.2 vs. 3.9 %; $p = 0.008$) and *C. rugosa* (5.6 vs. 1.5 %; $p = 0.001$). The 30-day crude and attributable mortality rates of candidemia patients were 44.7 and 19.6 %, respectively. Logistic regression analysis revealed significant independent predictors of mortality including admission to public sector hospital, APACHE II score at admission, underlying renal failure, central venous catheterization and steroid therapy. *Conclusion:* The study highlighted a high burden of candidemia in Indian ICUs, early onset after ICU admission, higher risk despite less severe physiology score at admission and a vast spectrum of agents causing the disease with predominance of *C. tropicalis.*

Keywords Candidemia · Intensive care unit · *Candida tropicalis* · Risk factor · Mortality

Introduction

Candida bloodstream infection (candidemia) is a life-threatening affliction in intensive care unit (ICU) patients. Its incidence varies from 0.24 to 34.3 patients/1,000 ICU admissions [1–4]. With a high mortality rate of 35–75 % [2], early antifungal treatment is essential for survival. ICU-acquired candidemia patients characteristically have several underlying medical and surgical risk factors, and are frequently exposed to high-risk medications [5]. Furthermore many regions of the world are witnessing a surge in non-*albicans Candida* species [6, 7], which have diverse virulence and susceptibility profiles [8]. Geographic variation in causative species, ethnically diverse at-risk population and varying diagnostic and management capabilities of ICUs further add to the complexity. As there are very few multicentric studies on candidemia from Asian countries, we undertook this study to comprehensively elucidate the disease burden, epidemiology, microbial circulation, resistance pattern and management

challenges of adult ICU-acquired candidemia in India. We aim to utilize this information for better management and survival of these patients.

Methods

Study design

This was a prospective, multicentric, observational study undertaken from April 2011 to September 2012 at 27 medical and surgical ICUs across India. The Postgraduate Institute of Medical Education and Research, Chandigarh, India was the coordinating centre. Ethics approval was obtained from each institution's review board. Being an observational study, it entailed no additional risk to the patients. Prior to commencing work, the study was registered as "SIHAM (Society for Indian Human and Animal Mycologists) Candidemia Network: an observational study" (identifier NCT01281345) with ClincalTrials.gov.

Definitions

A patient older than 18 years of age was considered an adult. Candidemia was defined as the isolation of *Candida* species from blood cultures. A case was defined as ICU-acquired candidemia if it occurred more than 48 h after ICU admission or less than 48 h after discharge from ICU. Patients already diagnosed with candidemia before ICU admission or those transferred from another ICU with a positive culture for any yeast infection were excluded from the study. A patient was defined to have contracted more than one episode of *Candida* bloodstream infection if the subsequent episode occurred more than 30 days after the previous one. Date of onset of candidemia was taken as the date when the first positive blood culture was drawn from the patient. A surgery or invasive procedure undertaken within 30 days of contracting candidemia was considered a potential risk factor. Outcome was determined at the end of 30 days after onset of candidemia and cure was considered complete microbiological resolution. A death attributed to candidemia was ascertained by the treating physician independently on the basis of clinical judgement and microbiology reports.

Data collection

All consecutive patients who contracted ICU-acquired candidemia during April 2011 through September 2012 were enrolled after informed consent. A total of 398 variables were recorded for every patient in standardized proforma. These included demographic details; clinical presentations at admission; severity scores including Acute Physiology and Chronic Health Evaluation II (APACHE II) and Glasgow Coma Scale (GCS); comorbid medical conditions; surgical and invasive procedures; exposure to antibiotics, corticosteroids, anticancer chemotherapeutics, prior antifungals; secondary bacterial infections; candidemia-associated complications; antifungal treatment instituted in the ICU; treatment adverse effects; *Candida* species isolated; antifungal susceptibility and final outcome. All data from participating centres were collected and analysed at the coordinating centre.

Microbiological methods

Candida isolates were identified and tested for antifungal susceptibility at the coordinating centre. Isolates were identified by a Vitek YBC system, and ITS2 and D1/D2 region sequencing was performed when concordance was less than 98 %. Antifungal susceptibility was performed using the Clinical and Laboratory Standards Institute's (CLSI) broth microdilution M27-A3 method [9]. MIC breakpoints were interpreted from the CLSI M27-S4 supplement for yeasts [10]. Isolates with a MIC greater than 1 μg/ml for amphotericin B were considered resistant. Multidrug resistance (MDR) was defined as resistance to two or more classes of antifungals.

Statistical analysis

Descriptive analysis is presented as frequencies and confidence intervals (CI); medians and range; or means and standard deviation (SD), as appropriate. Pearson's Chi square test and Fisher's exact test were used to compare categorical variables, while the Student *t* test, ANOVA, Mann–Whitney or Kruskal–Wallis tests were employed for continuous data. A predictive model for 30-day mortality was developed using logistic regression. Its predictive power was evaluated by the Hosmer–Lemeshow goodness-of-fit test and area under the receiver operating characteristic (ROC) curve. Kaplan–Meier statistics was used for survival analysis. Two-tailed p values <0.05 were taken as significant.

Results

Demography and burden

A total of 215,112 patients were admitted to 27 ICUs from April 2011 to September 2012. Of these 1,400 patients contracted ICU-acquired candidemia, amounting to a burden of 6.51 cases/1,000 ICU admissions (95 % CI

6.18–6.86). Eleven ICUs were from north, three each from east and west, four from central and six from south India (Fig. 1). Eleven were public sector institutions, while 16 were private/corporate hospitals. The incidence varied significantly across regions ($p < 0.001$), with the highest burden from the north (8.95/1,000 ICU admissions; 95 % CI 8.29–9.66) and lowest from west (3.61/1,000 admissions; 95 % CI 2.82–4.63). Of 1,400 patients, 913 (65.2 %) were adults with a median age of 50.0 years (interquartile range 34–63; mean ± SD 49.7 ± 17.7). Further analysis pertains only to adult patients.

ICU presentation

The majority of our adult patients were non-neutropenic (98.7 %) and were admitted to medical ICUs ($n = 464$; 50.8 %). The median duration of onset of candidemia in ICU was 8.0 (interquartile range 4–15) days. Adult candidemia patients had a median APACHE II score of 17.0 (interquartile range 14–20; mean ± SD 17.2 ± 5.9) at admission. GCS was measured in 34 patients with a median score of 15.0 (interquartile range 7–15).

Circulating *Candida* species

The majority of patients experienced only a single episode ($n = 855$; 93.6 %) of candidemia, though 58 (6.4 %) suffered from more than one episode and five (0.5 %) of these were infected with two different *Candida* species during different candidemia episodes. Of the 918 *Candida* strains thus isolated, *Candida tropicalis* ($n = 382$; 41.6 %) was the most prevalent followed by *Candida albicans* ($n = 192$; 20.9 %) and *Candida parapsilosis* ($n = 100$; 10.9 %) (Electronic supplementary material Fig. 1). Eight species caused 92.8 % (852) of the infections while the remaining 7.2 % were inflicted by 22 less common species. Non-*albicans Candida* infections affected 79.1 % (726) of cases. While *C. tropicalis* was significantly higher (44.8 % vs. 37.7 %; $p = 0.035$) in private/corporate ICUs, *C. auris* (8.2 % vs. 3.9 %; $p = 0.008$) and *C. rugosa* (5.6 % vs. 1.5 %; $p = 0.001$) were significantly more common in public sector ICUs. There was no significant difference between times of onset of candidemia when all species were compared. The emerging multidrug-resistant *C. auris* was isolated from 19 of 27 ICUs and comprised 5.2 % of all *Candida*

Fig. 1 Map of India depicting the 27 intensive care units which participated in this study. The *red dot* represents the coordinating centre for this study

isolates. The species was also significantly more common in patients with central venous catheterization (6.8 % vs. 2.9 %; $p = 0.035$).

Antifungal resistance

The antifungal susceptibility profiles of the commonest species are summarised in Table 1. Overall 46.6 % of isolates were sensitive to all antifungals. Resistance to amphotericin B was noted in 19 (2.1 %), azoles 108 (11.8 %), and echinocandin 63 (6.9 %) isolates, respectively. MDR was noted in 17 (1.9 %) isolates, with three (0.3 %) pan-resistant to all antifungal classes. Common MDR isolates were *C. tropicalis* ($n = 4$; 23.5 %), *C. auris* ($n = 4$; 23.5 %) and *C. krusei* ($n = 3$; 17.6 %).

Underlying diseases and risk factors

Underlying respiratory illness was noted in 228 (25.0 %) patients. Pneumonia ($n = 75$; 32.9 %), acute respiratory distress syndrome ($n = 41$; 17.9 %) and chronic obstructive pulmonary disease (COPD) ($n = 35$; 15.4 %) were the major respiratory afflictions. Underlying renal disease was equally prevalent ($n = 209$; 22.9 %), with the majority in acute ($n = 128$; 61.2 %) or chronic ($n = 63$; 30.1 %) renal failure. Malignancy was present in 117 (12.8 %) cases, 82.9 % being solid organ malignancies and 17.1 % haematological. Nearly half of the malignancies (47.9 %) were gastrointestinal while 60.7 % were intraperitoneal. More than a third ($n = 341$; 37.3 %) of patients had undergone one or more surgical procedures in the 30 days or less prior to the onset of candidemia. Nearly half ($n = 165$; 48.4 %) of these comprised gastrointestinal, hepatobiliary and pancreatic surgeries (Electronic supplementary material Table 1). Central venous catheterization was instituted in 74.0 % of patients for a median duration of 8.0 (interquartile range 7–26) days. Parenteral nutrition was instituted in 122 (13.4 %) patients for a median of 9.0 (interquartile range 5–16) days before the onset of candidemia. Median duration of any dialysis performed prior to development of candidemia was 8.0 (interquartile range 2–15) days.

Nearly all candidemia patients were receiving antibiotics ($n = 849$; 93.0 %) with the majority on broad-spectrum agents ($n = 784$; 92.3 %) before the onset of candidemia. The median duration of any antibiotic therapy prior to development of candidemia was 16.0 (interquartile range 7–36) days and that for broad-spectrum agents was 11.0 (interquartile range 4–23) days (Electronic supplementary material Table 1). Corticosteroids were given to 164 cases (18.0 %), at a median dose of 50.0 mg per day (interquartile range 25–100) and median duration of 7.0 (interquartile range 4–12) days before the onset of candidemia.

Antifungal exposure before onset of candidemia was recorded in 143 (15.7 %) cases for a median duration of 8.0 (interquartile range 5–13) days (Electronic supplementary material Table 1). Prior antifungal exposure significantly increased the propensity for subsequent non-*albicans Candida* infection (85.5 vs. 77.9 %; $p = 0.045$) and azole-resistant *Candida* infection (7.1 vs. 3.3 %; $p = 0.045$).

Treatment

Antifungal therapy after definitive diagnosis of ICU-acquired candidemia could be instituted in 59.9 % (547) cases with a median duration of 9.0 (interquartile range 5–15) days (Electronic supplementary material Table 2). Azoles ($n = 394$; 72.0 %) were preferred, followed by echinocandins ($n = 100$; 18.3 %) and amphotericin B (including dexoycholate and lipid preparations) ($n = 79$; 14.4 %). While amphotericin B deoxycholate was used more commonly in public sector ICUs (11.5 vs. 5.3 %; $p < 0.001$), azole (47.1 vs. 37.7 %; $p = 0.006$) and echinocandin (13.4 vs. 7.4 %; $p = 0.005$) use was more common in private/corporate hospitals. Antifungal regimen was altered during the course of therapy in 81 (14.8 %) patients, regimen escalation and antifungal resistance being the major reasons. Only eight (1.5 %) patients on treatment suffered any adverse reactions (Electronic supplementary material Table 2). Central venous catheter (CVC) was removed from 32.1 % (217/676) catheterized patients, with the majority (54.4 %) withdrawn within 48 h of diagnosis. Kaplan–Meier analysis revealed that CVC removal significantly increased 30-day survival (mean ± standard error 19.0 ± 0.9 vs. 15.9 ± 0.6 days; $p = 0.002$). Regression models of the effect of the antifungal therapy and CVC removal on the outcome after adjusting for the comorbidities (APACHE II) showed significant survival ($p = 0.016$) only when treated with antifungal agents with simultaneous removal of the catheter within 48 h (Table 2). Survival was poor in patients treated at public sector hospitals with respiratory and renal disease, invasive ventilation, CVC, dialysis, corticosteroid and polymyxin therapy (Fig. 2).

Outcome and mortality predictors

Candidemia microbiologically resolved in 251 (27.5 %) cases. The 30-day crude mortality was 44.7 % (408/913) and 30-day attributable mortality was 19.6 % (179/913) (Electronic supplementary material Table 1). Univariate analysis between survivors and non-survivors revealed 31 key factors associated with 30-day crude mortality (Electronic supplementary material Table 3). Logistic regression was used to construct a predictive model for 30-day crude mortality ($R^2 = 0.399$, $p < 0.001$,

Table 1 Antifungal susceptibility profile of highest burden *Candida* species circulating among adult candidemia intensive care patients from India, based on the CLSI M27-S4 (2012) guidelines

predictive accuracy = 69.5 %, area under ROC curve = 0.75). The most significant independent predictors of 30-day crude mortality include admission to a public sector hospital, APACHE II score at admission, underlying renal failure, central venous catheterization and steroid therapy (Table 3).

Discussion

This is the first and largest multicentre observational study of ICU-acquired candidemia from India. We found an overall incidence of 6.51 cases per 1,000 ICU admissions, though the incidence varied significantly across the country. The variation may be due to difference in patient groups and management protocol of respective ICUs. In addition, significant variation in the rate of candidemia between private/corporate and public sector hospitals was noted. A large number of patients attend public sector hospital (in the coordinating centre 10,000 new patients attend outpatient departments every working day) as the hospital charges are subsidized, which may lead to compromise in the standard of the health care and higher rate of candidemia. In comparison to the nationwide survey reports from other countries, the incidence in the present study approaches the higher end of values from Australia, France, Germany and the EPIC II study (0.24–6.9/1,000 ICU admission) [1, 11–13], yet is much lower than reported in Spain and Argentina (34.3/1,000 ICU admission) [2].

Our adult candidemia patients were considerably younger (mean 49.7 years) than in other countries (mean 59.0–66.2 years) [2, 14]. Notably our patients contracted ICU-acquired candidemia significantly earlier (8 days) than in other series (11–15 days) ($p = 0.03$) [1, 15]; however, Playford et al. from Australia and Leroy et al. from France have also reported similar early onset of infection [11, 16]. Our patients had lower mean APACHE II scores (17.2) than studies from Spain (20.1), Argentina (20.1) and the USA (18.6) [2, 17]. The reasons for such younger and comparatively less serious patients acquiring candidemia may be due to prior exposures to broad-spectrum antibiotics and steroids in large numbers of our patients and compromised health care.

Our study revealed high prevalence of *C. tropicalis* (41.6 %) while *C. albicans* and *C. parapsilosis* affected only 20.9 and 10.9 % of cases, respectively. This is in contrast to the developed world, where *C. tropicalis* is uniformly less common (5.6–12.0 %) [11, 17–20], and *C. albicans* (45.0–74.0 %) and *C. glabrata* (16.7–22.6 %) are more prevalent [1, 15–17, 20]. We encountered *C. glabrata* candidemia in only 7.1 % of patients. The rise in *C. glabrata* in the Western world can be linked to increased use of azole prophylaxis [1, 11, 15, 21]. Though our patients had a significantly higher propensity of developing candidemia due to non-*albicans Candida* species after azole exposure, such a link is not possible in our patients with *C. tropicalis* candidemia. Prior antifungal exposure ($p = 0.09$), prior azole therapy ($p = 0.24$) or prior fluconazole therapy ($p = 0.26$) was not significantly high in *C. tropicalis* candidemia. Moreover, the majority of our *C. tropicalis* isolates were sensitive to amphotericin B ($n = 378$, 99.0 %), azoles ($n = 344$, 90.1 %), fluconazole ($n = 372$, 97.4 %) and echinocandins ($n = 360$, 94.2 %), thereby indicating interplay of other undetermined factors for their high prevalence. In the present study, we did not attempt to find the possible reasons for the high prevalence of *C. tropicalis* candidemia as it was purely an observational study. A study form Paris and surrounding areas noted pre-exposure to the fluconazole as an independent risk factor for acquiring *C. tropicalis* candidemia [22], whereas the present study did not find this to be an independent risk factor for *C. tropicalis* candidemia. A detailed case–control and environmental study is essential to clarify the reason for the high prevalence of *C. tropicalis* candidemia in India. In an earlier study at the coordinating centre, 82 % of health care providers were found to carry yeast on their hands and 80 % were *C. tropicalis* [23]. Therefore, horizontal transmission and compromise of infection control systems are distinct possibilities for the high rate of *C. tropicalis* candidemia in India. The high rate of *C. tropicalis* candidemia was observed in other Asian countries as well [24]. But no study has evaluated the exact reasons for the high rate of *C. tropicalis* candidemia and hand carriage in these countries. We noted a low prevalence of *C. glabrata* despite prior exposure to antifungal agents in 15.7 % of patients. The higher rate of non-*albicans Candida* infections in patients exposed to prior antifungals was influenced by significantly the higher prevalence of *C. auris* (32.7 vs. 14.8 %, $p = 0.002$) and *C. krusei* (37.5 vs. 15.4 %, $p = 0.029$). In another study Fournier et al. reported a significantly higher proportion of *C. parapsilosis* due to prior exposure to caspofungin [25]. In contrast, Blot et al. reported no change in *Candida* species

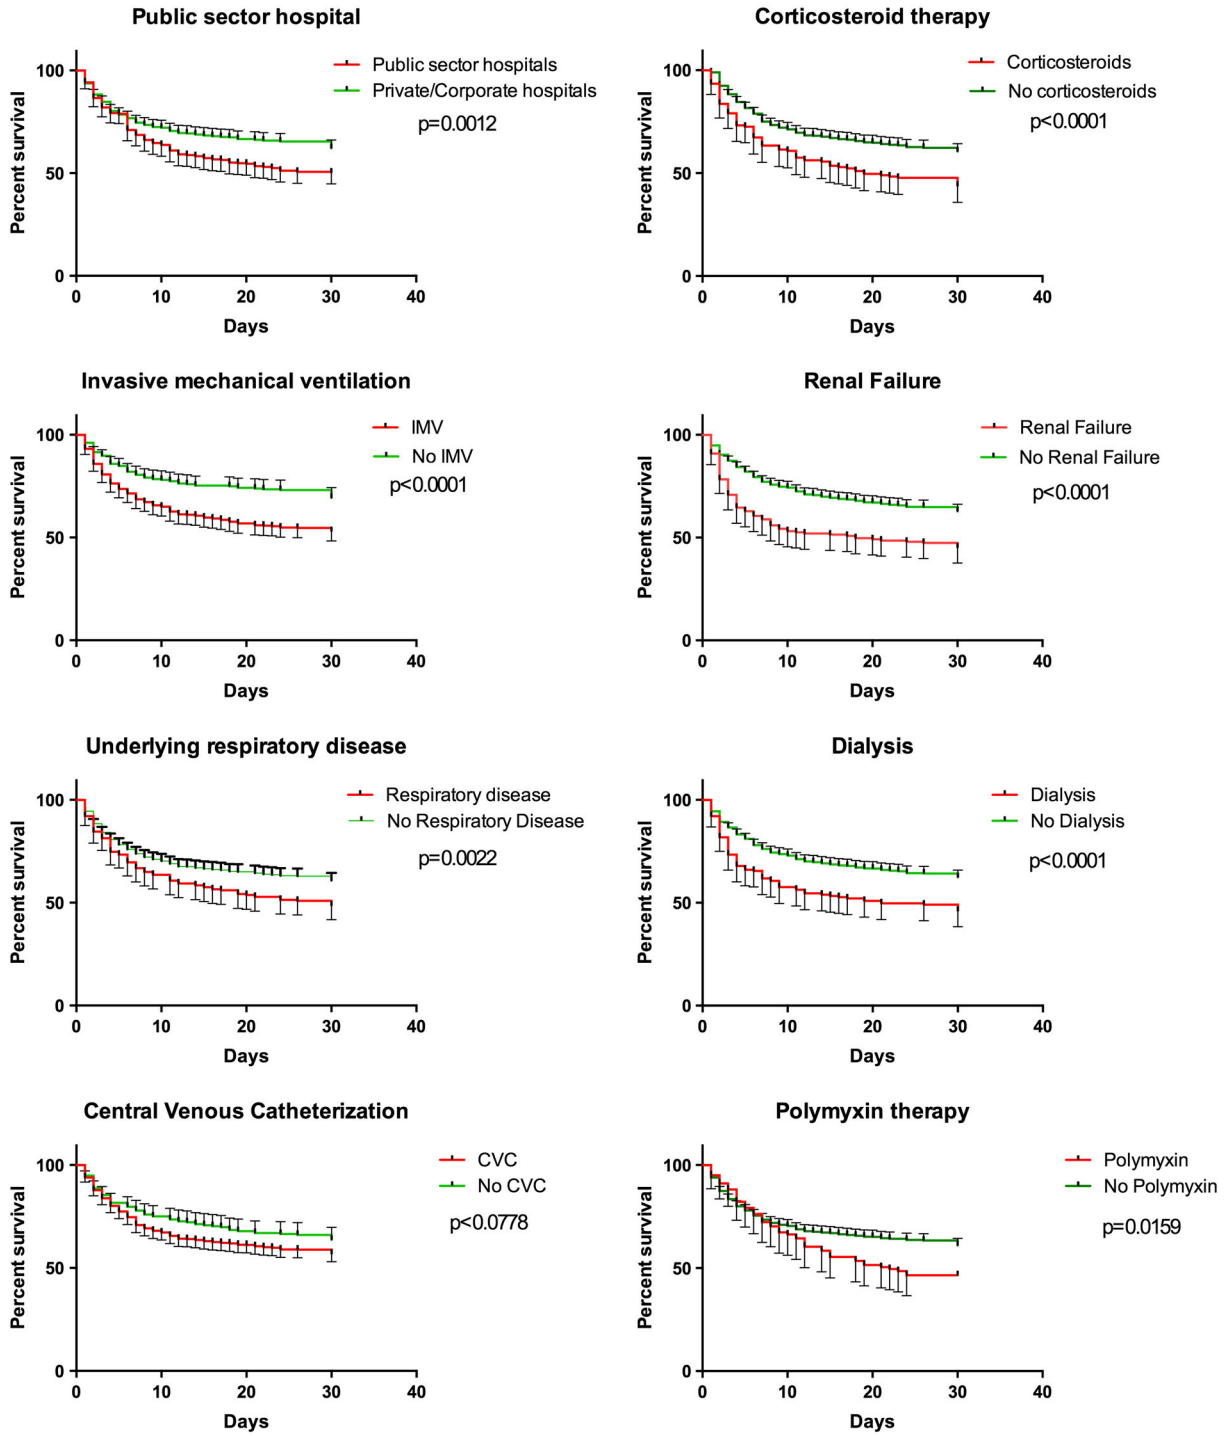

Fig. 2 Kaplan–Meier survival curves (with confidence intervals) according to risk factors for mortality. Comparison of the survival curve was performed by Log-rank (Mantel–Cox) test

distribution despite long-term exposure to fluconazole [26]. Therefore, more studies are required to understand the interplay of the factors responsible for any shift in *Candida* species distribution. In our study, *C. tropicalis* candidemia was more common in private/corporate sector ICUs, while *C. auris* and *C. rugosa* were more prevalent in public sector ones. The emergence of MDR *C. auris* in India is a matter of concern, as this fungus was isolated

Table 3 Logistic regression predictive model summarizing the risk factors for 30-day mortality in adult candidemia intensive care patients

Predictor	OR	*P*	95 % CI	
			Lower	Upper

[a] Therapy instituted after definitive microbiological diagnosis of candidemia in the ICU

from 19 of 27 ICUs and comprised 5.2 % of all *Candida* isolates in the present study.

Overall, 46.6 % of our isolates were susceptible to all antifungals. Species-specific resistance rates against fluconazole were 2.6 % in *C. tropicalis*, 5.2 % in *C. albicans*, 4.0 % in *C. parapsilosis* and 1.5 % in *C. glabrata*. Corresponding figures from across the globe include *C. tropicalis* (4.5–14.3 %), *C. albicans* (1.4–4.4 %), *C. parapsilosis* (2.7–10.5 %) and *C. glabrata* (5.9–93.8 %) [11, 14, 16, 20]. Likewise, resistance to voriconazole (1.2–5.9 %), itraconazole (4.7 %) and echinocandins (0.3–2.2 %) from international studies are different from our isolates [14, 20]. Low resistance of our *C. glabrata* isolates emphasizes the need to compare our isolates with MDR isolates from other centres, as cryptic species are already known under *C. glabrata* [27]. In contrast to *C. glabrata*, we observed more MDR *C. tropicalis*, *C. auris* and *C. krusei*.

Co-morbidities of our patients are similar to a certain extent to earlier reports. Like in our study, underlying respiratory, renal and gastrointestinal illnesses were significant in other studies as well. But they have also reported sizable proportions of diabetes (10.7–28.0 %), cardiovascular (15.8–48.3 %) and neurological (13.2 %) illnesses in their patients, which were much less common in our cohort, 0.1 %, 15.1 % and 19.5 %, respectively [2, 11–16, 19]. Underlying malignancy was present in 12.8 % of our patients, compared to 24.6–36.1 % in other studies [13, 14]. HIV/AIDS (0.4 %) and neutropenia (1.3 %) were rare, unlike in other series, 4.0–6.0 % and 6.6–19.7 %, respectively [15–17, 19]. A third of our patients (37.3 %) had undergone recent surgery as compared to 44.7–66.1 % seen in other series [2, 11]. Among types of surgery, abdominal surgery is considered a leading risk factor for candidemia [28]. Half of our surgeries (18.1 % of total) also were gastrointestinal, similar to other series (17.0–31.6 %) [2, 12, 28]. Central venous catheterization (74.0 %), invasive mechanical ventilation (52.9 %), urinary catheterization (75.9 %), haemodialysis (17.3 %) and total parenteral nutrition (13.4 %) prior to onset of candidemia were also encountered at lower proportions in our cohort as compared to other series (88.5–100 % [2, 13], 72.1–97.4 % [2, 13], 86.7–97.4 % [2, 16], 17.5–32.5 % [11, 15] and 43.7–71.1 % [2, 11]).

Antifungal therapy after microbiological diagnosis of ICU-acquired candidemia could be evaluated in only 59.9 % of cases because of delayed diagnosis and early death of our patients unlike other studies (74.5–94.1 %) [4, 16–18]. In certain situations the patient left for another hospital or could not afford the therapy. The delay in diagnosis at a few centres was due to use of conventional biphasic media for *Candida* isolation instead of commercial systems. Removal of CVCs and start of targeted antifungal therapy within 48 h of onset of candidemia improved 30-day survival in our patients ($p = 0.016$) like other reports [2, 16, 29, 30], yet the catheter was removed only in one-third of our patients. The reason is difficult to explain. We did not interfere with the existing protocol of any ICU and some critical care specialists believe those studies where a lack of benefit of CVC removal was demonstrated [4, 30].

Our 30-day crude mortality (44.7 %) is similar to the EPIC II international series (42.6 %) [13]. Mortality rates vary across the globe (35–75 %) [2]. Candidemia-attributable mortality also varies widely (5.0–49.0 %) between centres [2, 14, 18, 31] possibly because of lack of standardized criteria. Lower attributable mortality (10.9–21.7 %) has been reported in some studies [3, 20, 32], as compared to the present one (19.6 %).

Comparison of independent mortality predictors modelled in our and other series highlight common and divergent patterns, though the large number (398) of variables studied might act as a limitation of the study by increasing the likelihood of false positive results. However, we have factored in the higher alpha error expected out of multiple testing owing to the large number of variables tested. A stringent Bonferroni's test was used to filter out only those significant variables which stood the test. APACHE II scores in our study proved useful for developing a robust predictive model as has been previously described [30]. Other severity scores like SAPS II and SOFA, central venous catheterization, corticosteroid therapy, total parenteral nutrition, antibiotic use, sepsis/shock and antifungal treatment are common predictors [15–18, 33]. In contrast, admission to a public sector ICU and renal failure appear additional significant predictors for our patients. Similarly, increasing age, underlying diabetes, immunosuppression, neutropenia, *C. glabrata* and *C. parapsilosis* infection, mechanical ventilation, haemodialysis, gastrointestinal surgery and underlying malignancy were unique to other countries, but did not stand out in our study [4, 15–18, 33].

Conclusions

This is the largest prospective multicentre study of ICU-acquired candidemia from India. The overall incidence of ICU-acquired candidemia is high and marked by an early onset infection after ICU admission. Our patients are comparatively young and have lower APACHE II scores at admission. *C. tropicalis* is the leading pathogen in our patients, though its predominance is not explained by higher exposure to prior azoles or antifungals. Emergence of MDR *C. auris* in the majority of ICUs is a matter of concern. Our 30-day mortality prediction model can help triage and manage high-risk candidemia patients better.

Acknowledgments We wish to acknowledge Prof. Niranjan Nayak, President SIHAM for providing us invaluable logistic support and continuous encouragement to accomplish this study. Other members of the SIHAM Candidemia Network include (participating centres in parenthesis; in alphabetical order): Purva Mathur (All India Institute of Medical Sciences, New Delhi, India); Ratnamani (Apollo Hospital, Hyderabad, India); Aroma Oberoi, Ashu Sara Mathai (Christian Medical College and Hospital, Ludhiana, India); Shweta Sharma (Fortis Escorts Heart Institute, New Delhi, India); DC Thamke (Mahatma Gandhi Institute of Medical Sciences, Wardha, India); A Krishna Prasad (Nizam's Institute of Medical Sciences, Hyderabad, India); Camilla Rodrigues, Mahesh Lakhe, Mehul Panchal, Niyati Desai (PD Hinduja, Mumbai, India); Gagandeep Singh, Ashutosh Nath Aggarwal, Neerja Bhardwaj, L N Yaddanapudi, Joseph Jillwin, A Shamnath (Postgraduate Institute of Medical Education and Research, Chandigarh); Pradeep Kumar Verma, Harish Chand Sachdeva (Safdarjang Hospital, New Delhi, India); Sriram Sampath (St John's Medical College, Bangalore, India) are also acknowledged for their help. This work was supported by the MSD Pharmaceuticals Pvt. Ltd Educational Grant through the Society for Indian Human and Animal Mycologists, an affiliate of the International Society of Human and Animal Mycology. MSD did not play any role in study design, data analysis or manuscript writing.

Conflicts of interest The authors declare that they have no conflicts of interest and no financial relationship with the funding agency.

Abstract: ***Background*:** Carbapenem-resistant Enterobacteriaceae (CRE) has emerged as a global threat with mortality risk ranging from 48%-71% worldwide. The emergence of MBL resistance is threatening as carbapenem is one of the last line antibiotics. A total 24 variants of NDM resistance raises a concern to the clinicians and epidemiologists worldwide.

***Objective*:** The study aims at identifying MBL resistance (NDM, IMP, VIM, GIM, SPM, and SIM) and its coexistence in clinical isolates in a single tertiary care center.

***Methodology*:** Forty five clinical isolates characterized phenotypically for Carbapenem resistance obtained from PSG Institute of Medical Science and Research (PSG IMSR), Coimbatore, between February to March 2018 were taken for analysis.

***Results*:** Out of the 45 Clinical isolates, 38 isolates (84%) were detected as MBL carriers. VIM, NDM, GIM, and SPM were the predominant resistance genes, with detection rates of 48.8%, 28.8%, 24.4%, and 22.2% respectively. Fifteen isolates were observed to harbor more than one MBL gene in coexistence. Two isolates - U42 and R714 (K. pneumoniae) were found to harbor all 5 MBL variants in combination.

***Conclusion*:** 33% of clinical isolates harboring multiple MBL variants is a concern in clinical settings. The presence of SPM and GIM gene amongst isolates in this geographical location within India is an indicator demanding continuous monitoring of these resistance determinants.

Keywords: Clinical isolates, carbapenem resistance, enterobacteriaceae, metallo beta lactamase, multidrug resistance, MBL variants.

1. INTRODUCTION

There is a global concern due to the threat posed by a significant increase in infection caused by Multidrug Resistant (MDR) gram negative bacteria in recent years. Greater challenges prevail in countries like India. According to the 2013 estimate, around 58,000 newborns die in India each year due to sepsis from antibiotic resistant bacteria [1]. Carbapenems are powerful broad-spectrum antibiotics that are the last-line antibiotics by the clinicians particularly for critically ill MDR patients [2]. Carbapenemase (carbapenem hydrolyzing enzymes) are differentiated into two major groups by their hydrolytic mechanism in the active site. The first group of enzyme, serine carbapenemases contain a serine in the active site and the second group of enzyme which contains one or more zinc atoms at the active site represents Metallo beta lactamases (MBL) belonging to the class B carbapenemases [3].

MBL was discovered in the 1960's with low pathogenic potential. In the1990's, MBL genes found to be associated with mobile elements gained clinical importance with the dissemination of carbapenem-resistant *Enterobacteriaceae* worldwide [4]. The denoted variants of the most clinically paramount MBL groups, VIM (Verona Integron-encoded Metallo-β-lactamase), IMP (Imipenemase), and NDM (New Delhi Metallo-β-lactamase), whereas the other groups like GIM (German imipenemase), SIM (Seoul imipenemase), SPM (Sao Paulo Metallo-β-lactamase), AIM (Adelaide imipenemase) are rare [5]. Carbapenem resistance levels for MBL-producing strains vary and mortality rate ranges from 18% to 67% [6]. The IMP and VIM type MBLs are currently reported as a serious threat. The MBL, SPM-1 identified in 1997 is widespread in Brazil but is restricted to *Pseudomonas aeruginosa* until recently [7]. The GIM variant was reported in a non transferable plasmid in Germany (2002) [8] and SIM was discovered in Class 1 integron in Korea (2005). These variants are endemic in nature [9]. Detection and spread of NDM in 2007 raised a serious concern towards these resistance genes [6].

Anti-Infective Agents

South Indian reports revealed the presence of independent MBL genes from tertiary care centers. The present study was focused on detecting the presence of MBL gene(s) (and its variants) and to assess its coexistence in a variety of clinical samples. Detection was done through Direct PCR amplification rather than a conventional PCR approach. Further, Multiplex PCR strategy has been optimized to detect the co existing clinically relevant MBL genes.

2. MATERIALS AND METHODS

Forty five Carbapenem resistant clinical samples were identified from the PSG Institute of Medical Science and Research (PSG IMSR), Coimbatore. These isolates were selected to suit the diversity of sources from the regular antibiotic screening procedure followed in the center between February- March. The isolates were obtained from Respiratory (R), Blood (B), Urine (U) and Miscellaneous (M) samples. The clinical records of the samples, species, source of infection, for antibiotic resistance, antibiotic sensitivity were obtained from PSG IMSR and are listed in the order of samples selected for analysis (Table **1**).

2.1. Confirmation for MBL Genes

Colony PCR and Direct PCR were used for molecular detection of the MBL resistance. PCR is one of the gold standards for pathogen identification.

2.1.1. Colony PCR

The colony PCR was performed as per the protocol described by a study [10]. The single bacterial colony was added in eppendorf tube containing 25µl of TE buffer. Then, the tube was heated in the water bath for about 10 mins at 95°C. The mixture was centrifuged for 2mins at maximum speed. The supernatant was taken for PCR analysis.

2.1.2. Direct PCR

One loop full of the clinical sample (Sputum/ Tracheal aspirate) was taken and added in eppendorf tube containing 50µl of TE buffer. Then, it was subjected to soft vortexing followed by incubation in a water bath for 10 mins at 65°C. 2µl of the sample was directly used as a template for PCR. In the case of Urinary sample, 10µl of sample was taken and processed in the same way [11].

2.1.3. Multiplex PCR

After the independent amplification of MBL genes using Colony PCR and Direct PCR, Multiplex PCR (mPCR) was standardized with specific primer combinations to identify MBL genes.

The PCR conditions were as follows: 94°C /5 min; 36 cycles of 94°C /30 s, 55°C/40 s (depend on specific primer pair) and 72°C/50 s and a final elongation step at 72°C/5min. Primer combinations used are listed in Table **2** [12-15].

3. RESULTS AND DISCUSSION

The present study was carried out to detect the Metallo beta lactamase genes *viz.,* IMP, VIM, SIM, SPM, GIM and NDM in clinical isolates by performing PCR (using 16s rDNA as internal control). Out of the 45 samples collected from varied sections of the hospital, 22 were *K. pneumoniae*, 16 were *Acinetobacter spp*, 4 from *P. aeruginosa*, 2 from *E. coli* and only one from *Enterobacter spp*. The carbapenem resistant isolates taken for the study included, 26 respiratory specimens (57%), 10 urine specimens (22%), 5 from miscellaneous section (11%) (like pus, wounds etc) and 4 from blood cultures (8%). In the current study, the clinical isolates taken for the analysis carried resistance to the commonly used antibiotics (Table **1**). Colistin (84.5%) and tigecycline (62.2%) were the only drugs found to be active against the analyzed clinical isolates. High resistance was observed for imipenem (95.6%), meropenem (95.6%), ceftazidime (82.2) and gentamicin (80%). A study by Bhat et al, 2016 stated that *Acinetobacter* and *K. pneumoniae* strains were resistant to cephalosporins, fluoroquinolones, gentamicin and carbapenems greater than 50% [16] and a similar pattern was observed in the isolates obtained for the study.

3.1. MBL Occurrence

Among the 45 clinical isolates appraised, 38 isolates (84%) including tracheal aspirate, urine, pus, sputum and blood samples were found to be MBL producers. MBL resistance was predominant among *Acinetobacter spp* (87%), obtained majorly from tracheal aspirate samples followed by *K. pneumoniae* (77%) predominately from tracheal aspirate and sputum isolates (Table **3**). In India, 59% of MBL resistance was reported from Lucknow [17] and 82% from Chennai particularly in *P.aeruginosa* [18]. Turkey reported 5.8% of carbapenam resistant *K.pneumoniae* [19], 92.4% in *Acinetobacter spp* involving 73 clinical isolates [20]. Fig. (**1**) represents the MBL genes identified through Colony PCR.

Multiplex detection for MBL genes was also attempted successfully for these genes. Direct PCR amplification was attempted using crude samples (Sputum and Urine) for six isolates (R794, R797, R872, R877 and R906 (Respiratory samples) and only one sample from Urinary section (U1417)). The presence of the VIM gene was observed in 3 respiratory samples and 2 respiratory isolates harbored NDM gene. The results were concurrent with colony PCR detection. Fig. (**2**) represents the Direct PCR amplification of MBL genes.

Amongst the MBL resistance genes; the occurrence of VIM resistance (48%) was detected to be higher followed by NDM in 13 isolates (28%), GIM in 11 isolates (24%) and SPM in 10 isolates; whereas SIM and IMP occurrence were lesser than 10% (Table **1**). VIM and NDM resistant gene was predominantly detected in *K. pneumoniae* followed by *A. baumannii*. 42.5% NDM resistance in association with Insertion Sequence (IS) like ISAba125, ISEc33 and ISSen4 (among 120 isolates analyzed) was reported previously from the same geographical location [21]. VIM occurrence was not observed in *E.coli* and *Enterobacter spp* in the sample study as against reports from China and Italy. GIM-1 has not been reported outside Germany since 2002. Wendel et al., 2013 showed the presence of the GIM gene in 50 isolates from the suburbs of Germany [22]. The controlled spread had been attributed to the absence of mobile elements associated with this gene when it was identified in Germany [23]. However, an endemic MBL gene like GIM was identified in 13 isolates from sputum sample. Six isolates of *A. baumannii* and three isolates of *K. pneumoniae* considered in

Fig. (1). Colony PCR Amplification for MBL Genes (Individual and Multiplex).

Colony PCR based detection of MBL genes:
L1 – 100bp ladder, L2 – U1062 (16s rDNA), L3 – R906 (blaVIM), L4 – R672 (blaNDM), L5 – R877 (blaGIM), L6 – M1118 (blaNDM & 16s rDNA), L7 – R771 (blaGIM & 16s rDNA), L8 – R714 (blaNDM & blaVIM), L9 – R872 (blaNDM, blaIMP & 16s rDNA), L10 – U1075 (blaIMP, blaNDM, blaSPM & 16s rDNA), L11 – U42 (blaSPM, blaSIM, blaIMP & blaNDM), L12 – U1417 (Negative control), L13 – Blank.

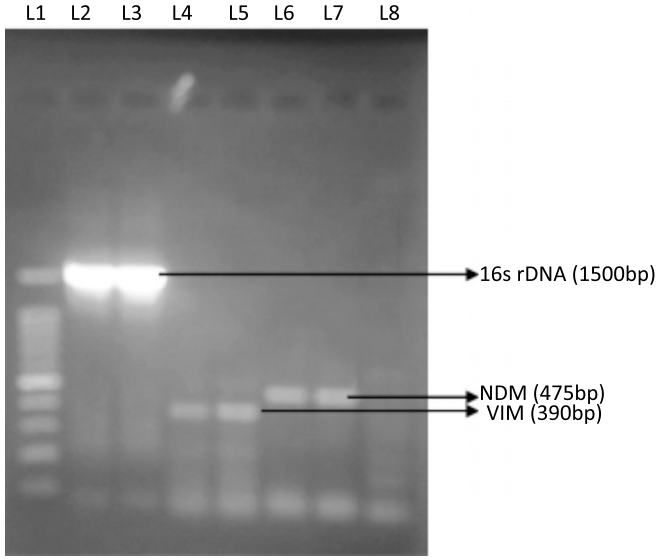

Fig. (2). Direct PCR amplification for MBL genes.

Direct PCR based detection of MBL genes:
L1 – 100bp ladder, L2 & L3 – 16s rDNA (R797 &U1417), L4 & L5– blaVIM (R794 & R877), L6 & L7– blaNDM (R872 & R906), L8 – Blank.

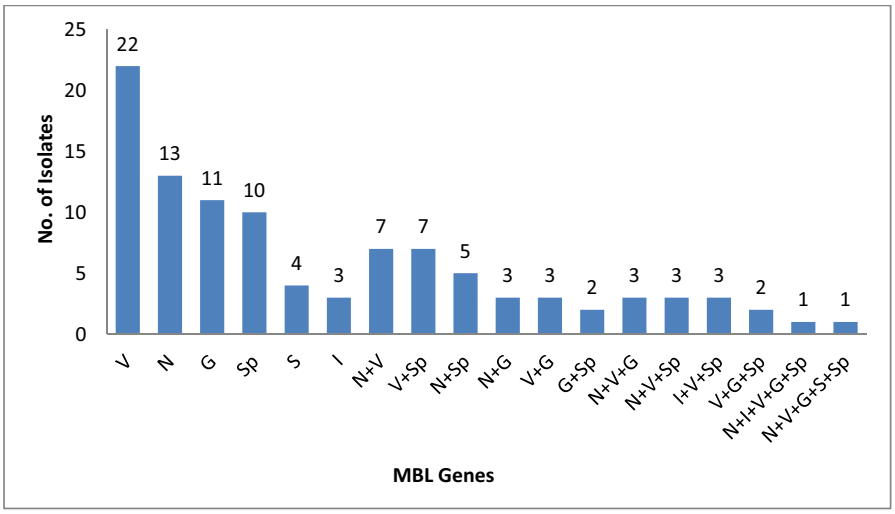

Fig. (3). MBL co resistance profile. V –VIM, I – IMP, N – NDM, S –SIM, SP –SPM, G-GIM. (*A higher resolution/colour version of this figure is available in the electronic copy of the article*).

this study were detected positive for GIM gene. The isolates were found to be colistin and tigecycline sensitive.

This investigation has also revealed the occurrence of the SIM gene in four clinical isolates (two each in *K. pneumoniae* and *Acinetobacter spp*); ten isolates positive for the SPM gene and three for the IMP gene. The isolates which harbor SIM, SPM and IMP genes were found to be resistant to various antibiotics and showed sensitivity to colistin and tigecycline. A study by Mohanam *et al.,* 2017 in Chennai had no report on SPM, SIM and GIM amongst 213 *P. aeruginosa* isolates analyzed [18]. However study by Abaza *et al*., 2017 in Egypt has analyzed 19 out of 30 *P. aeruginosa* isolates possessing SPM gene and 11 for IMP gene; although the occurrence of VIM was not reported [24].

3.2. Coexistence of MBL Genes

Optimization of mPCR amplification was done for MBL genes like NDM, VIM and IMP since these genes were found to be coexisting in the samples analyzed. mPCR was also performed for endemic MBL genes like SIM and SPM along with NDM by using 16s rDNA as an internal control. Multiplexing aids in the rapid detection of these resistance genes.

Of the 45 isolates, 15 (35.5%) were positive for more than one carbapenemase gene. The MBL genes like NDM and SPM were coexisting in 5 different isolates whereas GIM and VIM combination was seen in 3 isolates. The coexistence of VIM and NDM and VIM and SPM was detected in 7 different clinical isolates, majorly isolated from respiratory isolates (Fig. **3**). Two isolates, U42 and R714 (*K. pneumoniae*) was found to harbor all 5 MBL genes in combination. Four isolates from Respiratory section (R872 and R764 - *K. pneumoniae*; R672 and R877 - *A. baumannii*) carried 3 MBL genes in combination (Table **4**). Results indicating the coexistence of five MBL genes in a single isolate is a significant finding from this study; predicting restricted diagnostic and treatment options for the stated clinical conditions. Adwan *et al*., 2017 had discussed a similar scenario in Palestine [25]. A study by Mushi *et al*., 2014 revealed 15 out of 80 isolates had multiple genes coding for carbapenem resistance especially in *E. coli* and *P. aeruginosa* in Germany [26].

Twenty two out of 26 respiratory samples were found to have a single MBL gene; whereas 9 isolates possessed multiple MBL gene(s). Four isolates from urinary infection showed multiple resistance determinants yet they were sensitive to colistin and tigecycline. All the 10 MICU (Medical Intensive Critical Care) isolates (100%) taken for analysis showed the presence of at least one MBL gene. Three out of 10 isolates were found to have 3 MBL genes in a single isolate. Airborne transmission could contribute to the spread of MBL genes especially in respiratory specimens [27]. A similar study by Gladstone et al., 2005 detected the presence of carbapenem resistance (12.2%) among 460 NFGNB (Non Fermenting Gram-Negative Bacilli) isolated from ICU patients on a ventilator over a one-year period [28].

3.3. Risk Factors

In the current study, the minimum age of MBL instance was an infant (12 months) and a maximum of 83 years. The average age of positive samples was 50 years. Twenty seven males and 11 females reported to harbor MBL genes out of the sample group of 30 males, 15 females. Whereas 55% of people belonged to the age group between 50 to 85 years while 26% were younger adults and 6% were pediatric isolates found to have the presence of atleast one MBL gene. The study by Viehman et al., 2014 stated that carbapenem resistance is related to age of affected patients: it was present in 60-64% of all isolates in the elderly (age >65) and 46–51% in younger adults, while only in 13-17% of pediatric isolates [29]. The presence of VIM and NDM gene occurred in age groups between 40 to 80 years; whereas 6 out of 10 SPM positive isolates were between the age group of 50 to 60 years (Fig. **4**). A distinct result was seen in Abaza et al., 2017 study which reported that more than half of the patients who had *P. aeruginosa* isolates with IMP gene and SPM gene (54.5% and 47.4% respectively) were aged between 20 $\leq$ 30 years old [24]. Therefore, age related clinical complications could result in significant control challenges for the clinicians.

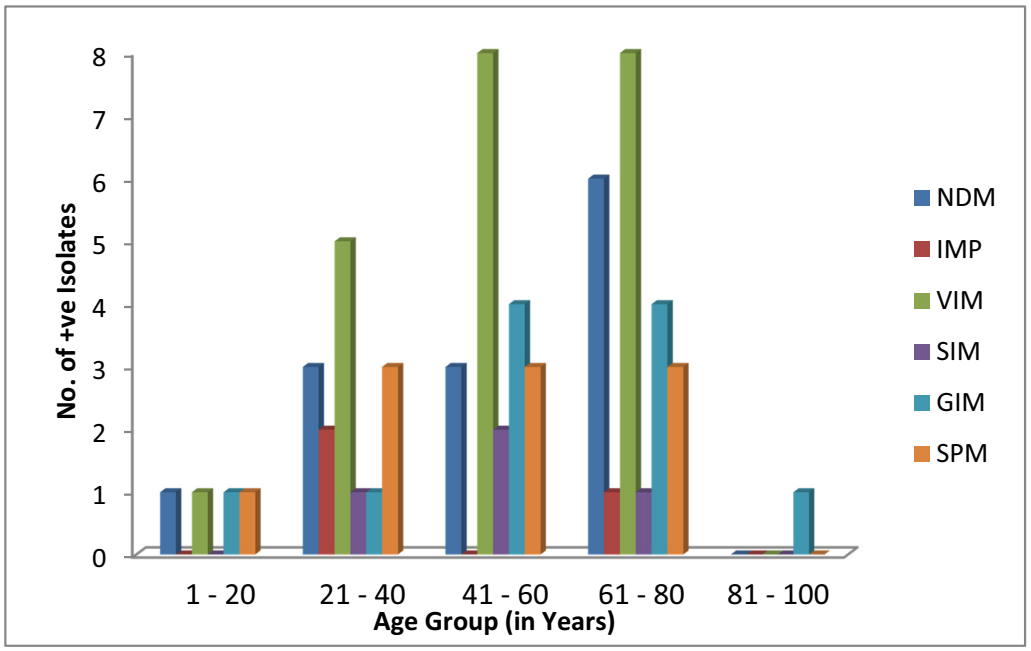

Fig. (4). MBL gene resistance occurrence with respect to patient's age group. (*A higher resolution/colour version of this figure is available in the electronic copy of the article*).

CONCLUSION

The present study analysed 45 samples chosen randomly from the list of isolates identified phenotypically as resistant to carbapenams from 10 - 15 resistant samples evaluated on a daily basis by the hospital between February – March 2018. The results confirm the presence and coexistence of MBL resistance gene(s) at the tertiary care center. The salient findings call for attention and further investigation on the prevalence and spread of these gene(s) at the center and there off in the geographical vicinity. *A. baumannii* and *K. pneumonia*e are currently potent carriers of MBL resistance in the sample set from the tertiary care centre. A rare MBL variant including SIM, SPM and GIM has been observed as a maiden case. The direct PCR amplification and multiplex detection methods prove enhanced and rapid detection for these gene(s) in the clinical setup. The sample size though limited due to the time period involved (Feb- March 2018), exhibits diversity on source and species that carry the resistant gene(s). The small sample size eliminates any outbreak incidents at the tertiary center. The report focuses attention on the prevalence of multiple MBL resistance gene(s) and warrants molecular methods for identifying the same to facilitate rapid, authentic diagnostic means to aid clinicians with cure and control spread. Future attempts to gain insights on the clonal diversity of the isolates taken for analysis will highlight the means of origin and spread. Further investigations in associated clinical set ups around the geographical limits can reveal substantial significance to these MBL variants reported from this analysis. This report could assure new insight for extensive, improved and rapid approaches for detecting MBL resistance.

Comparison of Weil Felix Test and ELISA with the Gold Standard IFA for the Diagnosis of Scrub Typhus in Clinically Suspected Cases of Scrub Typhus at a Tertiary Care Hospital in Tamil Nadu

Anisha Elizabeth Jacob[1], Marina Thomas[2], Boppe Appalaraju[3]

[1, 3] Department of Clinical Microbiology, PSG Institute of Medical Sciences and Research Coimbatore, Tamilnadu, India. [2]Department of Clinical Microbiology, Believers Church Medical College Hospital, Thiruvalla, Kerala India.

ABSTRACT

BACKGROUND

Scrub typhus is a febrile disease, the clinical diagnosis of which is difficult due to its vague symptoms. Scrub typhus is diagnosed mainly via serological tests. Sensitivity of Weil Felix was found to be poor, but the specificity of Weil Felix was variable in different studies. Enzyme linked immunosorbent assay (ELISA) IgM is known to be a sensitive test, but its specificity was variable in different studies. Therefore, in this study we have compared these two tests with the gold standard IFA.

METHODS

The study was performed as a cross-sectional study. Among the suspected scrub typhus cases, fifty consecutive IFA scrub typhus positive and fifty consecutive IFA negative samples were taken for comparison of Weil Felix and ELISA tests. The indirect fluorescent antibody test (IFA) was taken as the gold standard.

RESULTS

The sensitivity of ELISA and Weil Felix at a titre of 1 : 160 was found to be 96 % and 40 % respectively. The specificity of ELISA and Weil Felix at 1 : 160 and was found to be 88 % and 94 % respectively.

CONCLUSIONS

Scrub typhus should be kept in mind as a possible diagnosis in acute febrile illnesses. Weil - Felix was found to have a good specificity but low sensitivity. Hence, if the results by Weil Felix are negative, scrub typhus cannot be ruled out and may require further testing. ELISA showed good sensitivity making it a preferable screening test but is not highly specific and confirmation with IFA may be required when feasible.

BACKGROUND

Scrub typhus presents as an acute undifferentiated febrile illness and could become life threatening. It is caused by an obligate intracellular bacterium called *Orientia tsutsugamushi* that is transmitted by the bite of the larval trombiculid mite, which is the reservoir of the agent and the only life stage that feeds on a vertebrate host.[1,2] Recent reports from several parts of India, including South India, indicate that there has been a resurgence of the disease.[3]

The vague clinical symptoms and lack of a definitive protocol for its diagnosis often results in scrub typhus going undiagnosed. The diagnosis of scrub typhus depends largely on the laboratory diagnosis of which serology is the main stay. The oldest test is the Weil-Felix OX K agglutination reaction which is inexpensive, easy to perform and results are available overnight.[4] In Weil Felix test agglutinating antibodies are detectable 5 – 10 days following the onset of symptoms and the antibodies detected are mainly of IgM type.[5] ELISA for the detection of IgM antibodies against *Orientia tsutsugamushi* offers advantages of being able to test large number of samples at a time and can be automated. Indirect fluorescent antibody assay is the gold standard for the serological detection of antibodies in scrub typhus.[5,6]

All the serological tests that are currently available for scrub typhus have its limitations of which the clinician needs to be aware. Generally, a $\geq$ fourfold increase in antibody titre between two consecutive samples taken with a gap of 10 – 14 days is diagnostic, but this is usually retrospective and cannot guide in treatment. Serological diagnosis based on a single acute serum sample requires a cut off antibody titre depending on the endemic titre and could vary from 1 : 10 to 1 : 400.[6]

Diagnosis and surveillance of scrub typhus is challenging particularly in the absence of advanced diagnostic techniques. The availability and cost of other serological methods are a major problem in India.[7]

The purpose of this study was to evaluate the serological diagnostic methods: Weil Felix and ELISA against Indirect Fluorescent antibody assay (IFA) which is the gold standard for the diagnosis of scrub typhus.

METHODS

At the start of the study, approval was obtained from the Institutional Ethics committee and was renewed periodically during the study period which took place over a span of 2 years from October 2012 to August 2014. The study was performed as a cross sectional study. Considering the specificity of ELISA to be 94 % from previous studies with an absolute precision of 5 %, the minimum sample size was calculated to be 90. We tested Weil Felix, ELISA and IFA on a total of 100 samples collected from clinically suspected cases of scrub typhus during the period of study i.e., patients with acute undifferentiated illness of 5 days or more with or without eschar.

Weil Felix test was done using the PROGEN antigen suspension kit (Tulip Diagnostics (p) LTD, Goa). Titres of $\geq$ 1 : 160 was taken as significant. The ELISA test was done using the scrub typhus detect™ IgM ELISA kit (In Bios International Inc., USA). Samples showing values above the cut off titre according to manufacturer's instructions was considered as positive. *Orientia tsutsugamushi* IFA IgM antibody kit (Fuller Labs, California, USA) was used for IFA testing. Bright staining (at least 1+) of short pleomorphic rod forms in any of the 4 antigen areas was taken as a positive reaction. Each field was compared with the positive and negative control reactions with respect to the size, appearance, and density. If the reactivity pattern was different from the positive controls, it was considered non-specific. If the slides show positivity at a dilution of 1 : 64, it was considered positive and if negative at 1 : 64 dilution, it is reported as negative.

RESULTS

The results of Weil Felix, ELISA and IFA were entered via excel sheet and the data was analysed using the IBM SPSS software. The test parameters and McNemar's test were calculated with IFA as gold standard. Sensitivity of a test is defined as the ability to correctly identify the infected individuals and specificity is the ability to correctly identify the uninfected individuals.

Negative predictive value is the proportion of those with a negative test result who are uninfected and positive predictive value as the proportion of those with a positive test result who are infected.

Table 1.3. Comparison of Results of ELISA and IFA

Of the 50 IFA positive cases, 20 were Weil Felix positive (at a titre of 1 : 160) and 48 ELISA positive, and 20 were both Weil Felix (at a titre of 1 : 160) and ELISA positive. Of the 50 IFA negative cases, 47 were Weil Felix (titre less than 1 : 160) negative and 44 were ELISA negative and 40 were both together negative. The parameters of the test obtained are given in the table 2.

	Weil Felix at 1:160	Weil Felix at 1:80	ELISA
Sensitivity	40.0 %	54.0 %	96.0 %
Specificity	94.0 %	92.0 %	88.0 %
PPV	87.0 %	87.1%	88.9 %
NPV	61.0 %	66.1%	95.7 %

Table 2. Parameters of Weil Felix and ELISA

Out of the six ELISA tests which were false positives, two were positive for dengue, one had raised Widal titres of 1 : 160 for *S. typhi* H antigen. More details are given in table 3.

Sl. No. of Cases	Coinfection / Infectious Focus
1	*Salmonella typhi* H 1:160 others less than 1:20
2	Secondary dengue positive hepatitis A positive urine culture – Pseudomonas aeruginosa (10^5)
3	Urine culture – Escherichia coli (10^5)
4	Blood culture - Staphylococcus aureus
5	Nil
6	Secondary dengue positive

Table 3. Co Infections Observed in ELISA Positive and IFA Negative Cases (6 Cases)

DISCUSSION

Diagnosis of scrub typhus is challenging specially in the presence of co-endemic diseases like dengue, leptospirosis, and typhoid. The Weil Felix test is the oldest serological test for the diagnosis of Scrub typhus and non rickettsial antigens are used. Our study has reported good specificity for the diagnosis of scrub typhus as is reported in other studies[8,9] though in the latter study[9] a titre 1 : 80 was taken as the cut off. In the study by Pradutkanchana J et al.[8] the Weil Felix test at a break point of 1 : 160 gave a sensitivity of 52.1 % when compared to the gold standard IFA. A study from Sri Lanka reported low specificity with Weil Felix and a high Weil Felix titre of 1 : 320 in 54 % of healthy volunteers and 62 % of non-rickettsial fever patients.[10] In contrast in an unpublished data from our hospital a titre of $\leq$ 1 : 20 was recorded in healthy volunteers. The grossly insensitive results for Weil Felix in this study are in concordance with the other studies[8,9] and is attributed to the late appearance of antibody, suppression of their production by antibiotic treatment or due to its absence in re-infections that occurs frequently in endemic areas.[8]

Earlier ELISA with native *O. tsutsugamushi* were used either individually for Karp, Kato, Gilliam strains or pooled but now due to safety issues associated with the culturing of live rickettsia, the recombinant 56- kDa immunodominant protein from *O. tsutsugamsuhi* is used to develop serological ELISA for scrub typhus. Large quantities of this can be prepared using *E.coli* without needing BSL 3 facilities.[11] The r56 ELISA when compared with indirect immunoperoxidase showed a sensitivity of 86 % in one study[11] and 93 % in another study,[12] whereas in our study a sensitivity of 96 % was obtained with IFA taken as the gold standard. The specificity in our study was 84 % and it showed good correlation with one study[11] but showed 94 % specificity in another study.[12]

Our study observed false positive reaction for IgM ELISA in cases of dengue, typhoid fever and one case of blood culture positive for *Staphylococcus aureus*. False - positive reactions were observed in patients with falciparum malaria, pulmonary tuberculosis, *S. viridans* septicaemia and typhoid fever using IgM ELISA in other studies.[13]

CONCLUSIONS

We have observed good specificity but a low sensitivity with Weil Felix test. Therefore, if the results by Weil Felix are negative, scrub typhus cannot be ruled out and further testing may be needed. The good specificity we have observed could also be because of a low endemic titre in the local population. ELISA showed good sensitivity thus is the preferable screening test but is not highly specific and may require confirmation with IFA when feasible.

A B S T R A C T

Enterococci mainly being commensals in human faeces are now considered as an important cause of nosocomial infections. Of the infections, the commonly observed are urinary tract infections, abdominal infections followed by bacteremia, endocarditis and meningitis rarely. Speciation of *Enterococcus* aids in effective management of the infections caused by them. The initial treatment for enterococcal infections has become challenging due to development of resistance. The resistance has been observed mainly against aminoglycosides due to the presence of bi-functional gene. VRE strains are mostly isolated from patients with recurrent bacteremia, endovascular infections leading to increase deaths in the patients. To isolate and speciate enterococcal isolates from clinical samples, study the antibiotic susceptibility pattern and the genotype associated with the aminoglycoside and vancomycin resistance. *Enterococcus* isolates obtained from various sections were characterized by conventional phenotypic methods. The antibiotic susceptibility was studied by disc diffusion method. The resistant strains were further confirmed by MIC using automated methods following which the genotypic analysis was done. The incidence of *Enterococci* was 2.5% in which around 86.4% were obtained as pure isolates. Among the species *E. faecalis* was found to be the maximum. The urinary isolates exhibited sensitivity of around 92.3% to nitrofurantoin and among the non - urinary isolates the maximum sensitivity was for linezolid. The molecular study showed van A to be most common gene with vancomycin resistance (71.42%), and bifunctional gene among the aminoglycoside resistance (96%). *Enterococcus faecalis* was the commonest species isolated. The maximum number of isolates was obtained from urinary samples. The increase incidence of resistance gene to high level gentamicin could result in failure to the synergy treatment of gentamicin in combination with penicillin group of antibiotics. The emergence of vancomycin resistant strains among the clinical isolates makes treatment options more challenging.

Introduction

Enterococci are gram positive organisms having the property to grow at 6.5% NaCl concentration, pH of 9.6 and hydrolyze bile esculin. Initially they were grouped under group D Streptococcus but later with the help of DNA studies they are characterized under the genus *Enterococcus* in 1960. They were considered as harmless pathogens formerly, but in the recent years have been emerging as the most important causative agents in nosocomial infections (Murray *et al.*, 1990).

Enterococci being the commonest micro flora of both humans and animals share their source

of origin. They have been isolated from variety foods including cheese, fish, sausages, beef and pork. Studies have been reported that *Enterococci* have been isolated from various clinical and environmental samples all over the world. Among the isolates obtained clinically it has been observed that *Enterococcus faecalis* has been the predominant species clinically (Lancefield *et al.,* 1933; Cetinkaya *et al.,* 2000).

Enterococcal infections have been referred to as tough, tenacious and troublesome infections (Marothi *et al.,* 2005).In the past years there has been an increase in the prevalence of enterococcal infections in hospitals and of particular concern is the emergence of antimicrobial resistant strains. Being second commonest organism behind the abdominal and pelvic infections, third in causing blood stream infections, cases have also been reported in causing CNS and neonatal infections.

Reports have been confirmed with their association with clinical conditions including respiratory tract infections, osteomyelitis and cellulitis (Fischer *et al.,* 2009). *Enterococci* were initially regarded as the disease causing agent in the early nineties. But now various reports have been established reporting them as the second commonest pathogen (Kuhn *et al.,* 2003).

Species identification becomes essential for investigating outbreaks in case of nosocomial infections and also susceptibility pattern varies accordingly which is also helpful in clinical management of infections due these agents (Gordon *et al.,* 1992).

Infections caused by enterococcal pathogens were initially being treated with the combined treatment of cell wall active agents as penicillins and aminoglycoside as the synergistic effect was effective. But now due to the development of antibiotic resistance as high level aminoglycoside resistance, beta lactamase production and also resistance to vancomycin have led to serious concern in management of these nosocomial pathogens (Mendiratta *et al.,* 2008). Vancomycin resistant *Enterococcus* was initially reported in 1980s, after which there was a increase in the incidence of its spread. The main phenotypes associated with its spread are Van A, Van B and Van C. Van A and Van B are mainly associated with *E. faecalis* and *E. faecium*. Van C is noted in *E. gallinarum* and *E. casseliflavus*. Among the phenotypes Van A is predominantly associated in the resistant strains.

VRE strains are mostly isolated from patients with recurrent bacteremia, endovascular infections leading to increase deaths in the patients. Vancomycin resistance and penicillin resistance are often seen co-existing which makes the treatment harder (Murray *et al.,* 1990).

Resistance development in *Enterococcus* against glycopeptide antibiotics gets transferred from them to other bacterial pathogens which include *Staphylococcus aureus, Streptococci, Listeria monocytogenes* (Gold *et al.,* 1996).

Thus due to the recent emergence in association with significant clinical infections and development of resistance, *Enterococci* have gained importance. Studies are thus required especially in tertiary care hospitals for appropriate isolation, identification and speciating them.

Antibiograms should also be followed up in accordance to the species. Emergence of VRE needs to be checked and limit its spread in hospital environment. CDC also stresses the control of VRE in hospitals by educating the staff in detecting VRE early, reporting them and action plan taken promptly.

Our study aims to isolate, speciate the *Enterococcus* in a simplified manner and also to study the drug sensitivity and resistance patterns among the isolates obtained.

Materials and Methods

The Institutional Human Ethical clearance was obtained before the commencement of the study.

Type of study

Experimental study

Confidentiality

Confidentiality of the reports were maintained

Sample size estimation

A total of 250 isolates of *Enterococci* obtained from outpatient and inpatient samples from blood section, miscellaneous and urine section were processed for the species identification, antimicrobial sensitivity followed by molecular study.

Specimen processing: Specimens from various sections including urine, pus and blood for cultures were collected and processed in the laboratory.

Pus/wound swabs

The swabs were streaked in blood agar and MacConkey agar and were incubated at 37^0C for 24 hours.

Urine

A loopful of the uncentrifuged specimen was examined as a wet mount for the presence of pus cells and bacteria. One loopful of specimen was inoculated onto blood agar and Mac Conkey agar. Plates were incubated at 37^0 C for 24 hours.

Growth in sheep blood agar

Following overnight incubation of the samples, colonies of *Enterococcus* were seen as grey colonies of about 0.5-1mm in diameter with alpha, beta or gamma hemolysis.

Growth in Mac Conkey agar

Colonies were about 0.5- 1mm in size with a smooth surface and convex margins, tiny magenta colored following 18-24 hour growth.

Catalase test

A drop of the catalase reagent (30% hydrogen peroxide) was added to the slide.

The growth was further applied to it with an applicator stick. Appearance of bubbles was taken as positive test.

Enterococcal colonies showed a negative test due to the absence of bubbles.

Gram stain

Smears made from the colony showed Gram positive cocci arranged singly, in pairs or in short chains.

Storage

If the isolate was catalase negative, gram staining showing the presence of gram positive cocci in pairs or short chains and growth in MacConkey agar as tiny lactose fermenting colonies, they were sub cultured and pure growth was stocked in Robertson's cooked meat medium in tubes.

The tubes were sealed and stored at 4-8^0C for 3-6 months. When the test was to be done they were further sub cultured.

Identification tests

Growth in media with pH – 9.6

Isolated colonies of *Enterococcus* was streaked in a media with a pH 9.6 and incubated at 37^0C overnight. The presence of growth was taken as positive.

Tolerance with 6.5% NaCl

The colonies were inoculated in a broth with 6.5% NaCl, and incubated overnight. The next day the tubes were checked for any increase in turbidity. This was further confirmed by sub culturing onto the agar plates. Growth confirmed the presence of organism. Whereas absence of turbidity indicated organism was unable to grow in this concentration.

Heat tolerance test

Enterococcus was inoculated in Todd-Hewitt broth. It was later incubated in water bath set at 45^oC overnight and 60^0 C for half an hour, and then sub cultured. *Enterococci* survived both the temperature showing positive reaction.

Bile esculin test

Colonies from 24 hour culture were inoculated in media containing 40% bile. Blackening of the medium confirmed positive reaction for *Enterococci* and non-*Enterococci*.

PYR test

The colonies were inoculated in PYR broth and incubated for a period of 4 hours. Later 3 drops of PYR reagent was added to it and change of colour to red was confirmed positive indicating *Enterococci* whereas absence of colour change indicates negative test.

Motility test

Stab culture of the colony was done in a semi-solid media and motility was indicated by the spread of the organism into the media. The strains which did not diffuse into the media were considered non-motile. Tubes were incubated for up to 7 days for confirming motility.

Arginine test

A well isolated colony of *Enterococcus* from the culture was inoculated in Moeller's decarboxylase media with arginine as the amino acid and overlaid with mineral oil. After 24 hours of incubation the colour of the tube was changed to purple indicating a positive reaction. Yellow colour indicated only acid production only and no deamination.

Potassium tellurite reduction test

Colonies were streaked in media containing 0.004%potassium tellurite. *E. faecalis* formed black colonies with the reduction of tellurite to tellurium.

This test was used to differentiate *E. faecalis* from *E. faecium.*

Pyruvate test

When inoculated in a media containing pyruvate with bromothymol blue as indicator *E. faecalis* showed a colour change from green to yellow color after overnight incubation. Absence of colour change ruled out *E. faecalis.*

Pigment production

Ability to produce pigment was observed by a few species of *Enterococci*. This was tested by sub culturing colonies in nutrient agar.

Any color produced was visible and also further confirmed by touching the colony with a sterile swab.

Sugar fermentation tests

Species identification was further done by sugar utilization by inoculating the organism in peptone with 1% sugars with Andrade indicator. The sugars used were mannitol, arabinose, raffinose, sorbose, sorbitol, lactose and sucrose. Any change in colour from colourless to pink indicated the positive sugar fermentation test. Absence of colour change was taken as negative.

Antimicrobial susceptibility test: (CLSI 2015)

The 250 test isolates of *Enterococci* were checked for the antimicrobial susceptibility pattern using Kirby-Bauer disc diffusion method. Three or four pure colonies were inoculated in peptone water and incubated for about 3 hours. The turbidity of the growth was matched to 1 of Mc Farlands. A lawn culture of the broth with a sterile swab was done in Muller Hinton agar and the discs were placed at a distance of 24 mm.

About 6 discs were kept on each plate. The discs used were Penicillin (10U), Ampicillin (10µgm), Amoxicillin Clavulanic acid (20/10), Erythromycin (15µgm), Vancomycin (30µgm), High level gentamicin (120µgm), Linezolid (30µgm), Tetracycline (30µgm). For isolates from urine section Norfloxacin (10µgm) and Nitrofurantoin (300µgm) was kept. All discs were bought from HIMEDIA.

Zones of inhibition were measured and recorded and the organism was interpreted as sensitive or resistant as per the recommendations from CLSI guidelines. The quality Control used was *Enterococcus faecalis* ATCC 29212.

Screening for high level gentamicin resistance (CLSI 2015)

Screening media for high level gentamicin resistance was prepared. Screening for high level gentamicin resistance was done by agar dilution method. BHI agar with gentamicin at a concentration of 500µgm/ml was added and the plates were prepared. Inoculum of 10µL of 0.5 Mc Farland was spot inoculated. Presence of even 1 colony was interpreted as a resistant strain. These strains were collected for molecular studies.

Detection of beta lactamase (Marothi *et al.*, 2005)

The detection of beta lactamase test was done based on the chromogenic cephalosporin method. Nitrocefin disc was obtained commercially from BD. The disc was moistened with sterile saline and pure isolated colony was applied on it. The reaction was read within 5 min. Isolates producing beta lactamase produced a red color.

Molecular study of isolates

A representative sample of 50 high level gentamicin resistant isolates was selected for genomic analysis. The DNA was extracted using the QIAGEN kit. Followed by extraction, the isolates were analysed for the presence of Bifunctional resistant geneaac (6') le aph (2") la. The vancomycin resistant isolates were checked for the presence of van A gene simultaneously.

Detection of aac (6') le aph (2") la gene

The primers for HLGR with a base pair of 348 bp were amplified. The sequence was obtained from the studies done previously[11]. PCR Master mix: The master mix was prepared as follows: 2.5µl of PCR buffer,2.5µl of MgCl2, 2.5µl of DNTPs,

10.2µl of Mili Q H2O, 1µl of forward and reverse primers and 0.3µl of Taq Polymerase was added to eppend off. From the above mixture 18µl was taken and 5µl of the extracted DNA was added.

Primers for aac (6')Ie- aph (2")la with base pair of 348 bp (Vakulenko *et al.*, 2003):

F (5'CAGAGCCTTGGGAAGATGAAG3')
R (5'CCTCGTGTAATTCATGTTCTGGC3')

PCR program

The program consisted of initial denaturation step at 95^0C for 10 minutes followed by 30 cycles of denaturation at 94^0C for 300 seconds, annealing at 56^0C for 1 minute and extension at 72^0C for a period of 1 minute. The program had a holding temperature of 72^0C for 10 minutes.

Analysis

PCR products were analyzed by running gel electrophoresis with 1.5% agarose gel in Tris Boric acid buffer. The samples along with the controls obtained by running ladder were analysed.

The gel was stained with ethidium bromide and the bands were obtained were visualized under UV light and also in automated GEL DOC viewer.

Detection of vanA gene

The primers with a base pair of 732bp for detection of vanA were obtained from the studies done previously.

Primers for van A with base pair of 732bp (Dutka-Malen *et al.*, 1995):

F (5' GGGAAAACGACAATTGC-3')
R (5'GTACAATGCGGCCGTCGTTA-3')

PCR program

This program had a denaturation step at 95^0C for 5 minutes followed by 30 cycles of DNA denaturation at 95^0C for 1 minute, annealing at 54^0C for 45 seconds and primer extension at 72^0C for 45 seconds. This was followed by a holding temperature of 72^0C for 10 minutes.

Analysis

PCR products were analyzed by running gel electrophoresis with 1.5% agarose gel in Tris Boric acid buffer. The samples along with the controls obtained by running ladder were analysed. The gel was stained with ethidium bromide and the bands were obtained were visualized under UV light and in automated GEL DOC viewer.

Results and Discussion

All the 250 isolates of *Enterococcus* from various clinical samples including urine, pus, wound swab, blood and CSF were processed.

The maximum number of isolates was obtained from urine section (184) followed by wound swabs (24), blood section (14), 4 from peritoneal samples, 1 from CSF (Figure 1). The majority of the isolates were obtained as pure growth (216) and 34 was obtained as mixed from the samples processed. Figure 2 depicts the speciation of enterococcal isolates in which *E. faecalis* was the predominant species (157), succeeded by *E. faecium* (79), *E. raffinosus* (7), and *E. durans* (5) and *E. casseliflavus* (2).

Illustration 1 shows the genus specific biochemical tests used in the identification.

The antibiotic susceptibility pattern of the enterococcal isolates by disc diffusion method revealed that out of the 250 isolates, about 69.2% were ampicillin sensitive, 49.2% were

high level gentamicin sensitive, 89.3% were sensitive to erythromycin. The maximum number of isolates was found to be sensitive to vancomycin (97.2%) in our study (Table 1). Among the urinary isolates maximum sensitivity was noticed to nitrofurantoin (92.3%) (Table 2) and norfloxacin (83.1%).

The maximum sensitivity was observed for linezolid followed by vancomycin, teicoplanin, ampicillin and high level gentamicin. Among the non-urinary isolates erythromycin sensitivity was observed to be the highest.

The chromogenic nitrocefin disc was used to screen the isolates for the presence of beta lactamase. In our study none of the isolates were found to be positive for beta lactamase.

Figure 3 shows the presence of Bifunctional gene aac (6')1eaph(2")1a among the high level gentamicin resistant strains. Out of the 50 randomly selected resistant strains for genotype study, 48 had the gene.

Illustration 2 shows the presence of bands of size 348 bp during the gel electrophoresis.

In our study 7 out of the 250 isolates were found to be resistant to vancomycin. The genotypic analysis was done among these resistant strains using the van A gene. The results showed that 5 of the 7 strains were found to be positive for van A gene (Figure 4).

Illustration 3 shows the presence of van A gene of base pair 732, confirming its presence among the resistant strains.

Enterococcus has been noted to cause a majority of urinary tract infections. This being the most common followed by bacteremia, sepsis and even case reports of meningitis has been reported. In our study out of 250 samples studied the majority of the isolates were obtained from urinary tract infections (73.6%) followed by wound swabs (9.6%) and blood (5.6%). This correlates well with other studies in which *Enterococci* was obtained from urine isolates maximally (Karmarkar *et al.,* 2004, Mathur *et al.,* 2003). According to the studies *Enterococci* are considered as the commonest urinary pathogen justifying the increase in the rate of isolation from urinary samples (Murray *et al.,* 1990).

Among the various species, in our study *E. faecalis* was the most common isolate accounting for 62.8% followed by *E. faecium, E. durans, E. raffinosus* and *E. casseleflavus.* Similar findings were reported from other studies done in Bangalore in which *E.faecalis* was 59%, *E. faecium* was 38 % (Golia *et al.,* 2014).

Enterococci show intrinsic resistance to cotrimoxazole, clindamycin, cephalosporins and normal aminoglycosides. Thus these antibiotics are not tested (Mendiratta *et al.,* 2008).

The antibiotic susceptibility pattern of the isolates in our study showed the following:

The sensitivity to linezolid was maximum (98.8%) followed by vancomycin (97.2%), erythromycin (89.3%), teicoplanin (75.2%), ampicillin (69.2%), high level gentamicin (49.2%) and penicillin (25%).

Among the urinary isolates maximum sensitivity was noted in Nitrofurantoin (92.3%) followed by Norfloxacin (83.15%). Studies done in North India showed a similar susceptibility pattern with increased resistance to penicillin and aminoglycosides. Also the sensitivity percentage to linezolid and vancomycin was higher compared to other antibiotics (Mulla *et al.,* 2012).

Another study showed the percentage of high level gentamicin resistance to be 68% (Randhawa *et al.*, 2004). Reports from South India showed the resistance percentage of high level aminoglycoside to be more than 50% (Sreeja *et al.*, 2012).

The detection of beta lactamase production by the chromogenic nitrocefin disc method showed that none of the isolates had beta lactamase enzyme. Studies done in Delhi and in Maharashtra also showed similar results (Jain *et al.,* 2011; Mendiratta *et al.,* 2008). The resistance to beta lactams though common, the mechanism could be due to alteration in penicillin binding protein PBP 5 which is more common than beta lactamase production (Murray *et al.,* 1992).

The molecular study done to detect the presence of the resistant gene confirmed the presence of the bifunctional gene aac (6') le-aph (2") la of base pair 348 to be present in 48 (96%) out of the 50 randomly selected resistant strains.

Studies done in Chennai have showed the presence of this gene in 38.2% of the isolates (Padmasini *et al.,* 2014) whereas there are other studies in which all the resistant isolates possessed this bifunctional gene (Hasani *et al.,* 2012). The resistance to high level gentamicin indicates resistance to all the aminoglycosides except streptomycin (CLSI 2015). The combination effect of aminoglycoside with beta lactam antibiotic is not helpful in the treatment of patients possessing such resistant strains.

Out of the 250 isolates the vancomycin resistant isolates obtained in our study was 2.8%. Studies have shown the prevalence of vancomycin resistance to be less in India ranging around 1.7-20% (Sreeja *et al.,* 2012).

Molecular studies revealed the presence of van A gene in 5 (71.42 %) isolates. Studies have also been reported showing van A to be the most common genotype isolated among the vancomycin resistant strains (Praharaj *et al.,* 2013)

Out of the seven isolates, five were *E. faecium* and two were *E. casseliflavus*. The remaining two isolates were *E. casseliflavus* which would have exhibited intrinsic resistance to vancomycin with van C gene (Praharaj *et al.,* 2013).

The incidence of *Enterococci* from the clinical isolates in our study was 2.5%.

The incidence of the pure isolates was 86.4% in comparison to the mixed isolates which was found to be 13.6%.

Among the isolates of *Enterococci*, the predominant species was *E. faecalis* (62.8%) followed by *E. faecium* (31.6%), *E. raffinosus* (2.8%), *E. durans* (2%) and *E. casseliflavus* (0.8%).

The antibiotic sensitivity pattern of the urinary isolates showed 92.3% sensitive to nitrofurantoin and 83.15% sensitive to norfloxacin. Among the non-urinary isolates maximum sensitivity was observed in linezolid which was 98.8% followed by vancomycin (97.2%), erythromycin (89.3%), teicoplanin (75.2%), ampicillin (69.2), high level gentamicin sensitivity (HLG) (49.2%) and pencillin (25%) (Table 3).

The vancomycin resistance was found to be 2.8% in *E. faecium*.

All the isolates were found to be beta lactamase negative by chromogenic (nitrocefin) method proving the alteration in PBP5 to be the more common mechanism involved in penicillin resistance.

The molecular characterization of HLGR(high level gentamicin resistant) strains, 50 isolates selected randomly out of 127, showed the presence of bifunctional gene aac(6')le-aph(2")la to be around 96%. (Primers of base pair 348 - F (5'CAGAGCCTTGGGAAGATGAAG3') R (5'CCTCGTGTAATTCATGTTCTGGC3')

The presence of van A gene was found to be 71.42% in our study.

A B S T R A C T

Enterobacteriaceae are inhabitants of human, animal gastrointestinal tract and various other environmental sites. *Escherichia coli* and *Klebsiella pneumoniae* initially responded to betalactam antibiotics but there was an increase in resistance to betalactam antibiotics due to beta lactamase produced by them. Resistance to carbapenems has now become more prevalent due to production of carbapenemases. NDM-1 is a novel metallo betalactamase that is capable of hydrolysing all beta lactam antibiotics except Aztreonam. It was aimed for Molecular detection and subtyping of NDM-1 in *Escherichia coli* and *Klebsiella pneumoniae*. Hundred carbapenem resistant isolates (42 isolates of *Escherichia coli* and 58 isolates of *Klebsiella pneumoniae*) were selected randomly for Molecular detection and sequencing of subtypes. A total of 82% strains were found to be NDM-1 positive yielding 475bp amplicon by molecular methods. Nine samples were sequenced for subtypes, of which five were NDM-1, two were NDM-4, and remaining two were NDM-3, and NDM-5.Sequencing and finding out of the subtypes may help to select new drug targets and design novel antibiotics.

Introduction

Enterobacteriaceae are inhabitants of wide variety of niches, including the human, animal gastrointestinal tract and various other environmental sites. The family Enterobacteriaceae includes a large number and diversity of genera.

During the past decade, there has been an emergence of carbapenems-resistant *Enterobacteriaceae* that produce carbapenamases, enzymes that efficiently hydrolyze carbapenems, as well as most β-lactam drugs (Queenan *et al*., 2007). New Delhi Metallo-beta-lactamases-1 (NDM-1) are one such carbapenamase that makes bacteria resistant to a broad range of beta-lactam antibiotics. These include the antibiotics of the carbapenems family, which are a mainstay for the treatment of antibiotic-resistant bacterial infections. Bacteria that produce carbapenamases are often referred to in the news media as "superbugs" because infections caused by them are difficult to treat.

Such bacteria are usually susceptible only to polymyxins and tigecycline. NDM-1 was first detected in a *Klebsiella pneumoniae* isolate from a Swedish patient of Indian origin in 2008. It was later detected

in bacteria in India, Pakistan, the United Kingdom, the United States, Canada, and Japan (Kumarasamy *et al*., 2010).

Materials and Methods

Study population

After Ethical clearance from the institution, the study was conducted between April 2014 and August 2015 on various clinical samples. Two thousand and forty two isolates of *Escherichia coli* and thousand hundred and ninety two isolates of *Klebsiella pneumoniae*, were identified by IMViC tests. Of which Five hundred and sixty isolates of *Klebsiella pneumoniae* (47%) and hundred and forty eight isolates of *Escherichia coli* (7%) were resistant to carbapenems. Among them hundred isolates were selected randomly for the study (42 isolates of *Escherichia coli* and 58 isolates of *Klebsiella pneumoniae*)

Isolation of carbapenem resistant *Escherichia coli* and *Klebsiella pneumoniae*

The isolates were screened for the production of Carbapenam resistance as per CLSI 2014, using Ertapenem 10ug and Merapenam 10ug disc. The zone diameter of inhibition less than 19-21mm for Ertapenem and less than 16-21mm for Merapenam indicates Carbapenemase production. As per CLSI 2014 Ertapenem non susceptibility was the most sensitive indicator of Carbapenem resistance. Isolates were also tested by automated identification system (VITEK 2) for carbapenem resistance, based on Minimal Inhibitory Concentration. Among them a total of 100 isolates (42 isolates of *Escherichia coli* and 58 isolates of *Klebsiella pneumoniae*) were selected randomly for molecular study.

DNA extraction

The isolates were incubated overnight at 35ºC in Luria broth. About 2-3 ml of inoculum was centrifuged at 5000rpm for 10 minutes. After centrifugation the supernatant was discarded and the pellet was taken in a sterile Eppendorf tube. The pellets were resuspended in distilled water and kept in a water bath at 95ºC for 20 minutes. It was then cooled and centrifuged at 5000 rpm for 10 minutes. The supernatant was the extracted DNA and is stored at -20ºC.

Polymerase chain reaction

The extracted DNA was mixed with forward, reverse primers for NDM-1, master mix and PCR water and amplified in step one AB applied Bio system Real time PCR machine.PCR cycle consists of the following steps (Jeremiah *et al*., 2014). Initial denaturation at 94°C for 3 min, Denaturation at 94°C for 30 s Annealing at 60°C for 25 Extension at 72°C for 30 s, Final extension at 72°C for 3 min for 30 cycles. The amplified products are stored at -20ºC. Gel Electrophoresis was run. The images of the gel were captured by Gel doc and viewed. The presence of the NDM-1 gene was confirmed by the formation of bands at 475bp.

Gene sequencing and blasting

The amplied products which were confirmed for the presence of NDM-1 were sent for gene sequencing to Eurofins Genomics Bangalore. The sequenced genes were blasted using BIO EDIT software and results were interpreted in the NCBI (National centre for Biotechnology Information) website.

Results and Discusion

Two thousand and forty two isolates of *Escherichia coli* and thousand hundred and ninety two isolates of *Klebsiella pneumoniae*, were identified in various clinical samples during the study period, of which Five hundred and sixty isolates of *Klebsiella pneumoniae* (47%) and hundred and forty

eight isolates of *Escherichia coli* (7%) were resistant to carbapenems. Among them Forty two isolates of *Escherichia coli* and Fifty eight isolates of *Klebsiella pneumoniae* were selected for molecular study.

Polymerase chain reaction

Among the hundred isolates, eighty two (82%) were found to be NDM-1 positive (475bp) by PCR. Gel pattern of NDM-1 is depicted (Fig 1). Thirty seven (88%) of *Escherichia coli* and Forty five *Klebsiella pneumoniae* (77%) were NDM-1 producers.

Subtypes of NDM-1

Nine samples of amplified DNA (25ul) were sent randomly for sequencing at Euro fin genomics India pvt Ltd in Bangalore. Among them four were *Escherichia coli* and five were *Klebsiella pneumoniae*. The results send by the Eurofins Genomics were subjected to gene blasting using the BIO EDIT software and the sequence results were interpreted in NCBI (National centre for Biotechnology and Information) web site as shown in figures 2 and 3. On interpretation it was found that Amplicon-1, Amplicon -2, Amplicon -4, Amplicon -6 and 8 had amino acid sequences of NDM-1 and Amplicon -3 was NDM-5 and Amplicon -5 was NDM-3 and Amplicon -7 and Amplicon -9 were NDM-4. NDM-5 showed a point mutation variant differing from NDM-1 having a Met to Leu (M-L) substitution at 154 and Val to Leu (V-L)substitution at 88. NDM-3 showed a point mutation variant differing from NDM-1 having substitution of Asp to Asn (D-N) at 95.NDM-4 differs from NDM-1 by a single amino acid substitution (M-L) at 154 (Met to Leu) which is shown in table 1.

Gram negative bacteria belonging to the family of Enterobacteriaceae are the most frequently isolated organisms from clinical specimens. They are incriminated in virtually any type of infectious diseases and recovered from any specimen received in the laboratory. *Escherichia coli* and *Klebsiella pneumoniae* cause sepsis, endotoxic shock, urinary tract infections, meningitis in neonates and pneumonia in immune compromised.

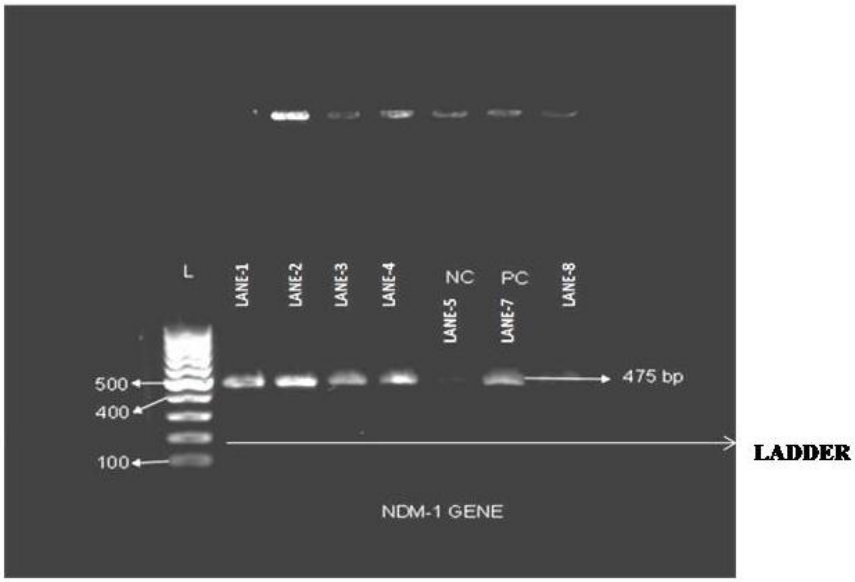
They are normally treated based on the antibiotic sensitivity, site of infection and co-morbidity conditions (Longo *et al*., 2011). *Escherichia coli* and *Klebsiella* infections initially responded to betalactam antibiotics, but there was a dramatic increase in resistance to beta lactam antibiotics due to betalactamases produced by them. This resistance was superseded by use of second and third generation cephalosporins and combination of betalactam antibiotics with betalactamases inhibitors (Nosocomial burn wound infections, 2004).

Further with the emergence of ESBLs and Amp C resistance, carbapenems became the drug of choice. There has been a rapid increase in carbapenems resistance in Enterobacteriaceae in the recent years. The carbapenems resistance may be due to carbapenamases production, Efflux pump and Amp C enzyme production with membrane impermeability. However, carbapenamases (betalactamases) were found to be the predominant mechanism of this resistance. Among the newly emerged carbapenamases, New Delhi Metallo betalactamases (NDM-1) represents a war between the bugs and drugs.NDM-1 producing organisms are called super bugs (BorA *et al*., 2012).

NDM-1 was first reported in 2008 in *Klebsiella pneumoniae* and *Escherichia coli*. Both of them were recovered from a Swedish patient of Indian origin who was previously admitted in a hospital in New Delhi, India. Thereafter, NDM-1 has increasingly been reported from India and from several other parts of the world.

Besides this, most of these NDM-1 positive bacteria are also resistant to a wide variety of Antimicrobials like aminoglycosides, flouroquinolones, macrolides and sulphonamides and carry several additional resistance mechanisms, leaving only few or no therapeutic options (Krishna, 2010). In our study period carbapenem resistance was observed in 47% of *Klebsiella pneumoniae* and 7% of *Escherichia coli* in our hospital.

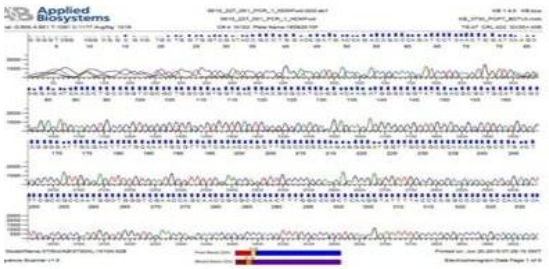
As per CLSI 2014 Ertapenem is a good marker for detection of Carbapenems resistance as others do not predict this resistance well. We randomly selected 42 *Escherichia coli* followed by 58 *Klebsiella pneumoniae* which were carbapenems resistant for molecular analysis. Molecular tests are the most accurate and usually taken as Gold standard. In our study we used the following primers (475bp) to detect NDM-1 by conventional PCR. NDM Forward: 5'-GGGCAGTCGCTTCC AACGGT and



NDM Reverse: 5'- GTAGTGCTCAGTGTC GGCAT

Amplification, sequencing and subsequent blasting were performed to identify the subtypes. Eighty-two (82%) strains were found to be NDM-1 positive (475bp) of which Thirty seven (45%) were *Escherichia coli* and Forty five were *Klebsiella pneumoniae* (54%). The presence of NDM-1 has also been reported in Bangladesh, Australia, Netherlands, USA, Canada, Japan, and China indicating that blaNDM-1is widely spread all over the world (Berrazeg *et al*., 2014).

Table.1 DNA sequencing results of NDM-1 carbapenamase genes studied



Amplicon	Aminoacid Substitution	Interpretation
Amplicon-I	Aminoacid sequences of NDM-1	NDM-1
Amplicon-2	Aminoacid sequences of NDM-1	NDM-1
Amplicon-3	Met to Leu (M-L) substitution at 154 and Val to Leu (V-L)substitution at 88.	NDM-5
Amplicon-4	Aminoacid sequences of NDM-1	NDM-1
Amplicon-5	Substitution of Asp to Asn (D-N) at 95.	NDM-3
Amplicon-6	Aminoacid sequences of NDM-1	NDM-1
Amplicon-7	Single amino acid substitution (M-L) at 154 (Met to Leu).	NDM-4
Amplicon 8	Aminoacid sequences of NDM-1	NDM-1
Amplicon 9	Single amino acid substitution (M-L) at 154 (Met to Leu).	NDM-4

NDM-5

Fig.3 DNA DNA sequencing results of amplified NDM-1

In a similar study from south India, NDM-1 was detected in 75% of K. pneumoniae and 66% of E. coli by PCR and the remaining isolates were assumed to posses other mechanisms of resistance like efflux pumps, other carbapenamases, Amp C production and membrane impermeability (Nagaraj *et al*., 2012). DNA and protein sequencing were started in the 1970s, when the virus Lambda (50,000 nucleotides) was sequenced by Sanger *et al*., DNA sequencing was initially carried out for small genomes such as viruses and organelles, and complete sequencing of a bacterial genome were started later on with the improvements in sequencing technologies. DNA mutations has resulted in changes in the amino acid sequences and produced an ever increasing range of subtypes or variants in each of carbapenamase.

Fifteen variants of NDM-1 have been identified. These variants were identified after sequencing and blasting. They differ by various aminoacid substitutions. We found NDM-1 in 5 strains (56%), NDM-4 in 2 strains (22%) NDM-3and NDM-5 in one strains each (11%). Further characterization of the 18 strains (5 were *Escherichia coli* and 13 *Klebsiella pneumoniae* which were negative for NDM-1 gene) for the mechanism of resistance was not done in our study. These isolates probably have other carbapenemases like VIM or it may have efflux changes or Amp C beta lactamase production with outer membrane impermeability.

Presently NDM-1 producing bacterial infections can be managed with Colistin and Tigecycline combination. Colistin should not be given alone as it provokes resistance in vivo due to hetero resistant strains. Fosfomycin may also serve as an option for combination therapy. Detection of NDM-1 like carbapenemases in members of Enterobacteriaceae will help in the management and prevention of spread of such

bacteria in hospital and community which in turn will save the patients and valuable drugs. Besides epidemiological surveillance sequencing would help to identify new drug targets, which can be used in the design of novel antibiotics.

Clinico-mycological and Antifungal Susceptibility Profiles of Candiduria in A Tertiary Care Hospital From South India

DINOOP KOROL PONNAMBATH, SWARAN KUMAR M, APPALARAJU BOPPE, KARTHIKEYAN SHANMUGAM

ABSTRACT

Introduction: *Candida* is one of the common causative agent of Urinary Tract Infections (UTI) worldwide. The most common reported species causing UTI is *Candida albicans*. Incidence of UTI due to non-albicans *Candida* species. is on rise in recent years because of their better adaptability and increased resistance to antifungals. Susceptibility profile reports of various *Candida* species. to newer azoles like voriconazole and beta-glucan inhibitors (e.g., caspofungin) are deficient in India, since the reference broth microdilution method is not widely utilized. In this study, a rapid reliable and easier alternative, VITEK 2 compact system was utilized to determine the antifungal susceptibility profile.

Aim: To analyse the clinical and mycological profile with determination of drug susceptibility pattern of *Candida* isolates from urine samples.

Materials and Methods: This observational study was conducted in PSG Institute of Medical Sciences and Research, during April to September 2015. *Candida* isolated with a colony count of ≥103 CFU/ml of urine from clinically suspected cases of UTI were included in the study. Urine samples (n=3821) from clinically suspected UTI cases (n=3821) were subjected to microscopic examination and semi quantitative estimation of yeast culture obtained by inoculated of calibrated volume of urine onto blood, Mac-conkey and HiCrome UTI agar. Clinical parameters of the cases were obtained for analysis. Speciation of *Candida* was performed using germ tube test, observation of morphology in corn-meal agar and pigment production in HiChrome *Candida* differential agar. Confirmation of the species identification and anti-fungal susceptibility profile were obtained using VITEK-2 compact system.

Results: Total 101 patients were identified with significant candiduria. Community-Acquired Candiduria (CAC) was seen in 11 (10.8%) of the cases. 23 (22.7%) cases of candiduria were associated with pyuria. Concomitant candidemia was observed in 4 (3.9%) cases of candiduria The most common species identified was *Candida* albicans (n=53, 52.4%). The commonest non-albicans *Candida* species causing significant candiduria cases were *C. glabrata* and *C. tropicalis* (n=18, 17.8% each). The antifungal susceptibility testing revealed an overall 94% susceptibility to amphotericin B, 89% susceptibility to flucytosine, 84% & 88% susceptibility to azoles, fluconazole and voriconazole respectively with 90% susceptibility to caspofungin. Significant high linear correlation existed between fluconazole and voriconazole resistance for *C. glabrata*, *C. albicans* and *C.tropicalis*. [Pearson's correlation coefficient, *C. glabrata* [r =1.00 (p<0.001)], *C. albicans* [r=0.91 (p<0.001)] and *C.tropicalis* [r=0.79 (p<0.001)].

Conclusion: *C. albicans* was found to the commonest species in our Tertiary Care Center in contrast to the reporting of non-*albicans Candida* species as the commonest species in most other recent studies. Determination of the antifungal susceptibility profile showed increasing trend of resistance to most antifungal agents, particularly azoles.

Keywords: Antibacterial agents, Antibiotics, Immunosuppression

INTRODUCTION

Candida species. has been reported as one of the common etiological agent of UTI, especially in a hospital setting. Advances in critical care management, immunosuppression and widespread use of antibacterial agents have led to their increased prevalence. Common risk factors associated with candiduria are extremes of age, diabetes mellitus, females in reproductive age group, structural abnormalities of the urinary tract, broad-spectrum antibiotic use, immunosuppression, indwelling catheters, abdominal surgeries, admission in ICU etc., [1]. Identification and susceptibility testing of the yeast helps targeted therapy of the infection and yields epidemiological

data for assessment of the prevalence and resistance pattern. Fungal UTI are mostly asymptomatic, occasionally can present with upper or lower urinary tract symptoms. Despite the lack of symptoms, increased colonization burden may predispose to invasive candidiasis particularly in debilitated individuals. It necessitates differentiation of asymptomatic and symptomatic candiduria since unnecessary treatment, catheter changes, and hospital prolongation can be avoided, since hospital cost burden and patient morbidity increases substantially. The scenario of presence of yeast in microscopic examination or isolation in culture needs to be evaluated with the clinical picture to determine its relevance and the decision on the commencement of antifungal therapy. Semi-quantitative/ quantitative urine culture is performed in evaluation of significant candiduria and a colony count of ≥1000 CFU/ml of urine, obtained in culture media in most situations represents significant candiduria. Significant candiduria occurs as 2 clinical presentations, asymptomatic and symptomatic candiduria. Patients with symptomatic candiduria need to be started on antifungal therapy, whereas asymptomatic candiduria needs to be interpreted with care. The significance of asymptomatic candiduria arises when the patient is severely debilitated/immunosuppressed, or is planned for urological instrumentation/procedures. Asymptomatic candiduria can also represent a picture of sample contamination (inappropriate collection) or colonization (in catheterized patients). In these cases, evaluating a repeat urine sample rules out contamination and colonization when the repeat sample has been collected after removal of indwelling catheter [2]. The most common reported species causing UTI is *Candida albicans* [3]. Incidence of Non-*albicans Candida* species. (e.g.: *C. glabrata*, *C. krusei*, *C. parapsilosis*, *C. tropicalis* etc.,) causing UTI have been increasingly reported due to enhanced adaptation potential and increased resistance to antifungal agents [4]. In the past few years, there has been emergence of drug-resistance in *Candida* species causing clinical infections, leading to high morbidity and mortality in hospitalized patients [5]. Testing for antifungal drug susceptibility in clinically significant *Candida* species isolates guides prompt treatment thereby improving the patient's outcome. Susceptibility profile reports of various *Candida* species. to newer azoles like voriconazole and beta-glucan inhibitors (eg: caspofungin) are deficient in India, since disc diffusion interpretation guidelines are not available for all antifungals and the reference broth microdilution method is not widely practiced. The VITEK 2 antifungal drug susceptibility determination system has emerged as an easier and an expeditious alternative to the reference broth microdilution method (CLSI and EUCAST) [6]. Studies report 95-100% essential agreement between the results of VITEK 2 and the reference methods [7,8]. This study was undertaken to analyse the clinical and mycological profile with determination of drug susceptibility pattern of *Candida* isolates from urine.

MATERIALS AND METHODS

This was an observational study conducted in PSG Institute of Medical Sciences and Research (PSGIMS&R) during the period April 2015 - September 2015 (6 months). The Institute's ethics committee approval was obtained before the conduct of the study. (IHEC approval number: 15/039).

Inclusion criteria: *Candida* being isolated with a colony count of ≥1000 CFU/ml of urine either in pure culture or as one among the 2 isolates obtained from urine samples collected from clinically suspected cases of urinary tract infection (UTI)/ screening prior to urological instrumentation/intervention of all ages and both sex.

Exclusion criteria: If growth of *Candida* with a colony count of <1000 CFU/ml of urine or when >3 types of growth was obtained.

Urine samples were received in sterile screw capped leak-proof container, immediately transported from the collection center to the microbiology laboratory and stored in refrigerator until further investigations were undertaken. Urine wet mount examination was performed to look for the presence of pus cells, epithelial cells, red blood cells, casts, crystals, budding yeast cells with/without pseudohyphae. The urine samples were inoculated onto blood, mac-conkey and chromogenic media (HiCrome UTI agar, HiMedia Laboratories) by a calibrated wire loop standardized to deliver 5µl for semi-quantitative estimation of yeast growth. The inoculated culture plates were incubated aerobically at 37°C for 24-48 hours. *Candida* isolates with colony count of ≥1000 CFU/ml of urine were considered significant and included in the study. Clinical parameters of the cases were obtained in the case study form which included age, sex, details of admission (outpatient/ ward/ICU), presence/absence of any risk factors like extremes of age (elderly and pre-mature neonates), diabetes mellitus, structural abnormalities of the urinary tract, broad-spectrum antibiotic use in preceeding 30 days, immunosuppression (neutropenia, HIV etc.,), indwelling catheters, abdominal surgeries and admission in ICU etc. Significant candiduria was classified as hospital-acquired and community-acquired. CAC was defined as candiduria observed in outpatients with no prior hospitalization or within 48 hours of hospitalization. When the onset of candiduria is >48 hours of hospitalization, it was classified as Hospital-Acquired Candiduria (HAC) [9]. Preliminary speciation of *Candida* was performed using Germ Tube Test (GTT), observation of morphology in corn-meal agar and pigment production in chromogenic medium (HiChrome *Candida* differential agar, HiMedia Laboratories) [10]. Confirmation of the species identification and anti-fungal susceptibility profile were obtained using VITEK-2 compact system (YST ID and AST card, bioMerieux, Marcy-l'Etoile, France) for the following antibiotics: amphotericin B, flucytosine, fluconazole, voriconazole and caspofungin. The VITEK 2 cards were stored at 2-8°C until testing was performed. An inoculum turbidity equivalent to 2.0 McFarland was prepared in sterile saline as per the manufacturer's instructions using the DensiChek instrument, for antifungal susceptibility testing [11]. *Candida albicans* ATCC 10231 was used as the control

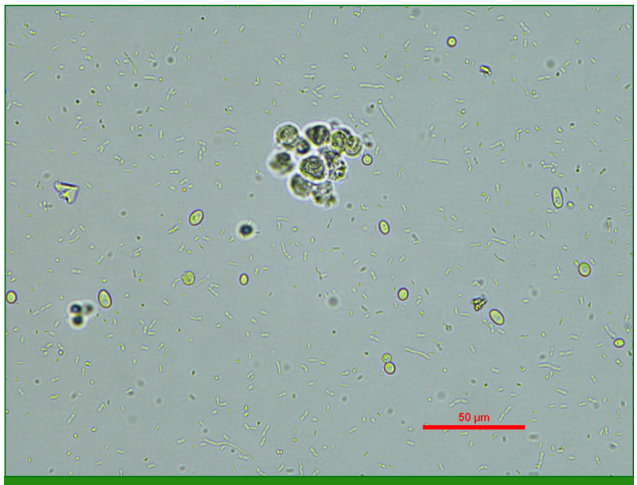
strain for the antifungal susceptibility testing.

STATISTICAL ANALYSIS

The data obtained were analyzed using SPSS software version 19. Fischer' exact/Chi-square test were used for comparative analysis and a p value of ≤0.05 was considered significant. Association/correlation between variables were analysed using Pearson's correlation coefficient (r).

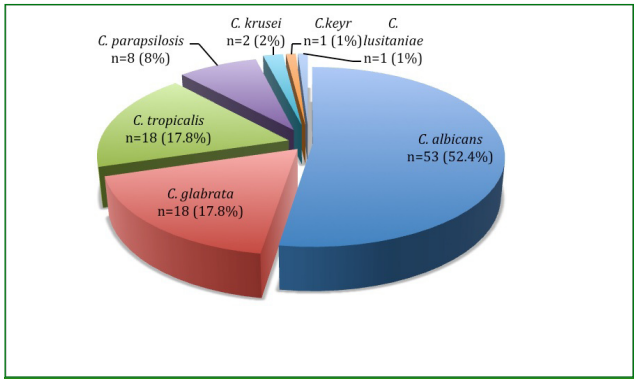
RESULTS

During the study period of April - September 2015 (6 months), 101 patients were identified with significant candiduria. The mean age of the study population was 55.9±16.9 years (Median age-60 years). The age distribution of the study population ranged between 12-89 years and the majority of the candiduria cases (76%) were observed in the 41-80 years age group with a peak observed in the 61-70 years age group [Table/Fig-1]. In the study population, males (n=56, 55.4%) were more commonly affected than females (n=45, 44.6%). Candiduria was observed more commonly in the in-patient wards (n=58, 57.4%), followed by intensive care units (n=32, 31.8%) and outpatient department (n=11, 10.8%).



Age Group (in years)	Number (n)
0-10	0
11-20	4
21-30	9
31-40	9
41-50	10
51-60	22
61-70	30
71-80	15
81-90	2

[Table/Fig-1]: Age distribution of the patients with significant candiduria.



Among the risk factors, the commonest cause was broad-spectrum antibiotic usage (67.3%) followed by indwelling foley's catheterisation (56.4%), diabetes mellitus (16.8%), immunosuppression (13.8%), previous abdominal surgeries (1.9%) and urinary tract structural abnormality (0.9%) [Table/Fig-2]. Among the broad spectrum antibiotics, cephalosporin (68%) and fluroquinolone (32%) were the common antibiotics observed to be used in patients with significant candiduria, in the preceeding 30 days. Pyuria was observed in 23 (22.7%) cases of significant candiduria [Table/Fig-3], while concomitant candidemia was observed in 4 (3.9%) cases. The various species of *Candida* identified in the candiduria cases are depicted in [Table/Fig-4]. The most common species of *Candida* identified was *Candida albicans* (52.4 %). A case of significant candiduria had both *C. albicans* and *Trichosporon* species. The commonest non-*albicans Candida* species causing significant candiduria cases were *C. tropicalis* and *C. glabrata* (18% each).

Risk Factors	Number (n)	Percentage (%)
Diabetes Mellitus	17	16.8
Structural abnormalities of Urinary Tract	1	0.9
Broad Spectrum Antibiotic usage	68	67.3
Immunosuppressive Conditions	14	13.8
Indwelling Foley's Catheter	57	56.4
Underwent Abdominal Surgeries	2	1.9

[Table/Fig-2]: Distribution of risk factors in patients with significant candiduria.

[Table/Fig-3]: Wet mount examination of urine from showing pus cells and budding yeast cells (Magnification – 400X).

[Table/Fig-4]: Frequency of *Candida* species in the study population.

The antifungal susceptibility testing revealed an overall 94% susceptibility to amphotericin B, 89% susceptibility to flucytosine, 84% and 88% susceptibility to azoles, fluconazole and voriconazole respectively with 90% susceptibility to caspofungin. Susceptible-Dose Dependent (SDD) for fluconazole was observed in 5 isolates (9.4%) of *C. albicans*, 2 isolates of *C. glabrata* and *C. tropicalis* (11.1% each). The species-based susceptibility profiles to the antifungal agents tested are provided in [Table/Fig-5]. A significant high linear correlation existed between fluconazole and voriconazole

Candida species	Sensitive									
	Amphotericin B		Flucytosine		Fluconazole		Voriconazole		Caspofungin	
	n	%	n	%	N	%	N	%	N	%
C. albicans	50	94.3	47	88.6	46*	86.7	47	86.7	48	90.5
C. glabrata	17	94	16	88.8	15*	83.3	15	83.8	17	94
C. tropicalis	17	94	16	88.8	15*	83.3	16	88.8	14	77.7
C. parapsilosis	7	87.5	7	87.5	7	87.5	7	87.5	8	100
C. krusei	2	100	2	100	1	50	2	100	2	100
C. kefyr	1	100	1	100	1	100	1	100	1	100
C. lusitaniae	1	100	1	100	1	100	1	100	1	100
All species	95	94	90	89	85	84	89	88	91	90

* includes susceptible-dose dependent (SDD) isolates

resistance for *C. glabrata* [Pearson correlation coefficient, r =1.00 (p<0.001)], *C. albicans* [r=0.91 (p<0.001)] and *C. tropicalis* [r=0.79 (p<0.001)].

DISCUSSION

Candiduria is a common nosocomial phenomenon and large scale observational surveys reveal *Candida* as the third most common organism isolated from urine in hospitalized patients [12]. During the study period, a total of 101 *Candida* species were isolated from cases of significant candiduria. Candiduria cases proportionally increased with age and were predominantly observed in the 41-80 years age group (76.2%). This observation could be due to the increased prevalence of co-morbid conditions like diabetes mellitus, benign prostatic hypertrophy, immunosuppression, frequent use of broad-spectrum antibiotics and foley's catheter etc. seen in the elderly age group. The median age and age distribution was similar to observational study reports by Nayman Alpat S et al., and Bobade O et al., [13,14].

Males and females were almost equally affected in our study population, whereas most reports from literature show the incidence of candiduria being more common in females [14,15]. Significant candiduria were observed commonly in hospitalized patients (inpatient and ICU settings) probably because of the presence of risk factors like broad spectrum antibiotic use, long term indwelling catheters and also to presence of other debilitating illness like uncontrolled diabetes commonly in the inpatient population than the outpatients. The broad-spectrum antibiotics implicated in cases of significant candiduria cases in our study population were cephalosporins (68%) and fluoroquinolones (32%) use in the preceding 30 days. There are documented reports of use of broad-spectrum antibiotics like cephalosporins attributing to causation of candiduria [16]. CAC was seen in 10.8% of the cases and the risk factors associated were diabetes mellitus, pregnant women and chronic indwelling catheters. Similar risk factors for CAC have been reported by Colodner R et al., [9].

Pyuria is defined as the presence of ≥3 leucocytes/hpf of unspun urine or ≥10 leucocytes per cubic mm of urine or positive dipstick test for leucocyte esterase [17]. In our study, 23 (22.7%) cases of candiduria were associated with pyuria. Pyuria is an important sign of candiduria yet lacks sensitivity and doesn't differentiate colonization from infection (lacks specificity) [18]. Concomitant candidemia was observed in 4 (3.9%) cases of candiduria. Studies report that approximately 1-8% of patients with candiduria particularly ICU admissions may have concomitant candidemia [3,12,19].

The commonest *Candida* species identified in our study was *Candida albicans* (52.4%), while non-*albicans Candida* species attributed to the remaining 47.6% of cases of significant candiduria. Among the non-*albicans Candida* species, *C. glabrata* and *C. tropicalis* were the common species isolated. Earlier multicentric reports on candiduria had similar findings of *Candida albicans* being the commonest species yet recent studies report the emergence of non-*albicans Candida* species as the commonest cause of significant candiduria due to the widespread use of antifungal agents for antifungal prophylaxis and treatment, particularly increasing incidence of *C. glabrata* and *C. krusei* infections which are intrinsically less susceptible to the commonly used azole drug, fluconazole [14,20,21]. Our report suggests relatively lower prevalence of non-*albicans Candida* species, in contrast to reports from other centers in India [22,23].

Analysis of the antifungal susceptibility pattern showed that most isolates were susceptible to amphotericin B. Resistance to the polyene drug, amphotericin B was observed in 6 isolates (6%) (3-*C. albicans*, 1-*C. tropicalis*, 1-*C. glabrata* and 1-*C. parapsilosis*). Increasing resistance was observed for azole group of drugs particularly fluconazole in non-*albicans Candida* species (16.7% for both *C. glabrata* and *C. tropicalis*, 50% for *C. krusei*) when compared to *C. albicans* (13.3%). These drugs (fluconazole and voriconazole) belong to triazole group of azoles and exert their action by inhibiting cytochrome P450-dependent enzyme lanosterol 14 alpha-demethylase. Voriconazole have better activity against *Candida* species (16-32 fold potent than fluconazole) due to effective binding to the cytochrome P450 enzyme. Yet, cross-resistance between fluconazole and voriconazole have been increasingly reported

in *Candida* species, particularly *C. glabrata* [24]. Pfaller et al, (2007) had reported the use of fluconazole as a surrogate marker to predict voriconazole susceptibility in resource-poor settings [25]. In our study, high cross-resistance correlation between azoles was observed in *C. albicans*, *C. glabrata* and *C. tropicalis*. One *C. glabrata* isolate was resistant to three classes of drugs (Polyene, azoles and β-glucan inhibitors). This is of high-concern because azoles and β-glucan inhibitors are increasingly recommended for prophylaxis, thereby leading to selection of drug-resistant non-*albicans Candida* strains [26,27]. The echinocandin, caspofungin had excellent activity against most *Candida* isolates, while 5 isolates of *C. albicans* (9.5%) and 4 isolates of *C. tropicalis* (22.3%) were found to be resistant. This observation predicts that echinocandins like caspofungin and micafungin may emerge in the recent future as the drug of choice for prophylaxis and treatment of cases with symptomatic candiduria.

LIMITATION

The limitation of our study was the lack of genomic characterization of the resistant isolates with MIC correlation and follow-up assessment of clinical/microbiological outcome.

CONCLUSION

This study describes the clinical profile and the distribution of various *Candida* species causing significant candiduria, where *C. albicans* was found to the commonest species in our Tertiary Care Center, in contrast to the reporting of non-*albicans Candida* species as the commonest species in most other recent studies. Although, *C. albicans* was the predominant cause of candiduria, increasing trend towards non-*albicans Candida* species causing significant candiduria was observed. Most health care centers in India do not routinely test for antifungal susceptibility for the clinical isolates due to the laborious phenotypic procedures, lack of expertise and lack of availability of updated interpretative guidelines, thereby leading to lack of drug-resistance data for fungal infections. Newer automated technologies like VITEK 2 compact system have emerged as an effective and promising alternative in determination of antifungal susceptibility thereby guiding prompt treatment and early detection of emerging drug resistance. In our study, antifungal susceptibility profile showed increased resistance to fluconazole and associated cross-resistance to voriconazole in commonly isolated *Candida* species., probably due to their increased usage for prophylaxis and treatment. Newer antifungal drugs like caspofungin and micafungin (echinocandins) are emerging as promising agents for prophylaxis and treatment of symptomatic candiduria. In addition, strengthening the hospital antimicrobial stewardship programs would taper this scenario of widespread drug resistance similar to Multi-Drug Resistant (MDR) bacterial isolates.

Declaration: A part of this study has been presented as a poster at the MICROCON 2015 conference organized by Jawaharlal Institute of Postgraduate Medical Education & Research (JIPMER), Puducherry. (Abstract available at http://microcon2015.co.in/abstracts/free_ePosters/Abstracts/abs-1153.html).

Prevalence of Vancomycin Resistant Enterococci Carriers from Rectal Swabs among High Risk Patients in a Tertiary Care Hospital

M MOHAMADIYA RIZWANA[1], S PARVATHI[2], B APPALARAJU[3]

(cc) BY-NC-ND

Keywords: Chromogenic media, *Enterococcus faecium*, *Enterococcus faecalis*, Urinary tract infections

Dear Editor,

Enterococci with acquired vancomycin resistance is a major concern amongst hospital. These resistant species have the ability to survive for prolonged periods and they can get transmitted easily. The infections caused by these organisms range from complicated Urinary Tract Infections (UTI) to life threatening Central Nervous System (CNS) infections making the treatment challenging [1]. The rate of Vancomycin Resistant Enterococci (VRE) colonisation in Northern India is nearly 34.5%, with *van A* genotype being the most common [2]. Studies have reported that active screening through rectal swabs is a definite tool in preventing complications in high risk patients by early identification and treatment of VRE carriers [3]. The conventional method of screening with bile esculin azide agar supplemented with 6 µg/mL of Vancomycin/ml is reasonably sensitive but requires confirmation by molecular techniques [4]. The molecular methods in the detection are limited to the referral laboratories. Development of highly specific chromogenic substrates in the VRE selective media help in effective screening of colonisers. The sensitivity and specificity of the chromogenic media was 100% and 99%, respectively [4]. This was in accordance to present study as well. This study was undertaken to screen the high risk patients in critical care for VRE colonisation from stool samples and identify the genotype. Early identification of the carrier state in high risk patients is helpful in planning the management strategy of these patients.

This was an observational study done over the period of three months from January to March 2016 at PSGIMS&R, Coimbatore, Tamil Nadu, India. The Institutional Human Ethical clearance number obtained was 14/118. Informed consent was obtained before collecting the rectal swabs. The criteria for high risk patients were defined as hospitalisation >7 days, chronic haemodialysis, use of multiple antibiotics and associated chronic disease status. Rectal swabs were obtained from 100 patients (no repeat isolates and the mean age group was 60 years 75% were males) following the identification as high risk as per the criteria explained above. The rectal swabs were streaked on chromogenic ChromID VRE media (Biomerieux) and incubated at 37°C for 24 hours. The presence of violet colour colonies indicated *Enterococcus faecium* and blue colour colonies indicated *Enterococcus faecalis*. Isolates with intrinsic resistance to vancomycin as *Enterococcus casseliflavus* and most of the other gram positive organisms were selectively inhibited by this media. Conventional biochemical tests as bile esculin, mannitiol, argininine and PYR (Pyrrolidonyl Arylamidase) were done for confirmation at the species level. The antibiotic sensitivity was also performed by Kirby Bauer method as per the CLSI guidelines [5]. The antibiotic susceptibility pattern of the 100 isolates showed the maximum sensitivity to linezolid (98%) followed by vancomycin (97%), erythromycin (89%), teicoplanin (75%), ampicillin (69.2%), high level gentamycin (49.2%) and penicillin (25%). The Minimum Inhibitory Concentration (MIC) of the resistant isolates was confirmed by using commercial E-strips. Molecular characterisation of the resistant isolates for the specific genotype was done by performing conventional PCR. The DNA from the resistant isolates was extracted using the QIAGEN kit. The primers of base pair 732bp for detection of *van A* were used. The PCR products were analysed by running gel electrophoresis and visualised under UV light in automated GEL DOC viewer. Primers for *van A* used were:

F (5' GGGAAAACGACAATTGC-3')

R (5'GTACAATGCGGCCGTCGTTA-3') [6]

Out of the 100 patients screened, three were found to be positive for VRE carriage (3%). All the three were *Enterococcus faecium*. The positive sample was used as the control strain. Analysis of the predisposing risk factors among the three patients revealed the association of chronic renal impairment, immunocompromised status (retroviral infection) and presence of co-morbid conditions such as diabetes mellitus along with prolonged hospital stay.

The VRE carriers can pose a risk to the patients harboring these pathogens as they can invade the host and result in bacteremia complicating the management. In such patients, treatment of the VRE carriage aids in better prognosis. Isolation and cohorting of these patients prevents the transmission and risk of infection in other patients, especially in healthcare setups. The choice of VRE screening can aid in proper infection control measures.

Thus, chromogenic VRE media was found to be a simple and rapid method for identifying VRE carriage.

Declaration: The present study was presented as poster presentation in 39th National Conference of the Indian Association of Medical Microbiologists MICROCON in 2015.

A B S T R A C T

Haemophilus influenzae is strictly a human pathogen, responsible for many diseases like community acquired pneumonia, meningitis, sinusitis, epiglottitis and otitis media. *Haemophilus* type b (Hib) was the most common strain responsible for all the infections. Non type b strains were at an emerging risk. Ampicillin was commonly used but resistance due to TEM-1gene is being reported. It is aimed to find out whether Hib continues to be isolated from childhood cases of pneumonia and its susceptibility to the drugs of choice and possible mechanisms of resistance. All purulent respiratory samples were processed for isolation of *Haemophilus influenzae*. They were identified based on its X&V factor requirement and a negative Porphyrin synthesis test. Biotyping and Serotyping was done using standard methods. Ampicillin resistance was characterized by phenotypic and genotypic methods. From the results, out of 1540 purulent respiratory samples, *Haemophilus influenzae* was isolated from 103 cases. Among the 103 isolates, 69 were Nontype b and 34 were type b *Haemophilus influenzae*. All the Hib isolates were from those above 20 years of age. Among 15 Ampicillin resistant isolates, 13 were positive for TEM-1 gene. Finally, Nontype b isolates were predominant and Hib was isolated only from adult age group.

Introduction

Haemophilus influenzae is strictly a human pathogen responsible for many diseases like community acquired pneumonia, meningitis, sinusitis, epiglottitis and otitis media (Mac Neil *et al.,* 2011). *Haemophilus influenzae* is a short pleomorphic Gram negative bacillary rod which is fastidious in nature. It is mainly recovered from the human respiratory tract and very rarely from other sites. The mode of spread of the infection is mainly airborne droplets (Puig *et al.,* 2014). Among the 6 capsulated strains (a, b, c, d, e, f) type b remains the most common cause of invasive diseases (Puig *et al.,* 2014; Jain *et al.,* 2006). Type b H. influenzae colonizes the respiratory tract of children at a rate of 2- 4% and this has shown substantial decrease after the introduction of the conjugate vaccine. Non typeable strains account for 25-35% of otitis media in children less than 5 years of age and exacerbations of chronic obstructive pulmonary disease in adults (Urwin *et al.,* 1996).

Haemophilus influenzae is confirmed by performing satellitism, in which the colony grows near a streak of Staphylococcus aureus. *Haemophilus influenza* is a fastidious organism which requires two important factors, namely, factor X (hemin factor) and factor V (Nicotinamide adenine nucleotide factor) for its growth. The detection of

porphyrins produced from b-Aminolevulinic acid is evaluated for use in speciation of the *Haemophilus* genus (Lund *et al.,* 1977). Porphyrin synthesis is positive for the non hemin requiring *H. parainfluenzae* and is negative for *Haemophilus influenzae* which requires both hemin and NAD factor for its growth.

Haemophilus influenzae can be classified in to eight biotypes based on three biochemical tests indole, Ornithine, urease and this has been used as an epidemiological marker for carriage in the upper respiratory tract. Of these biotypes, type b falls mostly in biotype I (Campos *et al.,* 2004).

Infections caused by *H. influenzae* were initially being treated with cell wall active agents like Ampicillin and protein synthesis inhibitors like Chloramphenicol. Now the favoured regimen is Ceftrioxzone, Tetracycline and Azithromycin (Barbour *et al.,* 1996; Guevara *et al.,* 2008).Some of the *Haemophilus influenzae* shows resistance to ampicillin which is mainly due to beta lactamase production. Beta lactamase may be due to two genes, TEM-1 and ROB-1 genes, but the most commonly isolated gene is the TEM-1 gene. Both phenotypic and genotypic methods were used to detect Ampicillin resistance (CDC, 1998).

The aim of this study is to identify the serotype predominance in childhood and adult cases of pneumonia and to know the whether the vaccination against Hib has had any effect on the serotype predominance in different age groups and whether the isolates are susceptible to the drugs of choice like Ceftrioxzone, tetracycline and Azithromycin. The study also characterizes resistance to Ampicillin, which was used as an empirical treatment by the clinicians in earlier days for upper respiratory tract infections.

Materials and Methods

Study population

The study was done during the period from March 2014 to August 2015. A total of 1540 purulent respiratory samples from patients suspected of having community acquired pneumonia were processed in our microbiology laboratory.

Isolation of *Haemophilus influenzae*

All samples as indicated above were inoculated on Chocolate agar, Fildes agar, Chocolate agar with antibiotics (Vancomycin, Bacitracin and Clindamycin), and Blood agar with Staphylococcus streak.

Blood agar (MacNeil *et al.*, 2011)

Blood agar was streaked with the sample along with Staphylococcus aureus and it was incubated at 37^0 C in the presence of 5-10% co_2 in a candle extinction jar for 24 hours. They form low, translucent, convex, pinpoint colonies around the staphylococcus which provides the factor V for its growth. The size of the colony decreases as it goes away from the staphylococcus streak. This is the satellite phenomenon shown by *Haemophilus influenzae*.

Chocolate agar (Kilian, 1976)

Heated blood agar or the Chocolate agar which provides both the hemin and NAD factor was streaked with the sample and it was incubated at 37^0 C in the presence of 5-10% co_2in a candle extinction jar for 24 hours. *Haemophilus influenzae* shows a shiny, tiny, smooth, flat colony which smells like wet fur.

Fildes agar (Campos *et al.*, 2004)

Fildes enrichment is an enzymatic digest of blood used to enhance the growth of fastidious organisms. The resultant digest is rich in growth factors including X and V factor required by *Haemophilus influenzae*. To the BHI chocolate agar of 100 ml, 5ml of Fildes enrichment broth was added and allow the media to set. The sample is streaked and incubated at 37^0C in the presence of 5-10% co_2in a candle extinction jar for 24 hours. Colony morphology is very similar to that on chocolate agar.

Chocolate agar with VBC (Harrison *et al.*, 2009)

The CHOC-VBC media was made by preparing chocolate agar and the following antibiotics were added in concentrations of 5 microgram/ml Vancomycin, 300 microgram/ml of Bacitracin, 1 microgram/ml of clindamycin 16.After that the media is allowed to dry and the samples are directly streaked on to the plates and incubated at 370C in the presence of 5-10% co_2in a candle extinction jar for 24 hours. *Haemophilus influenzae* shows a shiny, tiny, smooth, flat, slightly yellow colony which smells like wet fur.

Antibiotic susceptibility testing (Nag *et al.*, 2001)

Antibiotic susceptibility testing was done on chocolate agar for susceptibility to Ceftrioxzone, Azithromycin, Aztreonam, ciprofloxacin, ampicillin, tetracycline, Cotrimoxazole and Meropenem based on 2014 CLSI guidelines. Ampicillin resistant strains were then tested for beta lactamase production by acidimetric method. One of the genes responsible for beta lactamase production (TEM-1) was identified by conventional PCR. The following primers are used for detection of TEM-1 gene:-

5’TGGGTGCACGAGTGGGTTAC3’ and 5’TTATCCGCCTCCATCCAGTC3’

Porphyrin synthesis test (Campos *et al.*, 2004)

This test indicates the absence of requirement of X factor. If α-Amino levulinic acid is provided to the bacterium, it synthesizes it and excretes porphobilinogen and other porphyrins. This test is carried out by using kovac’s indole reagent (Para dimethyl amino Benzaldehyde) and formation of pinkish red colour in the lower water phase indicates the synthesis of porphyrin and absence of X factor requirement.

X and V requirement (Madore, 1996)

Make a lawn culture in the Muller Hinton agar plate and keep the commercially available discs X and V from HIMEDIA laboratories. The X factor (hemin) and V factor (Coenzyme- Nicotinamide adenine dinucleotide NAD+) are impregnated on the sterile filter paper discs of diameter 6 mm. If both X and V factors are

Typing

i) Biotyping was done using the biochemical tests as follows: - Indole production, Ornithine decarboxylation and urease production (Campos *et al.*, 2004).
ii) Serotyping was done using –Becton-Dickinson --- Kit.
iii)BD Difco catalogue no. Type b-222361
iv)Type a-222501
v) Type f-227921

Results and Discussion

Among the 1540 cases of suspected pneumonia, the purulent respiratory samples yielded. *Haemophilus influenzae* were noted in 103 cases. Out of 103 isolates, 84 were

from inpatient samples and 19 were from outpatient samples. Among 84 inpatient cases, 33% were associated with COPD, 26.2% with Bronchial asthma and 18.44% were provisionally diagnosed as pyrexia of unknown origin.

Distribution of *Haemophilus influenzae* in various age groups

Among the 103 *Haemophilus influenzae* isolates, 95 (92%) of them were isolated from patients above 20 years of age and 8 (7.7%) from below 20 years. Among the 95 strains of *Haemophilus influenzae* isolated from adults, 63 (61.2%) were in males and 40(38.8%) in female patients. The strains isolated were more during winter months of October to January (Figure 1).

Serotype

All the isolates of *Haemophilus influenzae* were serotyped with type b, type a and type f antiserum. A total of 34(33%) were type b and the remaining 69 were non-type b. Among the 69 non type b strains, 46.6% were other serotypes, 10.7% were type a and 9.7% were type f. (Figure 2). Comparison of *Haemophilus influenzae* serotype b in different age groups showed that all isolates of type b were from those above 20 years, whereas no type b were isolated from below 20 years and this is statistically significant ($p < 0.05$).

Biotypes

Haemophilus influenzae can be divided in to eight biotypes based on three biochemical tests, namely, Indole, Ornithine and Urease production. Out of the 103 *Haemophilus influenzae* isolates, strains belonging to all 8 biotypes were detected and 47 strains belonged to biotype I (Table 1).

Antibiotic sensitivity pattern

Antibiotic sensitivity testing of 103 isolates of *Haemophilus influenzae* showed that 91.2% were sensitive to Ceftrioxzone, 96.1% to Azithromycin, 99.02% to Aztreonam, 94.2% to ciprofloxacin, 85.4% to Ampicillin, 96.1% to Meropenem, 97.08% to Tetracycline and 65.04% to Cotrimoxazole.

Detection of Ampicillin resistance

Among the 103 isolates of *Haemophilus influenzae* isolated, 15(14.6%) strains showed Ampicillin resistance. Out of the 15 Ampicillin resistant strains, all 15 produced beta lactamases by acidimetric method and 13 showed presence of TEM-1 (Figure 3).

Haemophilus influenzae causes a variety of community acquired respiratory infections, including sinusitis, acute otitis media, bronchitis and community acquired pneumonia. Earlier, these infections were mainly caused by *Haemophilus influenzae* serotype b (Hib), but after the introduction of vaccines, the incidence of *Haemophilus influenzae* type b has markedly reduced.In our study, Non type b *Haemophilus influenzae* has emerged as an increasing cause of the pneumonia (67%) as compared to type b and this is similar to other studies also where it is isolated in 70-90% cases (Mac Neil *et al.*, 2011; Puig *et al.*, 2014) and Jain *et al.*, (2006).

Earlier studies done during the period from 1993-1997, show a high rate (86%) of isolation of Hib amongst children below 5 years of age (Lund *et al.*, 1977). Studies between 1996 and 2004 have reported lower isolations of 26-28% among children (Urwin *et al.*, 1996; Campos *et al.*, 2004 and Barbour (1996).

Among children in Asia and central European countries a considerable decrease has been demonstrated from 21 cases per 1, 00,000 populations per year in 1994 to 5 cases per 1, 00,000 populations per year by 2013 (MacNeil *et al.,* 2011; Puig *et al.,* 2014). A comparative study in Costa Rica have also reported a significant decline in the incidence of type b *H. influenzae* when the data from 1992 -1997 was compared with that between 1999 and 2004 (Guevara *et al.,* 2008). By June 2011, Hib vaccine was included in the National Immunization program of 170 countries in all regions of the world. After that the incidence of Hib invasive disease and oropharyngeal carriage in young children has drastically decreased to 0.3-0.7 cases per 1, 00,000 populations per year wherever vaccination programs have been implemented (Campos *et al.,* 2004; Barbour, 1996 and Madore, 1996). In our study none of the isolates were from cases below 20 years of age.

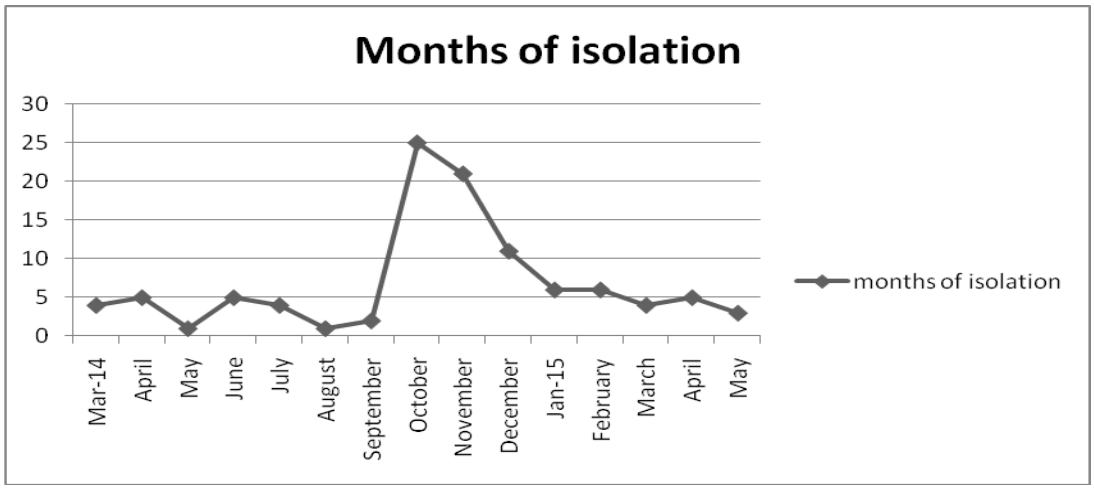
The *H. influenzae* isolates in this study were more commonly seen among male patients (61%), which are similar to other studies (Urwin *et al.,* 1996). In contrast, a study reports higher prevalence among female elderly patients, and a lower prevalence in female children (Mac Neil *et al.,* 2011). This infection has always shown a seasonal variation. Isolation of *H. influenzae* has shown higher incidence during winter months across many countries (Kilian, 1976; Zhu *et al.,* 2015). In our study also 61% were isolated during winter months. An increase in isolations during rainy season is also observed in some studies (Guevara *et al.,* 2008; Zhu *et al.,* 2015 and Leibovitz *et al.,* 2004).

In this study, strains belonging to all known biotypes were isolated and 44% were Biotype I whereas in other studies 60-70% belonged to this biotype (Landgraf *et al.,* 1993). COPD was an important risk factor for the development of *Haemophilus influenzae* pneumonia and their association was 25 to 30% percent in many studies (Jain *et al.,* 2006; Urwin *et al.,* 1996), when compared to 33% in our study. Association of *Haemophilus influenzae* with bronchial asthma cases were 26.2% in our study which correlated well with many studies where 28% association is noted (Jain *et al.,* 2006; Urwin *et al.,* 1996).

Ceftrioxzone being the drug of choice for invasive *H. influenzae* infections, 91% of our isolates were susceptible, and this correlated well (95%-97%) with other studies in both developed and developing countries (Zhu *et al.,* 2015; Harrison *et al.,* 2009). Infections caused by *Haemophilus influenzae*, particularly sinusitis and otitis media are now frequently treated with fluroquinolones and their sensitivity were 94% in our study which is comparable to other studies (Farrell *et al.,* 2005).

A susceptibility of 94.5% in 2012 as compared to 54% in the year 2000 was observed with tetracycline and this remarkable increase in susceptibility is reportedly due to decrease in its usage in the past 20 years (Bennett *et al.,* 2014). In this study also 97% of isolates were sensitive to tetracycline.

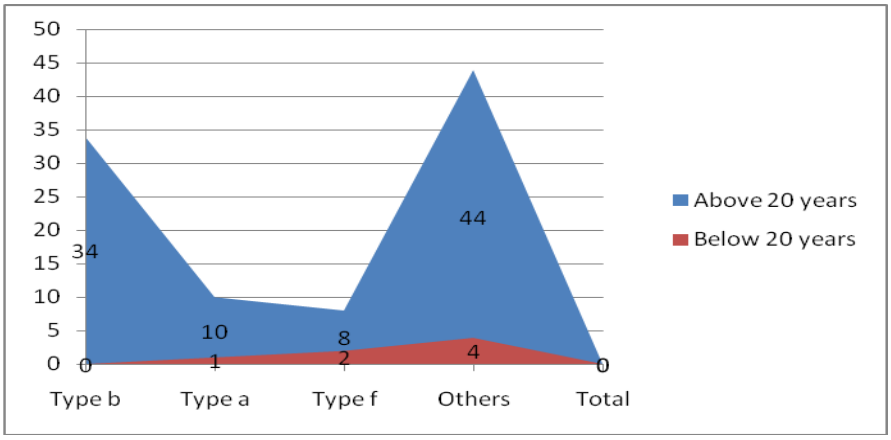
Azithromycin is an acid stable orally administered Macrolides antimicrobial drug that appears to be more active against many Gram-positive pathogens and several other Gram negative pathogens, notably *Haemophilus influenzae*. After oral administration, serum concentrations of Azithromycin are lower reflecting the rapid and extensive movements of the drug from the circulation into intracellular compartments resulting in increased tissue concentrations (Puig *et al.,* 2015). In our study 99% were susceptible to Azithromycin, which was similar to other studies (Appelbaum *et al.,* 2003; Jacobs *et al.,* 1999; Doern *et al.,* 1997).



High level resistances to Macrolides in *H. influenzae* (0.5%-2%) are rare as is reported in many studies (Appelbaum *et al.,* 2003; Jacobs *et al.,* 1999; Doern *et al.,* 1997). Macrolides are of particular use in children who are allergic to beta lactams (Jacobs *et al.,* 1999). There was no difference in susceptibility between type b and non-type b isolates to Ceftrioxzone, tetracycline, Azithromycin and ciprofloxacin (Zhu *et al.,* 2015; Nag *et al.,* 2001).

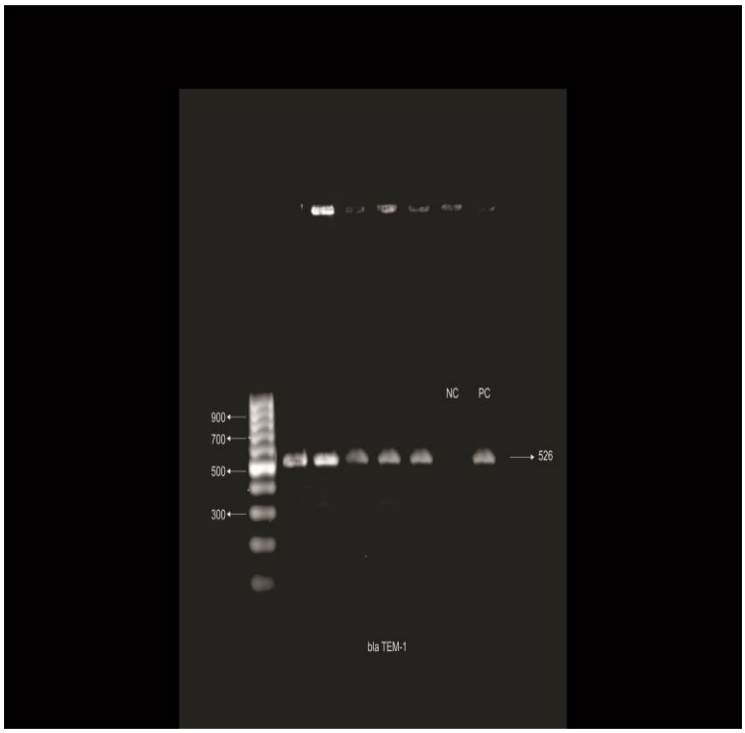
Table.1 Biotype distribution among different isolates of *Haemophilus influenza*

Biotypes	Number of isolates showing different biotypes	Percentage
I	47	45%
II	6	6%
III	5	5%
IV	1	1%
V	2	2%
VI	5	5%
VII	4	4%
VIII	33	32%



Haemophilus influenzae isolates, strains belonging to all 8 biotypes were detected and 47 strains belonged to biotype I (Table 1).

Fig.1 Seasonal variation of *Haemophilus influenzae*



The strains isolated were more during winter months of October to January

Fig.2 Serotypes in different age groups

No type b was isolated from below 20 years and this is statistically significant ($p < 0.05$)

Fig.3 TEM-1 gene detection by PCR

Beta lactamase mediated resistance was seen in 14.6% isolates in this study, whereas in multicentre studies done in US between 1984-1999 it was 15% to 36 % (Nag *et al.*, 2001) and in recent studies done in China, the percentage of Ampicillin resistant strains progressively increased from 4% in the year 2000 to 29% in 2012 (Zhu *et al.*, 2015). The resistance detected was higher among type b (60%) strains when compared to non type b strains (40%) which is similar to study by Nag *et al.*, (30% and 20%) suggesting that the strains that are invasive is showing a higher ampicillin resistance (Nag *et al.*, 2001).

All the ampicillin resistant isolates produced beta-lactamase enzyme when screened by the phenotypic acidimetric method, but when

analyzed by molecular method, only 13 isolates (86%) were positive for TEM-1 gene which is similar to many studies where the detection of TEM-1 gene (93%) is more when compared to the ROB-1gene (5%) detection (Hasegawa *et al.,* 2003; Farrell *et al.,* 2005 and Kuvat *et al.,* 2015).

ABSTRACT

Background: Highest intensity of soil transmitted helminthiasis (STH) is seen among school age children. The objective of this study is to find out the prevalence and factors associated with STH infection among school age children of 5-14 years in a rural area of Coimbatore district.
Methods: After getting ethical clearance, five of the fourteen villages of Vedapatti were selected by cluster sampling method. Totally 819 participated in the survey conducted between November 2015-July 2016 in the field practice area. Consent from parents and assent from child were obtained. Structured questionnaire was used to collect information. Totally 610 gave one adequate stool sample. Early morning samples were collected and transported to the laboratory within four hours. Formal ether concentration method was performed and examination was done. Data analysis was done with SPSS-19 software. Prevalence is expressed in percentage with 95% confidence interval (CI). Univariate and Multivariate analysis were performed. Strength of association was expressed in terms of odds ratio and adjusted odds ratio with 95% confidence interval. P value <0.05 was considered as statistically significant.
Results: The prevalence of STH was 7.70% (95% CI: 5.58- 9.82). Ascaris lumbricoides was highly prevalent 6.9% (4.89% to 8.91%) followed by hook worm 0.2(0.15% to 0.55%) and Trichuris trichura 0.7%(0.04% to 1.36%). Uni variate and Multivariate logistic regression analysis showed that pucca houses offered protection against STH.
Conclusions: STH is still a public health problem in Coimbatore. When regular deworming is accompanied by appropriate sanitation and hygiene activities designed to prevent re infection of STH, a long-term impact can be achieved.

Keywords: Soil transmitted helminthiasis, Prevalence, School age children, Coimbatore

INTRODUCTION

The soil-transmitted helminthes (STH) causing major illness among human beings are *Ascaris lumbricoides*, *Trichuris trichiura*, *Necator americanus* and *Ancylostoma duodenale*.[1] STH are considered Neglected Tropical Diseases (NTDs). [2] STH affects more than one fourth of the world's population, and it is reported more in tropical and subtropical areas.[3] The greatest numbers of cases are occurring in sub-Saharan Africa, the Americas, China and East Asia.[4] In India the reported prevalence of STH infection varied from 7.8% to 92.6%.[5-9] The reported prevalence varies according to the place and time of the study conducted.

The highest intensity of soil transmitted helminthes occur in school age children.[10] Children in their schooling age do not fully understand the connections between illness and behaviour.[11] It has been demonstrated that children often than adults tend to go barefoot, resulting in more contact with soil, and they often fail to use sanitary facilities even when they are present.[12] STH infections are considered as an important cause of sickness absenteeism. They are accounting for loss of 12.3% and 11.4% of disability adjusted life years (DALY) in girls and boys respectively .[13] Over 270 million preschool-age children and over 600 million school-age children live in areas where sanitation is poor and these parasites are intensively transmitted.[14] In India more than 241 million children are at risk of parasitic worm infections. Ministry of Health and Family Welfare (MoHFW), Government of India launched the National Deworming Day (NDD) on Feb 10, 2015. NDD aims to de-worm all children between the ages of 1 to 19 years.[15] The tablets were supplied to children through Government, Government-aided and private schools, and Anganwadi centers.

When regular deworming is accompanied by appropriate sanitation and hygiene activities designed to prevent re-infection, a long-term impact can be achieved Epidemiological studies are needed to identify risk factors which may represent critical control points. There is no recently published article on prevalence of soil transmitted helminthes in Coimbatore, where open air defecation is a common practice. As per 2011 census, 46% of the households in Coimbatore district lack toilets. Hence this cross sectional study was conducted with the objective of finding the prevalence and risk factors associated with soil transmitted helminth infections in school age children of 5-14 years in a rural area of Coimbatore district.

METHODS

The study was conducted in the field practice area of the Rural Health Training Centre (RHTC) Vedapatti, Coimbatore. RHTC caters to a total population of 23,841 distributed in 14 villages of Thondamuthur and Madukarai block of Coimbatore district. The total number of school aged children of 5–14 years is 3266.

Ethical clearance was obtained from IHEC, in 2014. The sample size was calculated to be 819 assuming 34.5% as prevalence , relative precision of 15%, design effect of 2, and non-response rate of 20%.[16] Five out of fourteen villages were selected by cluster sampling method. House to house survey was conducted in the five villages during November 2015 to July 2016. All school-age children (aged 5–14 years) who were permanent residents of Vedapatti field practice area of RHTC were included in the study. Children who were not available on three visits within a week time were excluded from the study.

At the home setting, after getting consent from the parent and assent from the child any of the parents of the child was interviewed in the evening hours of the day. A structured questionnaire was used to collect information on demographic, socioeconomic and environmental information like availability of type of drinking water and availability of functioning sanitary toilet etc. Few questions were asked regarding the knowledge and attitude of the parents on STH. Respondent was asked to give comment on the personal hygiene practices of childlike washing hands with soap before taking food and after defecation, eating fallen foods on the floor, wearing foot wear outside the house and intake of de-worming tablets in the last three months. Observations were also made regarding the personal hygiene of the children related to STH like clipped nails etc. Knowledge and attitude score was generated from the correct responses for the knowledge and attitude questions. The correct responses were given a score of one, and maximum score one could get was nine. Score five and above was considered as adequate knowledge and attitude score.

At the end of survey a screw-capped plastic container with identification of the child was given to collect the stool sample of the child on the next morning. Instructions regarding stool collection were given. The stool samples were transported to microbiology lab within four hours of sample collection. Stool samples were examined by saline wet mount and Iodine wet mount .[17] Iodine preparations was done for better visualization of morphological details of ova. All Samples were re-examined after concentrating with WHO recommended.[18] Formalin-Ether sedimentation method (FES). To reduce human error, duplicate slides (both direct and after concentration method) were prepared from each sample and the slides were read by two different Microbiologists and the opinion of Chief Microbiologist was considered as final. [19]

Statistical analysis

Data entry was made in the Microsoft Excel software in codes and analysis was done using SPSS-19 computer package. The Presence of ova of *Ascaris lumbricoides*, *Trichuris trichiura*, *Necator americanus* and *Ancylostoma duodenale* was considered as dependent variable. Prevalence is expressed in percentage with 95% confidence interval (CI). Uni-variate analysis and logistic regression were performed to find the associations between independent variables and dependent variables. Strength of association was expressed in terms of odds ratio and adjusted odds ratio with 95% CI and p value <0.05 was considered as statistically significant.

RESULTS

The results of this study are based on only 610 children, who gave one adequate stool sample. Totally 819 children participated in the survey, hence the non-response rate was 24.42%. Analysis showed that more number of risk group (29.13%) were found among the non-responders when compared to younger children (22.72%, p=0.02).

The distribution of study population and their risk factors is shown in (Table 1 and 2). The mean age of the study population was 8.92±2.68. Among them Children below ten year, female participants (52.1%), children belonged to nuclear family (62.1%) and children belonged to low socio economic status (52.3%) class IV and V according to modified Prasad classification were found in majority. Illiteracy was found among 20.2% of mothers 16.1% of fathers. Open air defecation was found among 33.4% of the children. Regarding the toilet usage only 50.7% of the children were using the toilets in the home. Around 66% did not wash their hands with soap before taking food. And 44.6% did not wash their hands with soap after defecation around 63 % children regularly used foot wear and around 70% of the children had trimmed nail during the visit. Nearly half of the parents of children were having adequate knowledge on STH. Only 59% reported intake of de-worming tablets in the last three months.

Table 1: Association of STH with socio economic and demographic factors by univariate and multivariate analysis.

Factors	Category	STH		Unadjusted odds ratio (95% CI)	Adjusted odds ratio (95% CI)	P value
		Yes	No			
Age (years)	≥10	24	229	1.52 (0.80-2.90)	1.45 (0.78-2.7)	0.24
	<10	23	334	1	1	
Sex	Male	24	268	1.15 (0.60-2.18)	1.07 (0.58-2.00)	0.82
	Female	23	295	1	1	
Total number of family members	Less than 4	22	253	1.08 (0.56- 2.05)	1.21 (0.64- 2.27)	0.55
	Four and above	25	310	1		
Type of house	Pucca house	4	115	0.36 (0.09-1.03)	0.34 (0.10- 0.91)	0.05
	Others (semipucca, kutcha house)	43	448	1	1	
Mother's educational status	Illiterate	10	113	1.08 (0.46-2.29)	1.03 (0.43- 2.30)	0.94
	Literate	37	450	1	1	
Socio economic status (modified prasad scale)	Lower SES (Class IV,V)	26	293	1.14 (0.60-2.19)	1.10 (0.56-2.20)	0.78
	High SES (Class I,II,III)	21	270	1	1	

Table 2: Association of STH with Risk factors by univariate and multivariate analysis.

Factors	Category	STH		Unadjusted odds ratio (95% CI)	Adjusted odds ratio (95% CI)	P value
		Yes	No			
Open air defecation	Yes	16	188	1.03 (0.51-2.00)	1.10 (0.56-2.20)	0.68
	No	31	375	1	1	
Type of safe drinking water	Pipe water	36	427	1.04 (0.50-2.33)	0.93 (0.45-2.06)	0.86
	Others (UV/ RO/ boiled water)	11	136	1	1	
Habit of eating unwashed vegetables	Yes	13	168	0.90 (0.42-1.80)	0.82 (0.38-1.72)	0.61
	No	34	395	1	1	
Habit of eating foods fallen on ground	Yes	1	21	0.56 (0.01-3.66)	0.62 (0.03-3.30)	0.65
	No	46	542	1	1	
Washing with soap before eating	No	27	313	1.08 (0.57-2.08)	0.89 (0.40-1.93)	0.76
	Yes	20	250	1	1	
Washing with soap after Toilet	No	24	248	1.32 (0.70-2.52)	1.57 (0.71-3.51)	0.27
	Yes	23	315	1	1	
Regular foot wear usage	No	16	207	0.89 (0.44-1.72)	0.92 (0.46-1.79)	0.81
	Yes	31	356	1	1	
Nail clipping	No	11	175	0.68 (0.30-1.40)	0.63 (0.28-1.34)	0.25
	Yes	36	388	1	1	
Deworming during past three months	No	22	228	1.29 (0.68-2.45)	1.43 (0.76-2.66)	0.26
	Yes	25	335	1	1	
Knowledge attitude score regarding STH	Inadequate	25	296	1.02 (0.54-1.96)	0.90 (0.47-1.72)	0.75
	Adequate	22	267	1	1	

The prevalence of STH among 610 children who had given one adequate stool sample and whose parents participated in survey was 7.70% (95% CI: 5.58-9.82). Among all STH, *Ascaris lumbricoides* was highly prevalent 6.9% (95% CI: 4.89-8.91) followed by hook worm 0.2% (95% CI: 0.15-0.55) and *Trichuris trichura* 0.7% (95% CI: 0.04-1.36).

There was no significant association found between STH and factors influencing STH by univariate analysis. Since none of the factors came as significant in univariate analysis, all independent variables were subjected to multivariate logistic regression analysis. Only pucca houses offered protection OR 0.36 [95% CI: 0.09-1.03] against STH, by multivariate analysis.

DISCUSSION

Relatively high non response rate (24.42%) was noted in this study. It is also evident from a similar study by Shubha et al that surveys involving bio samples shows high non response rate (30.9%) when compared to simple questionnaire based surveys.[20]

The prevalence of STH in the study population is 7.7% (95% CI 5.58- 9.82). Results of current study were lesser than other studies conducted in the nearby areas.

The explanations for low prevalence are more number of risk group (29.13%) were found among the non-responders compared to younger children (22.72%, p=0.02). The study results were based on single stool sample, Modified Formol-ether concentration (FEC) method with low sensitivity (63.1%) which could have estimated the low prevalence. [21]The other probable explanations are Mass Drug Administration under National Deworming Day (NDD) might have changed the scenario.[5-9] However there is no sufficient data from to compare prevalence before de-worming in this area to support this statement. Coimbatore first round of National De-worming Day was just completed and second round was on- going at the time of the survey (Febraury 2016). Kattula et al also explains the reason for low prevalence of STH (7.8%) in Vellore area is due to Albendazole supplied in Mass Drug Admininistation (MDA) along with Diethylcarbamazine since 2004.[8] Deworming using Albendazole rapidly declines the overall prevalence of STH, and this is evident from Mani et al study on efficacy of Albendazole in Tamilnadu.[22] However there are other studies reported with higher prevalence in nearby areas. Kaliappan et al explains the reason for the increased prevalence (39%) in Thiruvanamalai District in the year 2013 could be due to five stool samples collected among tribal population where open air defecation and bare foot walking were common practice.[23] Ragunathan et al explains the reason for higher prevalence (34.56%) reported in Pudhuchery, a coastal area using FEC method in year 2006 is due to poor hygienic practices of the participants.[16]

This study showed the most common soil transmitted helminth as *Ascaris lumbricoides* with the prevalence of 6.9% (95% CI 4.89-8.91) followed by Hook worm 0.7% (95% CI 0.04%-1.36%) and *Trichuris Trichura* 0.2% (95% CI 0.15-0.55). In general studies showed that *Ascaris* and *Trichuris* were more common among urban children and hookworm infestation among rural children.[24]

Regarding the factors influencing STH pucca houses offered protection OR 0.36 [95% CI 0.09-1.03] against STH, by multivariate analysis. A cross sectional study by Kattula et al showed that children living in Hut/ Kutcha houses, are at higher risk for STH.[8]

Kattula et al also showed that children of more than 10 years of age, living in households without toilet, open air defecation, unhygienic practices like keeping untrimmed nails are important risk factors for STH.[8] Kattula showed that consumption of deworming tablets offered protection. However there was no significant association between STH and factors influencing STH noted in this study.[8]

The major limitations of the study are, the results were based on single stool sample which could have estimated the low prevalence. The newer techniques with higher sensitivity would have given higher prevalence. Sample size was not adequate to comment on factors influencing STH. This is a cross-sectional study; hence the cause-effect relationship cannot be determined

In Asia, several countries, notably Japan, South Korea and Taiwan, showed that they have achieved sustained and successful control of STH infections over the last forty years (WHO, 1996). More recently, Sri Lanka has reduced prevalence to less than five percent.[25]

CONCLUSION

It is evident from our results that soil-transmitted helminth (STH) infections can be controlled by improving the coverage of NDD, and NDD should be evaluated for further control. Open air defecation is a biggest concern (33.4%), hence more private, public toilets should be built in this area. The children should be trained to use toilet facilities either private or public. It is also very important to raise the awareness about these infections, hence parents of children with inadequate knowledge should be given Health education. Regular deworming if accompanied by appropriate sanitation and hygiene activities designed to prevent reinfection, a long-term impact can be achieved.

Background: Levonadifloxacin is a novel antibiotic belonging to the benzoquinolizine subclass of fluoroquinolones with potent activity against MRSA and quinolone-resistant *Staphylococcus aureus*. IV levonadifloxacin and its oral prodrug alalevonadifloxacin have recently been approved in India for the treatment of acute bacterial skin and skin structure infections (ABSSSIs) including diabetic foot infections.

Objectives: To investigate the *in vitro* activity of levonadifloxacin against contemporary clinical isolates collected from multiple tertiary care hospitals across India in the Antimicrobial Susceptibility Profiling of Indian Resistotypes (ASPIRE) surveillance study.

Methods: A total of 1376 clinical isolates, consisting of staphylococci ($n = 677$), streptococci ($n = 178$), Enterobacterales ($n = 320$), *Pseudomonas aeruginosa* ($n = 140$) and *Acinetobacter baumannii* ($n = 61$), collected (2016–18) from 16 tertiary hospitals located across 12 states in India, were included in the study. The MICs of levonadifloxacin and comparator antibiotics were determined using the reference agar dilution method and broth microdilution method.

Results: Levonadifloxacin exhibited potent activity against MSSA ($MIC_{50/90}$: 0.5/1 mg/L), MRSA ($MIC_{50/90}$: 0.5/1 mg/L) and levofloxacin-resistant *S. aureus* ($MIC_{50/90}$: 1/1 mg/L) isolates. Similarly, potent activity of levonadifloxacin was also observed against CoNS including MDR isolates ($MIC_{50/90}$: 1/2 mg/L). Against *Streptococcus pneumoniae*, levonadifloxacin ($MIC_{50/90}$: 0.5/0.5 mg/L) showed superior activity compared with levofloxacin ($MIC_{50/90}$: 1/2 mg/L). Among levofloxacin-susceptible Enterobacterales, 80.6% of isolates were inhibited at $\leq$2 mg/L levonadifloxacin.

Conclusions: Levonadifloxacin displayed potent activity against contemporary MRSA and fluoroquinolone-resistant staphylococcal isolates, thus offering a valuable IV as well as an oral therapeutic option for the treatment of ABSSSIs. Furthermore, levonadifloxacin exhibited a broad-spectrum activity profile as evident from its activity against streptococci and levofloxacin-susceptible Gram-negative isolates.

Introduction

Levonadifloxacin is a broad-spectrum anti-MRSA antibiotic belonging to the benzoquinolizine subclass of fluoroquinolones. IV levonadifloxacin (WCK 771) and its oral prodrug alalevonadifloxacin (WCK 2349) are being developed for the treatment of acute bacterial skin and skin structure infections (ABSSSIs), hospital-acquired bacterial pneumonia (HABP) and community-acquired bacterial pneumonia (CABP). Both WCK 771 and WCK 2349 have completed a Phase 3 clinical study (Clinical Trial Registry India, CTRI/2017/06/008843) and have been recently approved in India for the indication of ABSSSIs. The *in vitro* activity of levonadifloxacin against staphylococcal and streptococcal clinical isolates collected from India, the USA and Europe[1–4] has been reported earlier. Levonadifloxacin has also been comparatively evaluated against 12 474 clinical isolates as a part of the 2014 global SENTRY surveillance programme.[5] These studies established potent activity of levonadifloxacin against diverse resistotypes, such as MRSA, quinolone-resistant *Staphylococcus aureus* (QRSA), macrolide- or penicillin-resistant streptococci and quinolone-susceptible Gram-negative bacteria. These studies also showed that, similar to other fluoroquinolones, levonadifloxacin lacks therapeutically relevant activity against quinolone-resistant Gram-negative bacteria.

Though India is known for a high level of antibiotic resistance burden, large-scale hospital-based surveillance data encompassing diverse regions of the country are scarce. Most epidemiological studies are limited to a single or a few hospitals and report antibiotic susceptibilities based on disc diffusion testing. For instance, the only pan-India surveillance data reported by the Indian Council for Medical Research involves a limited number of centres with susceptibility rates reported solely based on disc diffusion testing.[6] In order to generate antimicrobial susceptibility data based on MIC determination, a nationwide surveillance study [Antimicrobial Susceptibility Profiling of Indian Resistotypes (ASPIRE)], with the participation of 16 medical centres across India, was initiated in 2016. The objective of the present study was to assess the *in vitro* activity of levonadifloxacin against contemporary Indian clinical isolates. Antimicrobial susceptibility testing was performed using the reference agar dilution method and broth microdilution method to assess the activities of levonadifloxacin and 20 comparator antibiotics (vancomycin, linezolid, ciprofloxacin, moxifloxacin, levofloxacin, penicillin G, oxacillin, amoxicillin/clavulanate, piperacillin/tazobactam, cefepime, imipenem, meropenem, clarithromycin, azithromycin, clindamycin, gentamicin, amikacin, tobramycin, tigecycline and colistin) against contemporary clinical isolates collected between January 2016 and June 2018.

Materials and methods

Bacterial isolates

A total of 1376 clinical isolates, consisting of staphylococci ($n = 677$), streptococci ($n = 178$), levofloxacin-susceptible Enterobacterales ($n = 320$), *Pseudomonas aeruginosa* ($n = 140$) and *Acinetobacter baumannii* ($n = 61$), collected from January 2016 to June 2018 as part of the ASPIRE surveillance study, were included in this study. Levofloxacin-susceptible isolates accounted for 31.5% of total Gram-negative isolates collected in the ASPIRE surveillance study against which levonadifloxacin activity is presented. Sixteen tertiary care hospitals, located in 12 Indian states, participated in this study (Figure S1, available as Supplementary data at *JAC* Online). The inclusion criterion for participant patients was a minimum of 2 days of hospitalization in any of the following hospital departments: surgery, medicines, burns, ICUs, transplantation units and gynaecology. Only one isolate per patient (episode) was included in the study. Bacterial species were confirmed at a central laboratory (Metropolis Healthcare Ltd, Mumbai, India) using MALDI-TOF-based VITEK® MS (bioMérieux). Pure cultures were dispatched to Wockhardt Research Centre (Aurangabad, India) for MIC-based susceptibility testing. Prior to MIC determination studies, cultures were revived and passaged twice in tryptone soya agar (HiMedia, India) medium.

Antimicrobial susceptibility testing

MICs of antibiotics were mostly determined using the reference agar dilution method as described by CLSI.[7] The broth microdilution method was used for determination of MICs of colistin and tigecycline as recommended by CLSI.[7] Levonadifloxacin, clarithromycin, linezolid and clavulanic acid were synthesized at Wockhardt Research Centre. Penicillin G, piperacillin and oxacillin were procured from Sigma, USA. Other antibiotics were recovered from their respective commercial preparations and purity was ascertained by HPLC analyses. Since the final breakpoints have yet to be assigned, the proportions of strains inhibited by levonadifloxacin at 4 mg/L (proposed pharmacokinetic/pharmacodynamic breakpoint) have been reported. Susceptibility to other antibiotics was interpreted based on EUCAST (v 9.0) breakpoints.[8] *Escherichia coli* ATCC 25922, *S. aureus* ATCC 29213 and *Streptococcus pneumoniae* ATCC 49619 were included in each run as quality control strains.

Results

The clinical indication-wise distribution of Gram-positive and Gram-negative isolates is provided in Table S1. Isolates were recovered from documented ABSSSIs ($n = 501$), HABP ($n = 296$), urinary tract infections ($n = 180$), bloodstream infections ($n = 195$), intra-abdominal infections ($n = 50$) and other infection sources ($n = 154$).

Table 1 provides the cumulative distribution of levonadifloxacin MICs for the various resistant subsets. Table 2 presents MIC ranges, MIC_{50} values, MIC_{90} values and percentage susceptibilities for levonadifloxacin (percentage inhibition at 4 mg/L) and comparator antibiotics for *S. aureus* ($n = 390$). Based on susceptibility interpretive criteria for oxacillin, 49% of *S. aureus* were designated as MRSA phenotypes and, based on resistance to levofloxacin, 79% were QRSA. Levonadifloxacin exhibited potent activity against *S. aureus* including MSSA, MRSA and QRSA phenotypes, with MIC_{50} values being 0.5, 0.5 and 1 mg/L, while MIC_{90} values were 1, 1 and 1 mg/L, respectively. Notably, the MICs of levonadifloxacin for these groups of isolates were 4 times and 8–32 times lower than those of

[a]Viridans group streptococci: *Streptococcus mitis/oralis* (*n* = 19), *Streptococcus salivarius* ssp. *thermophilus* (*n* = 1), *S. salivarius* (*n* = 1), *Streptococcus sanguinis* (*n* = 1), *Streptococcus infantarius* ssp. *coli* (*n* = 1) and *Streptococcus constellatus* (*n* = 2).
[b]Group B and C streptococci: *Streptococcus agalactiae* (*n* = 27) and *Streptococcus dysgalactiae* (*n* = 6).
[c]IE indicates that there is insufficient evidence that the organism or group is a good target for therapy with the agent as mentioned in EUCAST (v 9.0) breakpoints.

moxifloxacin and levofloxacin, respectively. At a levonadifloxacin pharmacokinetic/pharmacodynamic breakpoint of 4 mg/L, 98.7%, 99% and 98.4% of all *S. aureus*, MRSA and QRSA were inhibited, respectively. There was little or no resistance to vancomycin, linezolid and tigecycline among *S. aureus*.

Despite 71.1% methicillin resistance and 70.7% levofloxacin resistance, levonadifloxacin displayed potent activity against CoNS with MIC_{50} and MIC_{90} values of 0.5 and 1 mg/L, respectively (Table 3). CoNS (*n* = 287) isolates consisted of *Staphylococcus haemolyticus* (*n* = 135), *Staphylococcus hominis* (*n* = 55), *Staphylococcus epidermidis* (*n* = 74) and other CoNS species (*n* = 23). For these isolates, levonadifloxacin was 4 times more active than moxifloxacin and 16–32 times more active than levofloxacin. At 4 mg/L levonadifloxacin, 97.2% of CoNS isolates were inhibited (Table 1).

Table 4 provides the activity of levonadifloxacin and other antibiotics against streptococci. Against *S. pneumoniae* (*n* = 62), levonadifloxacin demonstrated significantly lower MICs with an MIC_{90} of 0.5 mg/L, which was four times lower than that of levofloxacin. Considering a levonadifloxacin-susceptible breakpoint of 4 mg/L, 98.4% of these isolates were found to be susceptible to levonadifloxacin (Table 1). The *S. pneumoniae* isolates showed 75.8% azithromycin resistance and 41.9% clindamycin resistance. The isolates exhibited a meagre susceptibility rate to penicillin G of 27.4%. Levonadifloxacin exhibited potent activity against *Streptococcus pyogenes* (*n* = 58) with an MIC_{90} value of 1 mg/L, which was one dilution less than that of levofloxacin. Against viridans group streptococci (*n* = 25), levonadifloxacin showed limited activity. Levonadifloxacin showed good activity against group B and C streptococci (*n* = 33), with MIC_{50} and MIC_{90} values of 0.25 and 8 mg/L, respectively (Table 4).

Levonadifloxacin was also tested against levofloxacin-susceptible Enterobacterales (*n* = 320). Against this set of isolates,

S, susceptible; I, intermediate; R, resistant; NA, not applicable.
Levofloxacin-susceptible isolates are selected based on the levofloxacin EUCAST susceptible breakpoint. EUCAST breakpoints are used for all other antibiotics.

ciprofloxacin susceptibility was 78.9% (Table 5), whereas 90.9% of strains were inhibited by levonadifloxacin at the proposed breakpoint of 4 mg/L with MIC_{50} and MIC_{90} values being 0.5 and 4 mg/L (Table 1), respectively. Disturbingly, against Enterobacterales isolates, last-resort agents such as tigecycline and colistin showed susceptibilities of 65.7% and 87%, respectively, when EUCAST susceptibility breakpoints were applied. In the case of levofloxacin-susceptible *P. aeruginosa* isolates (*n* = 140), levonadifloxacin MIC_{50} and MIC_{90} values were 2 and 4 mg/L, respectively, with 97.1% susceptibility based on the pharmacokinetic/pharmacodynamic breakpoint (Table 1), which was similar to ciprofloxacin (Table 5). Against levofloxacin-susceptible *A. baumannii* (*n* = 61) isolates, levonadifloxacin MIC_{50} was 0.25 mg/L and MIC_{90} was 0.5 mg/L. Levonadifloxacin inhibited 98.4% of isolates at 1 mg/L, while the potency (in terms of MIC_{90}) of levonadifloxacin was comparable to that of ciprofloxacin.

Discussion

The present study aimed to assess the *in vitro* activity of levonadifloxacin against contemporary nosocomial Gram-positive and Gram-negative isolates collected from 16 medical centres across

Downloaded from https://academic.oup.com/jac/advance-article-abstract/doi/10.1093/jac/dkz493/5678110 by Goteborgs Universitet user on 17 December 2019

India. The study showed a high level of quinolone resistance (79%) among *S. aureus* isolates, while MRSA prevalence of 49% was noted. Previously, the Indian Network for Surveillance of Antimicrobial Resistance (INSAR) group reported an overall MRSA prevalence rate of 41%–47% in India during 2008–09.[9] A recent report from Rajkumar *et al.*[10] showed MRSA rates in the range of 21%–45%. Thus, MRSA rates encountered in this study are broadly in agreement with previous studies. The present study also substantiated the prevalence of high fluoroquinolone resistance in *S. aureus* reported by the Center for Disease Dynamics, Economics & Policy (CDDEP), wherein a 79%–90% fluoroquinolone resistance rate was observed in 2014 while 71% resistance was reported in the year 2017.[11] Despite a high prevalence of quinolone and methicillin resistance in *S. aureus*, levonadifloxacin displayed a therapeutically relevant antibacterial activity with >90% isolates inhibited at $\leq$1 mg/L. The quinolone resistance rate among CoNS was 70.7%, while the methicillin resistance rate was 71.1%, against which levonadifloxacin showed MIC_{50} and MIC_{90} values of 0.5 and 1 mg/L, respectively.

In conjunction with several previous studies undertaken over the last 10 years, the present study reaffirmed an unchanged levonadifloxacin MIC_{90} of 1 mg/L for MRSA even in the face of increasing fluoroquinolone resistance.[1–4] The stable activity of levonadifloxacin is attributed to its differentiated mechanism of action based on preferential targeting of DNA gyrase in *S. aureus*, an attribute distinct from topoisomerase IV-targeting levofloxacin and moxifloxacin.[12] This differentiated mechanism of action possibly emanates from its distinctive structural feature of a tricyclic core with the absence of the conventional amine at the C-8 position of the side chain.[13] Further, it was demonstrated that the DNA gyrase-targeting feature of levonadifloxacin helps overcome trovafloxacin and moxifloxacin resistance in *S. aureus*, which is invariably mediated by multiple mutations in topoisomerase IV.[12] A similar observation was apparent in the present study, which showed four times greater activity of levonadifloxacin compared with moxifloxacin against *S. aureus*.

Against streptococci, activity of levonadifloxacin was found to be superior to levofloxacin. The improved activity of levonadifloxacin against streptococci points towards a favourable interaction with bacterial topoisomerases in this pathogen as well. However, for viridans group streptococci, levonadifloxacin showed comparable activity to that of levofloxacin.

The potent anti-MRSA activity of levonadifloxacin observed in this study supports its therapeutic utility for MRSA-dominated indications such as ABSSSIs, HABP and bone and joint infections. In particular, availability of an oral administration option in the form of alalevonadifloxacin would offer the convenience of outpatient treatment for indications requiring longer or stepdown therapy for early hospital discharge. Promising activity against *S. pneumoniae* and other respiratory pathogens, including atypical pathogens, demonstrated in previous studies[14–16] points towards its potential as an empirical oral therapy option for lower respiratory tract infections. Furthermore, Rodvold *et al.*[17] studied intrapulmonary pharmacokinetics of levonadifloxacin following oral administration of alalevonadifloxacin, which showed higher unbound plasma and epithelial lining fluid (ELF) exposures (AUC_{0-24} =345.2 mg·h/L) compared with moxifloxacin. Considering an MIC_{90} of 0.5 and 1 mg/L for streptococci and MRSA, respectively, high ELF levels are likely to bestow a significant pharmacokinetic/pharmacodynamic advantage on levonadifloxacin in the treatment of CABP and HABP.

In summary, the study conducted on the contemporary pan-India isolates obtained in the ASPIRE study highlights the potent activity of levonadifloxacin against fluoroquinolone- and methicillin-resistant staphylococci, macrolide-resistant streptococci and quinolone-susceptible Gram-negative organisms.

Abstract

Introduction: Extended spectrum beta-lactamases (ESBLs) are beta-lactamases capable of conferring bacterial resistance to the Penicillins, first, second and third generation cephalosporins, and Aztreonam (but not the Cephamycins or Carbapenems). Clinicians, Microbiologists and hospital epidemiologists are concerned about ESBL-producing Gram negative bacteria because of increased incidence of such infections, limitations of effective antimicrobial therapy and adverse patient outcomes. **Aims and Objectives:** To find the incidence of infections caused by ESBL producing Gram negative bacteria among patients admitted in Medical ICU of tertiary care hospital. To compare the antimicrobial susceptibility patterns of the ESBL producing Gram negative isolates with ESBL non-producing isolates. **Materials and Methods:** Clinical samples were collected from patients admitted in Medical ICU & processed as per standard protocol. Antibiotic susceptibility was performed by Kirby-Bauer disc diffusion method. Screening for ESBL production was done as per CLSI guidelines. Presence of ESBL was detected by Phenotypic confirmatory disc diffusion method using discs containing 30µg of Ceftazidime with and without 10µg of Clavulanic acid on Mueller-Hinton Agar. **Results:** A total of 50 samples were collected. Of these, majority (38%) of samples were urine followed by sputum (36%). Of the 50 samples, majority of the isolates were *Klebsiella* spp and *E.coli*, 14(28%) each. Among 50 samples, 42(84%) isolates were ESBL producers. Of the 42 ESBL producing organisms, majority(13(30.9%)) of them were *Klebsiella* spp. **Conclusion:** In the present study, we found an alarming number (84%) of ESBL producing Gram negative isolates in Medical ICU patients. Strict antibiotic policies and measures to limit indiscriminate use of Cephalosporins should be undertaken to minimize the emergence of such resistance.

Key words: ESBL, Gram negative bacteria, Medical ICU.

Introduction

Extended spectrum beta-lactamases (ESBLs) are beta-lactamases capable of conferring bacterial resistance to the Penicillins, first, second and third generation cephalosporins, and Aztreonam (but not the Cephamycins or Carbapenems) [1]. Typically, they derive from genes TEM-1, TEM-2, or SHV-1 by mutations that alter the amino acid configuration around the active site of these beta-lactamases. This extends the spectrum of beta-lactam antibiotics susceptible to hydrolysis by these enzymes [2]. ESBL are most commonly produced by Klebsiella spp and E.coli.

Manuscript received: 28th April 2017
Reviewed: 8th May 2017
Author Corrected: 17th May 2017
Accepted for Publication: 24th May 2017

However, Enterobacter, Salmonella, Proteus, Citrobacter, Morganella,Serratia,Shigella, Pseudomonas and Burkholderia spp also produce them [3]. Clinicians, Microbiologists and hospital epidemiologists are concerned about ESBL-producing Gram negative bacteria because of increased incidence of such infections, limitations of effective antimicrobial therapy and adverse patient outcomes.

Special efforts should be undertaken by Clinical microbiology laboratories as recommended by the Clinical and Laboratory Standards Institute (CLSI) for ESBL detection [4,5]. ESBL detection is not commonly carried out in laboratories in developing countries due

to lack of awareness and facilities to conduct ESBL identification [6]. Detection of ESBL producing organism from samples is important because this represents an epidemiologic marker of colonization and therefore there is potential for transfer of such organisms to other patients [7]. Within countries, hospital-to-hospital variability in ESBLs may also be marked [8].

This prospective Cross-sectional study is conducted to find and compare incidence of infections with ESBL producing Gram negative bacteria among patients admitted in Medical intensive care unit of Karnataka Institute of Medical Sciences, Hubballi. Besides it is important to understand the extent of spread of these isolates in the community so as to formulate corrective measures.

Aims and Objectives

To find the incidence of infections caused by ESBL producing Gram negative bacteria among patients admitted in Medical ICU of tertiary care hospital. To compare the antimicrobial susceptibility patterns of the ESBL producing Gram negative isolates with ESBL non-producing isolates.

Materials and Methods

- The study has been carried out after obtaining the clearance of Institutional ethical committee.
- **Study design:** Prospective Cross-sectional study
- **Study site:** Medical Intensive care unit of KIMS Hospital, Hubballi.
- **Duration of study**: June 1st to July 31st, 2014.
- **Sample size:** 50

Inclusion criteria

- Patients admitted in Medical ICU during study period were included.
- Only Gram negative isolates were included.

Exclusion criteria

- Isolates other than Gram negative bacteria
- Repeat isolates from same patient.

Sample collection and processing: Clinical samples were collected from patients admitted in Medical ICU & processed as per standard protocol.

Methodology

Antibiotic susceptibility was performed by Kirby-Bauer disc diffusion method. Screening for ESBL production was done as per CLSI guidelines [9]. Presence of ESBL was detected by Phenotypic confirmatory disc diffusion method using discs containing 30µg of Ceftazidime with and without 10µg of Clavulanic acid on Mueller-Hinton Agar. ESBL production was inferred if the inhibition zone increases by 5mm towards Ceftazidime plus clavulanic acid in comparison to Ceftazidime disc alone [9].

Statistical Analysis was done by Chi-square test using SPSS software.

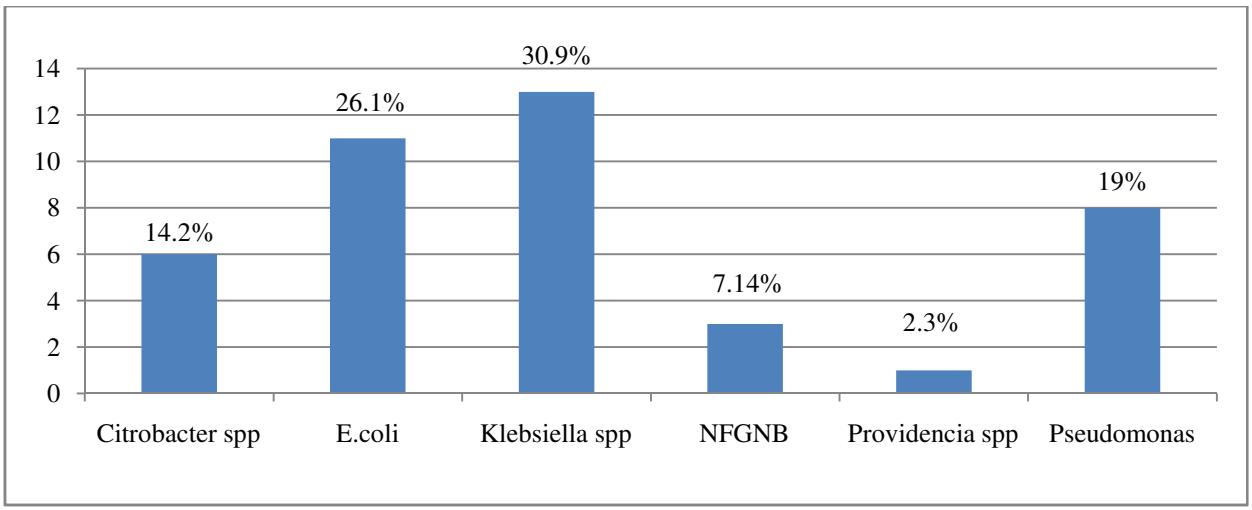
Fig 1: Phenotypic confirmatory test showing ESBL positive isolate

Fig 2: Phenotypic confirmatory test showing ESBL negative isolate

Observations and Results

The present study was carried out in the Department of Microbiology, Karnataka Institute of Medical Sciences (KIMS), Hubballi.

Table-1: Specimen-wise distribution of isolates.



Specimen	Number (n=50)	Percentage
Ascitic fluid	3	6%
CSF	4	8%
ET tube secretion	1	2%
Pleural fluid	4	8%
Pus	1	2%
Sputum	18	36%
Urine	19	38%
Total	**50**	**100%**

Majority (38%) of samples were urine followed by sputum (36%).

Table-2: Distribution of isolates.

Isolate	Number	Percentage(%)
E.coli	14	28%
Klebsiella spp.	14	28%
Pseudomonas spp	9	18%
Citrobacter spp.	7	14%
NFGNB	5	10%
Providencia spp.	1	2%

Of the 50 samples, majority of isolates were *Klebsiella* spp and *E.coli,*14(28%) each.

Graph-1: Distribution of isolates with ESBL

Of the 42 ESBL producing organisms, majority of them were *Klebsiella* spp which was 13 (30.9%).

Table-3: Comparison of antibiotic resistance pattern of ESBL positive and ESBL negative isolates.

Antibiotics	ESBL positive n=42		ESBL negative n=8		p value	Significance
	Resistant	%	Resistant	%		
Amikacin	11	26.19	1	12.5	0.017	S
Netilmicin	13	30.95	0	0	0.567	NS
Amoxy-clavulanic acid	24	57.14	1	12.5	0.009	S
Ceftazidime	5	11.90	1	12.5	0.738	NS
Cefepime	28	66.66	2	25	0.042	S
Cefaperazone	6	14.28	1	12.5	0.896	NS
Cefotaxime	27	64.28	2	25	0.002	S
Cefoxitin	21	50	4	50	0.882	NS
Ciprofloxacin	3	7.14	0	0	0.436	NS
Levofloxacin	8	19.04	0	0	0.191	NS
Norfloxacin	11	26.19	0	0	0.188	NS
Ofloxacin	7	16.66	1	12.5	0.402	NS
Pefloxacin	18	42.85	1	12.5	0.179	NS
Imipenem	6	14.28	0	0	0.007	S
Pip-tazobactam	10	23.8	2	25	0.029	S
Tetracycline	25	59.52	2	25	0.058	NS

Difference was statistically significant for Amikacin, Amoxy-clavulanic acid, Cefepime, Cefotaxime, Imipenem and Piperacillin+tazobactam. ESBL producing isolates were found to show higher rates of resistance when compared to non ESBL producers.

Discussion

A total of fifty isolates from various clinical samples from medical ICU were screened for ESBL Production. Screening for ESBL production is done as per CLSI guidelines. Of these 50 isolates, 42(84%) were ESBL producers. Of these, majority of the isolates were from urine and sputum, 16(38%) each.

In India, ESBL presence rate varies in different situations from 24 to 84% [10]. A study from Coimbatore, Tamil Nadu, presence of ESBLs to be 40%, while a study done from Nagpur showed it as 50% [11,12]. Another study in 2005, from New Delhi, showed 68.78% of the strains of Gram negative bacteria to be ESBL producers [13]. In our study, presence rate of ESBL was found to be 84%. This must be due to injudicious usage of Cephalosporins in Medical ICU patients.

Klebsiella and *E.coli* were the predominant ESBL producers (28% each) lower than the study done by Neelam Taneja et al who observed 51.2% *Klebsiella* spp followed by 40.2% *Escherichia coli* [14].

The incidence of ESBL was found to be 84% higher than in the study done by Kumar D, Singh AK, Ali MR, Chander Y to determine the antimicrobial sensitivity profile of ESBL producing *E. coli* isolates from various clinical samples such as pus, urine, blood, cerebrospinal fluid (CSF), stool, sputum, swabs, and different body fluids which was 55.5% [15].

ESBL producing isolates were found to show higher rate of resistance to Cefipime (66.6%), Cefotaxime (64.28%) and Amoxy-clavulanic acid (57.14%). Imipenem (14.28%), Piperacillin-Tazobactam (23.8%), and Ciprofloxacin (7.14%) were found to be the effective antibiotic in ESBL producing isolates. It is statistically significant for Amikacin, Amoxy-clavulanic acid, Cefepime, Cefotaxime, Imipenem and Piperacillin+tazobactam antibiotics.

Detection of ESBL production is of paramount importance in hospital settings as these strains are probably more prevalent than currently recognized; these enzymes constitute a serious threat to currently available antibiotics. Institutional outbreaks are increasing because of selective pressure due to indiscriminate use of expanded- spectrum Cephalosporins and lapses in effective control measures [16].

Screening of ESBL in Gram negative bacteria poses considerable therapeutic challenges in critical care patients. The infections which are caused by ESBL producing Gram negative bacteria have been reported with an increasing frequency in the intensive care units and they are associated with a significant morbidity and mortality [17].

One of the areas of interest in infections in ICU is in the trend in the antibiotic susceptibility patterns (AST) of common pathogens in ICU. This is important as antibiotic guidelines are commonly made based on them and changes in the AST patterns need o be reflected in regularly updated antibiotic guidelines [18]. Strategies to keep a check on the emergence of such drug resistant microbes by hospital environmental surveillance and laboratory monitoring should form an important aspect of Hospital Infection Control policy guidelines [3].

Conclusion

In the present study, we found an alarming number of ESBL producing Gram negative isolates. The laboratories should have the capacity to detect ESBL producers, so that appropriate therapy can be chosen for patient management. The report must also include a note that ESBL producer may result in therapeutic failure with antimicrobials such as Penicillin, Aztreonam and Cephalosporin.

Considering the gravity of the implication of wrong therapy in critical care, looking for ESBL producers must be made mandatory in all reporting in Microbiology laboratories and clinicians also educated on the issue. Strict antibiotic policies and measures to limit indiscriminate use of Cephalosporins should be undertaken to minimize the emergence of such resistance.

Prevalence of Vancomycin Resistant Enterococci Carriers from Rectal Swabs among High Risk Patients in a Tertiary Care Hospital

M MOHAMADIYA RIZWANA[1], S PARVATHI[2], B APPALARAJU[3]

(cc) BY-NC-ND

Keywords: Chromogenic media, *Enterococcus faecium*, *Enterococcus faecalis*, Urinary tract infections

Dear Editor,

Enterococci with acquired vancomycin resistance is a major concern amongst hospital. These resistant species have the ability to survive for prolonged periods and they can get transmitted easily. The infections caused by these organisms range from complicated Urinary Tract Infections (UTI) to life threatening Central Nervous System (CNS) infections making the treatment challenging [1]. The rate of Vancomycin Resistant Enterococci (VRE) colonisation in Northern India is nearly 34.5%, with *van A* genotype being the most common [2]. Studies have reported that active screening through rectal swabs is a definite tool in preventing complications in high risk patients by early identification and treatment of VRE carriers [3]. The conventional method of screening with bile esculin azide agar supplemented with 6 µg/mL of Vancomycin/ml is reasonably sensitive but requires confirmation by molecular techniques [4]. The molecular methods in the detection are limited to the referral laboratories. Development of highly specific chromogenic substrates in the VRE selective media help in effective screening of colonisers. The sensitivity and specificity of the chromogenic media was 100% and 99%, respectively [4]. This was in accordance to present study as well. This study was undertaken to screen the high risk patients in critical care for VRE colonisation from stool samples and identify the genotype. Early identification of the carrier state in high risk patients is helpful in planning the management strategy of these patients.

This was an observational study done over the period of three months from January to March 2016 at PSGIMS&R, Coimbatore, Tamil Nadu, India. The Institutional Human Ethical clearance number obtained was 14/118. Informed consent was obtained before collecting the rectal swabs. The criteria for high risk patients were defined as hospitalisation >7 days, chronic haemodialysis, use of multiple antibiotics and associated chronic disease status. Rectal swabs were obtained from 100 patients (no repeat isolates and the mean age group was 60 years 75% were males) following the identification as high risk as per the criteria explained above. The rectal swabs were streaked on chromogenic ChromID VRE media (Biomerieux) and incubated at 37°C for 24 hours. The presence of violet colour colonies indicated *Enterococcus faecium* and blue colour colonies indicated *Enterococcus faecalis*. Isolates with intrinsic resistance to vancomycin as *Enterococcus casseliflavus* and most of the other gram positive organisms were selectively inhibited by this media. Conventional biochemical tests as bile esculin, mannitiol, argininine and PYR (Pyrrolidonyl Arylamidase) were done for confirmation at the species level. The antibiotic sensitivity was also performed by Kirby Bauer method as per the CLSI guidelines [5]. The antibiotic susceptibility pattern of the 100 isolates showed the maximum sensitivity to linezolid (98%) followed by vancomycin (97%), erythromycin (89%), teicoplanin (75%), ampicillin (69.2%), high level gentamycin (49.2%) and penicillin (25%). The Minimum Inhibitory Concentration (MIC) of the resistant isolates was confirmed by using commercial E-strips. Molecular characterisation of the resistant isolates for the specific genotype was done by performing conventional PCR. The DNA from the resistant isolates was extracted using the QIAGEN kit. The primers of base pair 732bp for detection of *van A* were used. The PCR products were analysed by running gel electrophoresis and visualised under UV light in automated GEL DOC viewer. Primers for *van A* used were:

F (5' GGGAAAACGACAATTGC-3')

R (5'GTACAATGCGGCCGTCGTTA-3') [6]

Out of the 100 patients screened, three were found to be positive for VRE carriage (3%). All the three were *Enterococcus faecium*. The positive sample was used as the control strain. Analysis of the predisposing risk factors among the three patients revealed the association of chronic renal impairment, immunocompromised status (retroviral infection) and presence of co-morbid conditions such as diabetes mellitus along with prolonged hospital stay.

The VRE carriers can pose a risk to the patients harboring these pathogens as they can invade the host and result in bacteremia complicating the management. In such patients, treatment of the VRE carriage aids in better prognosis. Isolation and cohorting of these patients prevents the transmission and risk of infection in other patients, especially in healthcare setups. The choice of VRE screening can aid in proper infection control measures.

Thus, chromogenic VRE media was found to be a simple and rapid method for identifying VRE carriage.

Declaration: The present study was presented as poster presentation in 39th National Conference of the Indian Association of Medical Microbiologists MICROCON in 2015.

Phenotypic and Genotypic Characterization of *Enterococci* from Clinical Isolates in a Tertiary Care Hospital

Mohamadiya Rizwana*, S. Parvathi and B. Appalaraju

Department of Microbiology, PSG IMSandR, Coimbatore, Tamil Nadu, India
**Corresponding author*

A B S T R A C T

Enterococci mainly being commensals in human faeces are now considered as an important cause of nosocomial infections. Of the infections, the commonly observed are urinary tract infections, abdominal infections followed by bacteremia, endocarditis and meningitis rarely. Speciation of *Enterococcus* aids in effective management of the infections caused by them. The initial treatment for enterococcal infections has become challenging due to development of resistance. The resistance has been observed mainly against aminoglycosides due to the presence of bi-functional gene. VRE strains are mostly isolated from patients with recurrent bacteremia, endovascular infections leading to increase deaths in the patients. To isolate and speciate enterococcal isolates from clinical samples, study the antibiotic susceptibility pattern and the genotype associated with the aminoglycoside and vancomycin resistance. *Enterococcus* isolates obtained from various sections were characterized by conventional phenotypic methods. The antibiotic susceptibility was studied by disc diffusion method. The resistant strains were further confirmed by MIC using automated methods following which the genotypic analysis was done. The incidence of *Enterococci* was 2.5% in which around 86.4% were obtained as pure isolates. Among the species *E. faecalis* was found to be the maximum. The urinary isolates exhibited sensitivity of around 92.3% to nitrofurantoin and among the non - urinary isolates the maximum sensitivity was for linezolid. The molecular study showed van A to be most common gene with vancomycin resistance (71.42%), and bifunctional gene among the aminoglycoside resistance (96%). *Enterococcus faecalis* was the commonest species isolated. The maximum number of isolates was obtained from urinary samples. The increase incidence of resistance gene to high level gentamicin could result in failure to the synergy treatment of gentamicin in combination with penicillin group of antibiotics. The emergence of vancomycin resistant strains among the clinical isolates makes treatment options more challenging.

Introduction

Enterococci are gram positive organisms having the property to grow at 6.5% NaCl concentration, pH of 9.6 and hydrolyze bile esculin. Initially they were grouped under group D Streptococcus but later with the help of DNA studies they are characterized under the genus *Enterococcus* in 1960. They were considered as harmless pathogens formerly, but in the recent years have been emerging as the most important causative agents in nosocomial infections (Murray *et al.*, 1990).

Enterococci being the commonest micro flora of both humans and animals share their source

of origin. They have been isolated from variety foods including cheese, fish, sausages, beef and pork. Studies have been reported that *Enterococci* have been isolated from various clinical and environmental samples all over the world. Among the isolates obtained clinically it has been observed that *Enterococcus faecalis* has been the predominant species clinically (Lancefield *et al.,* 1933; Cetinkaya *et al.,* 2000).

Enterococcal infections have been referred to as tough, tenacious and troublesome infections (Marothi *et al.,* 2005).In the past years there has been an increase in the prevalence of enterococcal infections in hospitals and of particular concern is the emergence of antimicrobial resistant strains. Being second commonest organism behind the abdominal and pelvic infections, third in causing blood stream infections, cases have also been reported in causing CNS and neonatal infections.

Reports have been confirmed with their association with clinical conditions including respiratory tract infections, osteomyelitis and cellulitis (Fischer *et al.,* 2009). *Enterococci* were initially regarded as the disease causing agent in the early nineties. But now various reports have been established reporting them as the second commonest pathogen (Kuhn *et al.,* 2003).

Species identification becomes essential for investigating outbreaks in case of nosocomial infections and also susceptibility pattern varies accordingly which is also helpful in clinical management of infections due these agents (Gordon *et al.,* 1992).

Infections caused by enterococcal pathogens were initially being treated with the combined treatment of cell wall active agents as penicillins and aminoglycoside as the synergistic effect was effective. But now due to the development of antibiotic resistance as high level aminoglycoside resistance, beta lactamase production and also resistance to vancomycin have led to serious concern in management of these nosocomial pathogens (Mendiratta *et al.,* 2008). Vancomycin resistant *Enterococcus* was initially reported in 1980s, after which there was a increase in the incidence of its spread. The main phenotypes associated with its spread are Van A, Van B and Van C. Van A and Van B are mainly associated with *E. faecalis* and *E. faecium*. Van C is noted in *E. gallinarum* and *E. casseliflavus*. Among the phenotypes Van A is predominantly associated in the resistant strains.

VRE strains are mostly isolated from patients with recurrent bacteremia, endovascular infections leading to increase deaths in the patients. Vancomycin resistance and penicillin resistance are often seen co-existing which makes the treatment harder (Murray *et al.,* 1990).

Resistance development in *Enterococcus* against glycopeptide antibiotics gets transferred from them to other bacterial pathogens which include *Staphylococcus aureus, Streptococci, Listeria monocytogenes* (Gold *et al.,* 1996).

Thus due to the recent emergence in association with significant clinical infections and development of resistance, *Enterococci* have gained importance. Studies are thus required especially in tertiary care hospitals for appropriate isolation, identification and speciating them.

Antibiograms should also be followed up in accordance to the species. Emergence of VRE needs to be checked and limit its spread in hospital environment. CDC also stresses the control of VRE in hospitals by educating the staff in detecting VRE early, reporting them and action plan taken promptly.

Our study aims to isolate, speciate the *Enterococcus* in a simplified manner and also to study the drug sensitivity and resistance patterns among the isolates obtained.

Materials and Methods

The Institutional Human Ethical clearance was obtained before the commencement of the study.

Type of study

Experimental study

Confidentiality

Confidentiality of the reports were maintained

Sample size estimation

A total of 250 isolates of *Enterococci* obtained from outpatient and inpatient samples from blood section, miscellaneous and urine section were processed for the species identification, antimicrobial sensitivity followed by molecular study.

Specimen processing: Specimens from various sections including urine, pus and blood for cultures were collected and processed in the laboratory.

Pus/wound swabs

The swabs were streaked in blood agar and MacConkey agar and were incubated at 37^0C for 24 hours.

Urine

A loopful of the uncentrifuged specimen was examined as a wet mount for the presence of pus cells and bacteria. One loopful of specimen was inoculated onto blood agar and Mac Conkey agar. Plates were incubated at 37^0 C for 24 hours.

Growth in sheep blood agar

Following overnight incubation of the samples, colonies of *Enterococcus* were seen as grey colonies of about 0.5-1mm in diameter with alpha, beta or gamma hemolysis.

Growth in Mac Conkey agar

Colonies were about 0.5- 1mm in size with a smooth surface and convex margins, tiny magenta colored following 18-24 hour growth.

Catalase test

A drop of the catalase reagent (30% hydrogen peroxide) was added to the slide.

The growth was further applied to it with an applicator stick. Appearance of bubbles was taken as positive test.

Enterococcal colonies showed a negative test due to the absence of bubbles.

Gram stain

Smears made from the colony showed Gram positive cocci arranged singly, in pairs or in short chains.

Storage

If the isolate was catalase negative, gram staining showing the presence of gram positive cocci in pairs or short chains and growth in MacConkey agar as tiny lactose fermenting colonies, they were sub cultured and pure growth was stocked in Robertson's cooked meat medium in tubes.

The tubes were sealed and stored at 4-8^0C for 3-6 months. When the test was to be done they were further sub cultured.

Identification tests

Growth in media with pH – 9.6

Isolated colonies of *Enterococcus* was streaked in a media with a pH 9.6 and incubated at 37^0C overnight. The presence of growth was taken as positive.

Tolerance with 6.5% NaCl

The colonies were inoculated in a broth with 6.5% NaCl, and incubated overnight. The next day the tubes were checked for any increase in turbidity. This was further confirmed by sub culturing onto the agar plates. Growth confirmed the presence of organism. Whereas absence of turbidity indicated organism was unable to grow in this concentration.

Heat tolerance test

Enterococcus was inoculated in Todd-Hewitt broth. It was later incubated in water bath set at 45^oC overnight and 60^0 C for half an hour, and then sub cultured. *Enterococci* survived both the temperature showing positive reaction.

Bile esculin test

Colonies from 24 hour culture were inoculated in media containing 40% bile. Blackening of the medium confirmed positive reaction for *Enterococci* and non-*Enterococci*.

PYR test

The colonies were inoculated in PYR broth and incubated for a period of 4 hours. Later 3 drops of PYR reagent was added to it and change of colour to red was confirmed positive indicating *Enterococci* whereas absence of colour change indicates negative test.

Motility test

Stab culture of the colony was done in a semi-solid media and motility was indicated by the spread of the organism into the media. The strains which did not diffuse into the media were considered non-motile. Tubes were incubated for up to 7 days for confirming motility.

Arginine test

A well isolated colony of *Enterococcus* from the culture was inoculated in Moeller's decarboxylase media with arginine as the amino acid and overlaid with mineral oil. After 24 hours of incubation the colour of the tube was changed to purple indicating a positive reaction. Yellow colour indicated only acid production only and no deamination.

Potassium tellurite reduction test

Colonies were streaked in media containing 0.004%potassium tellurite. *E. faecalis* formed black colonies with the reduction of tellurite to tellurium.

This test was used to differentiate *E. faecalis* from *E. faecium.*

Pyruvate test

When inoculated in a media containing pyruvate with bromothymol blue as indicator *E. faecalis* showed a colour change from green to yellow color after overnight incubation. Absence of colour change ruled out *E. faecalis.*

Pigment production

Ability to produce pigment was observed by a few species of *Enterococci*. This was tested by sub culturing colonies in nutrient agar.

Any color produced was visible and also further confirmed by touching the colony with a sterile swab.

Sugar fermentation tests

Species identification was further done by sugar utilization by inoculating the organism in peptone with 1% sugars with Andrade indicator. The sugars used were mannitol, arabinose, raffinose, sorbose, sorbitol, lactose and sucrose. Any change in colour from colourless to pink indicated the positive sugar fermentation test. Absence of colour change was taken as negative.

Antimicrobial susceptibility test: (CLSI 2015)

The 250 test isolates of *Enterococci* were checked for the antimicrobial susceptibility pattern using Kirby-Bauer disc diffusion method. Three or four pure colonies were inoculated in peptone water and incubated for about 3 hours. The turbidity of the growth was matched to 1 of Mc Farlands. A lawn culture of the broth with a sterile swab was done in Muller Hinton agar and the discs were placed at a distance of 24 mm.

About 6 discs were kept on each plate. The discs used were Penicillin (10U), Ampicillin (10µgm), Amoxicillin Clavulanic acid (20/10), Erythromycin (15µgm), Vancomycin (30µgm), High level gentamicin (120µgm), Linezolid (30µgm), Tetracycline (30µgm). For isolates from urine section Norfloxacin (10µgm) and Nitrofurantoin (300µgm) was kept. All discs were bought from HIMEDIA.

Zones of inhibition were measured and recorded and the organism was interpreted as sensitive or resistant as per the recommendations from CLSI guidelines. The quality Control used was *Enterococcus faecalis* ATCC 29212.

Screening for high level gentamicin resistance (CLSI 2015)

Screening media for high level gentamicin resistance was prepared. Screening for high level gentamicin resistance was done by agar dilution method. BHI agar with gentamicin at a concentration of 500µgm/ml was added and the plates were prepared. Inoculum of 10µL of 0.5 Mc Farland was spot inoculated. Presence of even 1 colony was interpreted as a resistant strain. These strains were collected for molecular studies.

Detection of beta lactamase (Marothi *et al.*, 2005)

The detection of beta lactamase test was done based on the chromogenic cephalosporin method. Nitrocefin disc was obtained commercially from BD. The disc was moistened with sterile saline and pure isolated colony was applied on it. The reaction was read within 5 min. Isolates producing beta lactamase produced a red color.

Molecular study of isolates

A representative sample of 50 high level gentamicin resistant isolates was selected for genomic analysis. The DNA was extracted using the QIAGEN kit. Followed by extraction, the isolates were analysed for the presence of Bifunctional resistant geneaac (6') le aph (2") la. The vancomycin resistant isolates were checked for the presence of van A gene simultaneously.

Detection of aac (6') le aph (2") la gene

The primers for HLGR with a base pair of 348 bp were amplified. The sequence was obtained from the studies done previously[11]. PCR Master mix: The master mix was prepared as follows: 2.5µl of PCR buffer,2.5µl of MgCl2, 2.5µl of DNTPs,

10.2µl of Mili Q H2O, 1µl of forward and reverse primers and 0.3µl of Taq Polymerase was added to eppend off. From the above mixture 18µl was taken and 5µl of the extracted DNA was added.

Primers for aac (6')Ie- aph (2")la with base pair of 348 bp (Vakulenko *et al.*, 2003):

F (5'CAGAGCCTTGGGAAGATGAAG3')
R (5'CCTCGTGTAATTCATGTTCTGGC3')

PCR program

The program consisted of initial denaturation step at 95^0C for 10 minutes followed by 30 cycles of denaturation at 94^0C for 300 seconds, annealing at 56^0C for 1 minute and extension at 72^0C for a period of 1 minute. The program had a holding temperature of 72^0C for 10 minutes.

Analysis

PCR products were analyzed by running gel electrophoresis with 1.5% agarose gel in Tris Boric acid buffer. The samples along with the controls obtained by running ladder were analysed.

The gel was stained with ethidium bromide and the bands were obtained were visualized under UV light and also in automated GEL DOC viewer.

Detection of vanA gene

The primers with a base pair of 732bp for detection of vanA were obtained from the studies done previously.

Primers for van A with base pair of 732bp (Dutka-Malen *et al.*, 1995):

F (5' GGGAAAACGACAATTGC-3')
R (5'GTACAATGCGGCCGTCGTTA-3')

PCR program

This program had a denaturation step at 95^0C for 5 minutes followed by 30 cycles of DNA denaturation at 95^0C for 1 minute, annealing at 54^0C for 45 seconds and primer extension at 72^0C for 45 seconds. This was followed by a holding temperature of 72^0C for 10 minutes.

Analysis

PCR products were analyzed by running gel electrophoresis with 1.5% agarose gel in Tris Boric acid buffer. The samples along with the controls obtained by running ladder were analysed. The gel was stained with ethidium bromide and the bands were obtained were visualized under UV light and in automated GEL DOC viewer.

Results and Discussion

All the 250 isolates of *Enterococcus* from various clinical samples including urine, pus, wound swab, blood and CSF were processed.

The maximum number of isolates was obtained from urine section (184) followed by wound swabs (24), blood section (14), 4 from peritoneal samples, 1 from CSF (Figure 1). The majority of the isolates were obtained as pure growth (216) and 34 was obtained as mixed from the samples processed. Figure 2 depicts the speciation of enterococcal isolates in which *E. faecalis* was the predominant species (157), succeeded by *E. faecium* (79), *E. raffinosus* (7), and *E. durans* (5) and *E. casseliflavus* (2).

Illustration 1 shows the genus specific biochemical tests used in the identification.

The antibiotic susceptibility pattern of the enterococcal isolates by disc diffusion method revealed that out of the 250 isolates, about 69.2% were ampicillin sensitive, 49.2% were

high level gentamicin sensitive, 89.3% were sensitive to erythromycin. The maximum number of isolates was found to be sensitive to vancomycin (97.2%) in our study (Table 1). Among the urinary isolates maximum sensitivity was noticed to nitrofurantoin (92.3%) (Table 2) and norfloxacin (83.1%).

The maximum sensitivity was observed for linezolid followed by vancomycin, teicoplanin, ampicillin and high level gentamicin. Among the non-urinary isolates erythromycin sensitivity was observed to be the highest.

The chromogenic nitrocefin disc was used to screen the isolates for the presence of beta lactamase. In our study none of the isolates were found to be positive for beta lactamase.

Figure 3 shows the presence of Bifunctional gene aac (6')1eaph(2")1a among the high level gentamicin resistant strains. Out of the 50 randomly selected resistant strains for genotype study, 48 had the gene.

Illustration 2 shows the presence of bands of size 348 bp during the gel electrophoresis.

In our study 7 out of the 250 isolates were found to be resistant to vancomycin. The genotypic analysis was done among these resistant strains using the van A gene. The results showed that 5 of the 7 strains were found to be positive for van A gene (Figure 4).

Illustration 3 shows the presence of van A gene of base pair 732, confirming its presence among the resistant strains.

Enterococcus has been noted to cause a majority of urinary tract infections. This being the most common followed by bacteremia, sepsis and even case reports of meningitis has been reported. In our study out of 250 samples studied the majority of the isolates were obtained from urinary tract infections (73.6%) followed by wound swabs (9.6%) and blood (5.6%). This correlates well with other studies in which *Enterococci* was obtained from urine isolates maximally (Karmarkar *et al.,* 2004, Mathur *et al.,* 2003). According to the studies *Enterococci* are considered as the commonest urinary pathogen justifying the increase in the rate of isolation from urinary samples (Murray *et al.,* 1990).

Among the various species, in our study *E. faecalis* was the most common isolate accounting for 62.8% followed by *E. faecium, E. durans, E. raffinosus* and *E. casseleflavus.* Similar findings were reported from other studies done in Bangalore in which *E.faecalis* was 59%, *E. faecium* was 38 % (Golia *et al.,* 2014).

Enterococci show intrinsic resistance to cotrimoxazole, clindamycin, cephalosporins and normal aminoglycosides. Thus these antibiotics are not tested (Mendiratta *et al.,* 2008).

The antibiotic susceptibility pattern of the isolates in our study showed the following:

The sensitivity to linezolid was maximum (98.8%) followed by vancomycin (97.2%), erythromycin (89.3%), teicoplanin (75.2%), ampicillin (69.2%), high level gentamicin (49.2%) and penicillin (25%).

Among the urinary isolates maximum sensitivity was noted in Nitrofurantoin (92.3%) followed by Norfloxacin (83.15%). Studies done in North India showed a similar susceptibility pattern with increased resistance to penicillin and aminoglycosides. Also the sensitivity percentage to linezolid and vancomycin was higher compared to other antibiotics (Mulla *et al.,* 2012).

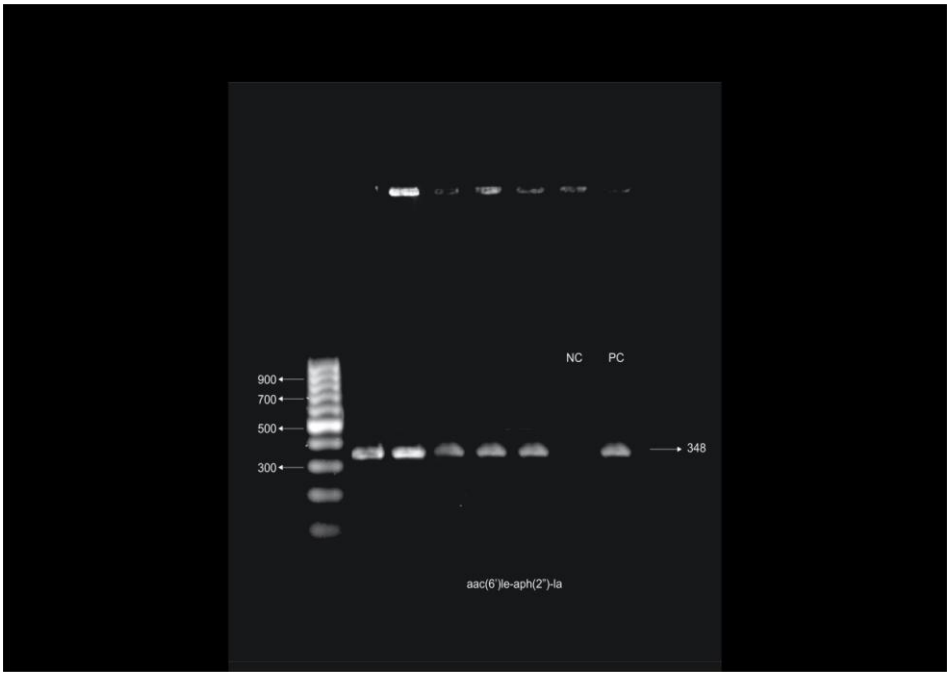

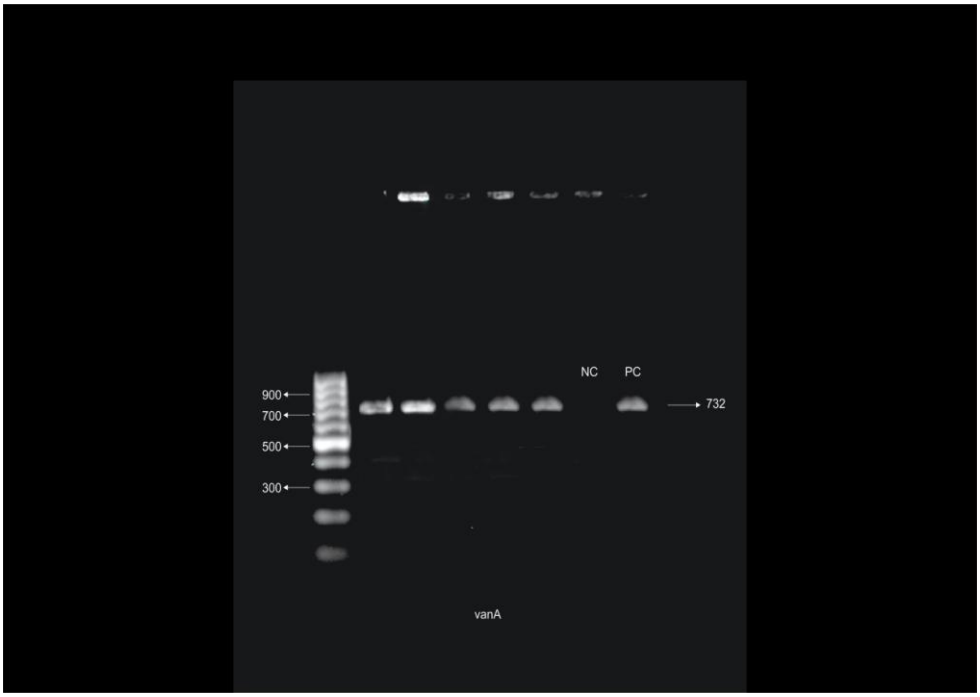

Illustration.3 PCR showing van A gene of band size 732bp

Another study showed the percentage of high level gentamicin resistance to be 68% (Randhawa *et al.*, 2004). Reports from South India showed the resistance percentage of high level aminoglycoside to be more than 50% (Sreeja *et al.*, 2012).

The detection of beta lactamase production by the chromogenic nitrocefin disc method showed that none of the isolates had beta lactamase enzyme. Studies done in Delhi and in Maharashtra also showed similar results (Jain *et al.,* 2011; Mendiratta *et al.,* 2008). The resistance to beta lactams though common, the mechanism could be due to alteration in penicillin binding protein PBP 5 which is more common than beta lactamase production (Murray *et al.,* 1992).

The molecular study done to detect the presence of the resistant gene confirmed the presence of the bifunctional gene aac (6') le-aph (2") la of base pair 348 to be present in 48 (96%) out of the 50 randomly selected resistant strains.

Studies done in Chennai have showed the presence of this gene in 38.2% of the isolates (Padmasini *et al.,* 2014) whereas there are other studies in which all the resistant isolates possessed this bifunctional gene (Hasani *et al.,* 2012). The resistance to high level gentamicin indicates resistance to all the aminoglycosides except streptomycin (CLSI 2015). The combination effect of aminoglycoside with beta lactam antibiotic is not helpful in the treatment of patients possessing such resistant strains.

Out of the 250 isolates the vancomycin resistant isolates obtained in our study was 2.8%. Studies have shown the prevalence of vancomycin resistance to be less in India ranging around 1.7-20% (Sreeja *et al.,* 2012).

Molecular studies revealed the presence of van A gene in 5 (71.42 %) isolates. Studies have also been reported showing van A to be the most common genotype isolated among the vancomycin resistant strains (Praharaj *et al.,* 2013)

Out of the seven isolates, five were *E. faecium* and two were *E. casseliflavus*. The remaining two isolates were *E. casseliflavus* which would have exhibited intrinsic resistance to vancomycin with van C gene (Praharaj *et al.,* 2013).

The incidence of *Enterococci* from the clinical isolates in our study was 2.5%.

The incidence of the pure isolates was 86.4% in comparison to the mixed isolates which was found to be 13.6%.

Among the isolates of *Enterococci*, the predominant species was *E. faecalis* (62.8%) followed by *E. faecium* (31.6%), *E. raffinosus* (2.8%), *E. durans* (2%) and *E. casseliflavus* (0.8%).

The antibiotic sensitivity pattern of the urinary isolates showed 92.3% sensitive to nitrofurantoin and 83.15% sensitive to norfloxacin. Among the non-urinary isolates maximum sensitivity was observed in linezolid which was 98.8% followed by vancomycin (97.2%), erythromycin (89.3%), teicoplanin (75.2%), ampicillin (69.2), high level gentamicin sensitivity (HLG) (49.2%) and pencillin (25%) (Table 3).

The vancomycin resistance was found to be 2.8% in *E. faecium*.

All the isolates were found to be beta lactamase negative by chromogenic (nitrocefin) method proving the alteration in PBP5 to be the more common mechanism involved in penicillin resistance.

The molecular characterization of HLGR(high level gentamicin resistant) strains, 50 isolates selected randomly out of 127, showed the presence of bifunctional gene aac(6')le-aph(2")la to be around 96%. (Primers of base pair 348 - F (5'CAGAGCCTTGGGAAGATGAAG3') R (5'CCTCGTGTAATTCATGTTCTGGC3')

The presence of van A gene was found to be 71.42% in our study.

A B S T R A C T

Enteric fever still remains as an important cause for morbidity and mortality throughout the world and the causative organism for Typhoid and paratyphoid fever are *Salmonella typhi* and *Salmonella paratyphi A, B* and *C* respectively. Objective of the study is to compare and evaluate the performance of Qualitative and semiquantitative Slide Widal test and Quantitative Tube Widal test for diagnosis of enteric fever. A cross sectional study was undertaken and about 400paired serum samples were obtained from the patients and were subjected to both slide and tube widal tests. The results were noted for further statistical analysis. Prevalence of Enteric fever by tube agglutination and slide agglutination tests were found to be 23% (92 out of 400 cases) and 13% (52 out of 400 cases) respectively. Though blood culture remains gold standard, its sensitivity is high only during the first week of fever. So, Widal test is the preferred test used by most clinicians especially during second week of fever. The sensitivity and specificity of tube widal test is much remarkable and so it can definitely be used as a diagnostic test. Slide Widal test can be used as supplementary test to Tube Widal test so as to fetch the results earlier and to facilitate early and appropriate management.

Introduction

Enteric fever has been an important cause of morbidity and mortality throughout the world for centuries. The causative organism for Enteric fever viz., Typhoid and paratyphoid fever are *Salmonella typhi* and *Salmonella paratyphi A, B* and *C* respectively (John *et al.*, 2016). Though the overall incidence and prevalence has decreased significantly, infection still remains endemic in most of the developing countries. Global prevalence of Typhoid and paratyphoid fever was 10-11.7% and 2.2-2.5% in 2016, respectively. Prevalence of Typhoid fever and paratyphoid fever in India was 31.5-36% and 8-9% in 2016, respectively (Dandona *et al.*, 2017). Poor sanitation largely contributes to the

persistence of infection. Improvement in hygiene and timely diagnosis coupled with appropriate treatment ensuring complete cure of cases and carriers remains the keystone in controlling the infection. Culturing the causative bacteria from various body fluids like blood, bone marrow, stool, bile and urine and detection of anti-Salmonella antibodies through serology remains the most common diagnostic tests. Isolation of Salmonella species using Wilson and Blair medium (selective media), which remains the gold standard investigation till date, is greatly influenced by the time duration of illness and appropriateness of the sample chosen for culture (Olopoenia and King, 2000; Mengist and Tilahun, 2017).

Yield of a positive blood culture is very high during the first week of the illness, followed by a marked decrease in its sensitivity. The habit of patients getting started on few doses of antibiotics before the culture has made the investigation lesser sensitive. Hence serological test-Tube Widal test is the most preferred choice by the physicians. It is found more useful in case of culture negative but clinically suspected cases. Widal was first introduced by Georges Fernand Widal in 1896. This test has evolved since then. With the introduction of commercial kits, it has becoming one of the easily available and performable tests.

The quicker result issued in one day, compared to culture (may need 7 days) makes it more useful investigation to decide on the treatment. Recent advancements like Slide Widal test have made the procedure much simpler and very rapid which offers results in one minute. The literature available on its diagnostic ability is however scanty (Olopoenia and King, 2000; Keddy *et al.,* 2011). Hence this study is undertaken to see if the performance of Slide widal is as efficacious as tube widal test.

Study rationale

Widal test works on the principle of agglutination and it is the only serological test available to diagnose enteric fever. If the performance of semi quantitative slide widal test in estimating the titres is found satisfactory, then turn around time for diagnosis of enteric fever and start of treatment can be reduced from 24 hours to 10 minutes.

Since slide widal test does not require additional glassware/instruments or involve complex procedure as in tube widal, moderately skilled technician can perform the test in small resource limited settings. This will benefit remote areas of the country where sophisticated lab facilities are absent. Also cost incurred on inventories and performance of widal can be largely reduced.

The main aim of this study, Comparison of performance of qualitative and semiquantitative slide widal test and quantitative tube widal test in diagnosis of enteric fever.

Also the main objectives of this study include, to compare the performance of qualitative slide Widal test against the semi-quantitative tube Widal test. And to compare the performance of semiquantitative slide Widal test against the semi-quantitative tube Widal test.

Inclusion criteria

In patients and out patients with probable Enteric fever attending various clinical departments of our hospital

Patient presenting with fever for 1 to 2 weeks.

Exclusion criteria

Chronic enteric fever.

Recurrent enteric fever.

Recently vaccinated with TAB vaccine.

Patients with Bleeding disorders.

Patient who did not give informed written consent for the study.

Cross infection with Proteus, Rickettesial infection etc…

Materials and Methods

A Cross sectional study was conducted after obtaining Institutional Human Ethics Committee Clearance (IHEC), and patient's informed written consent was obtained prior to the commencement of the study. A cross sectional study was undertaken from April 2018 to October 2018 and was conducted in the Department of Microbiology, Karpagam Faculty Of Medical Sciences and Research. About 400 serum samples were obtained from the patients with probable Enteric fever, who constituted the study population. Serum samples received in the Serology section of Diagnostic Microbiology Division, Central Service Laboratory of our Hospital were subjected to both qualitative and semi quantitative analysis using slide and tube widal test respectively as per Manufacturer's Instructions (Span Diagnostic Kit).

Serum samples were evaluated for the presence of Genus specific antibodies to poly 'O' Antigen *(Salmonella typhi)*, and also for the presence of species specific antibodies against 'H' Antigen *(Salmonella typhi)*, 'AH' Antigen (*Salmonella paratyphi A)*, 'BH' Antigen *(Salmonella paratyphi B)* respectively. Standard tube widal agglutination test was performed by making serial dilutions of the serum by using isotonic normal saline and 0.5ml of each antigen suspension (O, H, AH, BH) were added to the corresponding tubes (6 tubes), Comprising different dilutions viz., 1:20, 1:40, 1:80, 1:160, 1:320, 1:640. Antigen control to detect Auto-agglutination is also done simultaneously (7^{th} tube). Dreyers tube (round bottom) was used for demonstrating antibodies against 'O' Antigen and Felix tube (conical bottom) are used to demonstrate antibodies to 'H', 'AH', 'BH' antigens respectively.

Then these tubes were incubated at 37^{o}C for 24 hours and the reading of the tubes was done on the next day. Tubes showing 50% agglutination viz., for 'O' antigen – purple granular deposits along with clearing of the tube $\geq 2/3^{rd}$ of the suspension was considered positive. And for 'H', 'AH', 'BH' antigen – cotton wooly clumps along with $\geq 2/3^{rd}$ clearing of the suspension in the tube is considered as positive.

In case of semi-quantitative slide widal and tube widal agglutination test, titres of $\geq$ 1:80 is considered as significant titre for Antibodies to 'O' antigen, $\geq$ 1:160 is considered as significant titre for antibodies to 'H', 'AH', 'BH' antigens respectively. Qualitative widal agglutination tests are done using one drop (50µl) of patients serum and one drop (50µl) of desired antigen (O, H, AH, BH). Presence or absence of visible agglutination –granular clumps, at the end of a minute gentle rotatory shaking is interpreted as positive and negative respectively. Quality control was done using positive and negative quality control given along with the kit as per manufacturer's instruction. Four fold rise or decrease in titres between acute phase sera and convalescent phase sera is considered as significant titre for this serological test. And finally the results were tabulated for further statistical analysis using SPSS version 23.0 statistical software.

Results and Discussion

Out of 400 paired serum samples, Prevalence of Enteric fever by Tube agglutination and slide agglutination test are 23% (92 out of 400

cases) and 13% (52 out of 400 cases) respectively. Incidence of Typhoid fever, paratyphoid 'A' fever and paratyphoid 'B' fever were found to be 13% (52 out of 400 cases), 0 (0 out of 400 cases) and 0 (0 out of 400 cases) respectively by slide widal test. The incidence of Typhoid, paratyphoid 'A' fever and paratyphoid 'B' fever was found to be 23% (92 out of 400 cases), 0 (0 out of 400 cases), 0 (0 out of 400 cases) respectively by tube widal test. *Chi–square test* was applied, the results obtained by the Qualitative and Semi quantitative slide and tube widal test was found to be statistically significant. (X^2=113.31), df=1 ($p<0.0001$)

Enteric fever is one of the significant health problems in the community because of its mortality and morbidity, the diagnosis of Enteric fever can be made by testing the patients stool, blood, urine and other body fluids. Among which the Gold standard for diagnosing enteric fever is by isolation of bacteria by culture method but it takes almost a week to obtain the results, so then tube widal is the next best option which takes 24 hours to obtain the result, and recently slide widal was subsequently introduced for diagnosing enteric fever which almost gives results within Minutes. Among 400 samples tested for salmonella species, the sensitivity and specificity of the slide widal test is 80% and 85% respectively. Sensitivity and specificity of the tube widal is 84% and 96% respectively. Positive and Negative predictive value of the slide and tube widal test was 82% and 85% respectively.

Our results Matched the study done elsewhere, Thelma E. Tupasi *et al.,* in their study from various developing countries endemic to typhoid fever, found the sensitivity and specificity of tube Widal ranging from 61-90% and 88-100% respectively and that of slide agglutination method to be 53-80% (sensitivity) and 57-90% (specificity) (Tupasi *et al.,* 1991). Keddy H Karen *et al.,* in their study concluded that the semiquantitative slide agglutination test had shorter turnaround times than the Widal tube test and poor specificity and hence should not be used as diagnostic tool (Keddy *et al.,* 2011). John Wain *et al.,* stated that the quantitative slide agglutination test used instead of standard Widal test should always be interpreted with reference to clinical data (Wain John *et al.,* 2005).

Endemic titre of *Salmonella typhi* among healthy population was reported to be 1:40 and 1:80, respectively. And the Endemic titre of *Salmonella paratyphi A* and *B* were found to be 1: 40 and 1:80, respectively (Rucha Patki *et al.,* 2017). Although blood culture remains the gold standard test for diagnosing enteric fever, it may not be available in many rural areas. In that case tube widal can be used, which is relatively skill based, time consuming, inexpensive and Non-invasive. And when compared with the slide widal test, sensitivity and specificity of tube widal test is much remarkable than the slide widal test, so it can be indefinitely used as a diagnostic test.

Limitations of the Study

Time duration of the study is short. Sample size is less to arrive at a definitive conclusion. Cost effectiveness is a factor.

Post-centrifugation Hemolysis (practical issues).

Widal test is used to detect antibodies against *Salmonella typh*i, *Salmonella paratyphi A and B* only but no other *Salmonella* species, which are also human pathogens of medical importance but rare.

Table.1 Interpretation of Tube widal test

Interpretation of Tube Widal test	O	H	AH	BH
Positive for *Salmonella typhi* (Typhoid) fever	≥ 1:80	≥ 1:160	≤ 1:20	≤ 1:20
Positive for *Salmonella paratyphi A* (paratyphoid 'A' fever)	≥ 1:80	≤ 1:160	≥ 1:160	< 1:160
Positive for *Salmonella paratyphi B* (paratyphoid 'B' fever)	≥ 1:80	≤ 1:160	<1 :160	≥ 1:160
Negative for Enteric fever	< 1:80	<1: 160	<1:160	<1:160

Table.2 Incidence of Enteric fever

Study population (N=400)	SLIDE WIDAL (N, %)	TUBE WIDAL (N, %)
Incidence of *Salmonella typhi*	**(52, 13%)**	**(92, 23%)**
Incidence of *Salmonella paratyphi A*	(0, 0)	(0, 0)
Incidence of *Salmonella paratyphi B*	(0, 0)	(0, 0)
Total number of Enteric fever cases	52 out of 400 cases	92 out of 400 cases
Negative for Enteric fever	(348, 87%)	(308, 77%)

Anamnestic response due to recent vaccination and cross infection

Prozone phenomenon of antibody excess.

Recommendations

Hospital antibiotic policy to be adhered and revised periodically. Serological profile of salmonella infection would help us to understand type prevalence and can be a potential tool for Epidemiological study and infection control. Molecular methods like polymerase chain reaction, DNA probes could be the future scope.

Large number of samples can be subjected for the comparison between the slide and tube widal test to make the results still authoritative. Comparison of effectiveness between commercially available different widal kits. Comparison of results of widal test between the patients who have and have not consumed antibiotics prior to the widal test. Prospective study can be conducted to find the clinical correlation of the patient, who was positive for widal test.

Prevalence of Enteric fever evaluated by slide and tube widal agglutination tests were found to be 13% and 23% respectively. Though blood culture is the Gold standard for diagnosis of Enteric fever, the sensitivity is better only during first week of fever. Especially during second week of fever we could use widal test as an alternative or supplementary test of choice. We conclude our study with the fact that the performance of tube widal is better than the slide widal test.

Hence slide widal test alone cannot be used for diagnosis of Enteric fever especially during second week of fever. Though slide widal test is easy to perform and gives rapid results than the tube widal test, slide widal could only be considered as a supplementary test along with tube widal agglutination test.

Diagnosis of enteric fever earlier is very important, because of the prescription of irrational antibiotics where the results tends to be negative, so in that case tube widal test plays a major role in diagnosis of enteric fever. But now at present slide widal has been introduced in the diagnosis of the enteric fever. So this research is done to compare the qualitative and semi quantitative results of both the test, of which the results came satisfactory with tube widal which is highly superior in diagnosing the disease when compared to slide widal test, which can be applied as the diagnostic test.

Central Venous Catheter (CVC) remains a suitable form of vascular access for patients with chronic hemodialysis and has been estimated that almost 30-40% of patients are dependent on CVCs for their vascular access. Aim of the study is to determine the prevalence of Catheter Related Blood Stream Infections (CRBSIs). A Cross sectional study was undertaken after ethical committee approval, Blood samples (5ml-10ml) were collected from catheter site under sterile precautions and Blood Culture (Bac'T'Alert) performed and isolates grown were identified by routine methods as per standards. Antibiotic Susceptibility Testing was also performed and results noted. Out of the 60 samples processed 24 samples (40%) were "Culture Positives" and 36 samples (60%) were sterile and termed "Culture Negatives" after 5 days of incubation. The predominant Gram positive organism observed in our study was MRCONS followed by MSCONS. The prevalence of CRBSIs among chronic hemodialysis patients with central venous catheter in- situ was found to be 40%. Improving basic infection control measures and increasing the awareness by educating the health care providers could significantly reduce the occurrence of bacteremia could possibly aid in early diagnosis.

Introduction

Catheter Related Blood Stream Infections (CRBSIs) refers to bloodstream infection attributed to an intravascular catheter by quantitative culture of the catheter tip or by the difference in growth between catheter and peripheral venipuncture blood culture specimens (Harshal Shah *et al.,* 2013). Traditional classification of blood stream infections constitutes two variants viz., a. Community acquired, b. Health care associated or Hospital- acquired or Nosocomial infections (Friedman *et al.*, 2002). Central Venous Catheter (CVC) remains a suitable form of vascular access for patients with chronic hemodialysis and has been estimated that almost 30-40% of patients with

chronic hemodialysis are dependent on Central Venous Catheters (CVCs) for their vascular access. Nosocomial infections are the major cause for repeated hospitalization and death in hemodialysis patients in many countries (Masashi Suzuki *et al.,* 2016). The prevalence of Catheter Related Blood Stream Infections ranges between 10-30% in hemodialysis patients which occurs at a rate of 0.5-47/1000 catheter days (Ramasubramanian *et al.,* 2014). Catheter Related Infections are associated with substantial morbidity and mortality. Therefore, it is a potential menace and clinical challenge for Nephrologists and Physicians to diagnose CRBSIs early and to initiate appropriate management to prevent further complications. Strict adherence to Catheter care and Universal Safety Precautions by the health care providers will reduce the incidence of CRBSIs to a significant level.

Catheter Related Infections results from migration of skin commensals along the catheter into the blood stream or by contamination and or by colonization of catheter lumens by pathogenic microbes. Prevention strategies are directed at decreasing the growth and adherence of pathogens to catheter hub and or to the surface (Abhilash Chandra *et al.,* 2016). Recently, promising techniques like Antibiotic Lock Therapy was introduced where antimicrobial solutions are instilled into the lumen of the catheter between the hemodialysis sessions in order to address intra luminal sources of infection (Jun Zhang *et al.,* 2016). Antimicrobial solutions (Vancomycin-heparin (2.5mg/ml), Cefazolin-heparin (5mg/ml), Gentamicin–Sodium citrate (40mg/ml)) can prevent biofilm formation (Lars Skov Dalgaard *et al.,*).

Bio film acts as an important source of bacteremia and also a key factor favoring bacterial lodgement and in turn results in bacterial resistance thereby limiting the physician's antibiotic options for therapeutic management of CRBSIs. At the same time, concerns about the toxicity of antimicrobial lock therapy in case of over fill, especially at higher concentrations must be overlooked (Jun Zhang *et al.,* 2016). The risk factors for CRBSIs in chronic hemodialysis patients includes: i) Septicemia, ii) Stenosis, iii) Atheromatous plaques, iv) Aneurysm dilatation, v) Low serum albumin level, vi) Low BMI, vii) Diabetes, viii) infections, ix) High BUN (Tarek *et al.,* 2016). The specific aim of this study is to determine the incidence rate of Catheter Related Blood Stream Infections among chronic hemodialysis patients with central venous catheters in- situ. The objectives of our study are to evaluate the bacteriological profile, antibiotic susceptibility pattern and to screen for specific drug resistance among the culture isolates if any.

A study conducted by Masashi Suzuki *et al.,* on Bacteremia in hemodialysis patients showed that the risk of bacteremia was higher and the common causative organisms resulting in bacteremia were found to be Gram- positive bacteria (Masashi Suzuki *et al.,* 2016). Intricate details of review regarding Intravascular Catheter-Related Blood Stream Infections viz., epidemiology, pathogenesis and microbiology of CRBSIs and current guidelines for the diagnosis, management and prevention of these infections are very well elucidated by Harshal Shah *et al.,* in their study done elsewhere (Harshal Shah *et al.,* 2013). Deborah Friedman *et al.,* developed a new classification scheme for CRBSIs that distinguishes community- acquired CRBSI and nosocomial acquired CRBSI (Friedman *et al.,* 2002). The most common risk factor for bacteremia in hemodialysis patients is the use of central venous catheters. Previous hospitalization in turn serves as a second leading risk factor for CRBSIs. Membrane reuse was also found to be an important risk

factor for septicemia. Likewise, Diabetes mellitus and Hypoalbuminemia (<3.5mg/dl) were also found to be important risk factor for recurrent bacteremia. Analysis of "United States Renal Data System" reported 50% higher risk of septicemia in hemodialysis patients who were on temporary catheter. (Abhilash Chandra *et al.,* 2016) Bacteremia may be the result of either extra luminal or intra luminal catheter surface infections.

Extra luminal catheter surface infections are associated with percutaneous catheters. Following catheter hub contamination, infection spreads by exit site infection with subsequent migration into the blood stream along the extra luminal surface. Other unusual causes reported were intrinsic contamination of infusates and hematogenous seeding from distant infections (Harshal Shah *et al.,* 2013).

According to the guidelines for the diagnosis and management of the intravascular catheter-related infection by the Infectious Diseases Society of America (IDSA), a definitive diagnosis of CRBSI require/s the following: (a) a set of peripheral blood cultures; (b) blood cultures from the peripheral vein and from a culture of the catheter tip; or (c) cultures from an arterial and venous catheter hub that meet differential time-to-positivity criteria (Masashi Suzuki *et al.,* 2016). In this study, blood cultures from the peripheral vein and from a culture of the catheter tip were taken into account for diagnosis. In addition to this, Catheter Related Blood Stream Infections were suspected in a patient with an intravascular catheter who developed the signs of septicemia viz., fever, dyspnoea, edema and were also considered to have CRBSIs. Extensive research data are available which reports Antibiotic lock therapy significantly reduces the incidence of CRBSIs. Commonly used antibiotics for antibiotic lock therapy are Gentamicin, Cefotaxime, Cefazolin, Minocycline and Vancomycin. Generally the treatment of bacteremia includes administration of systemic antibiotics and care of the catheter site (Masashi Suzuki *et al.,* 2016).

The main aim of this study to determine the prevalence of Catheter Related Blood Stream Infections (CRBSIs) among chronic hemodialysis patients with central venous catheters in-situ attending dialysis unit of our hospital.

The objectives of this study include, to evaluate the bacteriological profile of Catheter Related Blood Stream Infections in chronic hemodialysis patients with central venous catheter in- situ. To detect the Antibiotic susceptibility pattern of the clinical isolates identified. And to screen for the specific drug resistance patterns among clinical isolates.

Inclusion criteria

Chronic kidney disease patients (age ≥ 18 years) with tunneled central venous catheter in-situ for hemodialysis presenting with/without the signs and symptoms of septicemia.

Exclusion criteria

Patients who had not given informed written consent.

Patients positive for Hepatitis B, HCV, HIV were excluded.

Patients who had taken antibiotics in the last 1 month.
Chronic kidney disease Patients on non-tunneled catheters.

Materials and Methods

A Cross sectional study was undertaken after obtaining clearance from Institutional Human Ethics Committee (IHEC). Informed written consent was obtained from the study

participants viz., In-patients and Out-patients clinically diagnosed to have chronic kidney disease from Medicine department constitutes the study population. Blood samples (5ml-10ml) were collected from catheter site and also from peripheral vein under sterile and aseptic conditions in a blood culture bottle (BacT/ALERT^{R} FA plus 410851, Automated Blood Culture System) (Liesa *et al.,* 2016). Second blood sample was collected from the same patient at a time interval of 10-15 minutes (Wasse *et al.,* 2007) and were transported immediately to the Microbiology laboratory. The specimens obtained were processed by performing routine diagnostic tests like Aerobic culture, appropriate biochemical tests to aid in the identification of bacteria. The Antibiotic Susceptibility Testing was done and susceptibility patterns observed, analyzed and recorded as per Standard Operating Procedures.

The blood samples after inoculation were incubated in an automated blood culture system (BacT/ALERT^{R}) for a period of 5 days. In the meantime, a beep alert was considered as positive after which the bottles were taken out and Semi-quantitative blood cultures were done with 84µL volume in a disposable 5ml sterile plastic syringe on routine plating media viz., Blood Agar Plate (BAP), Mac Conkey Agar Plate (MAP), Chocolate Agar Plate (CAP) and were then incubated aerobically at 37^{o}C for 24-48 hours (Dubey *et al.,* 2010). The culture plates were read for presence or absence of bacterial growth. In case of positive cultures, Gram stain was performed and gram reactions were recorded. The culture isolates were identified by routine methods as per standard guidelines by interpretation of colonial morphology, gram reaction and routine Bio-chemical reactions and also with some other special tests like catalase, oxidase, nitrate, motility and etc. Interpretation of "culture sterile" was given as preliminary report after 2 days and as final report after 5 days of incubation in case of no growth.

Antibiotic Susceptibility Test (AST) were done on Mueller-Hinton Agar using by Kirby Bauer's disk diffusion method according to Clinical and Laboratory Standards Institute (CLSI) guidelines with 0.5 and 1.0 Mac Farland turbidity standard of Gram-negative bacteria and Gram-positive bacteria respectively. A lawn culture of test organism was made on Mueller Hinton Agar Plate (MHAP) and commercially available antibiotic discs of fixed antibiotic concentrations were placed individually (5 to 6 antibiotic discs were kept at a distance of 1.5 cm between each disc on standard 90mm Petri plate). MHAP was incubated at 37^{o}C under aerobic incubation for a period of 16-24 hours and Antibiotic Susceptibility Patterns were noted by reading the zone of inhibition around the antibiotic disc (Sahu *et al.,* 2012). Specific drug resistance patterns viz., MRSA, VRE, CRE, AmpC, ESBL, K1 enzyme production were identified by combination or double disk potentiation method and etc., as per CLSI 2018 guidelines. Quality Control for Culture and AST were done using standard reference strains like *Escherichia coli* ATCC 25922 and *Staphylococcus aureus* ATCC 25923 standard reference strains. Data entry and Statistical analysis were done using IBM SPSS 23.0 Statistical Analysis software.

Results and Discussion

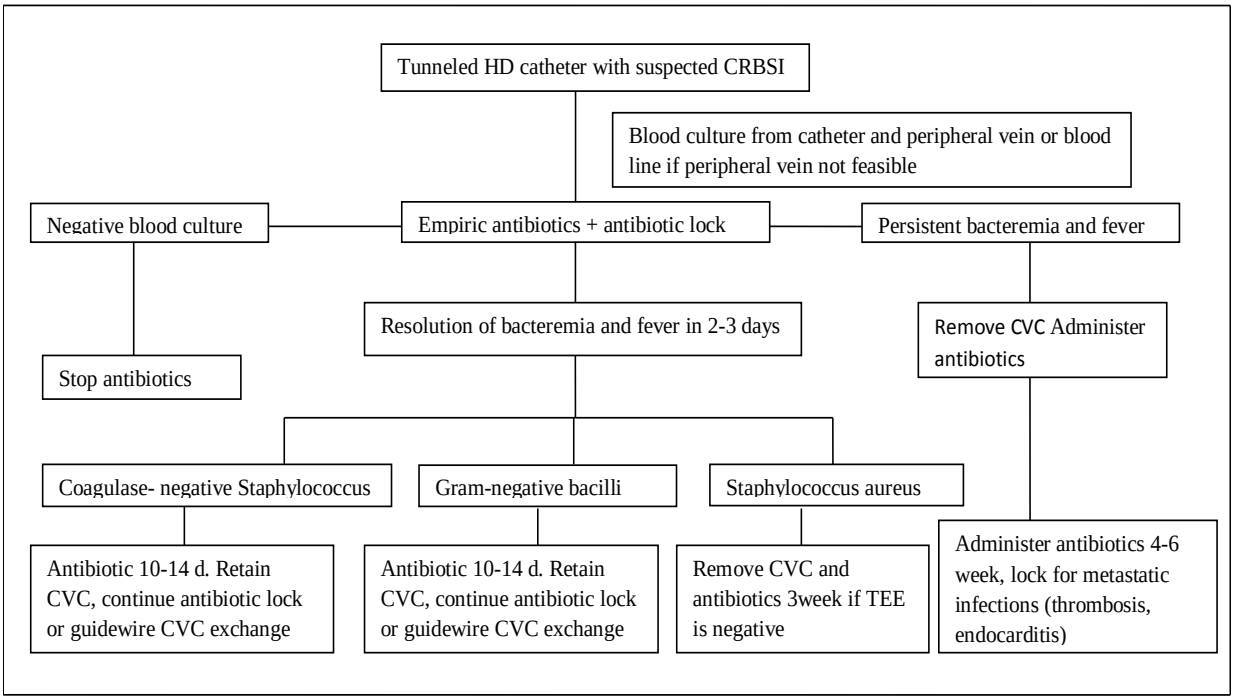
A total of 60 paired blood samples were collected from the study populations during the two months period. The male and female ratio was 1.07:0.93 with slight male preponderance (male 31 out of 60 (51.66%) & female 29 out of 60 (48.33%)). Out of the 60 samples processed for culture and sensitivity, nearly 24 samples (40%) were "Culture Positives" and 36 samples (60%) were sterile and termed "Culture Negatives" after 5 days of incubation.

Among culture positives, 19 out of 24 (79.16%) were identified as "Gram positive bacteria" namely Methicillin Resistant Coagulase Negative Staphylococcus (MRCONS, 8 out of 24, 33.33%), Methicillin Sensitive Coagulase Negative Staphylococcus (MSCONS, 3 out of 24, 12.5%), Methicillin Resistant *Staphylococcus aureus* (MRSA, 2 out of 24, 8.33%), Enterococcus (1 out of 24, 4.16%), Micrococci (2 out of 24, 8.33%), Aerobic spore bearing gram positive bacilli (3 out of 24, 12.5%).

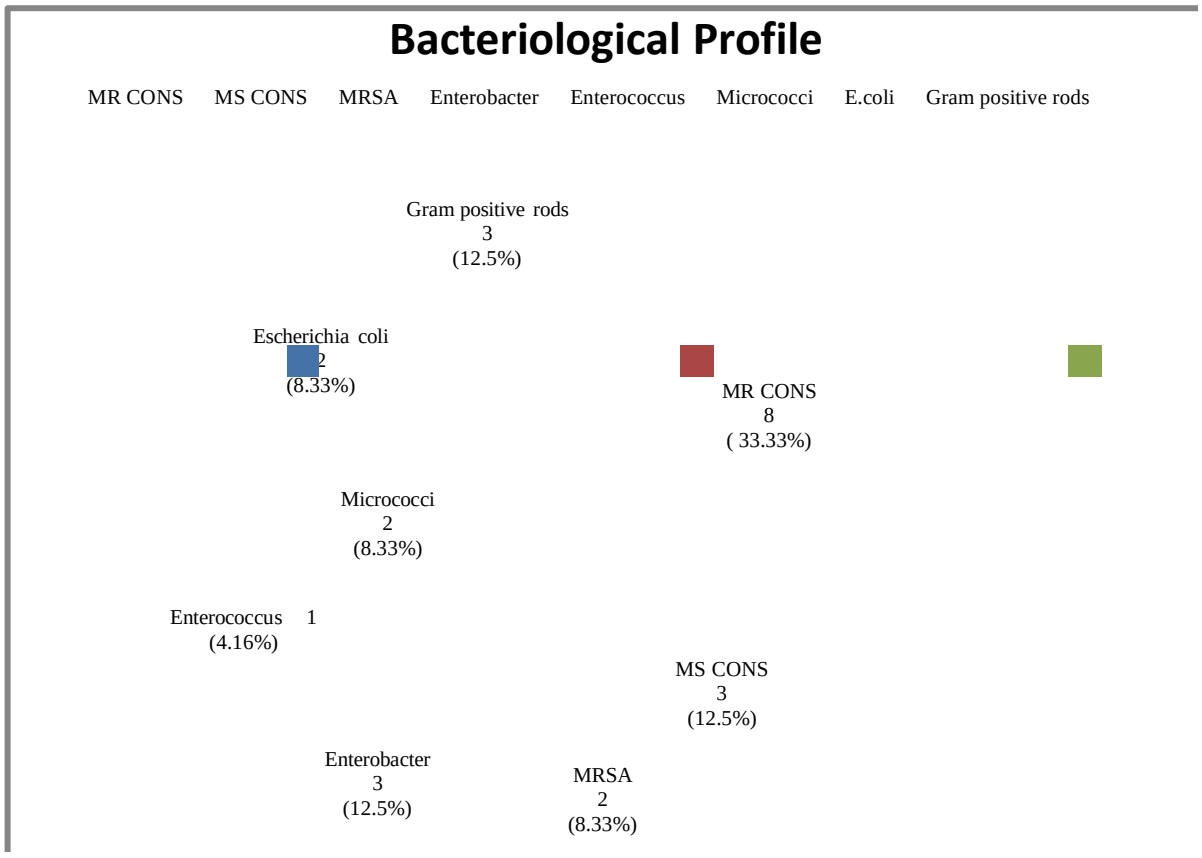
About 5 out of 24 (20.83%) culture positive isolates were identified as "Gram negative bacteria" namely Enterobacter species (3 out of 24, 12.5%), *Escherichia coli* (2 out of 24, 8.33%).

The predominant Gram positive bacteria observed in our study was MRCONS followed by MSCONS, MRSA and Micrococci.

The predominant Gram negative bacteria that were isolated from the study population was found to be Enterobacter species followed by *Escherichia coli*.



MRCONS culture isolates exhibited resistance to Erythromycin and Penicillin G. MSCONS manifested resistance to Erythromycin. MRSA manifested resistance to Gentamicin and Penicillin G. Among Enterococcal isolates, Gentamicin and Doxycycline showed resistance. In our study, all the Gram positive bacteria were found to be susceptible to Vancomycin, Linezolid, Doxycycline and Gentamicin. Among Gram negative isolates Enterobacter species showed resistance to Amoxycillin Clavulanate, Ampicillin and Ciprofloxacin. This isolate was susceptible to Tigecycline, Amikacin, Imipenem and Tobramycin. *Escherichia coli* isolates displayed resistance to Ampicillin, Amikacin and were susceptible to Ceftazidime, Cefotaxime, Piperacillin and Tazobactam.



In our study, the prevalence of Catheter Related Blood Stream Infections among chronic hemodialysis patients with central venous catheter in- situ was found to be 40%. Gram positive bacteria comprised 3/4th of the cases while the remaining 1/4th were Gram negative bacteria.

Most of the studies showed that prevalence rate of bacteremia due to MRSA (Masashi Suzuki *et al.,* 2016) as high whereas in our study prevalence rate of MRCONS (33.33%) was higher than that of MRSA (8.33%).

Recommended practices for prevention of catheter related bloodstream infections include: a) To limit the insertion of catheter to the trained personnel; b) To use > 0.5% chlorhexidiene plus alcohol or povidone-iodine for preparation of skin; c) Strict adherence to maximum sterile barrier precautions like head cap, face mask, sterile gown, sterile glove and sterile full body drape while insertion of catheter and also during guidewire exchange; d) Complete hand hygiene prior to insertion, assessment or changing the dressing is mandatory; e) To use subclavian vein instead of internal jugular or femoral vein; f) To scrub catheter hubs with appropriate antiseptics after cap is removed and before accessing; g) To replace gauze dressings every 2 days once and to replace semi-permeable transparent dressing every 7 days once; h) To remove intravascular catheter when it is no longer required for patient care (recommended) (Harshal Shah *et al.,* 2013).

Fig.1 Management guidelines for CRBSIs in chronic hemodialysis patients on Central Venous Catheter

The potential limitations of this study are: a) The Sample size is considerably low to understand the epidemiology of CRBSIs. b) Follow-up of patients was difficult. c) Anaerobic bacteriological profile was not done. d) Antibiotic consumption by patients during the last 1 month could have had been the reason for culture negatives in cases of unreliable drug history given by the patients. e) Lack of hospital antibiotic policy exempted as to correlate right prescription of antibiotics by Physician according to the culture & sensitivity report given by the Clinical Microbiologist. f) Drug resistant pathogens identified were not subjected for molecular confirmation by PCR and other special confirmatory tests. g) Lack of hospital environment surveillance system to screen for prevailing nosocomial pathogens creates concerns about the understanding of epidemiology of CRBSIs. h) Data about the prevalence of nasal MRSA carrier state among health care providers (doctors, nurses, medical students and sanitary workers) and other specific drug resistance pathogenic bacteria are unavailable in our hospital.

Implications of the study

The study will give a first-hand research experience to the principal investigator in data collection, sample collection and performing special laboratory tests and co-relating their results with clinical outcome of the patients.

Details like Prevalence of CR-BSI's, Bacteriological profile, antibiogram of susceptible and drug resistant bugs will help understand the nosocomial pathogens causing these infections and in turn would help us revise the Hospital Antibiotic Policy. To Plan and execute periodic Environmental surveillance for Nosocomial pathogens. Designing good preventive measures in the form of practical, low cost, low-technology system that is feasible to implement.

To conclude, when we encounter hemodialysis patients with catheter as vascular access presenting with fever, the first diagnosis to be considered is CRBSIs (Abhilash Chandra *et al.,* 2016). The prevalence of CRBSIs among chronic kidney disease patients receiving hemodialysis was found to be 40%. Evidence- based guidelines is available to plan appropriate antibiotic treatment and holistic catheter management when infection occurs. Risk of CRBSI can be reduced by optimizing catheter insertion and maintenance and by also removing catheters when they are no longer needed. Improving basic infection control measures viz., hand hygiene and other universal safety precautions. Increasing the awareness and educating the health care providers and patients, could significantly reduce the occurrence of bacteremia and could possibly aid in early diagnosis and prompt therapeutic management of CRBSIs. Although this is difficult because the blood streams of these patients frequently exposed to extracorporeal devices (Masashi Suzuki *et al.,* 2016).

Prevalence of Vancomycin Resistant Enterococci Carriers from Rectal Swabs among High Risk Patients in a Tertiary Care Hospital

M MOHAMADIYA RIZWANA[1], S PARVATHI[2], B APPALARAJU[3]

(cc) BY-NC-ND

Keywords: Chromogenic media, *Enterococcus faecium*, *Enterococcus faecalis*, Urinary tract infections

Dear Editor,

Enterococci with acquired vancomycin resistance is a major concern amongst hospital. These resistant species have the ability to survive for prolonged periods and they can get transmitted easily. The infections caused by these organisms range from complicated Urinary Tract Infections (UTI) to life threatening Central Nervous System (CNS) infections making the treatment challenging [1]. The rate of Vancomycin Resistant Enterococci (VRE) colonisation in Northern India is nearly 34.5%, with *van A* genotype being the most common [2]. Studies have reported that active screening through rectal swabs is a definite tool in preventing complications in high risk patients by early identification and treatment of VRE carriers [3]. The conventional method of screening with bile esculin azide agar supplemented with 6 µg/mL of Vancomycin/ml is reasonably sensitive but requires confirmation by molecular techniques [4]. The molecular methods in the detection are limited to the referral laboratories. Development of highly specific chromogenic substrates in the VRE selective media help in effective screening of colonisers. The sensitivity and specificity of the chromogenic media was 100% and 99%, respectively [4]. This was in accordance to present study as well. This study was undertaken to screen the high risk patients in critical care for VRE colonisation from stool samples and identify the genotype. Early identification of the carrier state in high risk patients is helpful in planning the management strategy of these patients.

This was an observational study done over the period of three months from January to March 2016 at PSGIMS&R, Coimbatore, Tamil Nadu, India. The Institutional Human Ethical clearance number obtained was 14/118. Informed consent was obtained before collecting the rectal swabs. The criteria for high risk patients were defined as hospitalisation >7 days, chronic haemodialysis, use of multiple antibiotics and associated chronic disease status. Rectal swabs were obtained from 100 patients (no repeat isolates and the mean age group was 60 years 75% were males) following the identification as high risk as per the criteria explained above. The rectal swabs were streaked on chromogenic ChromID VRE media (Biomerieux) and incubated at 37°C for 24 hours. The presence of violet colour colonies indicated *Enterococcus faecium* and blue colour colonies indicated *Enterococcus faecalis*. Isolates with intrinsic resistance to vancomycin as *Enterococcus casseliflavus* and most of the other gram positive organisms were selectively inhibited by this media. Conventional biochemical tests as bile esculin, mannitiol, argininine and PYR (Pyrrolidonyl Arylamidase) were done for confirmation at the species level. The antibiotic sensitivity was also performed by Kirby Bauer method as per the CLSI guidelines [5]. The antibiotic susceptibility pattern of the 100 isolates showed the maximum sensitivity to linezolid (98%) followed by vancomycin (97%), erythromycin (89%), teicoplanin (75%), ampicillin (69.2%), high level gentamycin (49.2%) and penicillin (25%). The Minimum Inhibitory Concentration (MIC) of the resistant isolates was confirmed by using commercial E-strips. Molecular characterisation of the resistant isolates for the specific genotype was done by performing conventional PCR. The DNA from the resistant isolates was extracted using the QIAGEN kit. The primers of base pair 732bp for detection of *van A* were used. The PCR products were analysed by running gel electrophoresis and visualised under UV light in automated GEL DOC viewer. Primers for *van A* used were:

F (5' GGGAAAACGACAATTGC-3')

R (5'GTACAATGCGGCCGTCGTTA-3') [6]

Out of the 100 patients screened, three were found to be positive for VRE carriage (3%). All the three were *Enterococcus faecium*. The positive sample was used as the control strain. Analysis of the predisposing risk factors among the three patients revealed the association of chronic renal impairment, immunocompromised status (retroviral infection) and presence of co-morbid conditions such as diabetes mellitus along with prolonged hospital stay.

The VRE carriers can pose a risk to the patients harboring these pathogens as they can invade the host and result in bacteremia complicating the management. In such patients, treatment of the VRE carriage aids in better prognosis. Isolation and cohorting of these patients prevents the transmission and risk of infection in other patients, especially in healthcare setups. The choice of VRE screening can aid in proper infection control measures.

Thus, chromogenic VRE media was found to be a simple and rapid method for identifying VRE carriage.

Declaration: The present study was presented as poster presentation in 39th National Conference of the Indian Association of Medical Microbiologists MICROCON in 2015.

A B S T R A C T

Enterococci mainly being commensals in human faeces are now considered as an important cause of nosocomial infections. Of the infections, the commonly observed are urinary tract infections, abdominal infections followed by bacteremia, endocarditis and meningitis rarely. Speciation of *Enterococcus* aids in effective management of the infections caused by them. The initial treatment for enterococcal infections has become challenging due to development of resistance. The resistance has been observed mainly against aminoglycosides due to the presence of bi-functional gene. VRE strains are mostly isolated from patients with recurrent bacteremia, endovascular infections leading to increase deaths in the patients. To isolate and speciate enterococcal isolates from clinical samples, study the antibiotic susceptibility pattern and the genotype associated with the aminoglycoside and vancomycin resistance. *Enterococcus* isolates obtained from various sections were characterized by conventional phenotypic methods. The antibiotic susceptibility was studied by disc diffusion method. The resistant strains were further confirmed by MIC using automated methods following which the genotypic analysis was done. The incidence of *Enterococci* was 2.5% in which around 86.4% were obtained as pure isolates. Among the species *E. faecalis* was found to be the maximum. The urinary isolates exhibited sensitivity of around 92.3% to nitrofurantoin and among the non - urinary isolates the maximum sensitivity was for linezolid. The molecular study showed van A to be most common gene with vancomycin resistance (71.42%), and bifunctional gene among the aminoglycoside resistance (96%). *Enterococcus faecalis* was the commonest species isolated. The maximum number of isolates was obtained from urinary samples. The increase incidence of resistance gene to high level gentamicin could result in failure to the synergy treatment of gentamicin in combination with penicillin group of antibiotics. The emergence of vancomycin resistant strains among the clinical isolates makes treatment options more challenging.

Introduction

Enterococci are gram positive organisms having the property to grow at 6.5% NaCl concentration, pH of 9.6 and hydrolyze bile esculin. Initially they were grouped under group D Streptococcus but later with the help of DNA studies they are characterized under the genus *Enterococcus* in 1960. They were considered as harmless pathogens formerly, but in the recent years have been emerging as the most important causative agents in nosocomial infections (Murray *et al.*, 1990).

Enterococci being the commonest micro flora of both humans and animals share their source

of origin. They have been isolated from variety foods including cheese, fish, sausages, beef and pork. Studies have been reported that *Enterococci* have been isolated from various clinical and environmental samples all over the world. Among the isolates obtained clinically it has been observed that *Enterococcus faecalis* has been the predominant species clinically (Lancefield *et al.,* 1933; Cetinkaya *et al.,* 2000).

Enterococcal infections have been referred to as tough, tenacious and troublesome infections (Marothi *et al.,* 2005).In the past years there has been an increase in the prevalence of enterococcal infections in hospitals and of particular concern is the emergence of antimicrobial resistant strains. Being second commonest organism behind the abdominal and pelvic infections, third in causing blood stream infections, cases have also been reported in causing CNS and neonatal infections.

Reports have been confirmed with their association with clinical conditions including respiratory tract infections, osteomyelitis and cellulitis (Fischer *et al.,* 2009). *Enterococci* were initially regarded as the disease causing agent in the early nineties. But now various reports have been established reporting them as the second commonest pathogen (Kuhn *et al.,* 2003).

Species identification becomes essential for investigating outbreaks in case of nosocomial infections and also susceptibility pattern varies accordingly which is also helpful in clinical management of infections due these agents (Gordon *et al.,* 1992).

Infections caused by enterococcal pathogens were initially being treated with the combined treatment of cell wall active agents as penicillins and aminoglycoside as the synergistic effect was effective. But now due to the development of antibiotic resistance as high level aminoglycoside resistance, beta lactamase production and also resistance to vancomycin have led to serious concern in management of these nosocomial pathogens (Mendiratta *et al.,* 2008). Vancomycin resistant *Enterococcus* was initially reported in 1980s, after which there was a increase in the incidence of its spread. The main phenotypes associated with its spread are Van A, Van B and Van C. Van A and Van B are mainly associated with *E. faecalis* and *E. faecium*. Van C is noted in *E. gallinarum* and *E. casseliflavus*. Among the phenotypes Van A is predominantly associated in the resistant strains.

VRE strains are mostly isolated from patients with recurrent bacteremia, endovascular infections leading to increase deaths in the patients. Vancomycin resistance and penicillin resistance are often seen co-existing which makes the treatment harder (Murray *et al.,* 1990).

Resistance development in *Enterococcus* against glycopeptide antibiotics gets transferred from them to other bacterial pathogens which include *Staphylococcus aureus, Streptococci, Listeria monocytogenes* (Gold *et al.,* 1996).

Thus due to the recent emergence in association with significant clinical infections and development of resistance, *Enterococci* have gained importance. Studies are thus required especially in tertiary care hospitals for appropriate isolation, identification and speciating them.

Antibiograms should also be followed up in accordance to the species. Emergence of VRE needs to be checked and limit its spread in hospital environment. CDC also stresses the control of VRE in hospitals by educating the staff in detecting VRE early, reporting them and action plan taken promptly.

Our study aims to isolate, speciate the *Enterococcus* in a simplified manner and also to study the drug sensitivity and resistance patterns among the isolates obtained.

Materials and Methods

The Institutional Human Ethical clearance was obtained before the commencement of the study.

Type of study

Experimental study

Confidentiality

Confidentiality of the reports were maintained

Sample size estimation

A total of 250 isolates of *Enterococci* obtained from outpatient and inpatient samples from blood section, miscellaneous and urine section were processed for the species identification, antimicrobial sensitivity followed by molecular study.

Specimen processing: Specimens from various sections including urine, pus and blood for cultures were collected and processed in the laboratory.

Pus/wound swabs

The swabs were streaked in blood agar and MacConkey agar and were incubated at 37^0C for 24 hours.

Urine

A loopful of the uncentrifuged specimen was examined as a wet mount for the presence of pus cells and bacteria. One loopful of specimen was inoculated onto blood agar and Mac Conkey agar. Plates were incubated at 37^0 C for 24 hours.

Growth in sheep blood agar

Following overnight incubation of the samples, colonies of *Enterococcus* were seen as grey colonies of about 0.5-1mm in diameter with alpha, beta or gamma hemolysis.

Growth in Mac Conkey agar

Colonies were about 0.5- 1mm in size with a smooth surface and convex margins, tiny magenta colored following 18-24 hour growth.

Catalase test

A drop of the catalase reagent (30% hydrogen peroxide) was added to the slide.

The growth was further applied to it with an applicator stick. Appearance of bubbles was taken as positive test.

Enterococcal colonies showed a negative test due to the absence of bubbles.

Gram stain

Smears made from the colony showed Gram positive cocci arranged singly, in pairs or in short chains.

Storage

If the isolate was catalase negative, gram staining showing the presence of gram positive cocci in pairs or short chains and growth in MacConkey agar as tiny lactose fermenting colonies, they were sub cultured and pure growth was stocked in Robertson's cooked meat medium in tubes.

The tubes were sealed and stored at 4-8^0C for 3-6 months. When the test was to be done they were further sub cultured.

Identification tests

Growth in media with pH – 9.6

Isolated colonies of *Enterococcus* was streaked in a media with a pH 9.6 and incubated at 37^0C overnight. The presence of growth was taken as positive.

Tolerance with 6.5% NaCl

The colonies were inoculated in a broth with 6.5% NaCl, and incubated overnight. The next day the tubes were checked for any increase in turbidity. This was further confirmed by sub culturing onto the agar plates. Growth confirmed the presence of organism. Whereas absence of turbidity indicated organism was unable to grow in this concentration.

Heat tolerance test

Enterococcus was inoculated in Todd-Hewitt broth. It was later incubated in water bath set at 45^oC overnight and 60^0 C for half an hour, and then sub cultured. *Enterococci* survived both the temperature showing positive reaction.

Bile esculin test

Colonies from 24 hour culture were inoculated in media containing 40% bile. Blackening of the medium confirmed positive reaction for *Enterococci* and non-*Enterococci*.

PYR test

The colonies were inoculated in PYR broth and incubated for a period of 4 hours. Later 3 drops of PYR reagent was added to it and change of colour to red was confirmed positive indicating *Enterococci* whereas absence of colour change indicates negative test.

Motility test

Stab culture of the colony was done in a semi-solid media and motility was indicated by the spread of the organism into the media. The strains which did not diffuse into the media were considered non-motile. Tubes were incubated for up to 7 days for confirming motility.

Arginine test

A well isolated colony of *Enterococcus* from the culture was inoculated in Moeller's decarboxylase media with arginine as the amino acid and overlaid with mineral oil. After 24 hours of incubation the colour of the tube was changed to purple indicating a positive reaction. Yellow colour indicated only acid production only and no deamination.

Potassium tellurite reduction test

Colonies were streaked in media containing 0.004%potassium tellurite. *E. faecalis* formed black colonies with the reduction of tellurite to tellurium.

This test was used to differentiate *E. faecalis* from *E. faecium.*

Pyruvate test

When inoculated in a media containing pyruvate with bromothymol blue as indicator *E. faecalis* showed a colour change from green to yellow color after overnight incubation. Absence of colour change ruled out *E. faecalis.*

Pigment production

Ability to produce pigment was observed by a few species of *Enterococci*. This was tested by sub culturing colonies in nutrient agar.

Any color produced was visible and also further confirmed by touching the colony with a sterile swab.

Sugar fermentation tests

Species identification was further done by sugar utilization by inoculating the organism in peptone with 1% sugars with Andrade indicator. The sugars used were mannitol, arabinose, raffinose, sorbose, sorbitol, lactose and sucrose. Any change in colour from colourless to pink indicated the positive sugar fermentation test. Absence of colour change was taken as negative.

Antimicrobial susceptibility test: (CLSI 2015)

The 250 test isolates of *Enterococci* were checked for the antimicrobial susceptibility pattern using Kirby-Bauer disc diffusion method. Three or four pure colonies were inoculated in peptone water and incubated for about 3 hours. The turbidity of the growth was matched to 1 of Mc Farlands. A lawn culture of the broth with a sterile swab was done in Muller Hinton agar and the discs were placed at a distance of 24 mm.

About 6 discs were kept on each plate. The discs used were Penicillin (10U), Ampicillin (10µgm), Amoxicillin Clavulanic acid (20/10), Erythromycin (15µgm), Vancomycin (30µgm), High level gentamicin (120µgm), Linezolid (30µgm), Tetracycline (30µgm). For isolates from urine section Norfloxacin (10µgm) and Nitrofurantoin (300µgm) was kept. All discs were bought from HIMEDIA.

Zones of inhibition were measured and recorded and the organism was interpreted as sensitive or resistant as per the recommendations from CLSI guidelines. The quality Control used was *Enterococcus faecalis* ATCC 29212.

Screening for high level gentamicin resistance (CLSI 2015)

Screening media for high level gentamicin resistance was prepared. Screening for high level gentamicin resistance was done by agar dilution method. BHI agar with gentamicin at a concentration of 500µgm/ml was added and the plates were prepared. Inoculum of 10µL of 0.5 Mc Farland was spot inoculated. Presence of even 1 colony was interpreted as a resistant strain. These strains were collected for molecular studies.

Detection of beta lactamase (Marothi *et al.*, 2005)

The detection of beta lactamase test was done based on the chromogenic cephalosporin method. Nitrocefin disc was obtained commercially from BD. The disc was moistened with sterile saline and pure isolated colony was applied on it. The reaction was read within 5 min. Isolates producing beta lactamase produced a red color.

Molecular study of isolates

A representative sample of 50 high level gentamicin resistant isolates was selected for genomic analysis. The DNA was extracted using the QIAGEN kit. Followed by extraction, the isolates were analysed for the presence of Bifunctional resistant geneaac (6') le aph (2") la. The vancomycin resistant isolates were checked for the presence of van A gene simultaneously.

Detection of aac (6') le aph (2") la gene

The primers for HLGR with a base pair of 348 bp were amplified. The sequence was obtained from the studies done previously[11]. PCR Master mix: The master mix was prepared as follows: 2.5µl of PCR buffer,2.5µl of MgCl2, 2.5µl of DNTPs,

10.2µl of Mili Q H2O, 1µl of forward and reverse primers and 0.3µl of Taq Polymerase was added to eppend off. From the above mixture 18µl was taken and 5µl of the extracted DNA was added.

Primers for aac (6')Ie- aph (2")la with base pair of 348 bp (Vakulenko *et al.*, 2003):

F (5'CAGAGCCTTGGGAAGATGAAG3')
R (5'CCTCGTGTAATTCATGTTCTGGC3')

PCR program

The program consisted of initial denaturation step at 95^0C for 10 minutes followed by 30 cycles of denaturation at 94^0C for 300 seconds, annealing at 56^0C for 1 minute and extension at 72^0C for a period of 1 minute. The program had a holding temperature of 72^0C for 10 minutes.

Analysis

PCR products were analyzed by running gel electrophoresis with 1.5% agarose gel in Tris Boric acid buffer. The samples along with the controls obtained by running ladder were analysed.

The gel was stained with ethidium bromide and the bands were obtained were visualized under UV light and also in automated GEL DOC viewer.

Detection of vanA gene

The primers with a base pair of 732bp for detection of vanA were obtained from the studies done previously.

Primers for van A with base pair of 732bp (Dutka-Malen *et al.*, 1995):

F (5' GGGAAAACGACAATTGC-3')
R (5'GTACAATGCGGCCGTCGTTA-3')

PCR program

This program had a denaturation step at 95^0C for 5 minutes followed by 30 cycles of DNA denaturation at 95^0C for 1 minute, annealing at 54^0C for 45 seconds and primer extension at 72^0C for 45 seconds. This was followed by a holding temperature of 72^0C for 10 minutes.

Analysis

PCR products were analyzed by running gel electrophoresis with 1.5% agarose gel in Tris Boric acid buffer. The samples along with the controls obtained by running ladder were analysed. The gel was stained with ethidium bromide and the bands were obtained were visualized under UV light and in automated GEL DOC viewer.

Results and Discussion

All the 250 isolates of *Enterococcus* from various clinical samples including urine, pus, wound swab, blood and CSF were processed.

The maximum number of isolates was obtained from urine section (184) followed by wound swabs (24), blood section (14), 4 from peritoneal samples, 1 from CSF (Figure 1). The majority of the isolates were obtained as pure growth (216) and 34 was obtained as mixed from the samples processed. Figure 2 depicts the speciation of enterococcal isolates in which *E. faecalis* was the predominant species (157), succeeded by *E. faecium* (79), *E. raffinosus* (7), and *E. durans* (5) and *E. casseliflavus* (2).

Illustration 1 shows the genus specific biochemical tests used in the identification.

The antibiotic susceptibility pattern of the enterococcal isolates by disc diffusion method revealed that out of the 250 isolates, about 69.2% were ampicillin sensitive, 49.2% were

high level gentamicin sensitive, 89.3% were sensitive to erythromycin. The maximum number of isolates was found to be sensitive to vancomycin (97.2%) in our study (Table 1). Among the urinary isolates maximum sensitivity was noticed to nitrofurantoin (92.3%) (Table 2) and norfloxacin (83.1%).

The maximum sensitivity was observed for linezolid followed by vancomycin, teicoplanin, ampicillin and high level gentamicin. Among the non-urinary isolates erythromycin sensitivity was observed to be the highest.

The chromogenic nitrocefin disc was used to screen the isolates for the presence of beta lactamase. In our study none of the isolates were found to be positive for beta lactamase.

Figure 3 shows the presence of Bifunctional gene aac (6')1eaph(2")1a among the high level gentamicin resistant strains. Out of the 50 randomly selected resistant strains for genotype study, 48 had the gene.

Illustration 2 shows the presence of bands of size 348 bp during the gel electrophoresis.

In our study 7 out of the 250 isolates were found to be resistant to vancomycin. The genotypic analysis was done among these resistant strains using the van A gene. The results showed that 5 of the 7 strains were found to be positive for van A gene (Figure 4).

Illustration 3 shows the presence of van A gene of base pair 732, confirming its presence among the resistant strains.

Enterococcus has been noted to cause a majority of urinary tract infections. This being the most common followed by bacteremia, sepsis and even case reports of meningitis has been reported. In our study out of 250 samples studied the majority of the isolates were obtained from urinary tract infections (73.6%) followed by wound swabs (9.6%) and blood (5.6%). This correlates well with other studies in which *Enterococci* was obtained from urine isolates maximally (Karmarkar *et al.,* 2004, Mathur *et al.,* 2003). According to the studies *Enterococci* are considered as the commonest urinary pathogen justifying the increase in the rate of isolation from urinary samples (Murray *et al.,* 1990).

Among the various species, in our study *E. faecalis* was the most common isolate accounting for 62.8% followed by *E. faecium, E. durans, E. raffinosus* and *E. casseleflavus.* Similar findings were reported from other studies done in Bangalore in which *E.faecalis* was 59%, *E. faecium* was 38 % (Golia *et al.,* 2014).

Enterococci show intrinsic resistance to cotrimoxazole, clindamycin, cephalosporins and normal aminoglycosides. Thus these antibiotics are not tested (Mendiratta *et al.,* 2008).

The antibiotic susceptibility pattern of the isolates in our study showed the following:

The sensitivity to linezolid was maximum (98.8%) followed by vancomycin (97.2%), erythromycin (89.3%), teicoplanin (75.2%), ampicillin (69.2%), high level gentamicin (49.2%) and penicillin (25%).

Among the urinary isolates maximum sensitivity was noted in Nitrofurantoin (92.3%) followed by Norfloxacin (83.15%). Studies done in North India showed a similar susceptibility pattern with increased resistance to penicillin and aminoglycosides. Also the sensitivity percentage to linezolid and vancomycin was higher compared to other antibiotics (Mulla *et al.,* 2012).

Another study showed the percentage of high level gentamicin resistance to be 68% (Randhawa *et al.*, 2004). Reports from South India showed the resistance percentage of high level aminoglycoside to be more than 50% (Sreeja *et al.*, 2012).

The detection of beta lactamase production by the chromogenic nitrocefin disc method showed that none of the isolates had beta lactamase enzyme. Studies done in Delhi and in Maharashtra also showed similar results (Jain *et al.,* 2011; Mendiratta *et al.,* 2008). The resistance to beta lactams though common, the mechanism could be due to alteration in penicillin binding protein PBP 5 which is more common than beta lactamase production (Murray *et al.,* 1992).

The molecular study done to detect the presence of the resistant gene confirmed the presence of the bifunctional gene aac (6') le-aph (2") la of base pair 348 to be present in 48 (96%) out of the 50 randomly selected resistant strains.

Studies done in Chennai have showed the presence of this gene in 38.2% of the isolates (Padmasini *et al.,* 2014) whereas there are other studies in which all the resistant isolates possessed this bifunctional gene (Hasani *et al.,* 2012). The resistance to high level gentamicin indicates resistance to all the aminoglycosides except streptomycin (CLSI 2015). The combination effect of aminoglycoside with beta lactam antibiotic is not helpful in the treatment of patients possessing such resistant strains.

Out of the 250 isolates the vancomycin resistant isolates obtained in our study was 2.8%. Studies have shown the prevalence of vancomycin resistance to be less in India ranging around 1.7-20% (Sreeja *et al.,* 2012).

Molecular studies revealed the presence of van A gene in 5 (71.42 %) isolates. Studies have also been reported showing van A to be the most common genotype isolated among the vancomycin resistant strains (Praharaj *et al.,* 2013)

Out of the seven isolates, five were *E. faecium* and two were *E. casseliflavus*. The remaining two isolates were *E. casseliflavus* which would have exhibited intrinsic resistance to vancomycin with van C gene (Praharaj *et al.,* 2013).

The incidence of *Enterococci* from the clinical isolates in our study was 2.5%.

The incidence of the pure isolates was 86.4% in comparison to the mixed isolates which was found to be 13.6%.

Among the isolates of *Enterococci*, the predominant species was *E. faecalis* (62.8%) followed by *E. faecium* (31.6%), *E. raffinosus* (2.8%), *E. durans* (2%) and *E. casseliflavus* (0.8%).

The antibiotic sensitivity pattern of the urinary isolates showed 92.3% sensitive to nitrofurantoin and 83.15% sensitive to norfloxacin. Among the non-urinary isolates maximum sensitivity was observed in linezolid which was 98.8% followed by vancomycin (97.2%), erythromycin (89.3%), teicoplanin (75.2%), ampicillin (69.2), high level gentamicin sensitivity (HLG) (49.2%) and pencillin (25%) (Table 3).

The vancomycin resistance was found to be 2.8% in *E. faecium*.

All the isolates were found to be beta lactamase negative by chromogenic (nitrocefin) method proving the alteration in PBP5 to be the more common mechanism involved in penicillin resistance.

The molecular characterization of HLGR(high level gentamicin resistant) strains, 50 isolates selected randomly out of 127, showed the presence of bifunctional gene aac(6')le-aph(2")la to be around 96%. (Primers of base pair 348 - F (5'CAGAGCCTTGGGAAGATGAAG3') R (5'CCTCGTGTAATTCATGTTCTGGC3')

The presence of van A gene was found to be 71.42% in our study.

Abstract

Background: Globally, type-2 diabetes mellitus is increasing in epidemic proportions. A major cause of concern in India is the increasing incidence of cases, especially troubling is the observed increase in younger age groups with no risk factors. New evidence suggests that many environmental factors, such as air pollution, persistent organic pollutants (POPs), and environmental estrogens are implicated as risk factors for type-2 diabetes mellitus. Animal and human epidemiological studies have shown ubiquitous lipophilic substances, including POPs, are frequently associated with type-2 diabetes mellitus. Such studies have not been undertaken in Indian youth. **Methods:** This is a cross-sectional study that explored the association between POPs and type-2 diabetes mellitus in Indian urban and rural population. About 7 ml of venous blood was collected from all consenting patients and serum was separated immediately and was transported to the lab for further analysis. Serum levels of POPs, including organochlorine (OC) compounds and organophosphorus pesticides, were estimated using sample gas chromatography-mass spectrometry (GC-MS). The fasting blood sugar values and the serum levels of POPS were tested using Pearson correlation coefficient. The magnitude of increase in blood sugar corresponding to increase in POPs was analyzed using linear regression analysis. The odds ratios (ORs) were expressed at 95% confidence intervals (CIs). **Results:** Three OC pesticides and one organophosphate pesticide were strongly associated with increasing blood sugar levels after adjusting for age, sex, and body mass index – lindane (OR 4.95, 95% CI 1.03–23.73), DDT o, p' (OR 3.50, 95% CI 1.04–11.73), dimethoate (OR 19.31, 95% CI 4.22–88.37), and dichlorvas (OR 6.33, 95% CI 1.28–31.18).

Keywords: DDT, dimethoate, health effects, persistent organic pollutants, pesticides, type- 2 diabetes mellitus.

Introduction

Incidence of diabetes is rapidly increasing worldwide.[1] The dominant risk factors include obesity, sedentary lifestyle, poor diet, old age, ethnicity, family history of diabetes, and dyslipidemia. Prevalence of diabetes for all age groups worldwide was estimated to be 2.8% in 2000 and expected to rise to 4.4% by 2030. The total number of people with diabetes is projected to rise from 171 million in 2000 to 366 million in 2030.[1] Type-2 diabetes is an epidemic in Asia, characterized by a rapid increase in onset at relatively young ages and low body mass index (BMI),[2] and environmental estrogens implicated in the rise of the same.[3] Persistent organic pollutants are a class of compounds characterized by their ability to persist in the environment, due to their low water, high lipid solubility and bio-magnification in the food chain.[4] POPs include polychlorinated dibenzo-p-dioxins, polychlorinated dibenzofurans, polychlorinated biphenyls (PCB), hexachlorobenzene, p, p'-dichlorodiphenyldichloroethylene (DDE), and several organochlorine (OC) mixtures. These have been studied by international organizations for their impact on environment and humans alike and have been implicated in several adverse effects on human health especially with impaired glucose metabolism and prevalence of diabetes mellitus.[4,5] India, a highly populated middle-income country, is subjected to environmental contamination of POPs from several activities

and sources like production units, illegal imports as well as stockpiles of obsolete pesticide.[6] Except for DDT seven other pesticide POPs listed in the Stockholm Convention are banned for manufacture but are in wide use because large stockpiles are still available. In a nationwide food survey in 2001, 75% of the samples had detectable levels of DDT with about 10–15% of the samples having levels of DDT that exceeded the levels prescribed by the Food and Agricultural organization and World Health Organization. Aldrin and dieldrin were also frequently detected pesticides in foodstuffs.[7,8] Racial and ethnic differences in responses to POPs are well known.[9] POPs may be associated with T2DM with a higher magnitude in Asians, contributing to the epidemic. Hence, prevention and control of diabetes is a top public health priority in Asian populations.[10]

Many studies based on self-reported diabetes and mortality rate analysis indicate an association between pollutants and diabetes/prediabetes.[11,12] Many POPs act as endocrine disrupting agents in animals and humans.[13] Concentrations of most of these pollutants have been diminishing in the environment, food chain, and human body over recent decades in Europe and the United States. However, there are subgroups within these populations that still show an elevated body burden because of dietary habits and current or past exposures.[11] Diabetes has been associated with dioxin-like chemicals, nondioxin like PCBs, DDE, and/or other OCs in several cross-sectional investigations.[4,11,14,15] Altered glucose transport, lipid metabolism, and modifications in the insulin signaling pathways are potential mechanisms that might be involved in the association between POPs and diabetes.[11] The Jørgensen group showed that POPs may affect insulin secretion rather than insulin resistance.[16]

POPs metabolism, particularly low-level exposures, warrants investigations using a cohort study design.[17] There have been few studies that have used fasting blood glucose levels (≥126 mg/dL or 7.0 mmol/L), HbA1c, or random glucose level (≥200 mg/dL or 11.1 mmol/L) to diagnose diabetes.[4,14] The Morgan lab at University of Iowa College of Medicine, Iowa observed that workers with incident diabetes had significantly elevated levels of DDE+DDT in their serum compared to workers without diabetes.[18] Vasiliu *et al*.[12] found that PCBs were associated with incident diabetes in women but not in men and remained associated when cases encountered during the first 15 years of follow-up were excluded, suggesting that reverse causality was an unlikely explanation for the relationship. Investigations on Operation Ranch Hand Veterans, who were exposed to 2,3,7,8- tetra chlorodibenzo-p-dioxin (TCDD) through application of Agent Orange in Vietnam, were found to have incident diabetes associated with TCDD exposure.[19] Also, diabetes was associated with DDE exposure but not with mono-ortho PCB-118, total PCBs, or years of sport fish consumption.[5] In another case-control study it was confirmed that p, p'- DDE exposure could be a potential risk factor for T2DM.[11] A cross-sectional survey conducted in a heavily polluted area of eastern Slovakia demonstrated increasing serum concentrations of individual POPs considerably increased prevalence of prediabetes and diabetes in a dose-dependent manner.[20] Based on the current literature, there is a strong implied linkage between POPs exposure in humans and type-2 diabetes. There have been many studies analyzing the presence of POPs in Indian population, but none connecting the link and establishing association between POPs and diabetes.[21] Hence in this study, we investigated the association of blood sugar with the serum concentrations of POPs in south Indian population.

Methods

This is a cross-sectional study conducted at the rural and urban outreach centers affiliated to the PSG Institute of Medical Sciences and Research, Coimbatore, India. The study was conducted with approval from Institutional Human Ethics Committee at PSGIMS&R. A written informed consent was obtained from all eligible participants. All participants who consented were recruited in the study. Details about the study were informed by health workers from the center by house to house visit in addition to distribution of pamphlets which included details of the study and requirement of 8 h fasting for the collection of samples. Both male and female of age above 18 were included based on convenience sampling. Diabetics were confirmed as evidenced by fasting blood sugar above 126 mg/dL or HbA1c above 6.4% or use of hypoglycemic medications. Participants with type-1 diabetes and terminally ill conditions were excluded from the analysis. Basic demographic details, socioeconomic status, family history of diabetes, hypertension, general health, and medical history were elicited using a questionnaire. Anthropometric measurements were recorded and blood pressure was recorded in the sitting posture in the right arm. Age, gender, body weight, and height were recorded for each patient. Body mass index

was calculated as weight in kilograms divided by height in meter squared. Blood was drawn after at least 8 h overnight fasting. Fasting blood sugar (FBS) was determined by hexokinase method which is a standard laboratory procedure. Serum POPs were determined by method described by Koc and Karakus.[22] Briefly, OC pesticide residues were determined using florisil packed-columns and GC-MS. Linear response between FBS and POPs were measured by the Pearson correlation method. The association between increasing sugar level and POPs was calculated by linear regression after adjusting for age, sex and BMI. All statistical analyses were conducted using R version 3.5.1 (R Development Core Team, http://www.r-project.org).

Results

The total numbers of participants in our study was 191, out of which FBS was not available for five participants. The demographic characteristics for the remaining 186 participants are given in Table 1. Box plots for age and BMI stratified as per gender are given in Figure 1a and 1b. Of the 44 compounds, 11 of them contributed to 93% of total POPs load [Figure 2]. The serum levels of the following four compounds – lindane, dichlorvas, DDT o p', and dimethoate were significantly correlated with increasing blood sugar levels [Table 2]. Among the remaining compounds 31 were not comparable and seven were below limit of detection. Correlation statistics among selected compounds is illustrated in Figure 3, nonsignificant correlation indicated by cross mark, positive correlation by blue solid circles, and negative correlation by red solid circles. Size the circle indicates the magnitude of correlation. Figure 4a-d illustrates the trend analysis by Pearson method showing increasing linear relationship as sugar level increases. Since POPs are obesogenic, we checked its correlation between different strata of BMI [Table 3] and with age [Table 4]. The participants were categorized as normal, overweight, and obese based on the height and weight. The odds ratio (OR) and 95% confidence intervals (CIs) of POPs showed significant risks for compounds like lindane (OR 4.95, 95% CI 1.03–23.73),

[Downloaded from http://www.ijoem.com on Saturday, October 9, 2021, IP: 49.206.118.240]

DDT o, p' (OR 3.50, 95% CI 1.04–11.73), dimethoate (OR 19.31, 95% CI 4.22–88.37), dichlorvas (OR 6.33, 95% CI 1.28–31.18). Similar compounds are found to be significantly associated with blood sugar after adjusting for age, sex, and BMI [Table 5].

Discussion

Our study demonstrated that environmental exposure to various OC and organophosphate pesticides are associated with prevalent type-2 diabetes in Indian population. Our findings are supported with published literature, which implicate OC pesticides in risk of diabetes among general population.[14,15] Benzene Hexachloride (BHC) beta isomer was shown to be a strongly correlated with age in our study. One possible mechanistic pathway for BHC isomers is via pancreatic and extra-pancreatic actions, i.e. caspase 3 activation due to reactive oxygen species generation causing membrane destabilization and mitochondrial dysfunction of the beta cell.[15,20,23,24] Other OCs like DDD and DDT were also moderately associated with sugar levels, their ORs a little above 1.00. Epidemiological evidence also substantiates the positive risk DDT and its metabolites can have on diabetes.[20,24] DDT and its metabolites are inducers of cytochrome P450 (CYP 2BA and CYP 4A1), enzymes involved in lipid and steroid metabolism.[25,26] Moreover, these compounds can inhibit aromatase, an enzyme that metabolizes steroids like cortisol.[27] As a result of aromatase inhibition, steroidal compounds tend to accumulate leading to anti-estrogenic effects, although at a receptor level, they are pro-estrogenic in action.[28] These

effects coupled with cross talk with catecholamines in the adrenal gland lead to endocrine disruption. These compounds are also known to inhibit expression of Dio-2, low-density lipoprotein (LDL), Protein kinase B (AKT), extracellular-signal-regulated kinase (ERK), Patatin-like phospholipase domain-containing protein (PNPLA), and Glut-4 genes in target tissues.[29] Although we could not find epidemiological evidence for dimethoate even after PubMed search with the following terms "Dimethoate" [MESH] AND "Diabetes" [MESH], we were able to find animal studies implicating omethoate (a break-down product of dimethoate) with insulin resistance.[30] The epidemiological evidences are summarized in Table 6. Major limitation of the study is the cross-sectional nature, which might not have captured the cause-effect relationship.

Conclusion

This exploratory study found that serum levels of several OCs and organophosphate pesticides were associated with type-2 diabetes in a south Indian population. This is the first study in the Indian population to report the association of POPs and type-2 diabetes mellitus. Our finding complement other studies on Asian groups providing evidence for adverse effects of POPs, which explains the current epidemic of type-2 diabetes in Asia.

Declaration of patient consent

The authors certify that they have obtained all appropriate patient consent forms. In the form, the patient(s) has/have given his/her/their consent for his/her/their images and other clinical information to be reported in the journal. The patients understand that their names and initials will not be published and due efforts will be made to conceal their identity, but anonymity cannot be guaranteed.

Abstract

The development of whole-body inhalational chambers for acute toxicity risk assessment of aerosols in rodents is of key importance in clinical and occupational hazard evaluations. The key aim of study is the design, development, optimization, and validation of an inhalational chamber using water aerosol, vehicle, and Aroclor 1232. The second goal has been to apply this chamber in the risk assessment of Aroclor 1232. Broncho-alveolar Lavage fluid cytology and chromatography, and lung histopathology were used to supplement the validation process. PCB concentrations were uniformly distributed across different places inside the chamber and a MMAD generation of 4.3 µm ± 1.7 µm GSD was suggestive of lower airway atomization of PCB particles. The chamber environmental parameters were within acceptable limits for rodents during the experimental procedures. Mouse behavioral alterations were minimal during water aerosolization. Acute exposure to Aroclor 1232 showed reproducibility of behavioral scores. Benchmark dose for further studies using Aroclor 1232 was derived at 4 mg/cu.m. Its toxicities could be verified by correlating the behavioral scores, neurobehavioral functions with concentrations in plasma and BAL fluid samples from Swiss albino mice. The rodent chamber can be utilized for risk assessment of occupational hazards such as complex pollutant mixtures and particulate matter aerosols. The inhalational chamber possesses the versatility to enable assessment of toxicological mixtures across sub-acute toxicity timelines.

Keywords Inhalation toxicity · Acute toxicity test · Whole-body chamber · Rodent toxicology · Behavioral toxicology · Respiratory system · Aerosol toxicity · Aroclor 1232 · Biphenyl · Polychlorinated biphenyl · Broncho-alveolar Lavage

Introduction

The first line of defense in any organism exposed to such intoxicants can be the skin (dermal exposures) or the gastrointestinal tract (oral exposures). But an especially important route of exposure is inhalation which should bypass the respiratory tract to produce toxicity in the organism. The dosing of inhaled toxicants and pathophysiologic responses to inhaled toxicants and mechanisms behind their toxicities are key determinants of current and future human health, due to various reasons. Currently pollution rates and pollutants levels in the environment including the atmosphere are increasing. Also, the increasing incidence and prevalence of respiratory disorders including occupational diseases and substance abuse through inhalation route could be considered as important justifications to carry out research in inhalation toxicology. The results of inhalation toxicity studies can then be used to extrapolate to further improve health and quality of life of patients. Clinical and pre-clinical studies of this nature make use of inhalation chamber models

to evaluate the toxicology of complex inhaled intoxicants. Based on the design and the exposure protocols, inhalation chambers can be used to evaluate the toxic effects of general exposures like whole-body chambers, or more specific exposures, e.g., nose-only or head-only chambers. They can also be utilized to assess health effects after even more localized exposures like whole-lung or partial lung chambers in animal models or human participants (Pauluhn and Mohr 2000; Colli Neto et al. 2014). Being the oldest models described in inhalation toxicology, whole body chambers are widely used, much like the utility of nose-only chambers.

The utility of inhalation chambers for pharmacological and toxicological risk evaluations cannot be undermined at the cost of their limitations, like difficulty in experimental extrapolations to real-life situations, ethical issues in exposure methods, and the presence of concurrent routes of exposures and other confounders apart from the inhalation route. Though few research evaluations have utilized exposure chambers in modeling inhalation toxicities in the past, their applications are of importance in regulatory policy making (Pauluhn 2003; Raju et al. 2014).

Standard environment exposure systems exist for inhalation exposures of animals like the BuxCo® system used to evaluate the effects of printer emitted particles (Pirela et al. 2014) and the Madison whole body chamber in fungal inhalant evaluations (Springer et al. 2013), though they may not be suited to deliver semi-volatile chemical and bioactive mixtures with potent but undetermined toxicities. Secondly, these chemical mixtures and congeners are complex and persistent, which makes it prudent to afford for safe elimination after the experiment without much provision to cause pollution and accumulation.

Aroclor 1232 is a semi-volatile PCB mixture which contains many individual Polychlorinated biphenyl, PCB congeners. Of the representative PCB congeners, we selected PCB 77, a tetrachlorobiphenyl, and PCB 180, a heptachlorobiphenyl, both being of toxicological significance (ATSDR, 2000). PCB 77 is a dioxin-like PCB, whereas PCB 180 is a highly lipophillic, biomagnifiable PCB congener.

There are only a handful of studies reporting the successful development and design of inhalation chambers in avian and rodent models of exposure (Kumamoto et al. 2013; Shaheen et al. 2016).

We describe the design and development of a whole-body rodent inhalation chamber for sub-acute inhalational toxicity testing, from its conception to its utility in evaluation of neurobehavioral parameters in mouse models. Since nose-only chambers usually do not simulate the occupational exposure better than whole-body chambers, we have applied the latter in toxicity assessment of a PCB mixture in rodents (Swiss albino mice). We have used water, water plus methanol, and Aroclor 1232 (PCB mixture) aerosols for validation of the chamber. We have also quantified PCB 77 and PCB 180 concentrations in plasma and BAL fluid of mice, after dosing Aroclor 1232 at dose increments, and evaluated using behavioral responses. Lung histopathology was used to supplement these results. The research was carried out at PSG Center for Molecular Medicine & Therapeutics laboratory, from March 2015 to July 2018.

Materials and methods

Chemicals and reagents

The PCB mixture, Aroclor 1232 was obtained from Sigma-Aldrich Inc., India. PCB 77, PCB 180 HPLC-grade standards were obtained from Sigma-Aldrich Inc., India. Acetonitrile of HPLC grade was purchased from Sigma-Aldrich, India. HPLC grade of methanol (carbinol) and Methyl tert-butyl Ether were purchased from Hi-Media, India. Ultrapure water (18.2 mΩ cm) was obtained from Millipore (Milford, USA) using MilliQ water purification system. Disodium EDTA calcium hydrate crystals and Sodium Hydroxide crystals were purchased from Sigma-Aldrich Inc., India.

Animals

Swiss albino mice were procured and quarantined at the PSG Animal Facility. They were housed under ambient light–dark cycle and optimum environmental conditions with water *ad-libitum*. Prior Institutional Animal Ethics Committee (IAEC) approval was obtained for study execution. All mice were of age 8–12 weeks with body weights ranging from 17 to 28 g at initiation of experiments. The Animal Facility is accredited by the local Regulatory Authority, the Committee for the Purpose of Control and Supervision of Experiments on Animals (CPCSEA 2003).

Structural design of the inhalation chamber

The inhalation chamber is a whole-body exposure chamber meant for small laboratory animals including laboratory rodents. The development process of the chamber has been undertaken in two stages viz., design-and-development, and characterization-cum-optimization.

Design and development

The whole-body inhalation exposure chamber consists of three different mechanical units. The units have been divided based on their utility and role in the function of the chamber—the inlet system, the central chamber system, and the outlet system. Additionally, the environment of the chamber system, and the connections of the systems are also included in the chamber construction (Fig. 1a).

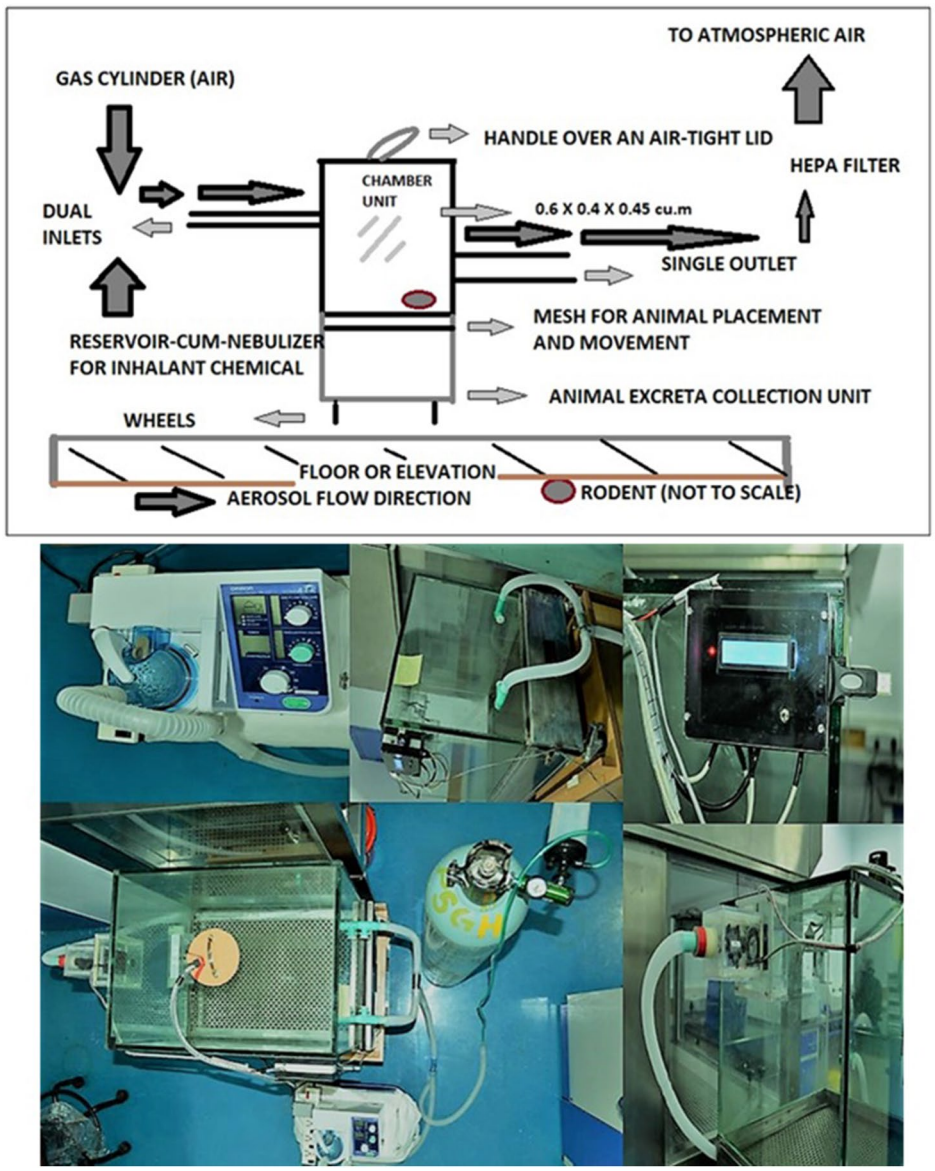

Fig. 1 Chamber Design—Line blueprint depicting chamber design (**a**) and photograph (**b**) depicting the key elements for inhalant exposures

Before initiation of the experimental procedure, the chemical mixture is prepared as per the dilution and dosing protocol of the experiment, for delivery of the test substance as aerosol particles. In order to achieve the desired flow rates of the aerosol particles by nebulization, air is used to forcibly propel the chemical mixture into the chamber after generation from the gas source (Air cylinder with control gauge and valve). The chemical pumping system (Ultrasonic nebulizer, Omron Inc.) is used to deliver the chemical aerosol of the test substance into the inhalation chamber. The central chamber core system is a glass transparent cuboid measuring 600 mm × 400 mm × 450 mm in dimensions. The base of this chamber comprises of another subunit made of stainless-steel mesh grid, below which a compartment is located to collect and dispose of the animal wastes. The roof of the chamber has a 10-cm diameter hole which can be sealed off or opened to place or retrieve the experimental animals. The wall along a breadth side has two inlet openings, each with a diameter of 10 cm, located about 10 cm from the base of the wall, which are connected to the aerosol pumping-cum-delivery system. The base compartment can be removed like the lid covering the roof hole, both of which are air-tight, then sealed to avoid gas or aerosol particles from escaping into the external environment. The internal environment of the chamber is controlled by five different sensors connected to a display panel through wires and a printed circuit board (pressure, temperature, relative humidity, oxygen level, and flow rate). This panel is then connected to a computer software (Serial Input–Output interface, SIOW) console for recording and storing the readings of different atmospheric variables. The outlet is meant for maintaining a uniform circulation and pressure of the aerosol particles in the chamber

atmosphere by continuously removing the exhaled gases and particles from the chamber. To achieve this purpose, the outlet system, consisting of a single circular hole, is located on the contralateral wall of the chamber about 40 cm from the base of that wall, with a diameter of 10 cm. A fan is encased behind the outlet opening for providing continuous ventilation to animals and rotates with a mean speed of 3400 rpm to achieve uniformity of flow rates inside the chamber. The terminal end of the outlet opens onto a Class II Type A_1 Biohazard workplace system with HEPA filters to eliminate the aerosols after circulation and recirculation inside the chamber system.

Five different sensors were pre-calibrated and fitted onto the chamber. These sensors were installed to continuously detect relative humidity, pressure, temperature, oxygen concentration and flow rate inside the chamber. We measured Mass Median Aerodynamic Diameter (MMAD) in the room wherein the chamber was housed during the experiment on three occasions using an impact cascade method. The Geometric Standard Deviation (GSD) of MMAD was calculated using the following formula:

$$\mathrm{GSD} = \frac{84.1\%\ \text{mark}}{50\%\ \text{mark}}$$

Allowed limits for the chamber environment parameters must not exceed 20%, and oxygen concentration must not fall below 19% in the chamber. The time to chamber equilibrium, $t\text{-}_{95\%}$ was calculated using the following formula:

$$t - 95\% = 3 \times \frac{\text{Chamber Volume}}{\text{Air flow rate in chamber}}$$

Periodical and regular variations in the chamber environmental conditions were recorded and visualized onto a display panel and computer console using Serial Input and Output software (SIOW, software v 1.2, hardware v 1.1, CCS, Inc.).

Characterization and optimization

Experiment 1 We checked for hourly variations in chamber atmosphere (Pressure, temperature, Relative humidity, flow rate and oxygen content) in response to water nebulization. The experiment was carried out water aerosol (350 mL daily dosing volume) for 4 h/day for two weeks (five days / week).

Experiment 2 The procedure consisted of standardization of methanol and water ratio using 54 animals inside for assessing any behavioral effects on animals. For the initial tests, a dose ranging from 0.1 to 1000 ppm of water aerosol in methanol was used in different combinations with dosing durations (1 s, 3 min, 5 min, 10 min, 30 min). Any acute signs of intoxication or mortality were noted later at each of these dose levels using 6 mice, with equal sex ratio. Animals were randomized using a Latin square design to various combinations of dose levels and dosing durations based on a c x t protocol. The behavior was measured periodically using Irwin scale (Table 1, Irwin, 1968).

Experiment 3 To assess the uniformity of aerosol distribution inside the chamber, PCB concentrations were measured after 4 mg/cu.m of Aroclor 1232 for 6 h-duration was introduced into the chamber without animals inside. The floor of the chamber interior was divided into 3×3 equal spatial circles. In each of these circular divisions, a 5 mL glass beaker was placed with 2 mL of 1:1 methanol: water inside. The analytes (PCB 77 and PCB 180) were quantified by Ultra-high performance liquid chromatography with Diode array detection (UPLC-DAD) after 6 h of exposures in each of the beakers (Ramanujam et al. 2017).

Risk assessment of PCB mixture (single duration exposure)

Experiment 4: Aroclor 1232 (1 mg/cu.m) in methanol–water aerosol at 1 ppm was used to ensure reproducibility of chamber conditions with animals. This was performed on three different days for assessment of replicability of acute 4-h behavioral toxicity. The behavior was measured periodically, and the respiratory physiological parameters were calculated, using the following formulae:

$$\text{volume of dissolved oxygen}\left(\frac{\text{ml}}{\text{dl}}\right) = 0.003 \times P02$$

Experiment 5 Three male and three female Swiss albino mice were exposed to 1 mg/cu.m of Aroclor 1232 for 6 h to assess gender-differences in behavioral scores. Irwin scale was used to assess behavioral scores across all eleven subdomains, and forty-seven functions from six physiological systems in Swiss albino mice.

Broncho-alveolar lavage (BAL) analysis

Experiment 6 Twelve female Swiss albino mice (12–14 weeks age) were assigned to four cages (three mice per cage), weighed and acclimatized. Isotonic (0.65%) sterile BAL ringer was prepared 6.5 g NaCl in 700 ml double distilled water with citric acid as buffer, till p H is adjusted to 7.0–7.2 at temperature of 4 °C. Methanol 1 ppm was used for exposure in the vehicle control group. Aroclor 1232 at 2, 4, and 16 mg/cu.m was used for test group exposures, with

three mice per group. Exposures were carried out for 6 h per group, and tracheostomy was performed after termination of exposure under Ketamine (75 mg/kg I.P) – Xylazine (3 mg/kg I.P) using 25 G needle. After tracheostomy was performed, a 40 n. thread was inserted under trachea, 21 G needle with long (25 cm) tube inserted to its other end, and using 1 m L syringe, 500 mcL of BAL fluid was pushed through plunger and aspirated thrice, finally being collected onto 2.5 mcL microcentrifuge tubes (Tarsons Inc.) for centrifuge at 300 g for 5 min till storage at 4 °C, and further analysis after freeze-thawing. Analysis was carried out for cytology (Giemsa stain for Total and differential counts), and UPLC-DAD estimation of PCB 77 and PCB 180; the analysis was carried out using a pre-defined protocol (Ramanujam et al. 2017).

Lung histopathology

Experiment 7 Ice cold PBS perfusate was prepared overnight and after tracheostomy was performed, the trachea and lungs were irrigated with the perfusate. This was followed by dissection of the carinae and / or lung parenchyma for storage in 8% Formalin solution for histopathological analysis at 40× in H&E stain.

Applicability to behavioral toxicology risk assessment: acute toxicity

Experiment 8 An acute Aroclor 1232 toxicity study was used to determine the sex differences and reproducibility

of behavioral scores on three days in response to 4 mg/cu.m exposure dose level for 6 h. For this objective, three male and three female mice behavior were compared for their variability. To ascertain the constancy of animal concentrations from different spatial co-ordinates inside the chamber, all animals were anesthetized for retro-orbital sampling of plasma. PCB 77 and PCB 180 were then quantified in these plasma samples using UPLC-DAD method in these six mice (three males and three females) after 6 h of exposure to 4 mg/cu.m of Aroclor 1232 (Ramanujam et al. 2017).

Benchmark dose derivation

Experiment 9 Acute toxicity study with control, 1, and, 4 mg/cu.m of Aroclor 1232 in 8 female Swiss albino mice each with a pre-defined Bench Mark Response Rate (BMR) from control of ± 50% change in basal behavioral scores and subsequent benchmark dose modeling in the BMDS version 2.4 (BMD Software, US-EPA) using polynomial model (Fig. 2):

$$y\,(\text{dose}) = \text{control} + \text{slope} * \text{dose}^{\text{power}}$$

Applicability to behavioral toxicology risk assessment: repeated dose neurotoxicity

Experiment 10 The optimization was further enhanced by addition of operant or instrumental assessments of mice exposed to Aroclor 1232 aerosols (4 mg/cu.m) for two-week occupational protocol. Briefly the mice were exposed to water aerosols (control group) via inhalational route, followed by washing of chamber thrice with 20% Isopropyl alcohol in methanol. This was followed by exposure to Aroclor 1232 at benchmark dose in similar manner. Occupational exposure was defined as 6 h a day (9 am to 3 pm), 5 days per week for two weekly exposures for this dosing group. Assessments were performed for neuro-cognitive endpoints a baseline, after one week and at termination for each dose level, on Y-maze, elevated plus maze and open field box in both groups. (Narayanan et al. 2017).

Results and discussion

Chamber (Fig. 1b) characterization, validation and optimization protocols were successful in yielding uniform and reproducible results in animal behavior and survival, within acceptable variability limits.

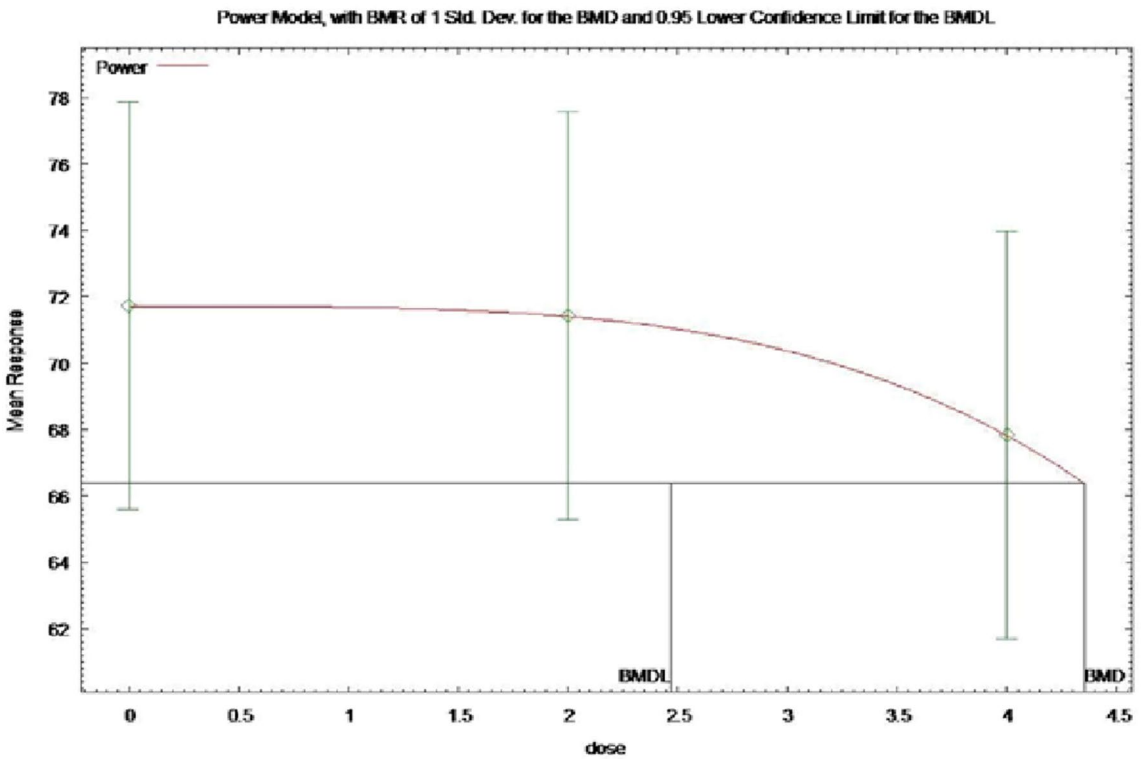

Fig. 2 Dose Response graph depicting the Bench-Mark Dose (BMD) with 95% Limit (BMDL) from the US-EPA BMDS Version 2.6, using Power modeling

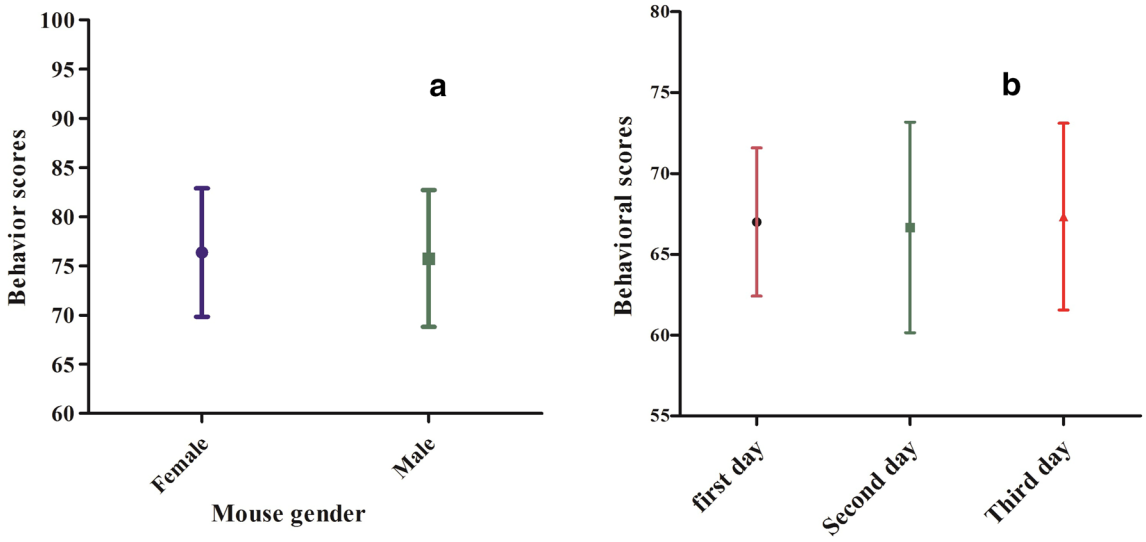

Fig. 3 **a** Chamber optimization for behavioral toxicity. **b** The effects are reproducible acutely. 3-male and 3-female mice were used for all three tests, at 1 ppm dose of water aerosol

Development

The chamber dimensions are well within the CPCSEA-regulatory limit of cage size for laboratory mouse (CPCSEA 2003). We optimized the air flow and PCB flow patterns inside the chamber in-silico using different permutations of inlet and outlet and the physicochemical properties of PCBs. Based on the simulation experiments, the best inlet–outlet configuration was determined to be with two-inlet and single-outlet chamber design (Fig. 3). The inlets were placed below the plane of the contralateral outlet, for optimum flow and uniform particle distribution in the chamber (Table 2). As per the Committee for the Purpose of Control and Supervision of Experiments on Animals (CPCSEA) guidelines, the minimum requirement for one mouse, each weighing up to 25 g, is 77.4 sq. cm per mouse with a height of 12 cm (cage) (CPCSEA 2003). Using a cascade impactor, we estimated the MMAD to be well within the Organization for Economic Co-operation and Development (OECD) toxicity guidelines (OECD 2009). The MMAD with GSD of the particle sizes was 4.3 µm ± 1.7 µm (Table 3). The time to 95% equilibrium ($T\text{-}_{95}$) in the aerosol under the chamber conditions was found to be 7.27×10^{-1} s. Then after the apparent completion of $T\text{-}_{95}$ as theoretically calculated, the inhalation exposure to test aerosol was initiated at pre-calibrated flow rates and other nebulization parameters.

Characterization

We have analyzed the environmental conditions in the chamber using five different sensors connected to a panel and a software console. Similarly, hourly atmospheric variations did not exceed 20%, which was preserved in our limit test and the sighting study over two-week exposures (Table 4). Oxygen saturation in the chamber was well at 21%.

The optimum ratio of methanol–water was 1:1 with optimum dosing duration of ≥ 90 min, based on minimal behavioral disruptions achieved for this protocol, compared to other methanol to water ratio x dosing duration permutations. The exposure duration for optimization of vehicle-solvent (methanol: water) ratio was below the 4 h as per OECD requirements

for acute inhalation toxicity. Based on this experiment, the behavioral scores did not vary much across different dosing combinations of methanol to water (77 ± 6). However, the variation was minimum with a 1:1 ratio of methanol to water for all durations tested in this phase.

Optimization

After 6-h exposure to 4 mg/cu.m of Aroclor 1232, the entire nine beakers (3 × 3 equal spatial circles) containing samples were quantified for PCB 77 and 180 using UPLC-DAD. PCB 77 and PCB 180 concentrations in the all the beakers were found to be 1795.65 ± 6.41 and 1964.42 ± 18.24 ng/mL. Hence, this indicates uniform distribution of test aerosols across the chamber floor and its vicinity.

No significant change in behavioral scores between male and female mice was observed after exposure to 4 mg/cu.m × 6 h of Aroclor 1232 (Fig. 4).The results of behavioral assessment of Aroclor 1232 acute exposures on three similar occasions with the exposure duration of four hours as shown in Fig. 4. The mean behavioral scores for water aerosol-treated animals were 65 ± 15.

The mean plasma PCB 77 and PCB 180 concentrations were 144.00 ± 16.51 ng/mL and 323.03 ± 34.95 ng/mL, respectively, at 6 h of exposure to 4 mg/cu.m in six (1:1: Male: Female) Swiss albino mice. The minimum variability of concentrations between animals in the group may be due to their movement across different parts of the inhalational chamber and the resultant uniform distribution of the PCB mixture at the bottom of the chamber during the exposures, as shown by the simulation results.

BAL fluid analysis and lung histopathology

The cytological analysis of BAL fluid samples showed dose-dependent leukocytosis with lymphocytes occupying majority of the WBCs in low power under Giemsa stain (Fig. 5a). The control (Methanol) group exhibited minimal signs of alveolar edema in the lung parenchymal specimen (Fig. 5a). There was dose-dependent increase in alveolar inflammation, mild interstitial fibrosis, alveolar edema, tracheitis and eosinophilic and mast cell infiltrates in the treatment groups (Fig. 5b–d). HPLC-FLD analysis of BAL-fluid showed dose-dependent increase in PCB 77 and PCB 180 concentrations (Fig. 5b).

Benchmark dose

The median scores of behavior in control (water aerosol), 2 mg/cu.m, and 4 mg/cu.m Aroclor 1232 dose levels were nearly 72, 71, and 68, respectively, at 2–4 h of single 6 h exposures, respectively (Fig. 4). The change in scores was more than 50% (behavioral depression) in the 2 mg/cu.m versus 4 mg/cu. group, as compared to control versus 2 mg/cu.m group comparison. Using a polynomial model,

Table 4 Normative values for neuro-cognitive indices assessed during the validation of the chamber using water aerosolization for 2 weeks at 1 ppb dose

Paradigm	Index	Week-0	Week-1	Week-2	*P* Value for the temporal interactions
Y-Maze novelty preference Test	NOR index (%)	60.72	56.29	47.30	No significant temporal interaction
Y-Maze alternation test	Alternation index (%)	31.83	17.42	25.28	No significant temporal interaction
Elevated plus maze anxiety test	Transfer latency (s)	31.33	23.00	22.50	No significant temporal interaction
Open field box test	Spontaneous motor activity index	21.95	22.57	25.61	No significant temporal interaction

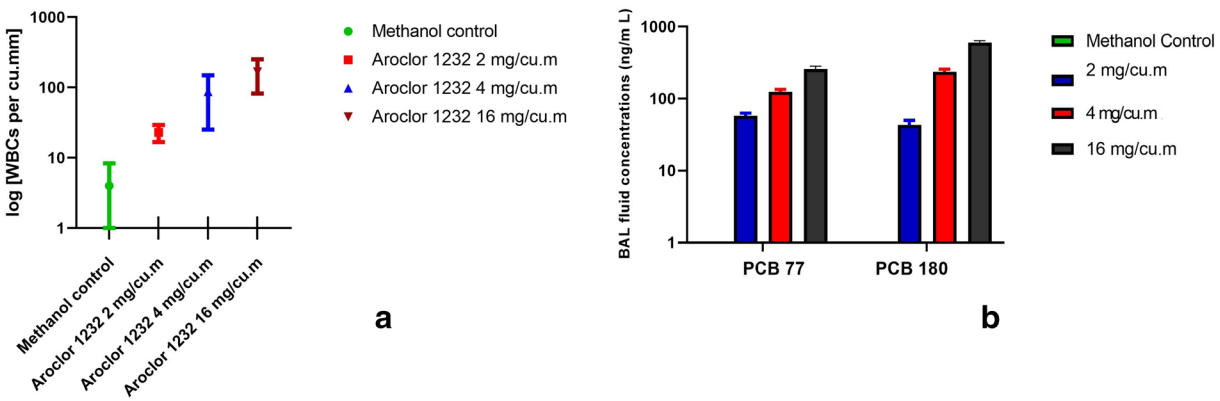

Fig. 4 **a** Bar chart depicting dose-dependent leukocytosis in the BAL-fluid cytology. **b** Bar chart depicting the dose-dependent PCB 77 and PCB 180 concentrations in the BAL-fluid aspirates

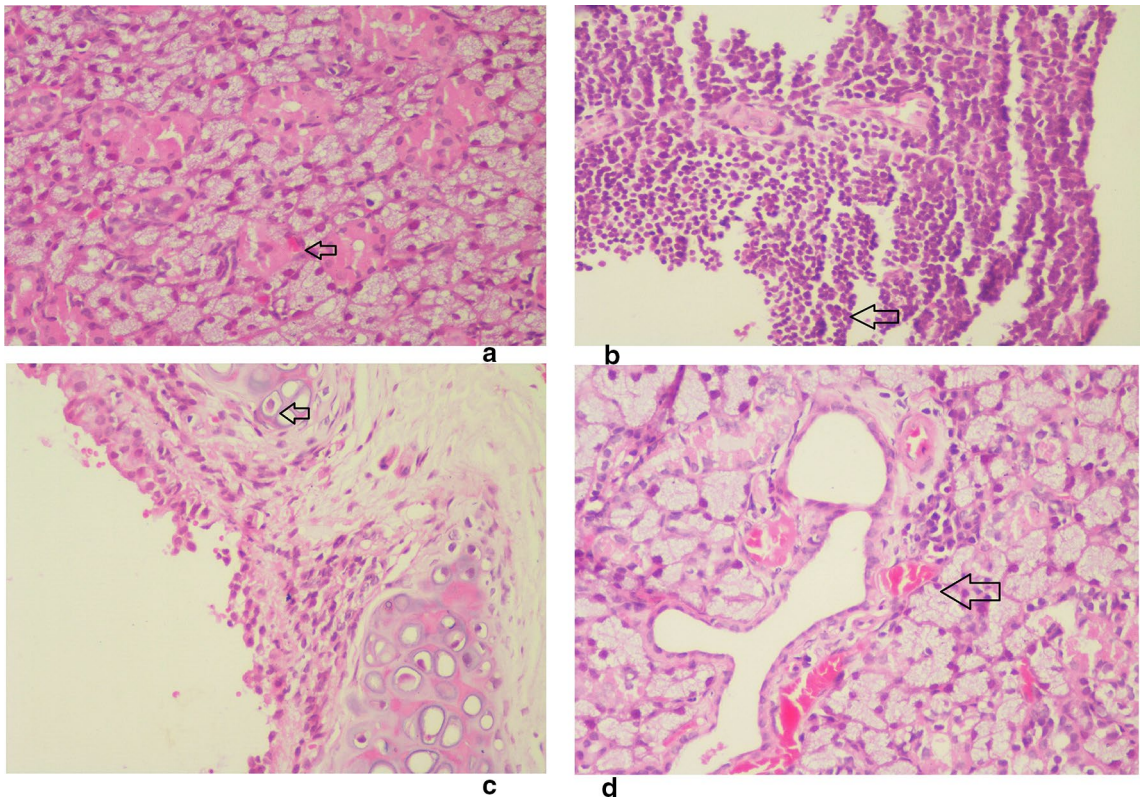

Fig. 5 **a** H&E stain (40x) showing alveolar edema in the methanol group. **b** H&E stain (40x) showing tracheitis in the low dose group. **c** H&E stain (40x) showing dense eosinophilic infiltrates in the intermediate dose group. **d** H&E stain (40x) showing mast cells and alveolar inflammation in high dose group

calculations on the BMD (Bench Mark Dose) Software yielded a BMD of nearly 4.35 mg/cu.m [BMDL = 2.46 mg/cu.m, 95% Confidence Interval for risk of deviation of control values from SD of test dose values, log-likelihood test, $p < 0.003$] for single 6 h exposures.

Sub-acute risk assessment

The neuro-cognitive indices across three time points over two-week water exposure at 1 ppm of water aerosol show preservation of the normative ranges, as shown by the two-way ANOVA (Table 4), for temporal interactions of each mean value. Hence, the chamber can be used for neurobehavioral efficacy or toxicity testing of chemicals by aerosols with minimum temporal variations. Also, the mean behavioral scores showed minimal inter-day and intra-group variations, which correlated well the neuro-cognitive indices of mice.

Discussion

We describe the successful designing, development, and characterization of a whole-body inhalation chamber for exposing mouse to aerosols and pollutant mixtures (Fig. 1b). Inhalation chambers can be used in animals and less commonly in human participants to deliver physical, chemical, or even biological agents to the animal model via the inhalation route. For example, inhalation of smoke from e-cigarettes have shown to decrease phagocytosis and other host defenses in mice following infection with respiratory bacteria and viruses in a whole-body chamber (Sussan et al. 2015). Similarly, using an inhalation chamber, pregnant mice exposed to diesel exhaust particles on daily basis exhibited developmental abnormalities in the off spring as determined by altered brain DNA methylation markers independent of -CpG- islands. Chemical agents like Acrolein have also been delivered to the respiratory tract and detected in the circulatory systems of animal models using inhalation chambers and gas cylinder systems (Tully et al. 2014). Fungal agents

like *Aspergillus conidia* have also been delivered to the respiratory tract of mice as a part of model development using inhalation chambers (Buskirk et al. 2014). Likewise, to evaluate the teratogenic effects of alcohol and alcohol spectrum disorders in mice, vapor chambers were designed and used successfully to deliver alcohol vapors(Morton et al. 2014). Studies assessing inhalation risk with vapor measurements in the upper respiratory tract and silicon dioxide, design of Aluminum chambers for rodent exposures(O'Shaughnessy et al. 2003), histopathological assessment after exposures to quartz exist in publication databases, with provision for risk assessment of diverse xenobiotic exposures.

Although the nose-only exposure chambers for rodents utilize or allow less durations of exposures (Duch et al. 2014) than whole-body chambers because of the differences in the portal of entry of aerosols, the chamber we developed was successfully tested at lower durations also. Unlike earlier semi-open inhalation chambers which were used for chronic dosing at high concentrations, the chamber we have developed is versatile and could be used for dosing low to high concentration aerosols and vapors from acute to chronic protocols. However, we also agree that our chamber can be used only for small laboratory animals including laboratory rodents (OECD 2009). It cannot be used for large animals like rabbits and monkeys which are more closely related to humans than rodents, making extrapolations of research data to humans more reliable in the latter.

Acute or even repeated dose toxicity studies in short term (sub-acute and sub chronic durations) do not affect the histology of lung of mice adversely as reported recently (Umezawa et al. 2013), which was taken as a rationale for acute testing of mice in ours study in the inhalation chamber. Although lung-only or nose-only exposure systems (Weber et al. 2010) would directly deliver the inhalant to the lungs than a whole-body inhalation chamber, they either do not reach lower airways, or do more damage if at all they reach the lower airways, and are better suited for vapors than aerosols. Since the conditions in the chamber were normobaric with Pressures ranging from 731–737 mm Hg, we are certain that the flow rates used will not affect the mouse respiratory physiology adversely.

Though the inhalation chamber was developed to evaluate the effects of pollutant aerosols with complex chemistry as described previously by others (Mainelis et al. 2013; McIntosh-Kastrinsky et al. 2013), the chamber can also be applied for a range of utilities ranging from cardio-respiratory assessments to chronic respiratory and occupational toxicological evaluations of pollutant mixtures. Indeed, it took nearly 0.7 s for the chamber's internal environment to equilibrate, which is very quick; preventing cross-contamination. Recently such assessments have been reported elsewhere using simple exposure systems (Weber et al. 2010; Gatzioufas et al. 2013). Many of these address the designing of nose-only inhalational chamber meant for short-term exposure durations of drug aerosols (Kaur et al. 2020). Nanotoxicology research inputs have also been used previously in the characterization of inhalation chambers (Taquahashi et al. 2013; Yi et al. 2013). Usually, respirable fraction via dry powder inhaler for rodents ranges from 47–54% and that via nebulizer ranges from 34–73% in previous studies(Sinha and Mukherjee 2012). Although nose-only inhalation is preferred to whole-body exposures to deliver drugs to target tissue specifically, whole body chambers simulate occupational exposures more naturally in rodents than nose-only chambers though the deposition of particles in lungs may be similar by both types of inhalation chambers (Pauluhn 2006; Oyabu et al. 2016). Hence, though nose-only inhalation usually achieves greater respirable concentrations and is specific for delivery of aerosol mixtures into the alveoli than whole-body chambers, the mode of aerosol generation which is reflected upon by time to equilibrium ($T\text{-}_{95\%}$) is more important determinant of total body concentrations of test mixtures than the method of aerosol exposure.

Although physical parameters in the chamber like humidity and oxygen saturation are key confounding determinants of the health of animal housed and exposed (Springer et al. 2013; Reis et al. 2013), we have maintained the chamber environment under strict allowed limits to ensure safety of the animals exposed in our study and avoid variations in the study results.

We conclude with certain limitations of our study such as the requirement of aerosol particles to be within the limits set by regulatory authorities may be difficult to meet with due to the complex chemical and unknown physical properties of the inhaled intoxicants and the non-generic nature of our chamber in that it can house small rodents only. We, however, have simulated the chamber conditions and ensured the safety of the housed animals with the uniformity of the results as incorporated in actual chamber development and testing (Olsgard and Smits 2008).

A novel technique of a whole-body inhalation chamber optimization has been reported and this type of biologically-accountable chamber can be used for inhalation neurological or neurotoxicity studies, climatic simulation experiments with animals and pharmacology and physiology studies after dosing drugs via inhalational route, with strict compliance to standard regulatory guidelines. In conclusion, the inhalational chamber developed in the above-mentioned manner is versatile and robust; it could cause minimum neuro-cognitive and behavioral alterations during the sub-acute exposure timelines, in small rodents. This inhalation chamber can be applied in regulatory pharmacology studies (e.g. aerosol/drug nebulization studies), toxicology studies (e.g., pollutants' inhalational risk assessment in rodents), and in biohazard studies (e.g., suspended viral hazards—risk assessments in rodents). It

can be specifically curated to neuropharmacology and neurotoxicity efficacy and toxicity studies in rodents via inhalational route.

Conclusion

The whole-body inhalation chamber has been constructed, developed, optimized, and validated for use in rodents to assimilate the Aroclor 1232 toxicity data at acute and subacute timelines. To achieve this objective and outcome, the in-vitro validation was confirmed with uniformity studies of PCB concentration across different chamber floor quadrants, followed by in vivo penetrability and neurobehavioral risk assessment of PCBs. To this end, Irwin scale and interoceptive memory and higher functional battery of tests were used to evaluate the risk hazard of Aroclor 1232 as an indoor and industrial occupational hazard as per regulatory guidelines for neurotoxicity studies in mice. The environmental and analytical optimization parameters hence developed can be applied to higher rodent models including rats and guinea pigs as per standard animal housing guidance available world-wide. The final output, i.e. the inhalational chamber hence developed could be utilized for risk assessment of complex chemical mixtures, including Aroclors, and related dioxins, via inhalational route, in regulatory toxicology studies assessing persistent environmental pollutants as occupational hazards. However, despite limitations like non-applicability of this inhalational chamber for risk assessment of non-volatile, non-hydrophilic, and non-air pollutant chemicals in rodents, these applications can be further explored, in addition to the currently broad scope of this chamber. Further, the BAL assessments and MMAD measurements confirm lower airway penetrability of PCBs, as a novel regulatory platform, confirming the chamber's robustness and working mechanism.

Background: Gastroesophageal reflux disease (GERD) is commonly associated with impaired quality of life. Chronic symptoms in this highly prevalent disorder could potentially lead to psychological manifestations such as anxiety, depression, and sleep disorders. **Aim:** The purpose of the study was to evaluate the magnitude of association of GERD symptoms based on health-related quality of life (GERD-HRQL) with anxiety, depression, and sleep quality using Hospital Anxiety and Depression Scale (HADS) and Pittsburgh Sleep Quality Index (PSQI). **Methods:** This was a cross-sectional study done at a tertiary care hospital in 241 participants. Cases were patients diagnosed with GERD, and the control group was participants who did not have GERD, devoid of all gastrointestinal symptoms according to GERD-HRQL. Data on age, gender, body weight, smoking/alcohol intake, and medication history were obtained from 98 cases and 143 matched control subjects. The three questionnaires, namely, GERD-HRQL, HADS, and PSQI questionnaires were administered by a trained blinded interviewer. **Results:** There was a statistically significant difference ($P < 0.001$) in the mean score of cases in the HADS depression scale (7.35 ± 3.65); the HADS anxiety scale (9.33 ± 4.51) and the mean global PSQI sleep score (4.62 ± 1.96) compared to the controls. Using Pearson's correlation, heart burn ($P = 0.036$), and regurgitation scores ($P = 0.026$), including the global quality of life score ($P = 0.003$), correlated significantly with the anxiety score. We found a statistically significant correlation between heart burn and poor sleep ($P = 0.012$) but not for regurgitation ($P = 0.772$). **Conclusions:** This study highlights the increased risk of anxiety, depression, sleep disorder in GERD, and the significant correlation between HRQL, especially heartburn with anxiety and poor sleep quality. This enlightens that specific screening and treatment strategies targeting such psychological manifestations are imperative for overall improved quality of life in GERD patients.

Key words: Mood disorders, sleep quality, Hospital Anxiety and Depression Scale, Pittsburgh Sleep Quality Index, gastroesophageal reflux disease-health related quality of life

INTRODUCTION

Gastroesophageal reflux disease (GERD) is a chronic disorder characterized by reflux of the stomach contents, which can give rise to symptoms and complications. Typical GERD symptoms affect patients' quality of life and overall work productivity.[1] In addition, it also contributes to enormous health-care costs. It is a highly prevalent disorder, and a recent systematic review showed that the prevalence of GERD is 18.1%–27.8% in North America, 8.8%–25.9% in Europe, 2.5%–7.8% in East Asia, 8.7%–33.1% in the Middle East, 11.6% in Australia, and 23.0% in South America.[2] Although conventionally considered as a disease affecting middle age and the older population, recent studies have shown that there is a significant increase in the proportion of the disease in the younger age group.[3]

Patient's quality of life is increasingly being considered as a medical outcome index in the evaluation of the impact of GERD symptoms on patients' health status. The impact of

GERD on quality of life can be evaluated by a detailed symptom analysis which typically includes heartburn, acid regurgitation and epigastric pain in the majority of the patients using GERD health-related quality of life (HRQL) questionnaire.[4]

Studies have shown that chronic conditions like GERD could secondarily result in psychological manifestations of anxiety, depression, and insomnia. Few studies have also demonstrated that anxiety and depression could decrease the threshold for perception of visceral stimuli, thereby exacerbating the risk of developing functional gastrointestinal (GI) disorders, thus elucidating a bidirectional cause and effect relationship.[5-7] The current research focuses on the interplay between the psychological manifestations of anxiety, depression, altered sleep, and the symptomatology of GERD with the objective to evaluate the magnitude of the correlation between the quality of life and the psychological status of patients.

Literature evidence reveals that there is a paucity of studies evaluating psychosocial impairment due to GERD symptoms in the Indian population. Hence, this study was aimed to evaluate the magnitude of association of GERD symptoms with anxiety, depression and sleep quality by assessing the correlation of the GERD-HRQL scores with that of anxiety, depression and sleep quality using the respective Hospital Anxiety and Depression scale (HADS) and Pittsburgh Sleep Quality Index (PSQI) scale in Indian patients with GERD. In addition, the study was also designed to analyze whether anxiety, depression, and sleep scores were affected by comorbidities in GERD patients.

METHODS

This was a hospital-based cross-sectional questionnaire study done at tertiary care teaching hospital after the approval by PSG Institute of Medical Sciences and Research-Institutional Human Ethics Committee (Approval no: 16/435 dated January 10, 2017). Patients attending Gastroenterology and Medicine outpatient department and diagnosed with GERD were included for the study after obtaining written informed consent. GERD was diagnosed based on the presence of the typical clinical presentation along with the endoscopic features of GERD. The control group were subjects who did not have GERD and were devoid of all GI symptoms, according to GERD-HRQL. GERD-HRQL questionnaire, a disease-specific tool, was used to measure the symptomatic outcomes and therapeutic effects in patients with GERD. The scale had 16 items that focused on heartburn symptoms, dysphagia, medication effects, and the patient's present health condition. Each item was scored from 0 to 5, with a higher score indicating a better quality of life. Two scores, namely heartburn score and regurgitation score, were obtained by the summation of the scores for questions 1–6 and 10–15 respectively in addition to the total score derived by summing all the 15 score values. The 16th question was a patient's satisfaction question based on a 3 point scale.

Velanovich *et al*. had examined the psychometric properties of the GERD-HRQL in GERD patients and reported that the Cronbach's α coefficient for each subscale ranged from 0.89 to 0.94 demonstrating a high test– retest reliability and internal consistency.[4]

The presence of anxiety and depression levels was assessed using the Anxiety and Depression Scale. The HADS, a widely used scale that had been designed for detecting depression and anxiety in out-patient clinic setting, was used to measure symptoms of anxiety and depression and consisted of 14 items, seven items for the anxiety subscale, and seven for the depression subscale. HADS Anxiety (HADS A) focused on the symptoms of generalized anxiety disorder, and HADS depression (HADS D) was focused on anhedonia, the main symptom of depression. Each item was scored on a response-scale with four alternatives ranging between 0 and 3. The overall score value 8 or higher was considered the cutoff value for the existence of anxiety and depression.[8]

The PSQI, an effective instrument was used for measuring the quality and patterns of sleep based on examination of seven domains: subjective sleep quality, sleep latency, sleep duration, habitual sleep efficiency, sleep disturbances, use of sleep medication, and daytime dysfunction over the past month. Scoring of responses ranged from 0 to 3, and all the seven components were summed together with scores of 5 or greater indicating poor sleep quality.[9]

The subjects included in this study were >20 years of age, either newly diagnosed or on proton-pump inhibitor (PPI) therapy. Patients who had concomitant diabetes, hypertension, liver, pancreatic, or chronic renal disease were also included in the study. The participants included were either non-smokers or those who were current or ex-smokers with a smoking index <100 and also non-alcoholic. However, patients who had serious comorbidities such as liver failure, renal failure, morbid obesity, patients with heart disease on antiplatelet therapy, osteoporosis patients and those on long-term nonsteroidal anti-inflammatory drugs (NSAIDs) or other chronic medications which cause gastric reflux and those with documented history of psychiatric illnesses including anxiety disorders, depression or bipolar illness and sleep disorders were excluded. Subjects aged <20 years, pregnant and lactating women were also excluded from the study.

A total of 98 cases by consecutive sampling were recruited from January 2018 to May 2018. Data on age, gender, body weight, alcohol intake, smoking, NSAID intake, concomitant GI medications other than PPI, including their daily dose were obtained. Similarly, data were also obtained from 143

[Downloaded free from http://www.jmedscindmc.com on Thursday, February 4, 2021, IP: 103.196.31.66]

control subjects who were matched so that they represented the same proportion of subjects with age, sex, and smoking status as in the case group. The three questionnaires, namely, GERD-HRQL, HADS, PSQI questionnaires, were administered by a trained interviewer blinded to the group to which the participant belongs.

Statistical analysis

All data were entered in excel, and the statistical analyses were performed using SPSS version 24 (IBM Corporation, United states). The mean HADS and PSQI scores of patients and controls were compared using an independent sample *t*-test to detect statistical significance. Similarly, Student's *t*-test was also used to analyze if the mean difference in the scores of the patients with and without comorbidities were significant. In addition, the correlation of the GERD-HRQL scores with anxiety, depression, and sleep quality scores in patients with GERD was performed using Pearson's correlation.

RESULTS

We recruited a total of 241 participants after obtaining written informed consent, among which 98 subjects were GERD patients and recruited to the case group, while the remaining 143 participants were the non-GERD control population. A total of 84 cases were on proton-pump inhibitor therapy, accounting for a percentage of 85.71%. The mean age of the cases was 46 years, whereas the mean age in the control group was 50 years. Among the cases, 55.10% were <50 years of age and 44.90% were in the age group of 50 years and above. Also, 67.35% cases were males and the rest were females with male: female ratio approximating 2:1. The analysis revealed that there was no difference in the mean scores between the cases in the age group <50 years and those who were aged 50 years and above. Among the cases, an independent sample *t*-test demonstrated that the mean score for anxiety was significantly higher in the female population compared to the males among the cases, but no such significant difference was evident for the depression or the sleep score [Table 1].

The mean score of the cases in the HADS D scale (7.35 ± 3.65) was significantly higher ($P < 0.001$) compared to the mean score of the control population (4.60 ± 3.34) using independent sample *t*-test. Likewise, the mean anxiety score of the cases (9.33 ± 4.51) was greater in comparison to the mean score of the controls (6.35 ± 3.74) using HADS A, and this difference was also statistically significant ($P < 0.001$). A similar significance in the PSQI sleep score between cases and controls was also obtained using Student's *t*-test [Table 2 and Figure 1]. A Chi-square test revealed that the proportion of cases found to have depression (50%); anxiety (66.32%), and sleep disorder (45.91%) were significantly higher compared to the control population [Table 3].

Analysis of the GERD-HRQL scores revealed that among the 98 cases in the study population, 35 patients (35.7%) had symptomatic heartburn, whereas 45 patients (45.9%) were symptomatic for regurgitation. On the satisfaction scale, 66.35% were satisfied with their present condition and 26.50% recorded a neutral response, while 7.15% were found to be dissatisfied with their current clinical status [Figure 2]. A comparative analysis of whether the mean scores vary

*P**	<0.001		<0.001		<0.001	

*Statistically significant

significantly among the patients with asymptomatic (scores of ≤12 with each individual question not exceeding 2 for questions 1–6 of the GERD-HRQL indicate heartburn elimination) and symptomatic heartburn with scores of >12, it was found that the though the mean depression and anxiety scores were higher in the symptomatic patients, there was no statistical significance between the mean difference in the scores detectable. However, patients with symptomatic heartburn had a statistically significant higher mean score for sleep disturbance ($P = 0.034$) compared to the asymptomatic group. However, when a similar analysis was performed for the regurgitation, there was no significant mean difference between those with scores >12 and those with lower scores in all the three scales [Table 4].

Comparison of the mean scores of the cases with and without comorbidities, there was no statistical significance in the mean scores obtained for those with and without diabetes, hypertensive and normotensive patients, those with other comorbidities such as liver disease, pancreatic, or chronic renal disease [Table 5].

Analyzing the correlation of heartburn, regurgitation and satisfaction components of the quality of life scores with the depression, anxiety and sleep quality scores, it was found that neither the heartburn nor the regurgitation score correlated

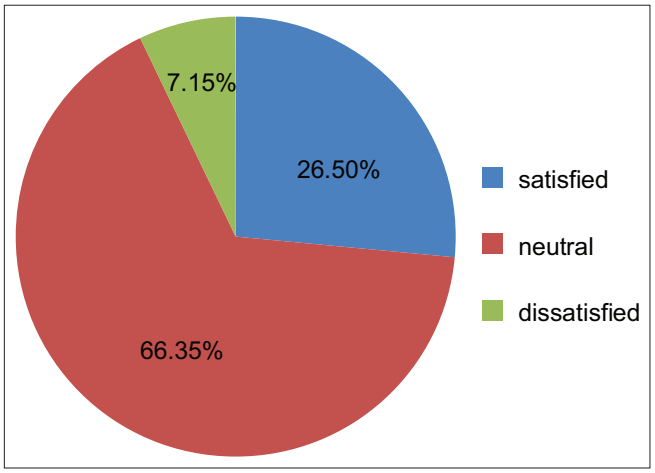

Figure 2: Chart representing satisfaction score in Gastroesophageal Reflux Disease-Health Related Quality of life Scale

with depression score whilst there was a correlation of the patient satisfaction with the depression score. However, both the heartburn and the regurgitation scores correlated with the anxiety score, including the global quality of life score. Interestingly, we found that there was a statistically significant correlation between heartburn and poor sleep, which was not detectable for regurgitation. In addition, it was found that the patients unsatisfied with their present clinical status were more likely to have depression and poor sleep quality rather than anxiety [Table 6 and Figure 3].

DISCUSSION

A statistically higher mean score for all the three clinical conditions, namely depression, anxiety, and sleep disturbance was demonstrable in the GERD cases compared to the control group indicating a high risk of these psychological manifestations in patients with reflux disease. Conceivably, impairment in quality of life was also elicited in the cases compared to the control population using GERD-HRQL.

Our study is one of the few studies evaluating the interplay between the HRQL changes in GERD with the various psychological manifestations such as anxiety, depression, and sleep manifestations in a South Indian population. Considering the cut off value of 8 for the diagnosis of anxiety and depression using the respective components of the HADS questionnaire, the study has effectively demonstrated that a high probability of anxiety disorder existed in the GERD population with a mean anxiety score of 9.33 ± 3.51 unlike with respect to depression wherein the mean score was marginally below the cut off value. A similar result was also obtained in another study done in 225 patients by Kessing *et al.*[10] However, our result was in contrast to a previous study

in which depression was found to be one of the most prevalent comorbidities in patients with GERD.[11] Our research revealed that a high proportion of cases (71.42%) had comorbidities amongst which concomitance of liver diseases recorded the highest. However, none of the comorbidities were significantly associated with the HADS or the sleep scores.

Although the literature evidence strongly supports the association of sleep disorder manifestations with GERD[7,12] the mean global PSQI score of cases in our study did not achieve the significant cut-off level of 5 indicative of poor quality sleep despite the mean score being significantly higher than the control population. This could be potentially because a large majority of patients (85.71%) were on treatment with PPI. A systematic review has delineated that a statistically significant improvement in sleep quality occurred after initiation of PPI therapy in GERD patients though it may not be completely successful in normalizing the sleep quality to achieve a global PSQI score that is not statistically different from the control population.[13] The large proportion of cases on PPI therapy precluded a between-group analysis of the depression, anxiety, and sleep scores with the patients not on PPI in our research. Symptomatic relief with PPI therapy can consequentially alleviate the psychological manifestations in GERD though evidences support that persistent symptoms despite PPI treatment is quite common which can impede the improvement in severity of the psychological parameters.

Studies have supported that chronic and mild inflammation in the GI tract due to GERD could result in up-regulation of the central nervous system (CNS) cytokine production which in turn can affect the CNS functions, ultimately resulting in psychiatric manifestations such as depressive and anxiety disorders.[14-16] Studies in animal models have also demonstrated that chronic peripheral inflammation induces central pro-inflammatory markers like interleukin IL-1β as well as tumor necrosis factor alpha-α;[17] the long term elevation of which significantly correlate with the occurrence of psychological manifestations supporting the hypothesis.[18]

In addition, the symptom complex of GERD enables envisioning the intertwined and bidirectional nature of the relationship between sleep disorders and GERD. GERD results in heartburn, acid reflux, sinusitis or sinus problems, and frequent dry cough necessitating throat-clearing that awakens the patient during sleep. Frequent arousal during sleep activates neuroendocrine systems, including the vagal nerve and triggers bronchoconstriction. Frequent bronchoconstriction narrows the diameter of the respiratory tract and arouses patients from sleep, intensifying sleep disorders.[19-21] Furthermore, GERD-related micro-aspirations inducing bronchial exudative mucosal reaction also adds to the narrowing in diameter of the respiratory tract, accelerating sleep disorder.[22] The flip side of the coin is that for several reasons, GERD symptoms aggravate during sleep. Anti-reflux mechanisms such as swallowing rate, upper and lower esophageal sphincter pressure, gastric emptying, and the awareness of heartburn have all been found to be depressed during sleep. Also, while recumbent, the force of gravity encourages the flow of gastric content towards the esophagus. Thus, current literature supports the fact that sleep disorder has a dual cause and effect relationship with GERD.[13,23]

A differential effect of the two predominant symptoms, namely heartburn and regurgitation analyzed using GERD-HRQL, illustrated that heartburn patients had a significantly lower mean PSQI score and a positive correlation with anxiety and poor sleep quality whilst regurgitation only correlated with anxiety score. A similar result has been documented by Lee *et al*. whose study disclosed that patients with heartburn had more severely impaired daily activity, including sleep interruption compared to those with a predominant regurgitation.[24] Likewise, increased anxiety level has been found to be associated with greater heartburn but not regurgitation.[10] This discrepancy perhaps stems from the

[Downloaded free from http://www.jmedscindmc.com on Thursday, February 4, 2021, IP: 103.196.31.66]

differences in physico-pathological mechanism underlying the key clinical presentations of GERD. Reflux episodes inducing regurgitation has been shown to have a higher proximal extent of the liquid component, but less esophageal pH drop, than episodes inducing heartburn.[25]

In the current study, a significant positive correlation between the GERD-HRQL and anxiety was demonstrable but not for depression and sleep derangements. A similar study using a different scale for evaluating depression, anxiety and HRQL was able to prove that there existed a significant correlation of the quality of life with both anxiety and depression.[26] The difference in results could be attributed to the fact that our study was done in a smaller subset of patients with GERD and that most patients were on treatment which also precluded a between-group analysis of untreated patients with those on treatment. Furthermore, the categorization of cases into the erosive and nonerosive disease was not done, and these were our study limitations.

However, the study has clearly brought out the need to understand the increased risk of psychological manifestations including depression, anxiety, and sleep disorders in GERD patients including those on treatment, which necessitates addressal by periodic assessments and redressal by specific planned psychiatric interventions, both pharmacological and behavioral, as a part of the comprehensive treatment plan.

CONCLUSIONS

The study highlights that GERD patients constitute a vulnerable population for psychological disturbances such as anxiety, depression, and sleep disorder, which may not be completely eliminated by the treatment of the underlying reflux disease. Hence, periodic evaluation and specific treatment strategies for such manifestations would be beneficial in improving the quality of life in these patients.

[illegible]

[illegible] Incomplete and erroneous prescriptions affect the effective management of patients. The undergraduates of today are the physicians of tomorrow. Hence, the need for inculcating good prescription writing practice from undergraduate level to improve quality of healthcare. The objective of this study was to assess the impact of a sensitization program on the effective prescription writing skills of second year MBBS students.

[illegible] This prospective study was conducted between January and November 2017 among 149 second year medical students. The prescriptions by students were assessed prior to and after a sensitization program which emphasized on the importance of each component of the prescription, need for generic prescribing and rational use of drugs.

[illegible] After the sensitization program, there was significant improvement in mentioning of all components ($p<0.05$) except for route of administration, instructions, and health advise which were still deficient. The rationality in prescribing was analyzed by scoring vital drug related information on a scale of 12. Majority of inscriptions (72%; n=107) were rational after the program. There existed a weak positive correlation ($r=0.15$) between students' knowledge of drugs assessed by theory examinations and scores of prescriptions assessed in practical examinations.

[illegible] The sensitization program served as an effective strategy in improving knowledge regarding every component of the prescription and enhanced the prescription writing skills at the undergraduate level. This could help prevent deficiencies in health care arising from errors in prescribing.

[illegible] Prescription writing, Medical students, Sensitization program, Rational prescribing

[illegible]

The prescription is a written order from the physician to the pharmacist for dispensing medications and plays a key role in the management of patients. Proper decision making and appropriate transcribing are integral for an ideal prescription.[1] Prescribing is a complex skill that requires a thorough understanding of the pathophysiology of a diagnosis, the pharmacology of an individual medication and how an individual's response may be affected by the pharmacokinetic and pharmacodynamic properties of a particular medication.[3] There is no global standard for prescriptions and every country has its own regulations. The most important requirement is that the prescription be clear. It should be legible and indicate precisely what should be given.[4] The parts of a prescription includes doctor and patient details, the superscription or heading with the symbol 'R' or 'Rx', which stands for the word recipe (in Latin, to take); the inscription, which focuses on the rational use of medicines; the subscription or directions for compounding the drug; and the signature of the prescriber.

In recent years, medical researchers observe deficiencies in health care occurring due to many prescribing errors, which arise because of two factors. One could be due to decision making and the other due to defect in the art of writing prescriptions. The factors related to the former could be inappropriate prescription, irrational prescription, under prescribing, or over prescribing. Those related to the latter is purely because of inappropriately writing the prescription.[5] Incomplete and erroneous prescriptions affect the well-being of patient adversely. Suboptimal or irrational prescription writing skills results in treatment failure, adverse clinical outcomes, wastage of our resources, and economical harm not only to the patients but also to the community.[2]

The second year MBBS Pharmacology curriculum includes training medical students in prescription writing. The students will incorporate this skill for the rest of their medical career. The results of a study of how well final years medical students performed in a prescribing exercise suggested that the root cause of prescribing errors was lack of a knowledge base that integrated scientific knowledge with clinical know-how.[6] Many studies opine that once the newly qualified doctors are exposed to workplace prescription writing, they retrospectively feel that there was insufficient emphasis on practical aspects of writing prescription in undergraduate curriculum.[15] Hence, prescription writing skill is an important target area for improvement. This study focuses on the prescription writing skills of Second MBBS students taking into consideration the completeness of the prescription, rational use of drugs and translational of theoretical knowledge to prescribing. This will enable to assess the prescription writing training provided by the department of pharmacology and determine the possible scope for improvement, if exists.

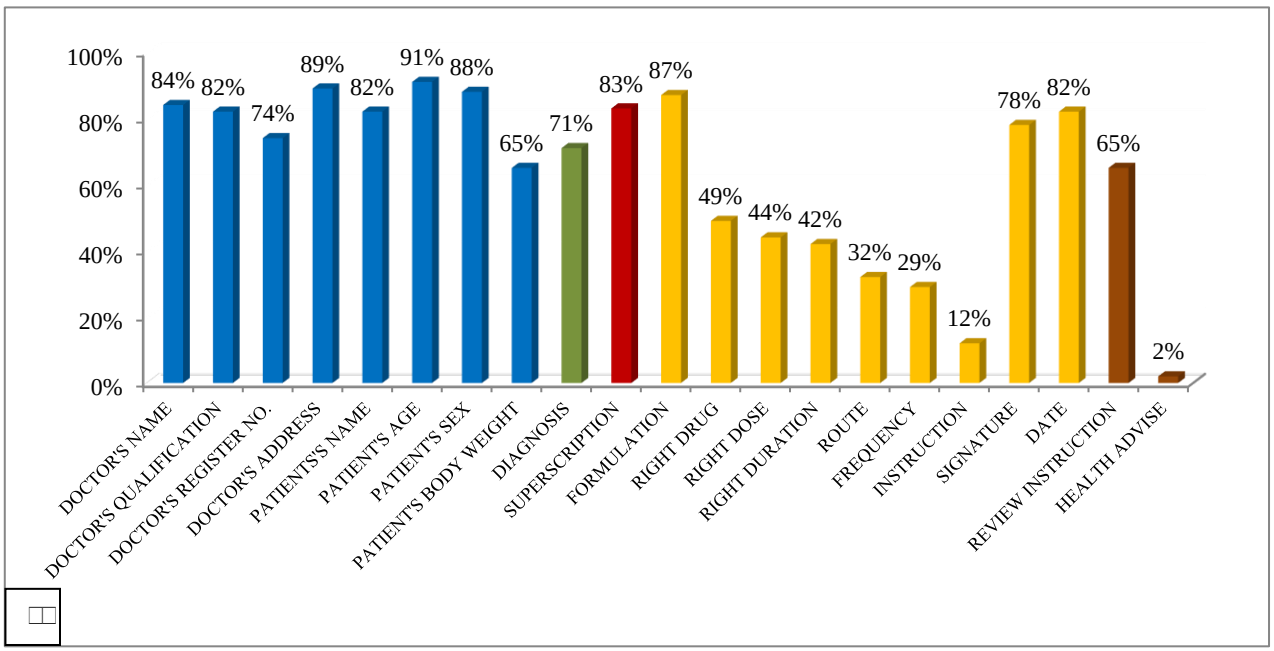
The objective of this study was to assess the prescription writing skills of second year MBBS students thereby reflecting the quality of learning pharmacology during their undergraduate period in the department of pharmacology.

M□□□□□□□

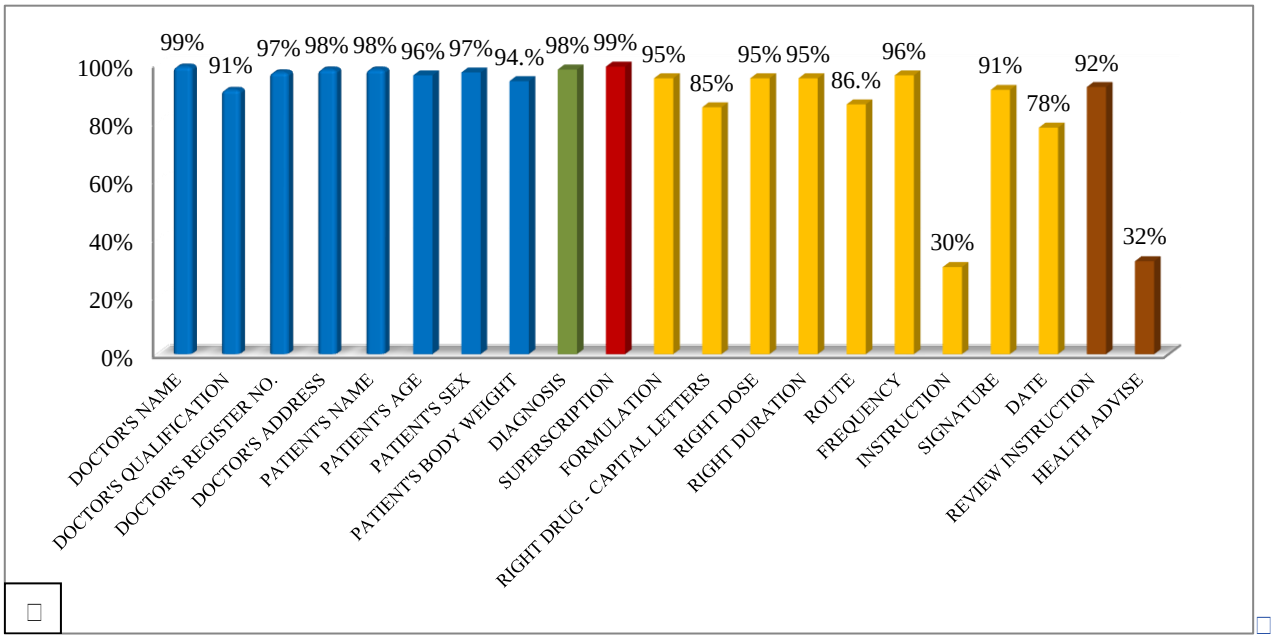
The present study was conducted in the Department of Pharmacology at PSG IMS & R, Coimbatore. Based on convenient sampling, the sample size was determined to be 149 students doing second year MBBS. After obtaining IHEC approval and permission from the HOD, department of pharmacology, data collection was initiated. The study period was between January to August 2017.

Prescription Order writing is a skill that is a part of the second MBBS curriculum and students are trained in this skill during their practical session at the department of pharmacology. In addition to the regular classes on prescription writing, a sensitization program emphasizing the importance of each component of the prescription, rational use of drugs and their clinical relevance was held at the department using suitable clinical examples and scenarios. In addition to the completeness of the prescription, students were insisted to apply 'rational use of medicine concept'- right drug (in generic name - in capital letters) in the right dose for the right duration at the right frequency. Data was collected from internal assessment exam (IAE) papers that comprises of a section on prescription order writing for a clinical scenario. Data was analyzed and interpreted for improvement in quality of prescription writing skills.

Statistical analysis



Data of all the 149 students were included in the statistical analysis. Analysis was performed using IBM SPSS software (version 20 SPSS Inc., Chicago, IL, USA). All categorical data were represented by frequency distribution while descriptive statistics was used for numerical data. To determine statistical significance between the difference in proportions chi-square test was used. The statistical significance was set at 5% i.e., $p<0.05$. Pearson correlation analysis was used to analyze the correlation between theory and prescription score.



□□□□□□□□

Prescriptions of students were analyzed for completeness in prescribing (n=149) (Figure 1) with reference to a standard format of prescription set by the department of pharmacology at PSGIMSR. In all the prescriptions 21 components as per the standard format were checked for presence or absence.

The basic demographic parameters of the prescription that included doctor's information and patient's information were initially analyzed. Before the sensitization program it was observed that doctor's information (doctor's name, qualification, register number, address) was provided by 125 (84%), 122 (82%), 110 (74%), 133 (89%) whereas after the sensitization program analysis revealed 147 (99%), 136 (91%), 144 (97%), 146 (98%) of students had provided the same information respectively. This difference following the sensitization session was statistically significant ($p<0.05$) for all components related to doctor's information (Table 1).

Patient's information (patient's name, age, sex, body weight) was provided by 122 (82%), 136 (91%), 131 (88%), 97 (65%) and following the sensitization program it was provided by 146 (98%), 143 (96%), 145 (97%), 140 (94%) of the students respectively (Figure 1 a and b). After the sensitization program the improvement in all patient related components was statistically significant except for the mention of patient's age which was mentioned by most students even before the program (Table 1).

On analyzing the prescriptions for presence of diagnosis it was found that before the sensitization program only 105 (71%) had mentioned it, while the proportion increased after the program to 146 (98%). This was a statistically significant improvement (Table 1). Rx symbol was provided by 124 (83%) of students which also increased after the program to 146 (98%) students and was analyzed to be statistically significant (Figure 1 and Table 1).

Analysis of the inscription part of the prescription containing drug related information and instruction (formulation, right drug - in capital letters, right dose, right duration, route of administration, frequency, instructions for intake, signature and date) revealed that prior to the program these information was provided by 130 (87%), 73 (49%), 66 (44%), 63 (42%), 48 (32%), 43 (29%), 18 (12%), 116 (78%), 122 (82%) respectively. Following the sensitization program the proportions increased to 142 (95%), 127 (85%), 142 (95%), 142 (95%), 39 (86%), 143 (96%), 43 (30%), 136 (30%), 116 (78%) of students respectively (Figure 1 a and b). There was statistically significant improvement with regard to all components of the inscription except for mention of date which had declined after the program, however this decline was not statistically significant (Table 1).

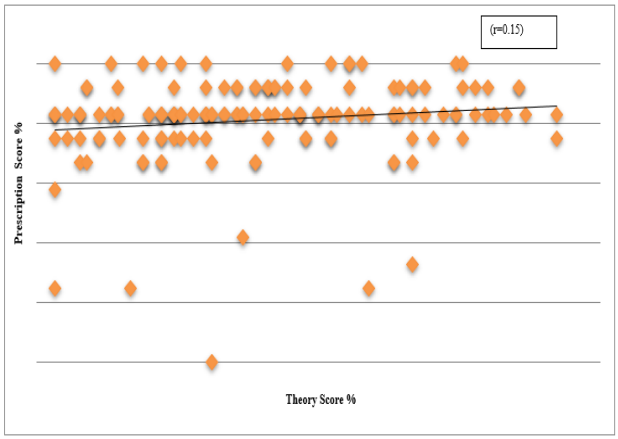
□

On analyzing for information on review and health advise it was observed that before the program only 97 (65%) and 3 (2%) of students respectively had mentioned it whereas after the program 137 (92%) and 47 (32%) of students respectively had provided relevant information (Figure 1). This improved was also found to be statistically significant (Table 1).



The rationality in prescribing was analyzed by scoring the 9 parameters included in the inscription that contains drug related information and instruction (formulation, right drug - in capital letters, right dose, right duration, route of administration, frequency, instructions for intake, signature and date). The scoring was done on a scale of 12 and percentage of the scores were calculated. Based on which rationality in prescribing was grouped as poor score 0%-34%; fair score 35%-49%; good score 50%-79% and excellent score ≥80%.

On analysis 3% of students (n=5) were grouped as poor, 1 (1%) were grouped as fair, 36 (24%) were grouped as good and 107 (72%) as excellent. Among the 72% of students - 9 % of the students (n=13) provided 100% complete prescription as per the standard format (Figure 2).

In order to assess the application of theoretical knowledge in writing a prescription, the theory score for a question related to the same diagnosis as that of the prescription audited was analyzed for correlation (Figure 3). The median prescription score (assessed for a maximum score of 12) was 10±6.4 and the median theory question score (assessed for a maximum score of 30) was 10.7±6.4. On analysis it was found that there was a weak positive correlation (r=0.15) between theory and prescription scores.

□□□□□□□□ □□

Prescribing drugs for common ailments are an important core competency of medical undergraduate.[8,9] The existing medical undergraduate curriculum includes prescription training in the second year under pharmacology. Once poor prescribing skills are habitualized, changing them during postgraduate life is more difficult and usually requires different education strategies, which are expensive and time consuming.[10,11]

Babar et al, conducted a study on 206 prescriptions to assess the quality of prescription writing, patients name and age was present in 180 (87%) and 115 (55%) prescriptions respectively.[12] In the current study we observed that the percentage of students completing the doctor's information (doctor's name, qualification, register number, address), patients information (patient's name, age, sex, body weight) and percentage of students mentioning diagnosis and superscription following the sensitization program was satisfactory with reference to the standards set by the department. A study conducted by James et al among third- and fourth-year medical students found that the 79.6% were able to correctly select the drugs, 69.4% and 68.2% were able to correctly mention duration and formulation of drug to be dispensed.[13]

In the current study it was observed that even after the sensitization program only 78% of students had mentioned the date which is a vital component of the prescription. In view of the fact that the prescriptions audited were those written in an exam setting rather than a clinical one, it is possible that the students have not attached due significance in mentioning it within the prescription as they had already mentioned it at the beginning on the exam paper.

Similarly, in spite of the program only 30 % of students had mentioned instructions pertaining to drug intake (with respect to food or specific time of the day) and only 32% of students had mentioned health advice which could be attributed to their beginning phase of clinical exposure. Probably more bedside observation of prescriptions with relevant instructions would positively reinforce the clinical importance of drug related instructions and health advises.

Although the percentage of students mentioning the right drug (in capital letters) and route of administration was above the expected standards, it can be further improved as it is the integral part of the prescription. In most instances students assumed route of administration to have been understood even without mentioning (e.g., Tablets are assumed to be taken only orally) which they probably would acquire by a deeper learning approach and better clinical exposure wherein they would be able to integrate learning with practical experience.[14]

Rational use of medicines is based on individualizing therapy and drugs, requiring an in-depth understanding of the mechanisms of drugs, their adverse effects and contraindications in addition to bedside learning. Among the parts of the prescription, the inscription containing drug related information reflects understanding by students of the rational use of medicine concept. The inscription scores and subsequent grouping showed that majority of students, 107 (72%) where able to understand the rational use of medicine concept although there is still a scope for improvement.

The limitations of the study were that, this study was done to determine the quality of prescription orders written by II MBBS students who have limited clinical exposure. Since the prescription orders that are assessed in the exam are same as that taught in the practical session there may be a possibility that students memorized the prescription order format that is taught in the practical session.

□□□□□□□□□□

The sensitization program served as an effective strategy in improving knowledge regarding every component of the prescription resulting in better completeness of prescriptions. The program also enhanced rational prescribing at the undergraduate level by promoting better correlation of theoretical knowledge with clinical scenarios. Such programs could help prevent deficiencies in health care arising from incomplete and erroneous prescriptions.

Recommendations

Sensitization programs coupled with bedside training of prescription order writing by virtue of its reinforcing nature could further improve the quality of prescribing in terms of completeness and rationality. Periodic monitoring of prescriptions of interns by clinical pharmacologists with feedbacks to interns might improve

the quality of prescriptions issued by the fresh outgoing graduates.

My sincere thanks to the entire department of pharmacology at PSG IMS & R, Coimbatore and the second year MBBS students of PSG IMS & R without whom this study would not have been possible.

(Received: 01 October 2019; accepted: 19 December 2019)

Gliptins are drugs that inhibit the enzyme dipeptidyl peptidase-4 and are one of the current treatment options for type 2 diabetes mellitus. The study aimed to compare the lipid lowering effects of teneligliptin with simvastatin in diet induced hyperlipidemic rats.22 Sprague Dawley male rats were administered high fat diet over a period of 4 weeks to induce hyperlipidemia, after which, 10 rats each in groups 1 and 2wereorally gavaged with simvastatin (standard) and teneligliptin (treatment) respectively for 2 weeks. 2 rats in group 3 were vehicle controls. Blood samples were collected at baseline, at the end of 4 weeks and 6 weeks to determine the levels of total cholesterol, triglycerides, low density lipoprotein cholesterol and high density lipoprotein cholesterol. Histopathology of liver and aorta of 2 control animals and 3 animals each from the groups 1 and 2 was done at the end of the study.A paired t test showed a statistically significant reduction in mean total cholesterol ($p<0.001$), triglycerides ($p<0.001$) and low density lipoprotein cholesterol ($p=0.003$), but no significant change in mean high density lipoprotein cholesterol ($p=0.796$) in teneligliptin group at the end of 6 weekscompared to the pre-treatment values. There was no statistically significant difference between the simvastatin and teneligliptin groups in all the four lipid parameters studied. Compared to baseline, there was a rise in body weight after induction and a reduction post-treatmentin both groups which did not achieve statistical significance. Histopathology of liver in both groups 2 and 3 demonstrated reversal of the congestion and mild fatty changes which were apparent in the control group while sections of aorta failed to reveal any significant changes even in the control group.The lipid lowering property of teneligliptin demonstrated in this study will be therapeutically beneficial in type 2 diabetic patients with dyslipidemia.

Keywords: Dipeptidyl Peptidase4 Inhibitors; Dyslipidemia; Hypolipidemic Activity; Teneligliptin.

Hyperlipidemia is a metabolic disorder that involves abnormally increased levels of lipids and lipoproteins in the blood. Most dyslipidemias (80%) are related to diet and lifestyle, although familial disorders (20%) are important as well. The American Heart Association estimates a prevalence

This is an Open Access article licensed under a Creative Commons license: Attribution 4.0 International (CC-BY).
Published by Oriental Scientific Publishing Company © 2020

of 11.9% which is around28.5 million adults =20 years of age having serum total cholesterol levels =240 mg/dl, which is considered a high level necessitating treatment.[1] A study conducted by Indian Council of Medical Researchshows a high prevalence in India with approximately 79% of the 16607 study subjects manifesting abnormalities inat least one of the lipid parameters.[2]

Hyperlipidemia is one of the major risk factors that causearteriosclerosis, cerebral stroke, coronary heart disease, myocardial infarction and renal failure. Statins are widely used to lower cholesterol levels because of their inhibitory effects on the 3-hydroxyl-3-methyl glutaryl coenzyme A (HMG-CoA) reductase, which catalyzes the rate-limiting step in cholesterol biosynthesis. The most important adverse effects of statins are increased concentrations of liver enzymes, myopathy, rhabdomyolysis and increased risk of diabetes.[3,4] In addition, reports of an increase in the potential risk of cognitive impairment with statins have been documented.[5]

Teneligliptin is a dipeptidylpeptidase-4 inhibitor that inhibits the enzyme dipeptidyl peptidase-4 (DPP-4) and is a potent treatment option for type 2 diabetes (T2DM) either as monotherapy or in combination with other hypoglycemic agents. Gliptins are used for the treatment of T2DM when patients fail to show adequate glycemic control after dietary changes and exercise or with a combination of lifestyle modification and metformin /sulfonylurea treatment.[6,7] They have relatively lesser adverse effects, weight neutral and do not cause any significant hypoglycemia.[7,8] Dyslipidemia is an important risk factor for cardiovascular complications in type 2 diabetic patients. It is unclear whether gliptins favorably improve lipid profile in type 2 diabetic patients as there are contradicting evidences from clinical studies.[9,10]

The DPP-4 inhibitors are also currently being evaluated for their effects on obesity and other metabolic traits.[11,12] In addition, their role in chronic liver diseases including non-alcoholic steatohepatitis is also under investigation.[13, 14]

In animal studies, a beneficial effect on blood lipids has been detected in type 2 diabetic animal models like Zucker fatty rats. studies indicate a potential lipid lowering effect of teneligliptinin T2DM, the efficacy of the drug as an independent anti-hyperlipidemic agent is not yet determined.Thus the aim of this study was to evaluate the lipid lowering effect of teneligliptin in high fat diet rat model as there is paucity of studies assessing the hypolipidemic action of gliptins in diet induced hyperlipidemia model. So, in this study, we compared the effect of gliptins(teneligliptin) to that of statins (simvastatin) on hyperlipidemia induced in ratsusing high fat diet.

MATERIALS AND METHODS

After the approval of the Institutional Animal Ethics Committee (Approval number:288/2015/IAEC),the study was done in the department of Pharmacology at a Medical college and research institute in Coimbatore. 22 healthy adult Sprague Dawley male rats of weight 180 g to 250g and age more than 2 months were chosen for the study. They were housed in polypropylene cages at normal ambient temperature and 12-hour light dark cycle. The animals were administered high cholesterol diet over a period of 4 weeks to induce hyperlipidemia after which,with 2 rats as controls, 10 rats were randomly allotted to each of the groups 1 and 2 following which they were administered the drug/vehicle during the last two weeks (5th,6th) along with normal standard chow diet.

Standard group (1): 10 rats given simvastatin(10mg/kg/day)

Treatment group (2): 10 rats given teneligliptin (20 mg/kg/day)

Control group (3): 2 rats given vehicle (sterile water)

The composition of high-lipid diet consisted of 1% (w/w) cholesterol, 10% (w/w) fat lard, 0.2% propylthiouracil, 5% yolk and 1% sodium tauroglycocholate.15The rats were allowed the high fat diet and water ad . The drugs simvastatin at a dose of 10 mg/kg and teneligliptin at a dose of 20 mg/kg were dissolved in sterile water and the control animals were given the vehicle (sterile water) all of which were administeredby oral gavage.

Blood samples (1.5 ml) were collected from tail vein of each rat using tail snip method under anesthesia. Blood sample collection was done at baseline, at the end of 4th week and 6th

week. Lipid profiling was done to determine the levels of total cholesterol (TC), triglycerides (TG), low density lipoprotein cholesterol (LDL-C) and high density lipoprotein cholesterol (HDL-C). The LDL-C, HDL-C and (TC) estimations were done in auto-analyzer using GenX lipid parameter kits from Proton Biologicals and the (TG) was estimated in auto-analyzer using Coral clinical systems kit.

At the end of the study, the two control animals and three animals from the group 1 (standard) and group 2 (treatment) were sacrificed for collection of liver and aorta specimens for histopathology examination.Tissue sections of liver and aorta were preserved in 10% neutral buffered formalin later processed and stained using H&E stain.The slides were observed under microscope for fatty degeneration in liver and sub-intimal fat deposition in aorta.

Statistical Analysis

The changes in lipid parameters within the groupswere analyzed using paired t-test to detect statistically significant difference. One way ANOVAwith post-hocTukey test was done to evaluate the statistically significant difference between the treatment and standard groups. The results were expressed as mean ± SD. A value of $p<0.05$ was considered statistically significant. The histopathological changes were analyzed descriptively.

RESULTS

All the three groups exhibited a rise in mean TG after induction which was statistically significant compared to the baseline. Following treatment with teneligliptin, the mean TG was

*$p<0.05$ is significant

57.51 ± 16.00 mg/dl while that in the simvastatin group was 46.21 ± 16.05 mg/dl (Table 1) and the mean reduction of TG (28.70 ± 7.61 mg/dl) in group 2 was statistically different (p< 0.001) as that of the mean reduction in group 1(24.71 ± 18.11 mg/dl) with p = 0.021 (Table 2).However there was no statistical significance in the mean difference in TG levels between the two groups at the end of 6 weeks with p = 0.318(Table 3).

Likewise, serum TC level which increased significantly due to induction with high cholesterol diet demonstrated a reduction following treatment both in standard as wellas the treatment groups (Table 2). There was no statistically significant difference (p= 0.923) between the mean TC group 2 (122.22 ± 28.75 mg/dl) compared to that of group 1(127.21± 24.86 mg/dl) after treatment (Table 1 & 3).

In addition, at the end of 6 weeks, serum LDL-C also revealed a parallel reduction in both groups with the mean of group 1 (44.96±7.61 mg/dl) and 2(40.70 ± 10.62 mg/dl) at the end of intervention beingstatistically significant compared to that of mean serum after induction with p=0.002 & p=0.003 for groups 1 and 2 respectively using paired t test (Table 1 & 2). A statistical significance in mean LDL-C levels could not be detected (p = 0.735) between the two groups using ANOVA (Table 3). However, a similar trend was not evident for serum HDL-C. A fall in HDL-C level could be noted in both groups with induction compared to the baseline. The mean HDL-C value after induction for group 1 (33.65 ± 4.41 mg/dl) and group 2 (32.06 ± 4.27 mg/dl) revealed a rise with the standard (36.82 ± 6.61 mg/dl) as well as

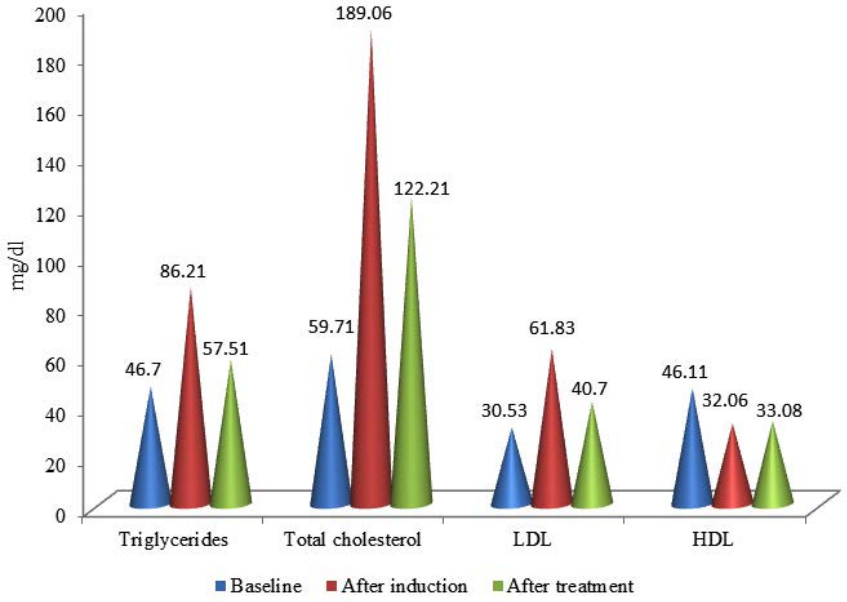

Fig. 1. Comparison of means of lipid parameters (mg/dl) of group 2 treated with teneligliptin

Table 3. Comparison between groups using one way ANOVA

Parameters	Mean difference between group 1 and 2	Standard error	Significance (p value)
Body weight(g)	9.25	14.67	.805
Triglycerides(mg/dl)	11.30	9.53	.318
Total cholesterol(mg/dl)	4.99	13.11	.923
LDL(mg/dl)	4.26	5.64	.735
HDL(mg/dl)	3.73	3.32	.516

*p<0.05 is significant

the treatment drug (33.08 ± 6.68 mg/dl) but the increase produced by either of the drugs was not statistically significantwith p=0.476 & p=0.796 for groups 1 and 2 respectively (Table 1 & 2).

Thus the net effect of teneligliptin evident was a statistically significant reduction in TC (p<0.001), TG (p<0.001) and LDL-C (p=0.003), but not the HDL-C (p=0.796) (Table 2 & Fig.1).A between group analysis using one way ANOVA revealed that there was no statistically significant difference between the groups treated with simvastatin and teneligliptin in all the four lipid parameters studied (Table 3).

Compared to baseline mean body weight of group 1(273.75±34.13 g) and group 2 (274.62±37.20 g), there was a rise in body weight in both standard (286.62±21.59 g) and treatment groups (280.87±40.99 g)after induction though the increase was not statistically significant. In addition, a reduction in body weight was discernable in the study animals of both groups with treatment using standard/drug, yet the fall in mean body weight was also not statistically significant in both groups. At the end of 6th week, the mean body weight of the standard group (267.62±18.91 g) did not differ significantly (p=0.805) from that of the treatment group(258.37± 37.20 g)(Table 1 & 3).

Histopathologic examination using H&E stain revealed a normal liver section in groups 1 and 2 while mild fatty changes in the form of intracytoplasmic vacuolation with occasional areas of congestion could be detected in the control group. This indicates therapy with both simvastatin and teneligliptin had reversed the mild fatty change induced by the disease model. Sections of aorta on histopathology examination failed to reveal any significant changes in all three groups including the control group indicating that induction for a period of 4 weeks withhigh fat diet had not caused any significant atherosclerotic changes in the aorta of our study animals (Fig.2).

Fig.2 shows normal liver section in groups 1 and 2 while mild fatty changes in the form of intracytoplasmicvacuolation with occasional areas

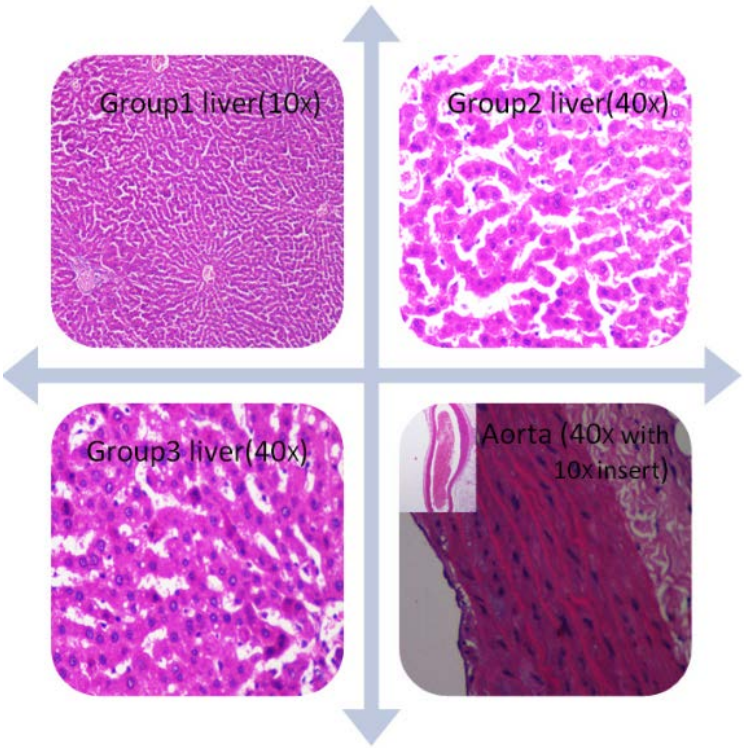

Fig. 2. Histopathological examination of the sections of liver under H&E staining

of congestion in the control group. Section of aorta of group3 reveals normal histology

DISCUSSION

This study which was done in a rat model of diet induced hyperlipidemia has explicitly brought out the lipid lowering property of teneligliptin. This study has demonstrated that there is no statistical significance in the reduction in blood lipids between simvastatin and teneligliptin including serum TC, TG, LDL-C. In addition, though the change in mean serum HDL-C revealed a greater rise with simvastatin compared to teneligliptin, the rise was not statistically significant in both groups implying that the beneficial effect of teneligliptin on HDL-C levels closely paralleled that of simvastatin though had lesser magnitude to be statistically significant.

Teneligliptin, classified as a class III DPP-4 inhibitor, has a unique structural feature that provides strong binding to DPP-4 enzymes compared with other gliptins and additional pleiotropic benefits[6]. The mechanism of action of teneligliptin which is used as a hypoglycemic agent in the treatment of T2DM is to amplify the levels of incretins namely glucagon-like peptide-1 (GLP-1) and glucose-dependent insulinotropic polypeptide in response to meal intake, in turn resulting in augmented insulin secretion and attenuated glucagon secretion.[6,7]

The hypolipidemic effect of teneligliptin is probably due to increased lipid mobilization from the adipose tissue and its oxidation by sympathetic activation facilitated through GLP-1 receptor activation, thereby reducing blood lipid levels as demonstrated by Boschmann *et al*.[16]

Also, the administration of teneligliptin has been shown to reduce the body weight in six-weeks-old C57BL/6N mice fed on a high-fat diet. The study has also established that teneligliptin increased oxygen consumption by 22% apart from proving that adipocyte hypertrophy and hepatic steatosis induced by a high-fat diet were suppressed by teneligliptin. In addition, a reduction in mean adipocyte size and hepatic TG content were demonstrable in this study.[12]

Another study investigating the effectiveness of teneligliptin in a mouse model of non-alcoholic steatohepatitis revealed that DPP4 inhibitors, by amplifying GLP-1 induced AMPK activation in hepatocytes inhibits hepatic lipogenesis, thus consequentially inhibiting cholesterol and TG biosynthesis. The AMPK activation also promotes fatty acid ß-oxidation and reduction of free fatty acid.14Thus it is obvious that multiple pathophysiological mechanisms are potentially contributory to the hypolipidemic effect of teneligliptin.

However two clinical studies in Japanese population have yielded conflicting results on teneligliptin's effect on lipid profile. But both these studies were done in a small sample size which could be one of the reasons in discordance in their results.[9,10] Yet another large clinical study done in a Korean population wherein about 1732 patients on any of the six other gliptins including alogliptin, gemigliptin, sitagliptin, vildagliptin, saxagliptin and linagliptin were switched over to teneligptin, the effects of which were recorded at the end of 12 weeks.This study demonstrated that the weight decreased significantly by a mean of 0.4 kg from baseline in addition to a statistically significantdecrease in the mean BMI by 0.1 kg/ m2. Among the serum lipid parameters, TC and LDL-C levels decreased from baseline to week 12 ($p <?0.05$). Though a favorable trend in the change from mean baseline values were noted for TG and HDL-C they were not statistically significant.[17]

The greater potency and additional beneficial effects of teneligliptin could be attributed to the fact that it binds more tightly to the DPP-4 enzyme compared to other gliptins because of the "J-shaped" structure formed by five rings.[18] Thus the long-duration and strong binding property of teneligliptin could potentially yield greater clinically meaningful metabolic benefits.

CONCLUSION

This study has delineated the hypolipidemic activity of teneligliptin which will be of potential clinical value in the therapeutic use of teneligliptinin type 2 diabetic patients especially in the face of increased concomitance in the occurrence of T2DM and hyperlipidemia.

A Study to Identify the Effect of *Momordica Charantia* on Smooth Muscle Activity in Isolated Guinea Pig Ileum

S. Shanmugapriya*, K. Bhuvaneswari and R. Muthamizh Veena

Department of Pharmacology,
PSG Institute of Medical Sciences and Research

Abstract

Background: *Momordica charantia (M. charantia),* bitter melon is commonly used in traditional medicine for its wide variety of medicinal properties.

Aim and objectives: To study the effect of successive extract of *M. charantia* on smooth muscle contractility of the isolated guinea pig ileum compared to that of standard drugs and to evaluate the receptors mediating the effects of *M. charantia* on intestinal smooth muscle using appropriate antagonists.

Materials and methods: An adult albino male guinea pig of weight 700 g was euthanased and the ileum was dissected out for isolated tissue experiment in organ bath using tyrode as physiological salt solution, aerated with air, maintained at pH of 7.4 and temperature 37°C. Successive extract of *M. charantia* was prepared in soxhlet apparatus using petroleum ether, methanol, ethanol and water. 100 mg of this extract was diluted in 10 ml of water to get a stock solution of 10 mg/ml w/v which was used after appropriate dilutions to obtain the working standard solutions. Experimental procedures were done in accordance to the standard principles of isolated tissue experiments.

Results: Contractile response was noted *for M. charantia* and its dose response curve was obtained following those of standard drugs, acetylcholine and histamine. The receptor actions were studied using atropine (muscarinic antagonist) and pheneramine maleate (histamine antagonist) and adrenaline (adrenergic agonist) which are gut smooth muscle relaxants and we found that all the three drugs did not alter the response of *M. charantia* proving that none of these three receptors systems, muscarinic, histaminic or adrenergic were involved in mediating the contractile actions of *M. charantia*.

Conclusion: This study has evaluated the contractile effect and the underlying receptor mechanisms contributing to this effect of *M. charantia* on the intestinal smooth muscle of guinea pig using isolated tissue experiment.

Introduction

Momordica charantia, commonly known as bitter gourd or bitter melon is a medicinal plant belonging

to the family Cucurbitaceae and commonly cultivated in many tropical and subtropical countries. Bitter melon is known for its wide variety of medicinal properties (1). It has an array of biologically active chemicals including saponins, steroids, alkaloids, triterpens, proteins and flavonoids due to which the fruit is shown to possesses anti-bacterial, anti-fungal, anti-viral, anti-parasitic, hypoglycemic and anti-carcinogenic properties (2-5). It is especially used in the treatment of diabetes due to its effect in reducing blood glucose, enhancing insulin sensitivity and preserving the islet cell function (6). It is also used in the treatment of rheumatism, gout and diseases of liver and spleen (7).

A study done using the methanolic extract of *M. charantia* has demonstrated its antidepressant and anxiolytic properties in mice and it has been proven that the antidepressant-like effect is dependent on the agonistic activity at central serotonergic (5-HT2 receptor), noradrenergic (α1 and α2 adrenoceptors), dopaminergic (D2 receptor), and muscarinic cholinergic systems (8). The effect of *M. charantia* on the peripheral tissues like the intestinal smooth muscles expressing such receptors have not been studied. Additionally, several studies have documented a laxative effect (9, 10, 11) with the use of *M. charantia* and the mechanism underlying this effect has not been investigated. So the current study aimed to identify the change in intestinal smooth muscle contractile tone by *M. charantia* with progressively increasing doses of successive extract *M. charantia* compared to that of the spasmogens like acetylcholine and histamine in isolated tissue experiment using guinea pig ileum and to interpret the receptor mechanisms underlying such actions by using relaxants like adrenergic agonist as well as receptor antagonists of muscarinic and histamine receptors.

Materials & Methods

The study protocol was approved by the institutional ethics committee (proposal number: 324/2016/IAEC). The *M. charantia* was procured from the local market. It was identified by a botanist from the PSG Institutions and a vocher sample of *M. charantia* fruit is preserved in the department of Pharmacology (Pha/ 03/ 2014).

Preparation of M. charantia successive extract (12):

250 g of *M. charantia* fruit was shade dried and grounded to fine powder. 200 g of the powder was weighed and subjected to extraction in a soxhlet apparatus at room temperature using petroleum ether, methanol, ethanol and water successively. Before extraction with the next solvent, the powder was air dried to remove the adhering solvent and was evaporated to dryness. The final extract was weighed after open dish evaporation to ensure removal of the solvents and stored at 4°C in refrigerator till further use.

Preparation of standard drugs for comparison:

Acetylcholine (1 mg/ml in 5% w/v NaH_2PO_4), Histamine (10 mg/ml), Adrenaline (0.1 mg/ml), Atropine (1 mcg/ml), Pheniramine (1 mg/ml) and stock solution of *M. charantia* successive extract was prepared by diluting 100 mg of the extract in 10 ml of water to obtain 10 mg/ml w/v which was mixed using magnetic stirrer at 300 rpm for 15 minutes to enhance the solubility. These were used for the isolated tissue experimental procedures after appropriate dilutions to working standard solutions.

Preparation of isolated guinea pig ileum tissue:

An adult male albino guinea pig (*Cavia porcellus*) aged 14 months and weighing 700 g was obtained from the animal house and fasted overnight. The animal was sacrificed by overdose of pentobarbitone (100 mg/kg) injected intraperitoneally followed by cervical dislocation for confirmation of euthanasia. The ileum was identified and dissected out. The ileal tissue was divided into two segments and mounted in two separate organ baths using Tyrode as the physiological salt solution (adjusted to pH = 7.4) provided with air for aeration and temperature maintained at 37°C. One end of the each tissue segment was tied securely to the tissue holder while the other end was tied to a frontal writing lever, adjusted for suitable tension and magnification. The ink-writing kymograph drum (INCO E8 recording drum using 220V/50 Hz power) wrapped with paper was run at a speed of 0.12 mm/sec to record the

contractions. The responses were thus recorded on the paper fixed to the travelling surface of kymograph drum.

Determination of the response of intestinal smooth muscle to Successive extract of M. charantia and receptors involved in mediating the effect:

Following 40 min of relaxation of the mounted tissue, graded dose responses were recorded for the standards namely acetylcholine, histamine and then for the successive extract of *M. charantia* preparation. Since graded contractions of the smooth muscle were obtained for *M. charanti*a successive extract, we proceeded to study the effect of antagonists/relaxants on the contraction induced by the extract on the intestinal smooth muscle.

Competitive antagonists for the receptors expressed in the smooth muscles of intestine which mediate contraction, namely atropine for muscarinic M2, 3 and pheniramine maleate for histamine H1 were utilized for receptor antagonism evaluation. Antagonism of the response to a single dose of *M. charantia* by these two antagonists was tested by adding increments of 10 times higher dose of each of the antagonists individually along with the agonist (*M. charantia* successive extract 8 mg) consequentially in 3 cycles to the isolated tissue preparation for determining antagonism by any of these doses on the smooth muscle contraction and if so, whether the antagonism signified competitive type by recording further responses keeping the dose of antagonist eliciting such reduction in response of *M. charanti* as constant and increasing the dose of *M. charantia* in geometric progression. In the event of antagonism not being demonstrable, ascertaining the nature of antagonism would not be performed and the protocol was to proceed to elucidating the role of adrenergic antagonism with a similar evaluation of the change in the contractile effect of the extract by adrenergic agonist adrenaline in order to delineate if anti-adrenergic action of successive extract on the gut smooth muscle was responsible for the stimulant effect of *M. charantia.*

Results

The graded dose responses were obtained for acetylcholine, histamine and the recordings ensured that the tissue was viable and sensitive. The threshold dose for acetylcholine was determined to be 0.1 µg and the maximal response was obtained for 3.2 µg (Fig. 1). Likewise for histamine, the first response was recorded for the dose of 0.2 µg and the maximal response was seen at 3.2 µg (Fig. 2). For the successive extract of *M. charantia*, the intestinal smooth muscle responses were found to be contractile and the threshold response was evident at 1mg dose. The doses were added to the inner organ bath in geometric progression as per the standard procedure. It was found that the magnitude of responses also showed progressive increase with increasing doses until the maximal response for *M. charantia* extract being recorded at 32 mg (Fig. 3).

Log dose response curves (LDRCs) were plotted (Fig. 4). The log dose response curves analyzed using Microsoft Excel 2007 revealed that the slope of the successive extract (4.740) differed significantly from those of acetylcholine (2.782) and histamine (6.389) (Fig. 5).

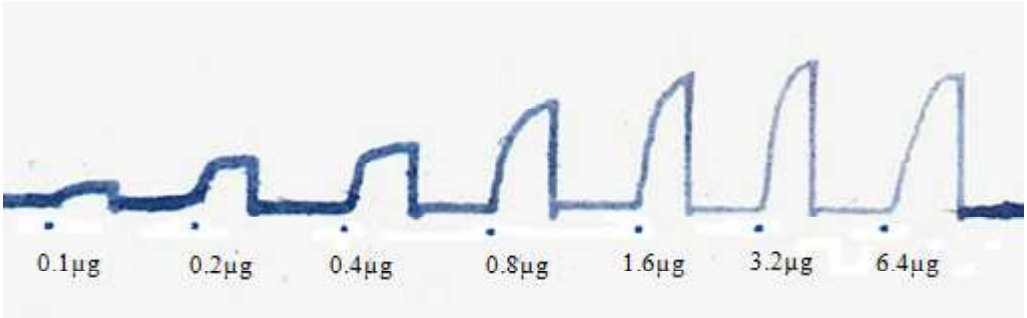

Fig. 1: Graded dose response curve for acetylcholine (Stock = 1 mg/ml) using guinea pig ileum.

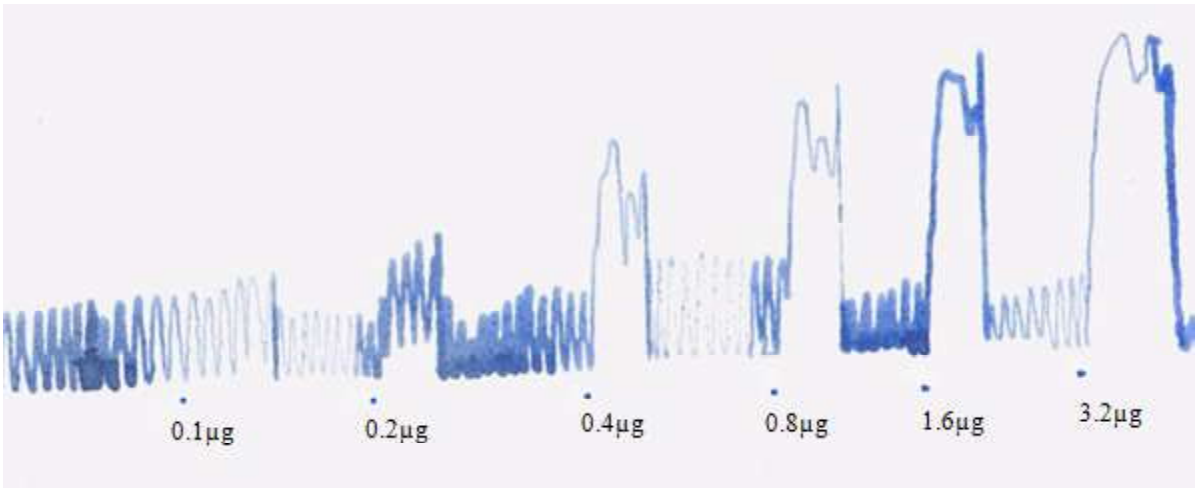

Fig. 2 : Graded dose response curve for histamine (Stock = 10 mg/ml) using guinea pig ileum.

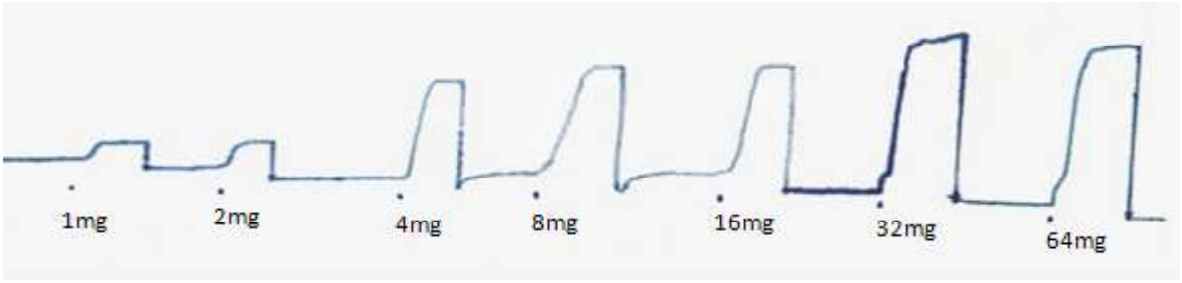

Fig. 3 : Graded dose response curve for successive extract of *M.charantia* (Stock = 10 mg/ml) using guinea pig ileum.

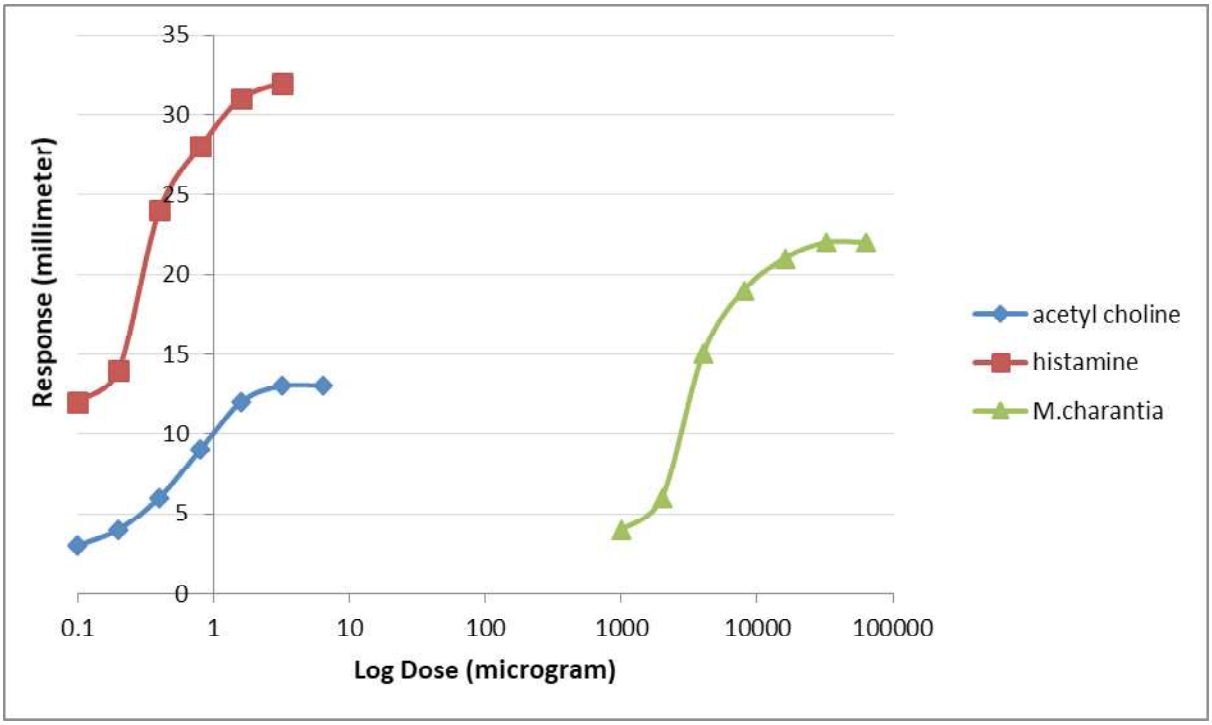

Fig. 4 : Comparison of log dose response curves of acetylcholine, histamine and *M.charantia*.

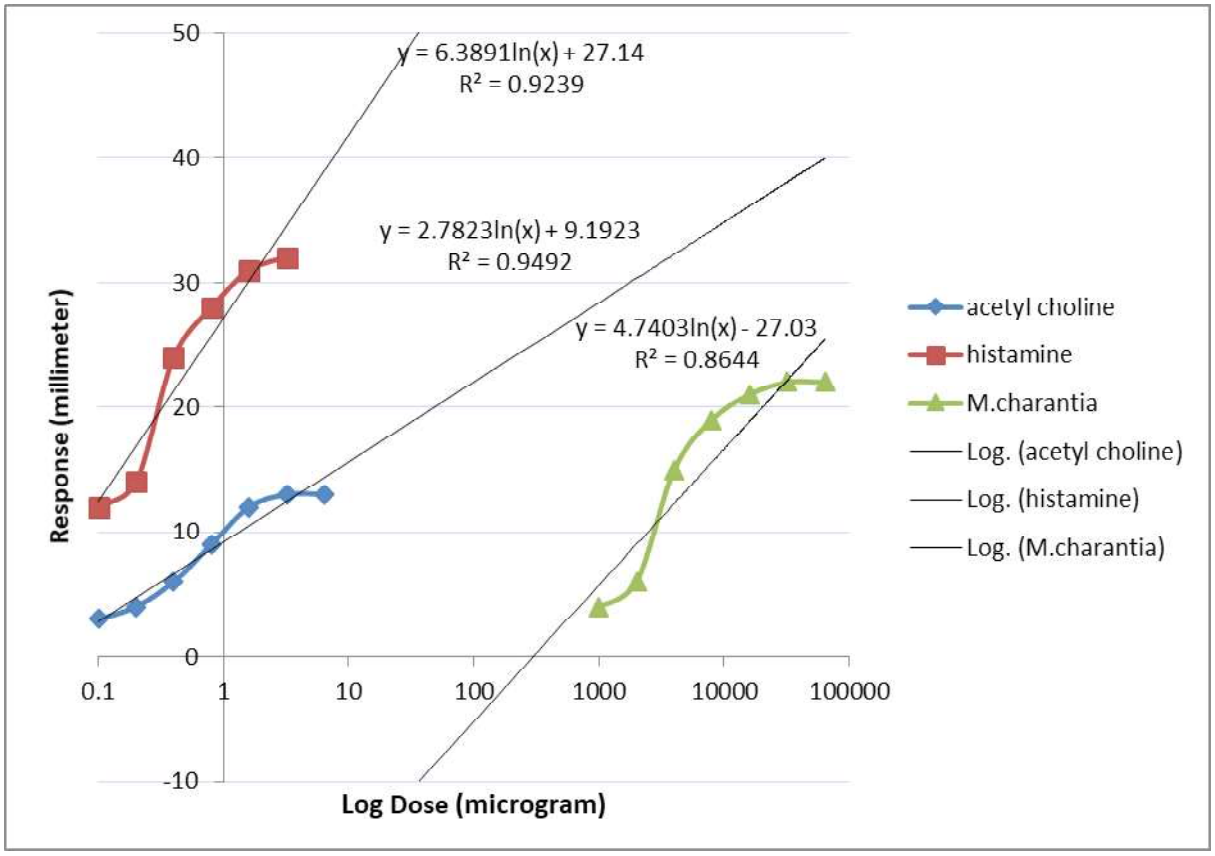

Fig. 5 : Comparison of slope of log dose response curves with trendlines of acetylcholine, histamine and *M.charantia.*

The change in contractile responses of *M. charantia* was then tested in presence of antagonist for the cholinergic receptors namely atropine and the histamine antagonist, pheniramine maleate. The dose of *M. charantia*, 8 mg was chosen to study the effect of increasing concentrations of antagonist. The choice of this dose was essentially to avoid higher doses which on repetitive administration, may contribute to bias by reducing the response of the tissue and thus affect the sensitivity of the tissue.

Interestingly, the study of antagonists revealed that the height of response to the successive extract of *M. charantia* was neither altered by atropine at the three dose levels studied (0.01 µg, 0.1 µg, 1 µg) nor by that of histamine antagonist Pheniramine maleate (0.01 mg, 0.1 mg, 1 mg). Hence we proceeded to evaluate the effect of adrenaline, an adrenergic agonist (0.01 mg, 0.1 mg) which is an intestinal smooth muscle relaxant on the contractile response of *M. charantia* and to this end, we noticed a similar lack of change in the contraction induced by successive extract of *M. charantia* indicating that adrenoreceptors were not involved in the contractions of the smooth muscles of the ileum in response to *M. charantia* successive extract (Fig. 6).

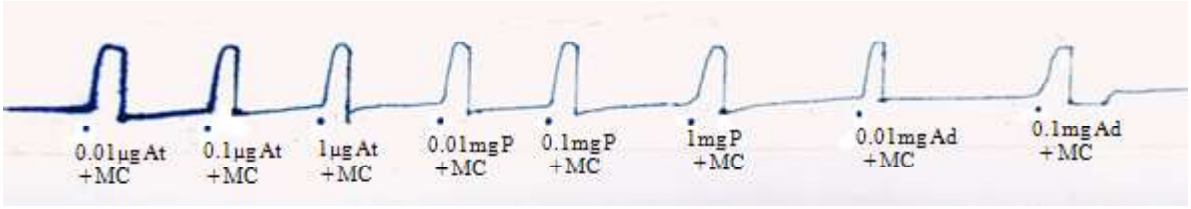

Fig. 6 : Study of antagonism of *M.charantia* response in guinea pig ileum using smooth muscle relaxants. Atropine – At; Pheniramine – P; Adrenaline – Ad; *M.charantia* - MC (4 mg)

Discussion

This isolated tissue animal experimentation study has brought out a very important effect of one of the commonly used natural products in food and traditional medicine. A contractile action of *M. charantia* on the intestinal smooth muscles of guinea pig ileum was evident and it was demonstrable that the height of responses increased with doses administered in geometric progression indicating that the magnitude of contractile responses was a function of the dose of *M. charantia* extract with R^2=0.864 (Fig. 5).Similar to the graded responses obtained for acetylcholine (R^2 = 0.949) and histamine(R^2 = 0.923), there was a dose dependent increase in the responses deductable up to the maximal dose, beyond which the supra-maximal dose did not show any further increase in response height; thus a complete graded dose response curve (GDRC) was obtained. The GDRC was thus demonstrative of the fact that the intestinal smooth muscle contractions induced by *M. charantia* extract were not a mere erratic phenomenon exhibited at certain high doses of the extract; on the other hand, proved to be a standard response that could be assayed on a standard tissue like the guinea pig ileum in accordance to the principles governing bioassay.

Additionally, logarithmic conversion of the dose response curve revealed a sigmoid dose response relationship akin to that of the standard spasmogens like acetylcholine and histamine. Moreover, it was evident that potency of the *M. charantia* extract was more than 1000 times lower in comparison to acetylcholine or histamine (Fig. 4). This essentially explains that it is safe for human consumption without undue spasmodic effect except at very high doses.

Literature exists for the laxative action of *M. charantia* especially at high doses and the effect illustrated in our study explicates the mechanism contributory to the increased intestinal motility with *M. charantia*. Few studies have proved that inhibition of glucose absorption in the gut is one of the mechanisms by which *M. charantia* exerts the well known anti-hyperglycemic effect and these studies have also shown that there is inhibition of intestinal fluid transport secondary to reduced transport of glucose and aminoacids in the rat everted gut sacs in vitro (11, 13). Such an effect could be potentially additive to increased contractility to produce a laxative effect.

Deciphering the receptors likely to be responsible for the pharmacological response of *M. charantia* elucidated in our study was done using the principles of antagonism. The change in response with addition of antagonists of the two major receptors, muscarinic and histaminergic, involved in intestinal smooth muscle contractility namely atropine, pheniramine maleate respectively were investigated apart from adrenaline, agonist for the adrenoreceptor causing gut smooth muscle relaxation. However, failure to reduce or abolish the contractile response to *M. charantia* extract was observed with all the three relaxants indicating that none of these receptors were involved in mediating the increased contractility of *M. charantia* extract (Fig. 6). The plausible explanation for this could be attributed to non-receptor mediated actions of *M. charantia,* acting directly on the ion channels like calcium or potassium ion channels. A potential increase in conductance of calcium channels or alternatively a decreased K^+ ion conductance could be the likely contributory mechanism for this activity. Another probable mechanism could be activation of the 5HT3 or 5HT4 receptors on the intrinsic primary afferents of the enteric nervous system, which however were not evaluated in this isolated tissue model and is therefore considered as a limitation of the study.

Moreover, literature evidence states that agonists whose log dose response curves (LDRCs) are not parallel are suggestive of acting through different receptors and hence said to have varying mechanism of action despite the same resultant effect (14). In our study, the slope of LDRC of *M. charantia* extract was significantly different from that of acetylcholine and histamine. Hence the LDRCs of all three weren't parallel, indirectly indicating that the mechanisms eliciting the stimulant response on the intestinal smooth muscle were diverse. This mandates the need for further molecular studies like receptor binding and ion channel conductance studies to confirm the results of our study.

Thus the study has delineated the effect of increased contractility of gut smooth muscle by the successive

extract of *M. charantia* which can be utilized therapeutically for conditions affecting intestinal motility like diabetic gastroparesis. Its effectiveness in such diabetic complication, which if confirmed by clinical studies, would be dually beneficial especially in the face of paramount importance of *M. charantia* in management of diabetes patients and the huge burden of disease that this metabolic disorder contributes to, owing to the sheer high proportion of population it affects.

Conclusion

This is the first study done to identify the smooth muscle contractile effect of *M. charantia* in isolated intestinal smooth muscle of guinea pig ileum. This study based on the concept of reverse pharmacology has ascertained one of the salient pharmacological actions of *M. charantia* and the potential underlying mechanism, enabling future studies in further evaluating the therapeutic benefit of this effect of *M. charantia* in clinical conditions associated with reduced gut motility including diabetic gastrointestinal dysmotility disorders.

ABSTRACT

Objective: *Momordica charantia* (MC) (bitter gourd) is known traditionally to possess medicinal values. This edible vegetable is known for its anti-inflammatory properties and has been studied for its bronchospasm preventive action. With the recent development in nanoformulations, this study was done to identify the effectiveness of MC nanoformulation in comparison to crude MC formulation in protecting animal from histamine-induced bronchospasm.

Methods: The optimized MC nanoformulation was prepared with polyethylene glycol and soy phosphatidylcholine. The MC crude powder was prepared by drying in hot air oven and grinding in a blender. Eight guinea pigs of both sexes were given once daily MC nanoformulation per oral by mixing with water for 7 days. Evaluation of the formulation was done on the 2nd, 4th, and 6th h on day 1 and day 7 after administration of MC for protection in developing pre-convulsive dyspnea due to histamine-induced bronchospasm.

Results: An analysis of variance test revealed statistically significant results in the protection of animals from developing bronchospasm after treatment with the MC nanoformulation in comparison to the control values. About 75% of animals were protected from developing bronchospasm on day 7 attributing to the cumulative effect of nanoformulation.

Conclusion: The study proved that the MC nanoformulation could effectively prevent histamine-induced bronchospasm in guinea pigs.

Keywords: *Momordica charantia*, Nanoformulation, Anti-inflammatory.

INTRODUCTION

Momordica charantia (MC) also known as bitter gourd is a common edible vegetable, known to possess medicinal values [1]. It is traditionally known for its medicinal properties such as anti-diabetic, anticancer, anti-inflammation, antivirus, and for cholesterol-lowering effects. It contains many phenol compounds that may have the potential as antioxidant and anti-mutagen [2]. The fruit, stems, leaves, and roots of MC have all been used in traditional medicine to help treat ailments such as hyperlipidemia, digestive disorders, microbial infections, and menstrual problems [3]. Studies have also shown that bitter melon has anticarcinogenic properties and can be used as a cytotoxic agent [4]. Many studies had confirmed the electrolyte balancing property, anti-inflammatory, and antioxidant property of MC with cytokine-inhibiting activity [5,6]. The anti-inflammatory activity of MC has been confirmed by its action through, interleukin 1 (IL)-1, IL-2, IL-6, IL-8, tumor necrosis factor-α, and nuclear factor kappa β normalization both in animal and human studies.

Asthma is a chronic inflammatory disorder of the airways and needs long-term use of anti-inflammatory drugs to control symptoms [7]. MC is known for its anti-inflammatory action and previous done have proven its property to prevent histamine-induced bronchospasm. However, no studies have been done on the nanoformulation of MC. This study was proposed as an attempt to prove the benefitting properties of MC nanoformulation pre-clinically in guinea pigs for its anti-inflammatory potent action in preventing histamine-induced bronchospasm.

The purpose of this study was to maximize the pharmacological property of the MC nanoformulation by making it available for maximum systemic absorption. As there is variation in the various extracts and powders of MC, there is probably variation in the formulation we provide to the patients. One such recent advance is the nanocapsule formulation [8]. They are considered as weapons of new drug delivery system. Hence, this study was proposed to identify the effectiveness of MC nanoformulation in protecting guinea pigs from histamine-induced bronchospasm in whole animal model.

METHODS

The study was done in two parts. First, the nanoformulation of MC and crude dry powder formulation of MC were prepared and shelf life of the two compounds was tested for 180 days. The second part of the study dealt with administration of the nanoformulation of MC per oral in guinea pigs and its efficacy in preventing histamine-induced bronchospasm was evaluated.

Preparation of nanoformulation of MC

MC crude powder was prepared by drying in hot air oven and grinding in a blender. Nanosuspension of crude bitter gourd powder was prepared by probe sonication and lyophilization technique [9,10]. Briefly, sufficient quantity (10 g) of crude bitter gourd powder was weighed and added to the aqueous phase (water) containing surfactant soy phosphatidylcholine. The aqueous mixture was sonicated using a bath sonicator for 15 min to get a homogeneous mixture. The resulting homogeneous mixture was sonicated using an ultrasonic probe sonicator (Vibra Sonics) for 30 min at 20,000 Hz to produce bitter gourd nanosuspension. This sample of nanosuspension particle size was measured using Malvern Zetasizer (Nano ZS90, Malvern Instruments) at 25°C and measured 291.3 diameter nanometer (d. nm). To improve the bioavailability of this MC nanoproduct, we added polyethylene glycol (PEG) and deep freezing was done at −80°C for 4 h following this, the sample was again freeze-dried in a lyophilizer (Lyodel) at a temperature and pressure of −50° and −1 bars, respectively, for 48 h to form powder.

The dry nanoparticles were, hence, ready and the final particle size noted was 536.4 d. nm [11].

Following this, a 180 days stability test was done on both the formulations of MC, filled in gelatin capsules and found that both were stable in room temperature (25°) and high temperature (45°). Stability was tested for its color, shape, consistency, pH, weight, and disintegration in acid buffers.

Protection of histamine-induced bronchospasm by MC nanopowder (Fig. 1)

Eight adult guinea pigs of both sexes were chosen and the animals were kept in rooms under standard conditions. The animals were provided with ambient temperature of 25°C and 55% relative humidity, 12 h light period. Granular mixed feed and drinking water were available for all animals *ad libitum* throughout the experiment. The Institutional Animal Ethics Committee approved the study and the study was conducted strictly with guidelines of ICMR and CPCSEA.

On day 1, all the eight guinea pigs were weighed and animal dose of MC nanoformulation at 600 mg/kg and was administered orally after dissolving in drinking water. After 2 h, the animals were exposed to 2% histamine aerosol for 120 s using histamine chamber. Preconvulsive dyspnea (PCD) was noted in seconds [12,13]. The same experiment was repeated after 4 h from the time of MC nanoformulation administration and the PCD values were noted in seconds.

Following this, all the eight guinea pigs were given MC nanoformulation at 600 mg/kg/day (standardized animal dose) OD from day 2 to day 7. On day 7, the animals were again exposed to bronchospasm induction with 2% histamine aerosol chamber for 120 s from 2 h of MC nanoformulation administration. Bronchospasm protection activity for both the formulations of MC was observed. All the three sets of values to develop PCD (control value, day 1 value, and day 7 value) were tabulated for statistical analysis. The mean value for developing PCD in a control animal (before giving drug) was found to be 61.10 s [14].

RESULTS

The animals were administered with MC nanoformulation from day 1 to day 7 every day at 8 am. Protection for bronchospasm was observed on day 1 and day 7. The time to develop PCD was as follows:

Table 1: Particle size, polydispersion unit, and zeta potential of the formulation of MC

Formulations	Particle size	PDI (polydispersion index)	Zeta potential
MC crude dry powder	3953 d. nm	1.000	−6.01
MC nano dry powder (SPL+PEG)	534.6 d. nm	0.612	−36.23

MC: *Momordica charantia*, PEG: Polyethylene glycol

On day 1, after 4 h from nanoformulation of MC administration, it was observed that 5 (62.5%) animals were completely protected from PCD and three animals had prolonged duration in developing PCD compared with the previous exposure at 2 h. (Further, exposure to histamine not done as >50% of animals were protected at the end of 4 h).

On day 7, six animals (75%) were completely protected from developing PCD, and hence, further, exposure to histamine was not done.

Statistical analysis

Analysis of variance (ANOVA) test was applied to compare the time difference to develop PCD in the animals in seconds between the three values (Day 1: 2 h and 4 h and day 7: 2 h).

ANOVA test done between the three values has effectively demonstrated that all the animals were significantly protected from developing bronchospasm on day 1 after 4 h of MC nanodrug formulation ($p<0.01$)*. Similarly, the animals were significantly protected from developing bronchospasm on day 7 after 2 h of drug administration ($p<0.01$)*.

Post-study animals were observed for a period of 2 months and no drug reactions or fatal effects were observed.

DISCUSSION

The aim of this study was to compare the efficacy and potency of MC nano dry formulation in contrast to its raw form as MC dry powder and MC fresh juice demonstrated by Bhuvaneswari *et al*. in animal model [14]. MC nanopowder was prepared and the particle size measurement showed 75% reduction in size of the particles in comparison to MC crude dry powder (Table 1). The nanoformulation was proved stable in high and low temperature after a 180 days stability testing (Table 2).

The mean of the control group was found to be 61.10 s [14]. Comparison was done for the same group animals on three different timings of histamine exposure post nanodrug administration and all the three sets of values were compared with ANOVA test (Table 3).

Guinea pigs being most sensitive for its histamine receptor sensitivity were chosen for this study [15]**.** Fig. 2 has clearly shown the number of animals protected from developing PCD. A normal control animal can hold from developing PCD for 61.1 s and animals treated with standard drug Montelukast could hold from developing PCD for 120 s, evinced from the previous studies [14].

Table 4 has illustrated that 50% of animals were able to attain protection from developing bronchospasm after 2 h of MC nano dry powder formulation administration. Following this, almost 100% of animals showed prolongation of duration from developing PCD in comparison to the control, hence, proving the bronchospasm protective activity of MC nanodrug. On the same day, 62.5% of animals were completely protected from developing PCD after 4 h of MC nanodrug administration on day 1 and further exposure to histamine

Table 2: Physical properties of individual capsules from day 0 to day 180 at room temperature and high temperature

Capsules	Color	Odor	Shape	Consistency
MC crude dry powder	Yellow+red capsule color was not altered	No odor	Shape maintained	Dry capsules
MC nano dry powder (SPL+PEG)	Yellow+red capsule color was not altered	No odor	Shape maintained	Dry capsules

Table 3: ANOVA test between the time to develop PCD on day 1 at 2 h and 4 h and day 7 at 2 h with control value

S. No.	Group	Mean	Control (mean value)	SD of group	*Post hoc* ANOVA between group and control
1.	Day 1 (2 h)	69	61	20.1	0.496
2.	Day 1 (4 h)	113.5	61	9.5	0.000* ($p<0.01$)
3.	Day 7 (2 h)	116.6	61	6.3	0.000* ($p<0.01$)

ANOVA: Analysis of variance, PCD: Preconvulsive dyspnea

Table 4: Time to develop PCD on day 1 after 2 h and 4 h and day 7 after 2 h of MC nanoformulation administration

S. No.	Guinea pig	Weight (g)	PCD (s) after 2 h on day 1	PCD (s) after 4 h on day 1	PCD (s) after 2 h on day 7
1	G1	775	67	104	120
2	G2	700	95	120	120
3	G3	600	60	96	79

6	G6	800	58	120	120
7	G7	678	78	120	120
8	G8	850	100	120	120
Average PCD time			69.25 s	113.5 s	116.6 s

PCD: Preconvulsive dyspnea, MC: *Momordica charantia*

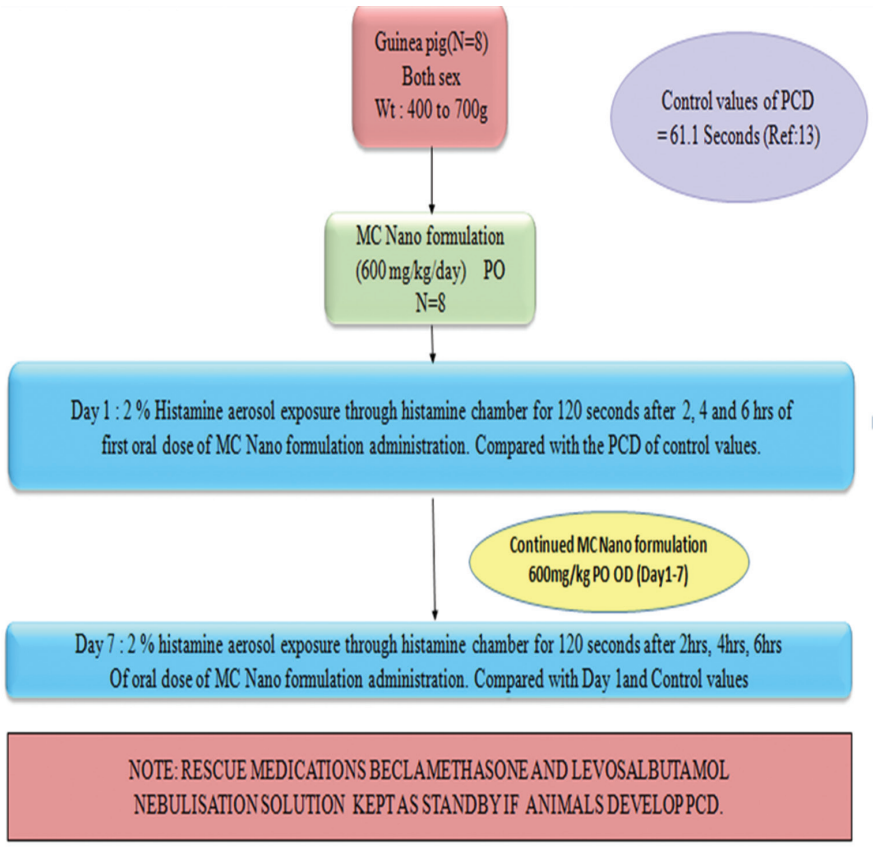

Fig. 1: Study method to assess the potency of *Momordica charantia* dry powder and nano dry powder in whole animal model

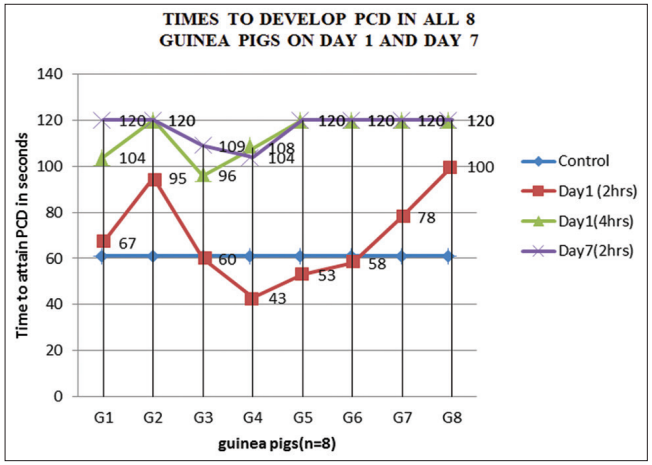

Fig. 2: Time to develop preconvulsive dyspnea on day 1 after 2 h and 4 h and day 7 after 2 h of *Momordica charantia* nanoformulation administration

was terminated on day 1. Tables 3 and 4 also illustrate cumulative doses of nanoformulation of MC given from day 1 to day 7 evidently showed that the effect was observed early. On day 7, 75% of animals were completely protected from PCD after 2 h of the nanoformulation administration (Fig. 2).

Statistical significance is shown with ANOVA test for a collective comparison between day 1 values at 2 h and 4 h and day 7 values at 2 h. *Post hoc* ANOVA comparison was done with control values and three values, respectively. This demonstrated the statistical significance ($p<0.01$)* of animal protection from developing PCD at 4th h value of day 1 and 2nd h value at day 7 (Table 3).

CONCLUSION

MC nanoformulation is found to be more efficient and potent in bringing pharmacological effect and protecting the animal from bronchospasm in comparison to MC dry powder and fresh juice. Nanoformulation is obtaining wide popularity in the pharmacotherapy for its better bioavailability, potency, and efficacy. MC being a natural product together with the optimization of the product into nanoparticles with

PEG and soy phosphatidylcholine has proved to be a potent formulation than the crude dry powder. Hence, this study can become a future platform to compare MC nanoformulation as an adjuvant management in the standard care of treatment for bronchial asthma after effective clinical trials.

ACKNOWLEDGMENT

As authors, we would like to thank PSG Institutions – Management and the Dean, PSG IMS and R and Hospital who provided us the infrastructure to complete the study. We also express our heartfelt thanks to the Principal, PSG College of Pharmacy, Dr. V. Shankar, Professor and Head, Mr. Karthick Siram, Assistant professor, Department of Pharmaceutics, PSG College of Pharmacy, for their kind technical support which made this study successfully. Furthermore, we thank all the technicians, laboratory assistants of the Department of Pharmacology, PSG IMS and R, PSG Animal Facility, Coimbatore, for their countless help in performing this research.

AUTHORS' CONTRIBUTIONS

Bhuvaneswari *et al.*, the corresponding author designed and supervised the study. Karthika P and Balachander R, the Principle investigator and coprinciple investigator, respectively, carried out the experimental work and drafted the manuscript. All the authors were involved in manuscript editing and finalization. All authors read and approved the final manuscript.

CONFLICTS OF INTEREST

All authors have no conflicts of interest to declare.

EFFECT OF *EMBLICA OFFICINALIS* FRUIT DRY POWER ON BEHAVIOR CHANGES AND ANTIOXIDANT LEVELS: AN *IN VITRO* AND *IN VIVO* STUDY

UMAMAHESWARI A*, BHUVANESWARI K, MUTHURAMAN PL

Department of Pharmacology, PSG Institute of Medical Sciences and Research, The Tamil Nadu Dr. MGR Medical University, Coimbatore, Tamil Nadu, India. Email: dr.uma.pharmac@gmail.com

Received: 15 April 2019, Revised and Accepted: 30 May 2019

ABSTRACT

Objective: This study aim was to compare the *in vitro* antioxidant property of fresh juice and dry powder of *Emblica officinalis* (EO) by chemical testing and 2,2-diphenyl-1-picryl-hydrazyl-hydrate (DPPH) assay and also to observe the *in vivo* effect of EO fruit dry powder on food intake, body weight, behavior changes, and antioxidant levels in restraint stress rat model.

Methods: *In vitro* study, EO fresh juice 1% v/v and its dry powder form were analyzed for chemical testing and DPPH assay initially. In the *in vivo* study, 12 adult male Wistar rats were obtained. Initially, baseline parameters (Body wt, food intake, behavior changes, blood levels of superoxide dismutase, and malondialdehyde) and control values were assessed. Later 12 animals were divided into two treatment groups (1 and 2) and pre-treatment was given with dry powder of EO at a dose of 250 mg/kg and 500 mg/kg orally once a day, respectively. Animals from both the groups were restrained for 2 h/day and the same parameters were analyzed at the end of 24 h and 7 days of stress induction.

Results: *In vitro* study, fresh juice and dry powder preparations of EO were found to be positive for all the four chemical testing. In DPPH assay, dry powder showed better antioxidant activity (97%) than the fresh juice form (57%). *In vivo* study, significant antioxidant activity was seen at the dose of 500 mg/kg after day 1 and 7 days of stress induction.

Conclusion: Dry powder of EO has brought out the reversal of restraint stress-induced behavioral changes and reduced food intake, body weight, and antioxidant levels.

Keywords: Antioxidant property, 2,2-diphenyl-1-picryl-hydrazyl-hydrate assay, *Emblica officinalis*, Restraint stress, Rats.

INRODUCTION

Oxidative stress is the result of an imbalance between oxidants and antioxidants. Physical or psychological stress induces a change in the hypothalamic–pituitary–adrenal axis which releases glucocorticoids and chemical mediators including adrenocorticotropic hormone, norepinephrine, serotonin, dopamine, and acetylcholine. The metabolism of these mediators leads to more production of free radicals and reactive oxygen species (ROS), which later causes an imbalance between oxidants and antioxidants. Acute stress in any organism will produce compensatory responses to restore previous stability. However, in chronic stress, ROS put forth negative effects and becomes a major causative factor implicated in several pathologies – cardiovascular, immunological, neurodegenerative, or neuro behavior changes [1]. Antioxidant enzymes such as superoxide dismutase (SOD), catalase, and glutathione peroxidase play important roles in scavenging free radicals and preventing cell injury. When the mechanism of antioxidant protection becomes unbalanced in the human body, an antioxidant supplement may be used to help reduce oxidative damage [2]. Synthetic antioxidants are commercially available. By considering potential health risks and toxicity of synthetic antioxidants (butylhydroxytoluene and butylhydroxyanisole), researchers have drawn their attention toward the natural occurring antioxidants (plant materials) [3,4].

Studies have demonstrated that plant phenolics as a major source of natural antioxidants. The fruit of Indian Gooseberry (*Emblica officinalis* [EO]) is rich in Vitamin C and it acquires maximum antibacterial and antioxidative activities [5]. The unique antioxidants such as Gallic acid, Vitamin C, ß-carotene, and SOD enzyme have been reported to be present in the fruit. Various studies have shown the antioxidant property of EO in various forms of its extractions (ethanol and methanol) [5,6].

Stress is well known to change body weight and food intake in animal models. Many studies have shown that restraint stress suppresses body weight gain and food intake in rodents [7]. No studies have explored the *in vivo* effects of EO fruit dry powder on a combination of food intake, body weight, behavior changes, and antioxidant levels in a whole animal model. Hence, the study was designed to compare the *in vitro* antioxidant property of fresh juice and dry powder preparations of EO by chemical testing and 2,2-diphenyl-1-picryl-hydrazyl-hydrate (DPPH) assay and also to observe the *in vivo* effect of EO fruit dry powder on food intake, body weight, general behavior changes, and antioxidant levels (SOD), malondialdehyde (MDA) in an adult male Wistar rat model after restraint stress induction.

MATERIALS AND METHODS

Fresh fruits of EO were obtained from the local market and washed thoroughly in running water. Under sterile condition, the fruits were cut into pieces and seeds were removed and weighed. Then dried in a hot air oven at 60°C aseptically and grinded to get a fine powder form. EO fresh juice 1% v/v was prepared. Both the preparations were used for DPPH assay and chemical testing.

Chemical testing

Detection of phenolic compounds

- Ferric chloride test: Juice and the dry powder forms of EO were added to 5% $FeCl_3$ reagent and the formation of deep blue color was observed
- Lead acetate test: Juice and the dry powder forms of EO were added to 10% lead acetate solution and mixed. Formation of white precipitate was observed [8].

Detection of flavonoids

Aqueous sodium hydroxide test: Juice and the dry powder forms of EO were treated along with aqueous NaOH solution. Formation of yellow-orange color was observed.

H_2SO_4 test: Juice and the dry powder forms of EO were added to concentrate H_2SO_4 and observed for the formation of the orange color [8].

DPPH assay

The dry powder and fresh juice of EO were prepared in 1% w/v and 1% v/v solutions, respectively. The samples were reacted with the stable DPPH radical in an ethanol solution. The reaction mixture consisted of adding 0.5 mL of samples (dry powder and Fresh juice), 3 mL of absolute ethanol and 0.3 mL of DPPH radical solution 0.5 mM in ethanol. When DPPH reacted with an antioxidant compound, which donated hydrogen and it was reduced. The change in color (from deep violet to light yellow) was read (Absorbance [Abs]) at 517 nm after 100 min of reaction using an ultraviolet-visible spectroscopy spectrophotometer. The mixture of ethanol (3.3 mL) and sample (0.5 mL) served as blank. The control solution was prepared by mixing ethanol (3.5 mL) and DPPH radical solution (0.3 mL). Reference standard compound being used was ascorbic acid 50 ng/ml. Lower Abs of the reaction mixture indicated higher free radical activity [9-12]. Percentage inhibition was calculated by.

DPPH scavenging effect (%) = A0-A 1/A0 × 100.

Where A0 was the Abs of control reaction and A1 was the Abs in the presence of test or standard sample (control = 0.856).

In vivo

After getting approval from the Institutional Animal Ethics Committee, 12 adult male Wistar rats weighing 150–250 g were obtained and divided into two groups of six each. Initially, six animals were assessed for the baseline values of the parameters (body weight, food intake, behavior changes, blood levels of SOD, and MDA) and then those six animals were used as control (without treatment) and subjected to psychological stress by restraining for 2 h and the above said parameters were assessed at the end of 24 h and after 7 days of stress induction. This method was aimed toward reducing animal usage in the study. Then, 2 weeks interval period was allowed to acclimatize the animals back to its normal laboratory environment and to overcome the stress induction. Later then, total of 12 animals were randomly divided into two treatment groups. For Groups 1 and 2, pre-treatment with EO dry powder at a dose of 250 mg/kg body weight and 500 mg/kg body weight orally [13,14] was given once daily. Pre-treated animals from both groups were restrained for 2 h/day, and the same tests were repeated at the end of 24 h and after 7 days of stress induction. The body weight of the animals was measured in each group at the end of 24 h and after 7 days. Food intake in grams was measured for each animal in both groups at the end of 24 h and after 7 days using Oxylet system. Food intake in dark/light phase cycle was measured and compared with controls.

Behavior changes

Open field test: locomotor activity (quiet room)

On the day of testing, rats were allowed to adapt to the environment for 1 h before testing. After 5 min of acclimatization in the open field apparatus, each animal from the respective treatment group was placed individually in the center of the open field and number of squares crossed, number of rearings (number of times the animal stood on its hind legs), grooming (duration of time the animal spent licking or scratching itself while stationary), and fecal pellets were observed for a period of 5 min [15].

SOD and MDA levels

End of 24 h and on the 8th day, 1 ml of blood was withdrawn from rat tail vein for the analysis of SOD and MDA levels.

Estimation of SOD

Reagents used were Tris buffer – 50 ml (containing 50 mM of Tris and 1 mM of ethylenediaminetetraacetic acid), hydrochloric acid – adjust PH at 8.5, and Pyrogallol – 25 mg added to 10 ml of distilled H2O (20 mM conc.). For blank: 2.9 ml Tris + 0.1 ml Pyrogallol– Mixed well. Abs A was read at 420 nm using colorimeter at 1 min 30 s and Abs B at 3 min 30 s. For Sample: 2.8 ml Tris + 0.1 ml sample and 0.1 ml Pyrogallol were added and mixed well, and the Abs were read at 420 nm after 1 min 30 s (Abs A) and after 3 min 30 s (Abs B) [16].

SOD levels (in Units) were calculated using the formula: Abs (A-B)/Abs A × 50

Estimation of MDA

Reagents used were trichloroacetic acid (TCA) – 40% (40 g in 100 ml), thiobarbituric acid (TBA) – 0.67% (0.67 g in 100 ml). Then, 0.5 ml sample + 0.5 ml TCA + 2 ml TBA were added very slowly. The test tubes were kept in a boiling water bath at 90–100°C for 10 min. After 10 min, the tubes were brought back to the room temperature. Samples were centrifuged for 10 min at 3000 rpm. Separated the supernatant and readings were taken at 540 nm using colorimeter [16].

MDA levels (in units) were calculated using the formula: Abs at 532 nm × 105/1.56

Statistics

Data from the control and two treatment groups were analyzed by ANOVA in SPSS software version 24.

RESULTS

***In vitro* study**

Chemical testing

Fresh juice and dry powder preparations of EO were found to be positive for all the four chemical testing.

DPPH FREE RADICAL ASSAY

In DPPH assay, dry powder of EO showed 97% inhibition of free radical scavenging activity compared to its fresh juice preparation and standard (ascorbic acid), which were about 57% and 76%, respectively.

***In vivo* study**

In this study, after the 1st day of stress induction, rats showed changes in the mean values of body weight, food intake pattern, behavior changes, and SOD and MDA levels in both the treatment group of EO (250 mg/kg and 500 mg/kg) in comparison to the control group (without treatment) and their baseline values. More statistically significant values were seen in the EO 500 mg/kg treated group for body weight (*p=0.01), behavior changes (*p<0.01), and SOD (*p=0.01) (Figs. 1-3).

Similarly, after 7 days of repeated stress induction, rats showed, change in the mean values of body weight, food intake, behavior changes, and

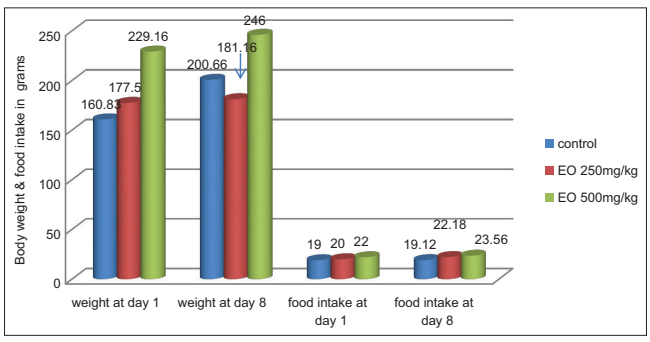

Fig. 1: Mean ± standard deviation values of body weight (*p<0.05) and food intake pattern after stress induction

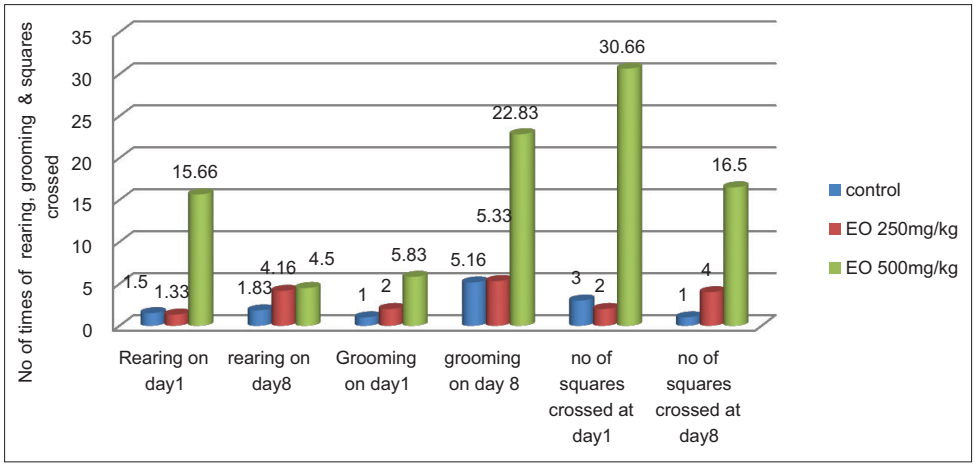

Fig. 2: Mean ± SD values of behavior parameters in open field test after stress induction (*p<0.01)

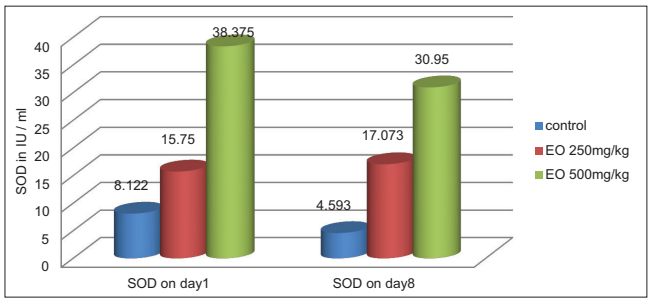

Fig. 3: Mean ± SD values of superoxide dismutase in IU/ml after stress induction (*p<0.05)

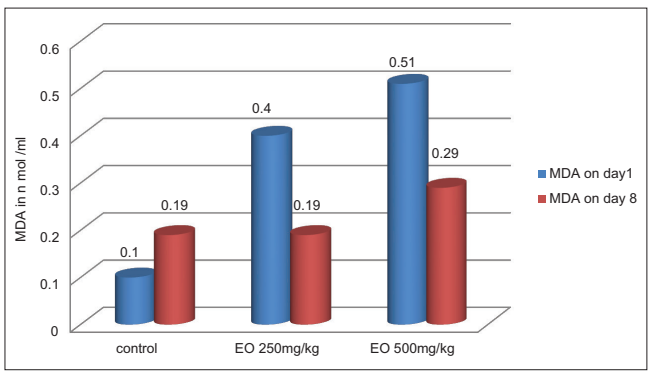

Fig. 4: Mean ± SD values of malondialdehyde levels after stress induction (*p<0.05)

SOD and MDA levels in both the treatment groups. However, statistically significant changes were seen in the body weight (*p<0.01), SOD (*p=0.01), and MDA (*p=0.04) levels only in the treatment group of EO 500 mg/kg (Figs. 1, 3 and 4).

Mean values of baseline parameters were weight–160.833±11.58 g, food intake–19.260±10.00 g, rearing–3.500±4.0866, grooming–13.500±7.7136, squares crossed–5.333±11.2190, SOD–11.007±10.45 IU/ml, and MDA–1.0596 ± 1.1341 IU/ml.

DISCUSSION

In vitro study

In this study, both the dry powder and the fresh juice of EO tested positive for flavonoids and phenolic compounds (Table 1). In terms of chemical testing, these results were similar to the studies which showed the presence of flavonoids and phenolic compounds in the aqueous methanolic fruit extract of EO [17]. In DPPH assay, dry powder of EO showed 97% inhibition of free radical scavenging activity compared to its fresh juice preparation, which was about 57% (Table 2). In the previous DPPH assay, studies of EO showed that the maximum antioxidant activity was found to be in the methanolic extract [6,17].

In vivo study

Stress has identified to modify body weight and food intake in animal models. Especially the restraint stress model effectively depicted the physical and psychological stress and used as an animal model of depression [1]. Many studies have shown that restraint stress suppresses body weight gain and food intake in rodents [18]. In the present study, mean values of body weight and food intake were increased in both the treatment groups after the 1st and the 7 days of repeated stress induction compared to the control group (without treatment) in which there was a reduction in the mean values of body weight and food intake pattern after repeated stress induction. This showed that there was reduction in the body weight and food intake pattern in restraint stress animals whereas, in the treatment groups (EO 250 mg/kg and 500 mg/kg) the animals had overcome the stress induction and they have followed the normal physiological increase in the body weight and food intake pattern (Fig. 1).

In case of behavior changes and blood levels of SOD and MDA, there were reduction in the mean value of rearing, grooming, number of square crossed and decreased level of SOD and increased level of MDA values in the control group (without treatment) compared to its baseline values indicating a state of psychological depression immediately after the 1st day and the 7 days of repeated stress induction. The two groups treated with the EO (250 mg/kg and 500 mg/kg) showed a better increase in mean values of rearing, grooming, number of squares crossed in parallel to increase in SOD, and decreased in MDA values after the 1st day and the 7 days of repeated stress induction (Figs. 2-4) This ensures that the treatment with EO had overcome the changes of stress induction, including antioxidant levels, which were comparable to the results of a few previous studies wherein the antioxidant property of EO was due to the presence of polyphenols in the fruit [19,20].

The results of the study clearly revealed the antioxidant effect of EO in overcoming stress induction. Improved changes in the body weight, food intake, and behavior might depict the antidepressant and antianxiety property of *E. officinalis*. These results were proven by the previous studies, by forced swim test, tail suspension test, elevated plus maze, and open field method with standard drugs. Apart from increased antioxidant levels, no other clear mechanism could be elicited behind the improved changes in food intake and body weight after repeated stress induction. Therefore, the proposed pharmacological mechanism behind these effects could be the involvement of monoaminergic neurotransmitters [19,21,22].

Table 1: Results of chemical testing

Preparations	Phenolic compound		Flavonoids	
	Ferric chloride test	Lead acetate test	Aqueous sodium hydroxide test	Sulphuric acid test
Fresh juice of EO	+	+	+	+
Dry powder of EO	+	+	+	+

EO: *Emblica officinalis;* +: Presence/Test positive

Table 2: Percentage inhibition of free radical scavenging activity in 2,2-diphenyl-1-picryl-hydrazyl-hydrate assay

Samples	Absorbance	Percentage inhibition
Ascorbic acid (50 ng/ml)	0.206	76
EO (dry powder 1% w/v)	0.024	97
EO (fresh juice 1% v/v)	0.364	57

EO: *Emblica officinalis*

The previous studies also confirmed that the present of phytochemicals in the EO such as tannic acid, gallic acid, flavonoids, and ascorbic acid might contribute to increase the levels of monoaminergic neurotransmitters and neurotropic action in the hypothalamus [21,22]. The monoamine receptors such as 5-hydroxytryptamine (5HT1A) and 5HT2C have their involvement in the appetite and satiety center in the brain. Hence, further studies could look into the involvement of 5HT, behind the effects of EO.

CONCLUSION

In vitro study, both the chemical testings' and DPPH assay showed maximum antioxidant activity in the dry powder preparation of EO compared to its fresh juice. *In vivo* study has brought out the reversal of restraint stress-induced behavioral changes and reduced antioxidant levels in a rat model. Further studies might focus to elucidate the various possible molecular mechanisms of action of EO in overcoming stress induction.

AUTHORS' CONTRIBUTIONS

Umamaheswari Anbarasu design the study executed the assays and participated in the writing of the entire manuscript. Bhuvaneswari K initiated the hypothesis and designed the study. Muthuraman PL participated in the animal handling and performance of *in vitro* and *in vivo* assays.

CONFLICT OF INTEREST

The authors report no conflicts of interest regarding this manuscript.

(Received: 12 July 2019; accepted: 30 October 2019)

Polycystic Ovarian Syndrome (PCOS) is a common disease exclusively seen in women of reproductive age group. World Health Organization reports that Polycystic Ovarian Syndrome approximately affects 5-10% of the reproductive female population worldwide. Women with PCOS have chronic inflammation. This in turn leads to increased incidence of non-communicable diseases like cardiovascular disease and diabetes[2]. Chronic inflammation in PCOS patients can be identified using serum markers such as C - reactive protein [CRP], Interleukin-6 [IL-6] and Interleukin-18 [IL-18].So the main objective of the study was to assess the status of inflammation in patients with Polycystic Ovary Syndrome (PCOS) and to assess the influence of drugs prescribed for PCOS on inflammation. Patients were divided into three groups as healthy volunteers, newly diagnosed PCOS patients, already on treatment patients for PCOS. High sensitivity CRP (hs-CRP), IL-6 and IL-18 were assessed. There was an increase in the hs-CRP, IL-6 and IL-18 compared to healthy volunteers in both newly diagnosed and already diagnosed groups. But there was no statistical significance (hs-CRP=0.975, IL-6=0.746, IL-18 = 0.148) between them. The mean value has decreased in the already on treatment group as duration of treatment increases. There was no statistical significance between them. There was an inversely proportional relationship between the mean values of inflammatory markers and duration of treatment.

Keywords: Polycystic ovarian syndrome, Insulin Resistance, Inflammation, inflammatory markers, hs-CRP, IL-6, IL-18.

Polycystic Ovarian Syndrome (PCOS) is a common disease exclusively seen in women of reproductive age group.World Health Organization reports that Polycystic Ovarian Syndrome approximately affects 5-10% of the reproductive female population worldwide. A study by Ridhi R *et al*. shows it affects the Indian female adolescents approximately by 9.13%[1].

Women with PCOS have chronic inflammation. This in turn leads to increased incidence of non-communicable diseases like cardiovascular disease and diabetes[2]. **Chronic inflammation** in PCOS patients can be identified using serum markers such as C - reactive protein [CRP], Interleukin-6 [IL-6] and Interleukin-18 [IL-18].

Insulin resistance[IR] and its associated hyperinsulinemia leads to a sequence of events collectively called as insulin resistant syndrome. The sequence of events includes cardiovascular disease, hypertension, polycystic ovary syndrome and non-alcoholic steato hepatitis[3]. Insulin resistant syndrome and diabetes are inter-related but are different entities. All insulin resistant individuals need not be diabetic, but develops diabetes only if he is not able to make up the degree of hyperinsulinemia needed to overcome the insulin resistance. Even though an insulin resistant individual need not be diabetic the risk of developing the consequences of insulin resistance syndrome are high. Patients with insulin resistance syndrome have increased concentrations of plasminogen activator inhibitor-1, C-reactive protein and increased white cell count. Hence these patients are at increased risk of developing PCOS.

Low grade inflammation which is of chronic is related to obesity, IR syndromes such as polycystic ovary syndrome, and an increased risk of cardiovascular disease[4]. In obese patients enlargement of adipose tissue causes adipocyte hypertrophy and hyperplasia and this huge adipocytes outshine the local supply of oxygen causing the cell hypoxia independently with stimulation of cellular stress pathway[5]. This leads to independent inflammation of the cells and cytokines and otherpro-inflammatory signals to get released. As a fragment of this chronic inflammatory process, locally released chemokine draws pro-inflammatory macrophages into the adipose tissue. These then produce structures similar to crown round the huge lifeless or dying adipocytes. These tissue macrophages release cytokines which then trigger the inflammatory process in adjacent adipocytes, aggravating inflammation and insulin resistance.

There is also genetic basis for the inflammation observed in PCOS[6].Variants in the gene encoding TNFá[7], type 2 TNF receptor and IL-6[8-10] and its signal transducer[11] have been reported in association with PCOS in European population. These findings are in conceptual agreement with a common evolutionary background for PCOS and metabolic disorders.Interleukin-6 is an endocrine cytokine produced by mononuclear cell and adipose tissue that is directly responsible for stimulating hepatic CRP synthesis[12-15]. CRP in turn has emerged as a major predictor of metabolic dysfunction in asymptomatic individuals, and is also produced by adipose tissue[16, 17]. Hence **C-reactiveprotein** is the most consistent circulating marker of low- grade chronic inflammation in PCOS. Like C-reactive protein and IL-6, IL-18 is also a proinflammatory cytokine which promotes secretion of TNF-á[18], which further stimulates the production of IL-6.

So this study was basically carried out to see if there is any association between inflammation and PCOS. If the serum inflammatory markers are higher then there is an association between inflammation and PCOS in Indian Population.

In addition to it we would also like to see drugs used in PCOS have any influence over the inflammation in PCOS.Numerous therapies have been projected for the treatment modalities of polycystic ovarian syndrome, but the ideal treatment for infertile women with polycystic ovarian syndrome has not yet been clear. Drug treatment comprises clomiphene citrate, insulin sensitizing agents, gonadotropins and gonadotropin- releasing hormone (GnRH) analogs. Surgical treatments include laparoscopic ovarian drilling and the application of assisted reproduction techniques. Besides this loss of weight, diet and physical exercise have been shown to develop hyper insulinemia, menstruation abnormalities and ovulatory rates. Even though these many drugs and modalities of treatment were available for PCOS, only few drugs targeted in reduction of inflammation.Studies showed that there was a decrease in interleukin-6 and interleukin-18 level after metformin treatment for three months in polycystic ovary syndrome patients. This shows metformin decreases the inflammatory markers and have beneficial effect on inflammatory process of PCOS[19]. Many earlier studies spoke about metformin and their anti-inflammatory properties. There were no studies demonstrating the anti-inflammatory effect of other drugs used to treat PCOS in practise. So we thought to see any other drugs used to influence the inflammation.

MATERIALS AND METHODS

This study was a prospective cross sectional study. The study population was from all the patients who attended the outpatient Department of Obstetrics and Gynecology in PSGIMSR

Hospital, Coimbatore. We included all the PCOS patients according to Rotterdam consensus criteria with age group 18-45 years and excluded those patients presenting with a history of inflammatory diseases or intake of inflammatory drugs and also pregnant women. Healthy Volunteers of age group 18- 45 years women with normal reproductive cycle were included and those who present with history of inflammatory drugs or diseases are excluded. Further those who have hypertension or diabetes are also excluded from the healthy volunteers.

The overview of the study design is given in the figure below. The patients were divided into three groups.

Group 1: Healthy volunteers

Group 2: Newly diagnosed PCOS

Group 3: Already on treatment for PCOS

Sample size estimated according to previous literature search.30 participants in each group was taken.The study design was submitted to the Institute Human Ethics Committee (IHEC) stating its purpose preceding the study. After its approval the study was initiated. The details and the usefulness of the study design were described to every participant individually and clarified their doubts before getting the informed consent forms. The informed consent forms provided to the participants were either in English or in Tamil. The participants, who gave written informed consent, came under the inclusion criteria were enrolled for the study. Healthy volunteers were also given the informed consent. The patients who declined to give informed consent were also excluded from the study.

PCOS patients were selected according to Rotterdam Consensus Criteria 2003 which is given below.

• Polycystic ovaries(12 or more follicles in each ovary, each follicle measuring 2-9 mm in diameter and/or ovarian volume > 10 ml, one polycystic ovary is sufficient for diagnosis)

• Oligo-/anovulation; clinical diagnosed as Oligo-/amenorrhea (menstrual cycles longer than 35 days or less than 10 menstruation/year)

• Hyperandrogenism (clinical or biochemical)

Basic demographic data like name, age and measurements like Height, weight, body mass index were recorded. History of the patient and if the patient is on already treated group then their treatment history were noted.

Our study was to observe if there were abnormalities in High sensitivity C - reactive protein, Interleukin-6 and Interleukin-18 in PCOS patients and to compare those with the healthy volunteers.

The high sensitivity CRP was tested in the Clinical Biochemistry lab using theCobas Integra C - reactive protein (Latex). This machine works by the methodology of "Particle enhanced turbidimetric assay".

The Interleukin-6 and Interleukin-18 were

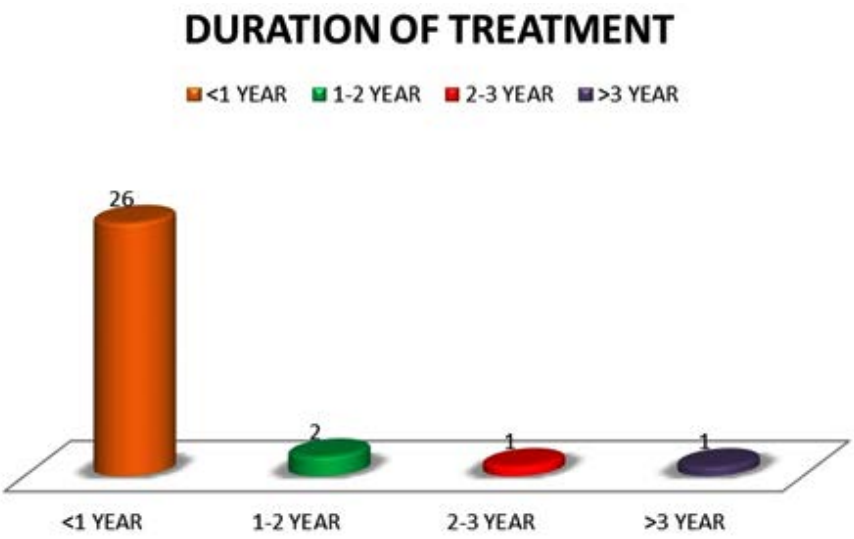

Fig. 1. Duration of treatment

estimated in the Pharmacology laboratory using Krishgen Biosystems, imported from California, USA and read by an Elisa reader which is a Bio-rad system at an absorbance of 405 and 450 nM.

Statistical analysis was performed by using SPSS software version 19. The results were analyzed using one way ANOVA and post hoc analysis was done using LSD.

RESULTS AND DISCUSSION

Our study was intended to evaluate the status of inflammation, by measuring hs-CRP, IL-6 and IL-18, in PCOS patients in Indian population. It was also aimed to assess the influence of drugs prescribed in PCOS patients on the inflammation.

Polycystic Ovary Syndrome is an endocrine disorder which is very common in the female population in the reproductive age group[20]. Most women shows the features of metabolic syndrome. It is also concomitant with hypertension, diabetes, dyslipidaemia, gestational type 2 diabetes[21].

PCOS is associated with obesity and also increased incidence of insulin resistance[22]. There is also increased risk of cardiovascular complications. The inflammation which is of chronic low grade is related to PCOS. The C-reactive protein levels are an acute phase reactant and is circulating marker of cardiovascular events. CRP > 3mg/L in a patient is equal for metabolic syndrome as in ATP III guidelines. IL-6, TNF-á, IL-18 concentrations in serum is the predictors of cardiovascular events[1]. So, in this study we proposed to measure the IL-6, IL-18 and hs-CRP levels in PCOS patients in Indian population. There are various studies showing the

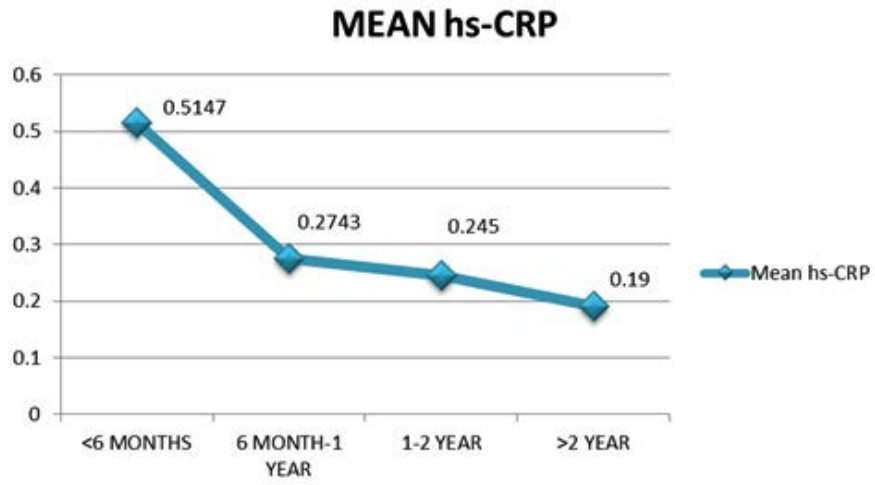

Fig. 2. Meanhs-CRP levels

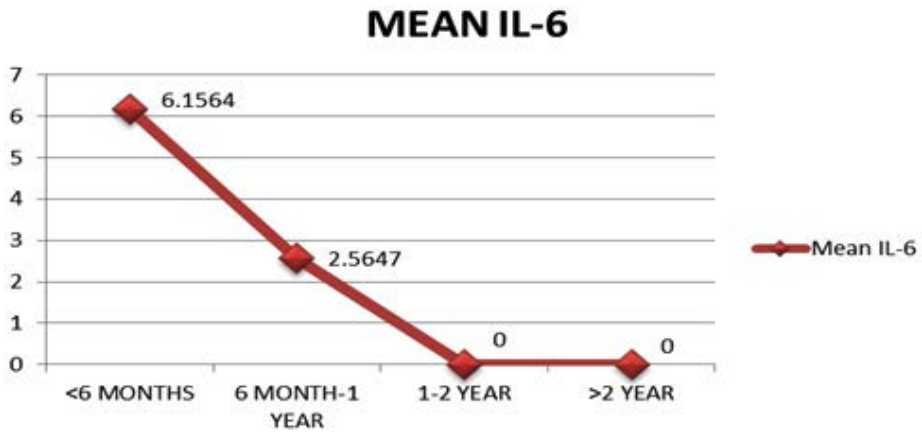

Fig. 3. MeanIL-6 levels

significance of IL-6, IL-18 and hs-CRP in PCOS in other countries. There are no studies showing this significance in Indian Population.

There were many therapies of polycystic ovarian syndrome including drugs as well as surgical therapies and life style modifications. In previous studies drugs like metformin and thioazolidinones like pioglitazone, rosiglitazone decreases insulin resistance and also known to decrease the inflammation. Other drugs like myoinositol, clomiphene citrate improves ovulation alone. Their role in inflammation was not known in PCOS.

Ninety participants were recruited in our study. These participants were divided into three groups as normal controls, newly diagnosed patients and already diagnosed on treatment patients. Low grade chronic inflammation is associated with Polycystic Ovary Syndrome and it can be assessed using inflammatory markers like IL-6, IL-18 and hs-CRP. These are strong predictors of cardiovascular complications. Kelly *et al*. reported a study exhibiting an increase in CRP which shows a low grade chronic inflammation in PCOS patients. In this study they showed a mean value of PCOS patients was greater than normal controls[2].

In our study there was no significant increase in the CRP levels (p=0.975).There was no significant difference between the newly diagnosed and already diagnosed patients suggesting that hs-CRP didn't rise significantly in already diagnosed group as they were on treatment (Table 2&3).

In the same way there was also no significant changes in the IL-6 levels (p=0.746). There was an increase in their mean values when compared to normal controls. Mean value for normal controls was 34.35±93.88 whereas for newly diagnosed patients it was 90.58±308.62 and for already diagnosed it was 91.41±476.6 suggesting there was a rise in IL-6 levels in PCOS when compared to normal controls but that was not significant. Between newly diagnosed patients and already diagnosed patients there was no much difference between the levels (Table 2&3).

Another study by Hector *et al* showed there was an increase in IL-18 independent of obesity[23]. In our study the results showed there was an increase in the mean values of IL-18 in PCOS patients when compared to normal controls. The mean value for Normal control was 131.4±224.17 whereas for newly diagnosed

and already diagnosed group of patients it was 264.86±316.33 and 282.2±403.92 respectively. The difference was not statistically significant (p=0.148) (Table 2 &3). There were also, as in IL-6, no difference in newly diagnosed and already diagnosed patients.

When we considered the treatment prescribed to the patients in already diagnosed group, most of the patients were in Metformin combination. Nearly 70% of patients were in metformin combination. Metformin was given along with myoinositol, clomiphene citrate, Human Chorionic Gonadotropins (HCG). Only 46.67% patients were on monotherapy of metformin (Table 1). The other common drug prescribed was myoinositol combination. It was also given along with metformin, clomiphene citrate and HCG. Metformin along with myoinositol was given to 13.3% of patients.

86.67% of patients were on these treatments for less than 1 year and only 13.33% of patients were on these therapies for more than 1 year (Figure 1).

Mekkawi *et al* stated that there was a statistical significant change in the Interleukin-6 and Interleukin-18 levels before and after

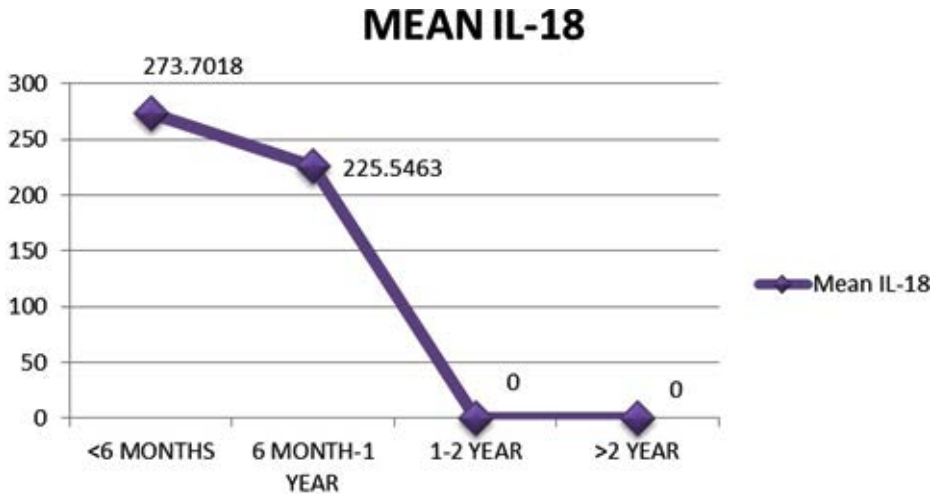

Fig. 4. MeanIL-18 levels

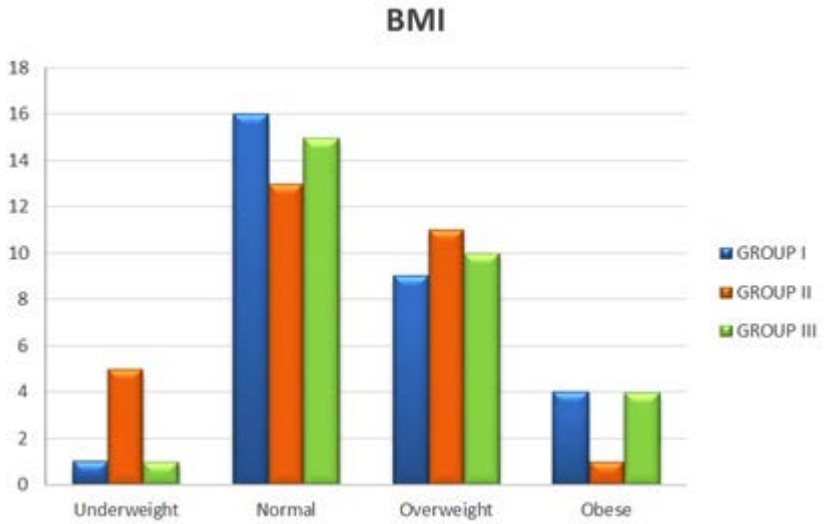

Fig. 5. Body Mass Index of the study population

metformin therapy showing metformin decreases the inflammatory markers in PCOS patients[19]. In previous studies it was known that there was an increase in the nuclear factor ê B (NFêB) in PCOS. Metformin inhibits NFêB which inhibits IL-1â and inhibits the production of pro inflammatory gene[24].

In our study, the mean ± SD for hs-CRP, IL-6,IL-18 were decreased between the patients as there was an increase in the duration of treatment (Figure 2,3,4).

Our results were consistent with Mohlig *et al*. who showed there was no substantial decrease in CRP and IL-6 levels. In their study these levels were increased in both normal and PCOS obese patients compared to the lean patients. There was a positive relationship between the obesity, insulin resistance and inflammatory markers than the PCOS itself. When a linear regression was done in their study it showed obesity was the one which increases the inflammatory marker than the insulin resistance[9]. Another study by Escobar-Morreale *et al*. also showed obesity causes an increase in the inflammatory marker and not the disease itself[25].

Our study had only 13.3% of obese study population in the already diagnosed and on treatment group and 3.33% in the newly diagnosed PCOS group(Figure 5).

Also in our study there were about 86.7% of already diagnosed group of patients' on treatment for less than one year(Figure 2). So even though there was a fall in the mean values of inflammatory markers there was no statistical significance in them.

The lack of statistical significance which may be due to small sample size in each group and wide range of values between the patients. The duration of treatment which was less than one year in most of the patients and hence the effect of drugs on the inflammatory markers could not be assessed. As this was a cross sectional study and blood samples were taken at one time the difference in the inflammatory markers could not be studied for the same group of patients. The influence of drugs prescribed was also in combination for most of the patients and so they could not be studied individually.

CONCLUSIONS

Though there are various pharmacological drugs available to treat PCOS, only few drugs targeted in reduction of inflammation. There were various studies, as we quoted earlier, demonstrating the effect of inflammation on PCOS. These studies were all done in other parts of the world. There were very less number of studies done in India. So we proposed to study the status of inflammation on PCOS in Indian population in particular South Indian population.

The pro inflammatory cytokines were produced when NFêB was stimulated. Metformin inhibits this NFêB and thus reduces the inflammation. Other drugs used in PCOS in practise like myoinositol, clomiphene citrate, hormones target at the disease per se and not on the inflammation produced by the disease.

Our study has shown that mean values of inflammatory markers were increased in Polycystic Ovary Syndrome (PCOS) in newly diagnosed and already on treatment for PCOS. 86.7% of the patients who were on already treatment for PCOS group were on treatment for less than one year. It has shown that there was an inversely proportional relationship between the mean values of inflammatory markers and duration of treatment.

We suggest larger follow up studies with longer duration of treatment so that influence of drugs on the inflammatory markers can be studied exhaustively in Indian population. Further studies are needed to demonstrate the effects of drugs for PCOS targeting on the inflammatory pathway so that these drugs not only brings down the severity of PCOS but also reduces the cardiovascular risk factors associated with it.

Table 2 and 3 represents the comparison of hs-CRP, IL-6 and IL-18 for the three groups.

ACKNOWLEDGEMENT

I am grateful to Dr. Seetha Panicker (HOD, Obstetrics & Gynecology) and Dr. G.Jayachandran (HOD, Biochemistry) of PSG Medical College and Research Institute for the necessary permissions granted and for the excellent amenities offered to carry out my study. My thanks to Professors Dr.Reena Abraham and Dr.Kanchanamalai, Obstetrics &Gynecology Department of PSG Medical college and Research Institute for giving me patients for my work. I am indebted to all the patients of my study for their

kind participation and to the faculty and staff of Obstetrics and Gynecology department and to all the technical staff of Clinical Biochemistry and Pharmacology Laboratory for having spared their time and effort towards my thesis work.

(Received: 15 January 2019; accepted: 02 February 2019)

To understand the biological basis of the effect of *Momordicacharantia* and also it's effectiveness as a mono-therapy for metabolic syndrome. Thirty four adult male Sprague-Dawley rats weighing were divided into Groups I, II, III and IV having 10, 10, 8 and 6 animals respectively. Pellets with 66% fructose were fed to 28 animals [Groups I, II, III] while 6 normal control animals [Group IV] were fed with standard rat chow diet for 6 weeks. Later, for next 6 weeks, animals in Groups I, II and III were treated with *M.charantia* 300mg/kg/day, and600mg/kg/day and Standard treatment respectively. Serial measurements of body weight, BMI, fasting blood sugar, noninvasive blood pressure, serum lipid profile, LDA, SOD and serum NF-êB were assessed at the base line, at the end of 6 weeks of fructose diet and following treatment (12 weeks). Following induction, there was statistically significant increase in body weight, BMI, FBS, serum triglycerides, total cholesterol, LDL, lipid derived aldehydes and serum NF-êB while there was reduction in HDL cholesterol and SOD compared to baseline values. Following treatment Group II and III shown reversal of the parameters to the level of normalization. *M.charantia* 600mg/kg/day had exclusively matched the therapeutic efficacy of the standard therapy given in combination. The biological basis of the effects of *M.charantia* was by inhibiting the inflammatory pathway in metabolic syndrome both at the levels of ROS generation and transcription of pro-inflammatory marker NF-êB.

Keywords: Metabolic syndrome, *Momordicacharantia*, Serum NF-êB, Lipid derived aldehydes.

'Metabolic syndrome'[1] is a constellation of metabolic derangements such as, abdominal obesity, hypertension, insulin resistance, hyperinsulinemia, impaired glucose tolerance, dyslipidemia, proinflammatory and prothrombotic states as well. It is the disorder reaching epidemic proportions worldwide in recent times[2]. The recently anticipated global prevalence of metabolic syndrome is approximately 16%.[3] It was also found that prevalence as 23.7%[4] in United States heeding to third National Health and Nutrition Examination Survey (NHANES III). The overall prevalence of cardio-metabolic syndrome in India is estimated to be ranging from 11% to 41%.[5]

The annual direct healthcare cost for diabetes and its associated diseases worldwide of age 20 to 79 years is estimated to be around 286 billion dollars or even more. And it is predicted that this figure would rise to 396 billion dollars by 2025 accounting 13% - 40% of global health care budget due to perpetual inflation of prevalence.[6]

There is no well clear cut-off point in treating metabolic syndrome, as of now, individual components are treated in addition to the risk factors of the patients and moreover, no single drug is available to treat all the individual components of the syndrome altogether. On the other hand, *Momordicacharantia*(bitter gourd) tends to possess anti-diabetic, anti-hypertensive, hypolipidemic and anti-inflammatory properties individually as a sole agent.

With this background, our study aimed to study the effectiveness of *Momordicacharantia,* as a mono-therapy for metabolic syndrome. In addition our study also aimed at understanding the biological basis of the effect of *Momordicacharantia*in the treatment of metabolic syndrome.

MATERIALS AND METHODS

Institutional Animal Ethics Committee (IAEC) approval was obtained, and 34 adult, male Sprague-Dawley rats weighing 150-200g aged 3 months were included in our study.

Animals were randomly allocated into 4 groups;

- Group I: Treatment group 1 (*M.charantia* extract-300 mg/kg/day) -(10)
- Group II: Treatment group 2 (*M.charantia* extract-600 mg/kg/day)-(10)
- Group III: Standard treatment group (Metformin-180mg/kg/day + Telmisartan-2.5mg/kg/day + Rosuvastatin -2.5mg/kg/day)-(8)
- Group IV: Normal control-(6)

The animals were group housed, 4 rats per cage at a constant ambient temperature on a 12 - h light, 12 - h dark cycle. Pellet diet containing 66% fructose[177] made from D- fructose [purchased from Lobachemie laboratories] was given to 28 animals and standard rat chow diet to 6 controls and water were provided *ad libitum* out of 34 for 6 weeks. Then serial measurements of body weight, BMI, fasting blood sugar were done at the baseline and every week thereafter, whereas noninvasive blood pressure, serum lipid profile, LDA, SOD and serum NF-êBwere assessed at the base line and at the end of 6 weeks (i.e., following induction). Then at the end of induction, 28 animals of 3 groups, which were fed with fructose were provided *M.charantia* extract-300 mg/kg/day, *M.charantia* extract- 600 mg/kg/day and standard treatment respectively. And those animals were provided with standard chow and water *ad libitum* all through the 6 weeks of treatment. Then serial measurements of all the parameters were assessed at the end of 6 weeks (i.e., following treatment).Finally, at the end of the study 2 rats from each of the groups were sacrificed for histopathological examination of liver and heart to seek for pathological changes developed during induction and magnitude of the reversal of changes following treatment [Figure 1].

Tail cut bleeding (tail snip method)[7] was the method of blood collection used in our study,BMI[8] was determined from body weight and body length (nose-to-anus length) using the formula; BMI (Body mass index) = body weight (g) / length2 (cm2). We followed the method of blood glucose estimation with glucometer, according to the Institutional animal care and use committee (IACUC)[9] standard procedure for glucose monitoring of blood in rats and mice. LE 5002, non-invasive blood pressure meter (Panlab-Harvard apparatus) was used for measuring the blood pressure in rats. The lipid parameters estimated using GenX lipid parameters estimation kit, manufactured by Proton Biologicals India Pvt. Ltd (Bangalore) were serum total cholesterol, triglycerides and HDL (high density lipoprotein) cholesterol. LDL cholesterol was estimated using Friedewald's formula;[10] LDL = TC – HDL – $[TG/5]^2$.The principle behind the superoxide dismutase estimation done by us was inhibition of pyrogallol's auto-oxidation by superoxide dismutase. Then, the superoxide dismutase levels are analyzed from the 2 absorbance values (A,B) measured at two minutes interval using spectrometric method,

SOD (in Units) = [Absorbance (A-B) X 50/ Absorbance A]

Estimated malondialdehyde from the supernatant of the centrifuged samples by colorimeter,

Malondehyde (in Units) = [Absorbance at 532nm X 105/1.56]

Rat nuclear factor-kappa-B (NF-êB) assay was a quantitative sandwich enzyme immunoassay technique done by ELISA kit [Cusabio,China]. The microplate provided was pre-coated with NF-êB

specific antibody. NF-êB present on the standards and samples when pipetted into the wells would bind to antibody that was immobile. After removal of the substance that were not bound, a biotin-conjugated antibody specific for NF-êBwould be pipetted into the wells. Subsequently, wells were washed and addition of Horseradish Peroxidase (HRP) done. An addition of substrate solution to the wells would lead on to color development that would be in proportion to bound NF-êB, and the color intensity was measured.

The animals to be sacrificed for histopathological examination were anaesthetized with ether before the procedure. Once the level of anaesthesia is certain, the rats were dissected and the organs liver and heart were collected separately in a promptly labeled sterile container with formalin. Those specimens were immediately sent for histopathological examination.

Paraffin blocks were made and 4m thick sections were made from the chosen blocks for routine haematoxylin and eosin staining. Reagents required for this staining were Harris haematoxylin and eosin.The analysis done was Paired-t-test for analyzing the paired data i.e., parameters before and after induction and also for comparing data at the end of treatment with that following induction. One-way ANOVA and post hoc LSD were done to analyze the difference between groups.

RESULTS

Body mass index [BMI]

An increase in BMI was evidenced after a period of 6 weeks in animals [N=28] on 66% fructose diet in comparison to the normal control animals with a mean difference of 0.132 g/cm^2.

Following treatment for a period of 6 weeks, when compared with induced animals, Group I rats on *M.charantia* 300 mg/kg/day, Group II rats on *M.charantia* 600 mg/kg/day and Group III rats on Standard treatment showed a statistically significant reduction [P =0.021,P =0.001 and P=0.020 respectively] in BMI (Table 1). In contrast to all the treatment groups, the untreated normal control animals showed a statistically significant increase in BMI [P <0.001].ANOVA (Analysis of variance) assessed at baseline there was no statistical significant difference in BMI between groups. Following induction with 66% fructose all the three groups showed a statistically significant increase in body mass index compared to normal control [P <0.001]. Further, following treatment, though all the three groups showed reduction in body mass index, there was no statistically significant difference when compared to control [P=0.441,0.064,0.651 respectively] indicating normalization of BMI.

Fasting blood sugar

Change in fasting blood sugar in individual groups on induction

All the 3 groups showed a statistically significant increase in fasting blood sugar [P <0.001] from the baseline on induction of the disease been illustrated in the chart.

The difference in fasting blood sugar between groups was analyzed using ANOVA showed that a statistically significant increase [P <0.001] in all the 3 groups when compared to normal control on induction. Following treatment, Group II and III had reduced fasting blood sugar to a level similar to normal control [P=0.250,0.457 respectively], while reduction of the fasting blood sugar by *M.charantia* low dose (Group I) was not to the extent of that of normal control.

While following treatment of the animals for a period of 6 weeks all the three groups [Groups I,II and III] a paired t test detected a statistically significant reduction in fasting blood sugar [P <0.001], while the normal control group did not show significant change in blood sugar [P =0.610] (Table 1).

The difference in fasting blood sugar between groups was analyzed using ANOVA showed that a statistically significant increase [P <0.001] in all the 3 groups when compared to normal control on induction. Following treatment, Group II and III had reduced fasting blood sugar to a level similar to normal control [P=0.250,0.457 respectively], while reduction of the fasting blood sugar by *M.charantia* low dose (Group I) was not to the extent of that of normal control.

Mean arterial pressure[MAP]

Change in MAP in individual groups on treatment following induction:

Though all the 3 groups of animals fed on 66% fructose diet showed an increase in Mean arterial pressure (MAP) from the baseline within6 weeks, the induction was not homogeneous among all the groups with maximum rise in standard

treatment group [Figure-5].

A paired-t-test showed a statistically significant increase [P=0.006] only in the animals assigned to standard treatment group in comparison to baseline values. A paired-t-test was done to compare the difference in MAP following treatment found that the reduction though evident, was statistically significant in none of the groups [P =0.707, 0.173, 0.065] from the period of induction (Table 1).

The difference in MAP between groups was analyzed using ANOVA, at baseline and there was no statistical significant difference between groups indicating homogeneity of the animals while on induction, only Group III animals showed a statistically significant increase [P=0.002] compared to normal control. Further, on treatment, all the 3 groups of animals had demonstrated a reduction of MAP to reach the level of normal control rats.

Serum triglycerides on induction and treatment of metabolic syndrome

As shown in Table 2, all the 3 groups showed a statistically significant increase in triglycerides [P <0.001] from the baseline following induction of metabolic syndrome with 66% fructose diet for a period of 6 weeks [Figure-6].

Following treatment period for 6 weeks, all the 3 groups showed a statistically significant reduction in triglycerides [P <0.001] from the period of induction when a paired t test was used to test significance.

ANOVA (Analysis of variance) was done to assess the significant change in triglycerides levels between the 4 groups of animals. At baseline there was no statistically significant difference in triglycerides between groups indicating homogeneity of the animals. Following induction, all the three groups [Group I,II and III] showed a statistically significant increase in triglycerides compared to normal control [P =0.001,0.33,0.000 respectively]. Further, following treatment, all the three groups showed reduction in triglycerides, not statistically significant from that of control, [P=0.177,0.355,0.123 respectively] indicative of normalization of triglycerides levels.

Total cholesterol levels

Similar to triglycerides, total cholesterol of all the 3 groups showed a statistically significant increase [P <0.001] from the baseline following induction [Figure-7]. Compared to the normal control, Groups II and III on treatment showed a statistically significant [P=0.001] reduction in total cholesterol, while the reduction in Group I rats on *M.charantia*300 mg/kg/day (low dose) failed to demonstrate statistical significance [P=0.085] (Table 2).

ANOVA done to evaluate the significant change in total cholesterol between groups showed a significant increase in total cholesterol [P <0.001] compared to normal control following induction and after treatment, all the 3 treatment groups showed reduction in total cholesterol, in addition to which the mean total cholesterol in Groups II and III were not statistically significant compared to normal control rats indicating normalization of cholesterol level in these groups at the end of treatment.[P=0.126, 0.282].

LDL cholesterol levels

Following induction and treatment of metabolic syndrome

As shown in Table 2, all the 3 groups showed a statistically significant increase in LDL [P <0.001] from the baseline following induction of metabolic syndrome with 66% fructose diet for a period of 6 weeks [Figure-8]. Following treatment period of 6 weeks, Group II and III showed a statistically significant reduction in LDL [P <0.001] from the period of induction while Group I animals did not show significant reduction in LDL [P=0.366].

ANOVA (Analysis of variance) was done to assess the significant change in LDL levels between the 4 groups of animals at three time zones namely baseline, following induction and following treatment. At baseline, there was no statistical significant difference in LDL levels between groups. Following induction all the three groups [Group I,II and III] showed a statistically significant increase in LDL levels compared to normal control [P < 0.001].

Further, following treatment, Group II and III, when compared to control showed a statistically significant reduction in LDL [P=0.476,0.130 respectively] indicative of normalization of LDL levels while Group I animals on *M.charantia* low dose did not show significant reduction in LDL to the level of normal control.

HDL cholesterol levels

Following induction and treatment of metabolic syndrome

Comparison of serum HDL levels done among all the 3 groups showed a statistically significant reduction [P <0.001] at the time of disease induction to baseline level.

A paired-t-test showed a statistically significant increase in mean HDL levels [P =0.001, 0.001, and 0.003 respectively (Table 2)] at the end of treatment when compared to the mean following the period of induction, while normal control did not show statistically significant change in HDL levels [P=0.161].

ANOVA done to evaluate the significant change in HDL levels between groups showed a significant reduction in HDL levels [P <0.001] compared to normal control following induction and after treatment, there was an increase in HDL levels all the 3 treatment groups, despite this increase the mean HDL cholesterol in Groups II was not statistically significant compared to normal control rats indicating normalization of HDL level in this group at the end of treatment [P=0.808].

Thio-barbituric acid reactive substance levels

As shown in Table 3, a paired-t-test had shown a statistically significant increase in Thio-barbituric acid reactive substance, Malondialdehyde (MDA) in all the 3 groups [P=0.007,0.001,0.003] [Table-3] from the baseline following induction of metabolic syndrome with 66% fructose diet over a 6 weeks period [Figure-10].

Following treatment period of 6 weeks, a paired t test was done to detect the difference between groups found that though all the three groups had reduced the TBARS levels, it was only II and III showed a statistically significant reduction of malondialdehyde levels [P=0.024, 0.001] respectively.While the group I animals on low dose *M.charantia* did not show significant reduction [P=0.066] in malondialdehyde in comparison to the other groups.

ANOVA done to assess the significant change in MDA levels between groups revealed a statistically significant rise in the levels of MDA [P =0.002,<0.001, <0.001 respectively] compared to normal control following induction. Following treatment, the MDA levels in all the 3 treatment groups, was not statistically significant different from that of normal controls indicating normalization of MDA level all the groups at the end of treatment [P=0.078,0.743,0.454 respectively].

Superoxide dismutase [SOD]

SOD following induction and treatment of metabolic syndrome

All the 3 groups showed a statistically significant reduction in SOD levels [P=0.001, 0.005, 0.000 respectively] from the baseline following induction of metabolic syndrome with 66% fructose diet [Figure-11] for a period of 6 weeks when tested using paired-t-test.

Following treatment period for 6 weeks, all the 3 groups though showed a increase in SOD levels from the period of induction, but was not of statistical significance when a paired t test was used to test the significance [P=0.087,0.107,0.214 respectively (Table 3)].

When ANOVA was done to evaluate the significant change in SOD levels between groups following induction, a statistically significant reduction in SOD levels [P=0.020, 0.001, 0.000 respectively] was detected compared to that of normal control. After treatment, there was an increase in SOD levels in all the 3 treatment groups, with the increase in the mean SOD cholesterol in Groups I and II not being statistically significant compared to normal control rats indicating normalization of SOD level in this group at the end of treatment.

Nuclear factor kappa-B [NF-êB]

NF-êB following induction and treatment of metabolic syndrome

The mean serum NF-êB levels of the normal control animals in our study at baseline was established as 22.033±5.657 pg/ml [Figure-12].All the 3 groups showed a increase in NF-êB levels, but not of statistical significance [P=0.303, 0.270 and 0.327 respectively] from the baseline following induction when a paired-t-test was used (Table 3).

In comparison to the normal control values in their individual groups, all the 3 groups showed a statistically significant reduction in serum NF-êB levels [P=0.043, 0.001 and 0.027 respectively].

ANOVA done to analyze the difference between groups had found that there was a reduced serum NF-êB levels, which is not statistically significant when compared to normal control rats indicating normalization of serum NF-êB levels

in groups I and III at the end of treatment, while group III animals showed a statistically significant difference with that of normal control indicating non-achievement on normalization.

Histopathological examination

Histopathological changes in liver

On comparing the liver of treated animals with that of normal control, all the 3 groups showed fatty infiltration [micro &macrovesicular steatosis]. Group II and III animals showed fatty changes of grade 2+ while the fatty liver was graded as 3+ in Group I animals treated with low dose *M.charantia* (Figure 13).

Histopathological changes in heart

On comparing the histopathology of heart of the treatment groups with that of normal control, it was evident that all the 3 groups showed hypertrophy of heart due to fructose diet. The grade of hypertrophy was found to be homogenous in Groups I, II and III and did not any show any changes related to reversal of the hypertrophied heart. But the fatty change that is observed in the disease control is not seen in sections of Groups I, II and III heart (Figure 14).

DISCUSSION

The aim of our work was to study the biological basis of effects of *Momordicacharantia*in metabolic syndrome by measuring serum NF-êB, lipid derived aldehydes and superoxide dismutase levels. And we also focused to identify the therapeutic advantage, of *M.charantia*as a sole agent in the treatment of all the entities of metabolic syndrome with respect to available standard treatment, by ascertaining the changes in body mass index, fasting blood sugar, lipid profile and blood pressure.

Body mass index showed a statistically significant [P <0.001] increase in all the groups of animals after an induction period and also in the control animals compared to baseline values. The increase in BMI noted in normal control can be explained as due to the linear growth that is normally observed.[11] Following treatment, all the treated groups of animals showed a statistically significant reduction. Inspite of not achieving statistical significance in body weight reduction in the Groups I and III, BMI showed a significant reduction and this disparity can be accounted by the fact that the length and the thoracic circumference would become static at around 4-5 months and thus, signifying the advantage of BMI over body weight, as diet induced obesity could be easily estimated from the BMI in rats in addition to being a predictor of dyslipidemia and oxidative stress.[12]

Fasting blood sugar was estimated every week for a period of 12 weeks showed a statistically significant increase in all the groups [P <0.001] from the baseline to induction. It is well established that the enzyme fructokinase, would phosphorylate the surplus fructose absorbed from the intestine. And also, the metabolism pertaining to fructose is not similar to that of glucose, the difference being fructose-1-phosphate that is formed from fructose would be converted to several 3-carbon molecules, like glyceraldehyde, glyceraldehyde-3-phosphate and dihydroxyacetone phosphate and they are considered as the potential source for gluconeogenesis, and thereby raise blood glucose levels.[13]

Following treatment all the three groups [Groups I,II and III] showed a statistically significant reduction in fasting blood sugar. A study which was done earlier to analyze the anti-diabetic effect of *M.charantia* with reference to glibenclamide found that all the doses used in the study from lower to higher doses [250 mg/kg, 500 mg/kg, 750 mg/kg] showed a statistical significant reduction in blood sugar similar to that resulted from our study.[14]

On comparison of the mean of treated groups to normal age control at the end of treatment, it was evident that, though *M.charantia*low dose had reduced the blood sugar significantly but not to the extent of normalization. The probable reason for this could be due to shorter duration of treatment. There are numerous studies demonstrating hypoglycemic activity of *M.charantia*, apart from the observation that the active component being structurally similar to insulin. Accordingly, it is also shown to exhibit insulin secretagogue action with additional activity of inhibiting two key gluconeogenic enzymes fructose 1, 6-diphosphatase and glucose-6-phosphatase.[15,16]

Our study animals though have demonstrated an increase in Mean arterial pressure in response to high fructose diet, the rise was not identical in all the groups of animals and there was inter and intra group variation with statistically

significant [P=0.006] rise in animals grouped for standard therapy (Group III). Though studies had demonstrated the induction of hypertension by fructose diet, contradictorily, there are also studies demonstrating inconsistent elevation of blood pressure.[17,18] A study done in male Sprague-Dawley rats with high fructose diet showed a demonstrable rise in systolic blood pressure but not mean arterial pressure (MAP) which was rationalized by the variability between animals and also the scale of metabolic dysfunction not being sufficient to defer an effect on blood pressure.[17] The probable reason for the increased MAP response in Group III rats unlike the other groups in our study, would have been due to the associated rise in serum triglycerides. Similar observation was also made in a previous study.[19]

Subsequently after the treatment period of 6 weeks, all the 3 groups of animals [groups I, II and III] showed a reduction in mean arterial pressure from the period of induction though not statistically significant.

When the difference between groups were analyzed at the end of treatment, a constructive finding illustrated in our study was that groups on high dose *M.charantia* and standard therapy showed a reduction in MAP to the level of normalization, while low dose *M.charantia*in contrast showed a rise in blood pressure following a fall indicative of its inconsistency in treating hypertension.

There exists an analogous pattern of MAP changes in the groups II and III in the line chart indicating a potentially similar mechanism of BP lowering by *M.charantia* and telmisartan. This could be explained by a recent study signifying the existence of a peptide named VY-7 in *M.charantia*that possesses antihypertensive property by inhibiting angiotensin converting enzyme,[20] and in turn reducing aldosterone production. In addition, naturally, it has high potassium content and both could be contributory to increased natriuresis and thereby a fall in blood pressure. Telmisartan, an angiotensin receptor antagonist, also acts similarly by reducing aldosterone production. Yet, another homology that exists between telmisartan and *M.charantia* is that both possess PPAR ã agonistic activity.

Our study evinced a statistically significant increase in triglyceride levels at induction of metabolic syndrome as consistent with another study. [21] It had been documented earlier with studies that mechanism of fructose induced gluconeogenesis and hypertriglyceridemia were interlinked. The analogy that exists is that 3 carbon molecules formed from fructose-1-phosphate could be utilized eventually in the formation of fatty acids and glycerol, which on esterification would form triglycerides. There could be few other mechanistic contributions, for instance, either up regulation of lipogenic pathway or down regulation of PPAR-á activity involved in catabolism of triglycerides.[21]

Subsequently after treatment, all the 3 groups showed a statistically significant reduction in triglycerides, it was evident that, *M.charantia*low, high doses and standard treatment had reduced the triglycerides to the extent of normalization. Yet, another study evaluating the hypolipidemic effects of *M.charantia*showed a similar reduction including low dose of 300 mg/kg as with our study.[22] The milieu of reduction in triglyceride levels caused by bitter melon was due to increased expression of PPAR-á activity in the liver. As a sequel of increased activity of PPAR-á, the key receptor in down regulation of apolipoprotein C-III involved in hydrolysis of triglycerides by lipoprotein lipase (LPL) contributed to the lipid-lowering effect of *M.charantia.*[23]

All the 3 groups of animals included in our study had attained a statistically significant increase in total cholesterol levels following induction same as that observed in previous studies with high fructose diet induction.[24] The reason behind the elevation of total serum cholesterol level by fructose as a retort to the increased weight and insulin resistance which would lead on to activation of the enzymes HMG CoA reductase and fatty acid synthase along with increased expression of hepatic sterol response element binding protein (SREBP).[25]

Compared to the normal control, group II and group III animals on showed a statistically significant reduction in total cholesterol, and further the results of a study done on off springs of rats fed with 66% fructose diet showed that bitter melon had significantly reduced the total cholesterol as seen with our study. [26] On comparing the groups with that of normal animals at the end of treatment period revealed the reversal of serum cholesterol level to the degree of normality in those animals on high dose *M.charantia*and standard treatment. The

probable mechanism as demonstrated by an earlier study is inhibition of the bile acid reabsorption, thereby leading on to increased elimination of bile acids in feces. In addition, it is also known to regulate cholesterol 7á-hydroxylase (CYP7A1) by increasing the level of hepatic CYP7A1 mRNA expression contributing to increased conversion of cholesterol to bile acids.[27]

This study also elucidated a statistically significant increase in LDL levels in all the 3 groups from the baseline, and a similar effect was produced earlier in another study. The perception behind the occurrence of increased LDL with fructose is that at large amounts it would undergo glycation rather than fructation, which is considered to be detrimental to the cellular proteins by the production advanced glycation end products (AGEs),[28] thereby furnishing oxidative damage. Once the LDL is glycated, they are poorly recognized by the lipoproteins and scavenging receptors, which consequentially leads on to increased LDL levels.[29]

After treatment, Group II and Group III animals showed a statistically significant reduction in LDL from the period of induction to normalization. This action of *M.charantia*could be justified by its antiglycating activity proven by a study that demonstrated the percentage inhibition of AGE as 40% at 1 mg/ml concentration by AGE fluorescence. [30] Furthermore, Momordin (charantin), the active component of bitter melon, by promoting PPARä activity decreases LDL, with subsidiary action of decreased primary lipoprotein of LDL apolipoprotein B (Apo B) production, and apolipoprotein C- III expression on VLDL.[31]

Comparison of serum HDL levels among all the groups at induction, showed a statistically significant reduction and this result

was homogenous to that of former studies.[32] It has been well entrenched by studies that caveolins are found to be involved in the export of bile salts from the liver, and there exists a concordant relationship between exportation of bile salts and HDL levels i.e., any reduction or increment in the earlier would lead on to reduction or increase of the HDL levels respectively. Based on this mechanism, ingestion of high fructose diet would lower the HDL levels by reducing the bile salt export.[33]

Following treatment, all the 3 groups showed a statistically significant increase as observed in earlier study. [34] Revealed that the restoration of serum HDL level to the degree of normality in those animals on high dose *M.charantia*only. In adipocytes, the enzyme lipoprotein lipase was responsible for both release of fatty acid and conversion of VLDL to cholesterol-rich LDL. Normally, macrophages embedded in the vessel wall would take up VLDL and ox-LDL actively and excess cholesterol would then be fluxed out through the HDL pathway. As demonstrated by studies that the balance between lipid influx and efflux is carried out by PPAR-ã in humans and PPAR-ä in lower animals. Any agent with the PPAR agonistic activity would increase HDL levels by decreasing LDL and *M.charantia* is one such agent with PPAR-ä agonistic activity thus reducing HDL levels.[31]

The estimated levels of thiobarbituric acid reactive substance malondialdehyde (MDA) showed a statistically significant rise. It was well recognized by studies that the animals fed on high fructose diet were known to produce remarkable changes in serum triglyceride levels, which in turn would increase the activity of fatty-acyl-coA oxidase leading on to â-oxidation. Further, excess usage of non-esterified fatty acid (NEFA) for â-oxidation would lead on to the down-regulation of malonyl-CoA, and the reduced NEFA

transport via CPT-1 across mitochondria thereby increasing oxidation at endoplasmic reticulum and peroxisomes. In addition, oxidation of organelles in the cytoplasm releases ROS, which when formed in excess, damages the mitochondrial membrane rich in polyunsaturated fat thus serving as a source for lipid peroxidation derived aldehydes. However, the process does not terminate there, as those systemically released MDA would inhibit the defensive anti-oxidant enzymes SOD and catalase.[35]

Following treatment Groups II and III showed a statistically significant decrease in lipid derived aldehydes. Analysis done to scale the difference between groups revealed no statistically significant difference between the treated groups and normal control indicating the normalization of lipid peroxidation. Ours is the first study to demonstrate the effect of *M.charantia* on Lipid derived aldehydes in metabolic syndrome model even though the mechanism contributing to the effect has been studied.

Superoxide dismutase estimation done in our study revealed a statistically significant decline in their levels during the span of induction with fructose. It was recognized that ROS plays a key role in regulating various cellular functions but at higher concentration are responsible for disruption of structural integrity of cells and thereby damage the proteins, DNA and lipid. Any condition that disrupts this balance could lead on to oxidative stress by causing profound reduction in the enzyme superoxide dismutase, one such state is hyperglycemia induced by high fructose diet.[36]

The subsequent determination of enzyme levels following the treatment period though endowed ascend in their serum levels did not achieve statistical significance when compared to the values at induction. When we analyzed the difference in mean superoxide dismutase levels between the treated and age control rats, there was no statistically significant difference indicative of its acceleration towards normal with both the doses of *M.charantia*. While the standard therapy did not favorably usher the free radical scavenger, superoxide dismutase towards the expected magnitude, the reason could be credibly due to the mean reduction in their level was huge at the time of induction with respect to other two groups.

In our study, serum NF-KB levels were

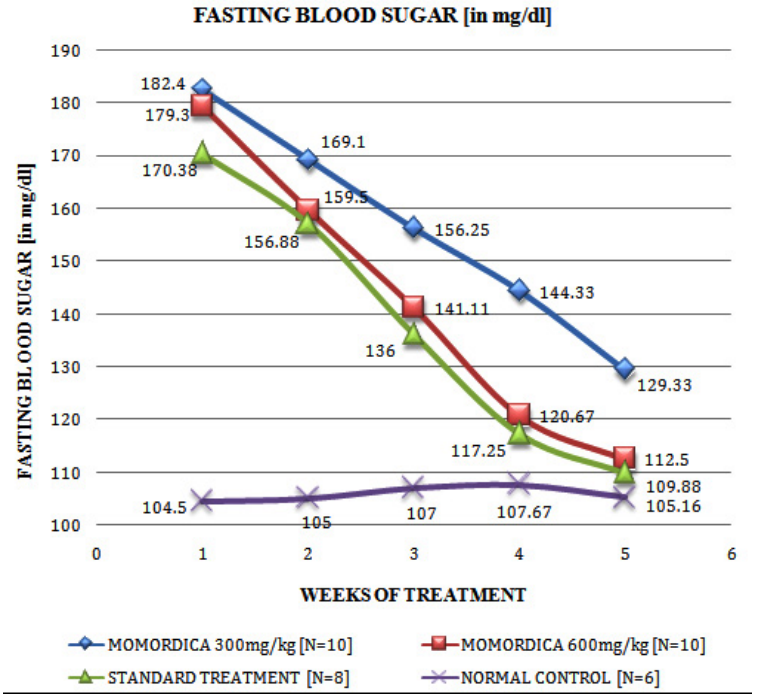

Fig. 4. Change in fasting blood sugar during treatment

êBfound that there is difference between groups at baseline as in concordance with our study.[37] The mean serum level at baseline was established as 22.033±5.657 pg/ml in our study. All the 3 groups of animals showed an increase in the levels from that of baseline but were not to the level of significance.

Following treatment all the 3 groups of

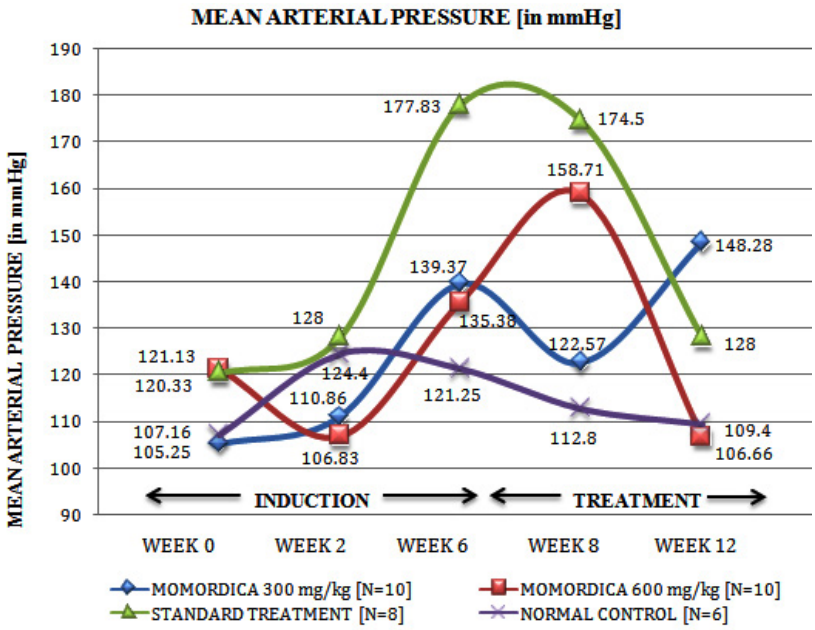

Fig. 5. Change in MAP during induction and treatment

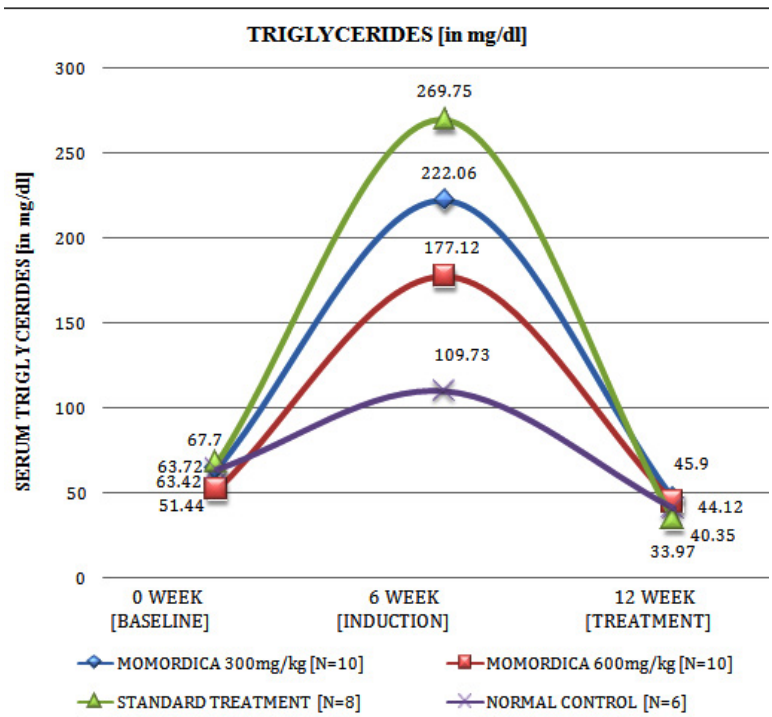

Fig. 6. Change in triglycerides levels on induction and treatment

animals revealed a statistically significant reduction in serum NF-êBlevels [P=0.043, 0.001, 0.027]. As of now, there are only 3 studies done with the objective of establishing the role of *M.charantia*on pro-inflammatory marker NF-êB, one being the work done to demonstrate the inhibitory activity of *M.charantia* as one of the tested compounds on NF-êBtranscriptional activation in HepG2

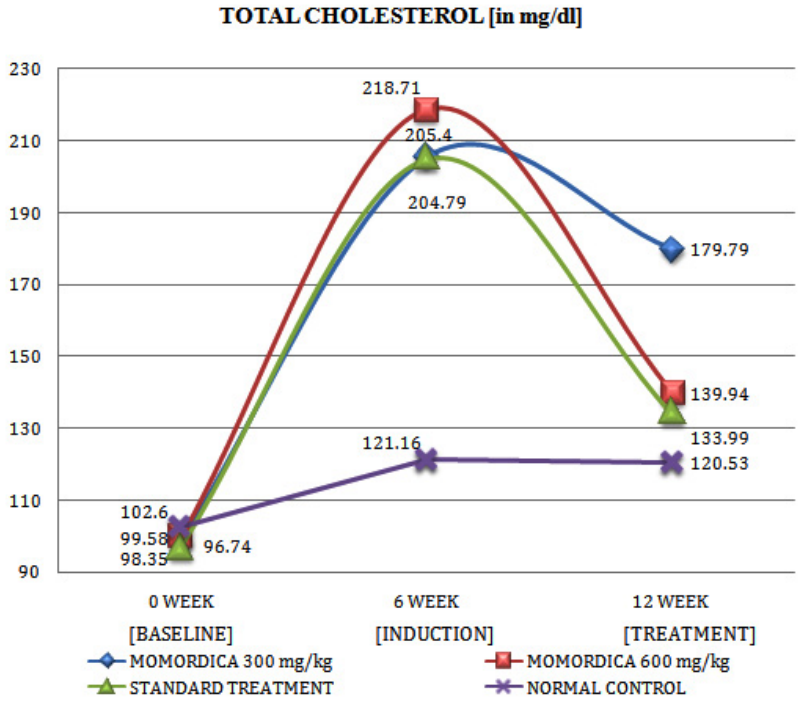

Fig. 7. Change in total cholesterol following induction and treatment

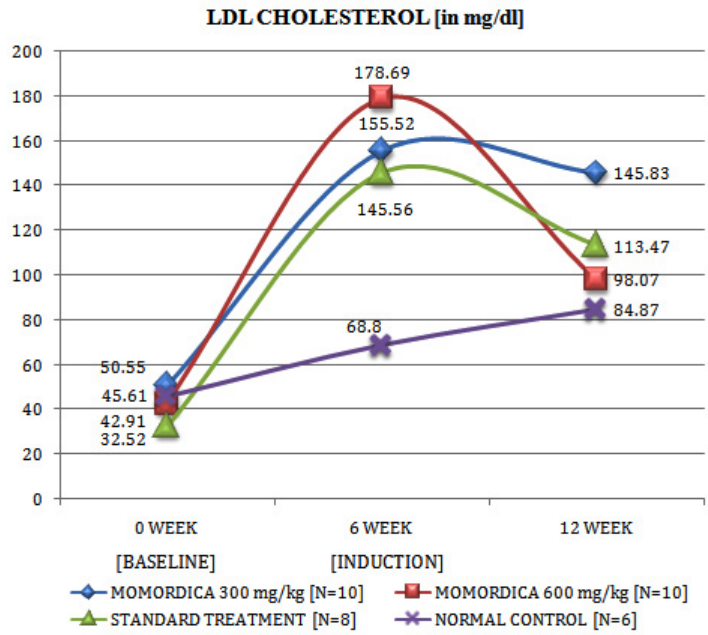

Fig. 8. Change in LDL levels following induction and treatment

cells (human hepato-carcinoma) in Dulbecco's modiûed Eagle's medium had proven its inhibitory effect.[38] Another was an m-RNA study on heart tissue of the obese Zucker rats demonstrated that down-regulation of nuclear factor-êB (NF-êB), and interferon-ã by *M.charantia*.[39] The third

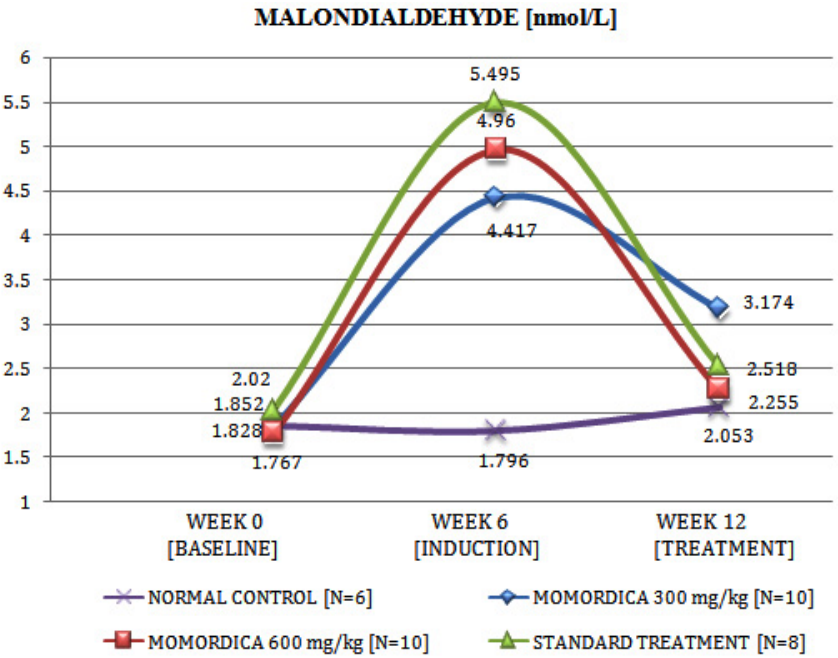

Fig. 10. TBARS during induction and treatment of metabolic syndrome

being an electrophoretic mobility shift assay with the ethanol extracts and the hot aqueous extracts of *M.charantia*showing inhibition of NF-êB activation.[40] But so far no research is done to assess the effect of *M.charantia*extract in vivo on serum NF-êB levels.

The histopathological examination of the liver and heart was done in our study. Due to liability of ethical concern, we have taken the pictures of diseased liver and heart in response to fructose intake from standard research articles. In comparison to normal control all the liver showed fatty infiltration, both microvesicular and macrovesicular steatosis that was in ordinance to

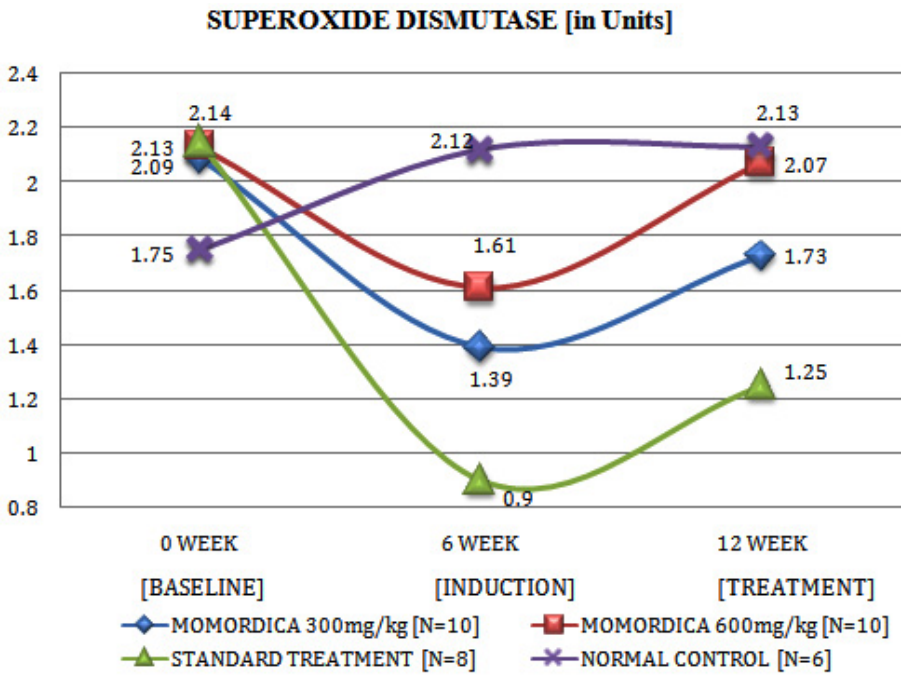

Fig. 11. Changes in SOD levels on induction and treatment

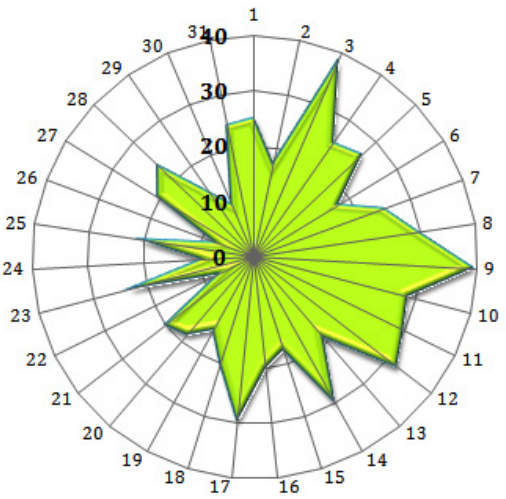

Fig. 12. Normal serum NF-êB levels [in pg/ml] observed in our study

high fructose diet as apparent in prior studies. In addition, the changes in histopathology of the liver and heart by *M.charantia*unlike that of pancreas, has not been studied in literature till date.

In distinction, the fatty change that was observed in these groups in comparison to the diseased picture revealed a significantly minimal change. There also exists a difference in fatty changes among groups, HPE of liver of Group I showed maximum change of grade 3+ while that of Groups II and III were presented with only grade 2+ changes.

So far there are no studies dealt on the role of *M.charantia* on the fatty changes precipitated on consumption of the fructose. So ours is the first work done to learn the changes, and we obtained an affirmative result that the changes in both *M.charantia* high dose and standard treatment

groups were homogenous and the fatty change in these groups were of a lower degree in comparison to the low dose *M.charantia* group.

In comparison to normal control all the heart HPE sections showed hypertrophy that was in accordance to previous studies with reference to high fructose diet.

The cardiac hypertrophy was highly

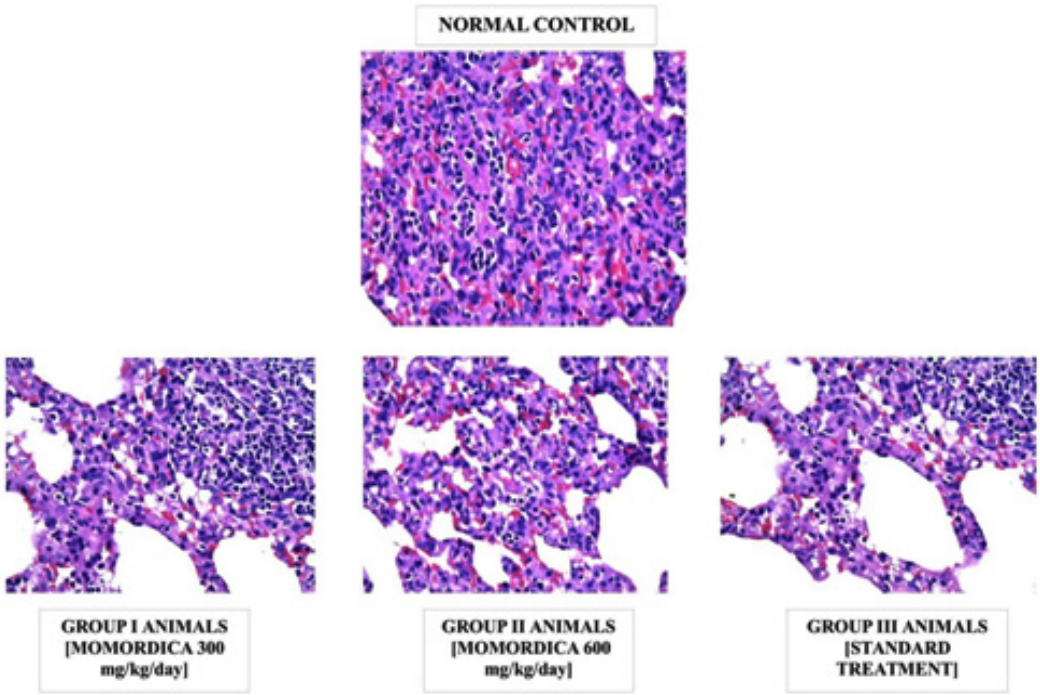

Fig. 13. Histopathological examination of Liver [H&E, 40X]

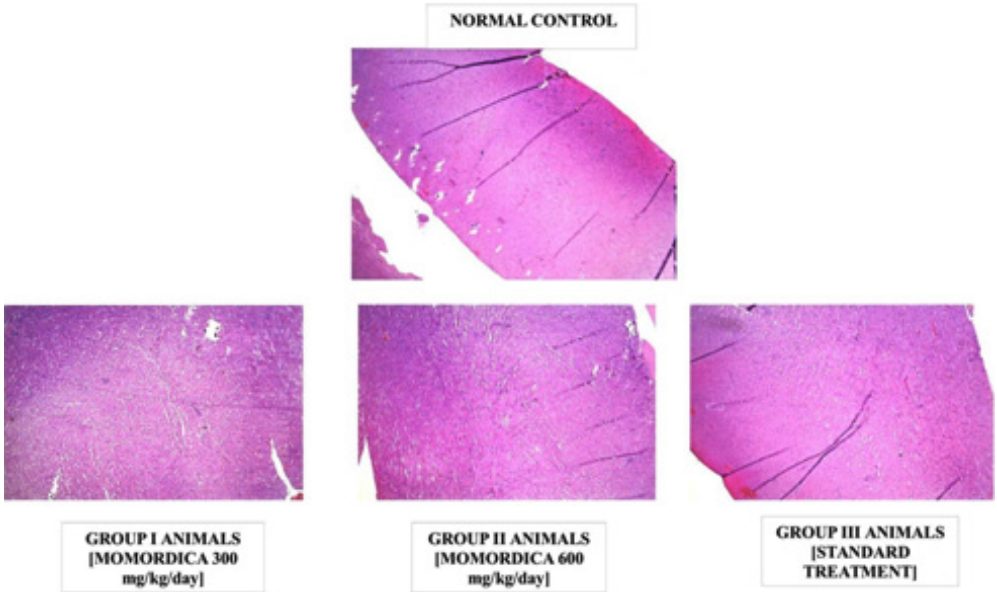

Fig. 14. Histopathological examination of Heart [H&E, 40X]

evident but observations made in these 3 groups were homogenous with no difference among them. The reason for this could duly be explained by the relatively brief span of treatment was not sufficient to bring about the scale of expected changes in the hypertrophied myocytes. But the positive finding illustrated was that the fatty change observed in the picture of disease control was not evident in the HPE sections of all three groups of treated animals. So, further studies pertaining to this could be done in future to assess the effect of *Momordica* on progression of cardiac hypertrophy.

CONCLUSION

High fructose diet (66%)was affirmatively found to be the animal model appropriate for inducing metabolic syndrome to study the effect of drugs as the model effectively reproduced all the metabolic changes [BMI,FBS,BP, Lipid parameters]seen in the syndrome. We included two different doses of *M.charantia*, of which 600mg/kg/day had exclusively matched the therapeutic efficacy of the standard therapy given in combination. *M.charantia's*efficacy in a chronic inflammatory disease like metabolic syndrome is successfully demonstrated in our study with respect to reduction of inflammation and oxidative stress evidenced by a decline in serum NF-êB and LDA along with increased free radical scavenger, SOD. The biological basis of the effects of *M.charantia* by inhibiting the inflammatory pathway in metabolic syndrome both at the levels of ROS generation and transcription of pro-inflammatory marker NF-êB was proven. The histopathological examination findings has imparted that metabolic syndrome is a multi-organ inflammatory disease condition inducing detectable pathological changes in various organs like liver and heart and that *M.charantia* is a potentially effective agent to reverse such significant changes.

(Received: 10 July 2018; accepted: 30 August 2018)

Insulin resistance and endothelial dysfunction which shares multiple signaling pathways likehyperinsulinemia, glucotoxicity and inflammation in type 2 Diabetes Mellitus (DM) leads to several micro and macrovascular complications. Studies have shown the anti-inflammatory effects of certain oral hypoglycemic agents which will be helpful in preventing the impact of diabetes related complications. The study aimed to compare the anti-inflammatory effects of Sitagliptin and Acarbose in combination with Metformin and Sulfonylurea in Type2DM patients by using Anti-inflammatory markers Interleukin-6 (IL6), high sensitive C-reactive protein (hsCRP) and also to compare the clinical outcome between these two groups by using the parameters Fasting blood sugar (FBS), Post prandial blood sugar (PPBS), hemoglobin A1c (HbA1C), Plasma Insulin. In this open labeled prospective parallel group clinical study 30 type 2 diabetes patients on Metformin and Sulfonylurea combination, with HbA1c value >/=7.5 were recruited in tertiary care hospital and divided into two groups based on their HbA1C levels and were added on either Acarbose or Sitagliptin along with Metformin Sulfonylurea combinations and were followed for 3 months. Parameters like FBS, PPBS, HbA1c, Plasma Insulin hs CRP, IL-6were measured before and after the study. In the study the mean value of FBS, PPBS, HbA1c, Plasma Insulin, Insulin Resistance, hsCRP were reduced in both Sitagliptin and Acarbose group, which were similar to the results of previous studies except IL6 which got reduced in Sitagliptin group but increased in Acarbose group. The study had showed the synergism of Sitagliptin with Metformin Sulfonylurea combinationin reducing inflammation however; still long term studies are required to confirm their anti-inflammatory effects.

Keywords: Acarbose, Cardiovascular risk, high sensitive C-reactive protein, Interleukin-6, Sitagliptin.

Diabetes mellitus is one of the non communicable diseases which have become a major global health problem[1] This is mainly due to insulin resistance or decreased production of insulin. Insulin resistance, one of the key factor common to obesity and type 2 DM, is associated with endothelial dysfunction and increases the cardiovascular risk[2] by sharing multiple signaling pathways which include hyperinsulinemia, glucotoxicity, lipotoxicity and inflammation[2]

In 2010, it was found that 285 million people around world have diabetes, of which 80% are from developed countries. The prevalence of diabetes is expected to reach about 438 million by 2030[1, 3]

Type 2 DM is characterized by improper secretion of insulin, resistance to insulin, increased glucose production in liver, and abnormal lipid metabolism. Most studies say that insulin resistance occurs before the insulin secretory defect and type 2 diabetes develops only when insulin secretion become less. In the earlier stages of diabetes, glucose tolerance is found to be normal, because pancreatic beta cell gives a compensatory increase in insulin output which further leads to insulin resistance after a certain period of time leading to a state called Impaired Glucose Tolerance (IGT), where there will be high postprandial glucose level. Later reduction in secretion of Insulin and high hepatic glucose formation leads to overt diabetes with increasing blood glucose values, indicating the failure of beta cells[4]

The obesity in diabetes increases the levels of fat cell products like, nonesterified free fatty acids, retinol-binding protein 4, leptin, Tumor Necrosis Factor (TNF)-á, resistin, adiponectin and free fatty acids (FFA) in circulation. Adipokines modulate the sensitivity of insulin plus increase in FFA production, causes resistance of insulin in hepatic and skeletal muscle. Products of adipocyte ground a state of inflammation and in turn they involve in the pathogenesis of insulin resistance and endothelial dysfunction[5-11]

Diabetes -Inflammation - Cardiovascular risk

The hypotheses propose that hyperglycemia and insulin resistance increases FFA and forms diacylglycerol leading to stimulation of protein kinase C (PKC). PKC modifies the gene transcription of endothelial cells[12] Endothelial dysfunction presents in patients with insulin resistance in stages prior to the development of impaired glucose tolerance (IGT) and type 2 DM. This suggests that insulin resistance is key factor and endothelial dysfunction is not simply a result of hyperglycemia.

Rise in FFA stimulates toll like receptor (TLR) and Nuclear Factor-kB (NF-kB) and subsequently promotes the genes of inflammation like TNF-α and Interleukin-6 (IL-6), which is followed by PKC activation and decreases insulin sensitivity. Impaired Insulin sensitivity in endothelium of the blood vessels promotes Reactive oxygen species (ROS) formation, FFA oxidation, which subsequently stimulates PKC activation leading to advanced glycated end products (AGE)synthesis, and down-regulates Prostacyclin(PGI2). Finally endothelial nitric oxide synthatase(eNOS) activity is impaired leading to endothelial dysfunction[12-14]

Obese diabetic patients treated with Metformin have proven to lower the levels of hsCRP, expression of TNF-á and TLR 2/4[15] Previous studies proved that Sitagliptin apart from stimulating the Adenosine Mono phosphate (AMPK)phosporylation, it also inhibit the activation of Mitogen activated protein kinase (MAPK) including p38 and Extracellular signal regulated kinase(ERK)and arrest the progression of atherosclerosis leading to decreases in adhesion molecules and inflammatory cytokines like hsCRP, IL-6 and FFA levels after 12 weeks of therapy[16-19] It concludes the anti-inflammatory action of Sitagliptin and its effect in inhibition of atherosclerosis[20] The results from the previous studies revealed, that the Acarbose treatment showed hopeful benefits in cardiovascular disease by decreasing the proinflammatory transcription factor (NFê B) activity and hsCRP levels[21-24]

Based on this background information, the study targeted the oral hypoglycemic agents like Acarbose and Sitagliptin to look for their anti-inflammatory action.Hence the study aimed to compare the anti-inflammatory effects of Metformin sulfonylurea and Sitagliptin combination with Metformin Sulfonylurea and Acarbose combination in Type2DM patients by using Anti-inflammatory markers (IL6, hsCRP) and also to compare the clinical outcome between these two groups by using the following parameters like FBS, PPBS, HbA1C, and Plasma Insulin.

MATERIALS AND METHODS

This study was an open labeled prospective parallel group clinical study. After getting approval from the Institute Human Ethics Committee (IHEC) (proposal no: 12/282), 30 type 2 diabetic patients (convenient sample) attending Endocrinology and Medicine OPD in a Tertiary care hospital Coimbatore were recruited. We included all type 2 diabetic patients in an age group of 25-65 years, who were on conventional treatment of Metformin Sulfonylurea combination with HbA1C level $\geq$ 7.5%.Patients with diabetes other than type 2, history of cardiac, renal and

cerebrovascular diseases, patients on treatment with statins and steroids, history of altered liver function and pancreatitis, known history of alcohol intake and smoking were excluded from the study. The details of the study were explained to each participant individually before getting the informed consent. Basic data's like name, age and height, weight were recorded and comorbid conditions were noted.

Then the clinical examination and the base line investigations (Fasting blood glucose, postprandial blood glucose, HbA1C, hsCRP, IL6, Plasma Insulin) were done before starting the treatment. Later those 30 participants were divided into two groups based on their HbA1C values with 15 patients in each group. One group was on Sitagliptin, and the other group was on Acarbose treatment along with their conventional Metformin and Sulphonylurea combination. Sitagliptin was started on 50mg OD and then titrated to 100mg according to the patient's blood glucose level by the physician. In the same way, Acarbose was started on 25mg BD initially and later it was titrated to 50mg BD or 25mg TDS according to the patient's blood glucose level .The study participants were advised to come for review after two weeks for titration of the drug dosage and followed for 3 months. In between the 3 months of study period, the participant's FBS, PPBS levels were noted in the case file.

Finally at the end of three months the clinical examination and the investigations (FBS, PPBS, HbA1C, IL6, hsCRP and Plasma insulin) were done again and the study was completed.

The results of the parameters were analyzed in the hospital laboratory for FBS, PPBS, HbA1c, hsCRP, Plasma Insulin. By using the formula of Homa Index, HOMA-IR = [Fasting glucose (nmol/L) * insulin (μU/mL)/22.5]Insulin Resistance for all the 30 patients were calculated. The Interleukin-6 (Krishgen Biosystems) was estimated in the Pharmacology laboratory by enzyme immunoassay which wasprogrammed for quantification of human interleukin-6 and analyzed.

Statistical analysis

Data was analyzed using SPSS soft ware version 19.0. Values between the two groups were interpreted using independent sample *t*-test and before and after values within the same groups with paired t test.

RESULTS

Among the total number of 30 patients 77% of study population were under 55 years of age and 23% were between 55 to 65 years of age. In that 57% were male and 43% were female patients.

Regarding the duration, 50% were in between 0-5 years , 37% of patients were between 6-10 yrs, and 13% of patients were beyond 11years of duration of DM .This mainly implied the chronicity and progression of disease pattern in those study participants.

Results of BMI in Acarbose and Sitagliptin groups showed no statistical significance even though there was greater reduction in Sitagliptin group in which mean value decreased from 27.02 ± 4.64 SD to 26.32 ± 4.81 SD (p value 0.033) (Table 1). End values of FBS in the study showed reduction in mean value in both Acarbose and Sitagliptin group ranging from 183.71 ±44.99 SD to 142.92 ±33.60 SD, 178.07 ± 46.73 SD to 138.84 ±25.13 SD with p value 0.007, 0.020 respectively(Table 1). Regarding PPBS it showed reduction in mean value in both Acarbose and Sitagliptin group ranging from 272.35 ± 64.08 SD to 204.85 ± 57.97 SD , 263.92 ± 101.60 SD to 194.23 ± 44.50 SD with p value 0.006, 0.025 respectively(Table 1).

Results of HbA1c in the study showed statistical reduction in mean value in both Acarbose and Sitagliptin group ranging from 10.01 ± 1.51 SD to 8.17 ± 1.28 SD , 9.69 ±1.53 SD to 7.75 ± 1.32 SD (p value of 0.001, 0.004) respectively(Table 1). Results of Plasma Insulin in the study showed reduction in mean value in both Acarbose and Sitagliptin group ranging from 18.71 ± 16.42 SD to 14.18 ± 6.71 SD , 27.72 ±25.98 to 22.58 ± 17.68 SD respectively. This was of no statistical significance because of p value = 0.327, 0.324 respectively (Table 1). End values of IR in this study showed reduction in mean value in both Acarbose and Sitagliptin group ranging from 9.00 ± 8.38 SD to 5.12 ± 3.14 SD , 11.49 ±9.42 SD to 7.63 ± 5.78 SD respectively (p value = 0.100 , 0.101) (Table 1) but no statistical significance.

Results of hsCRP in this study showed reduction in mean value in both Acarbose and Sitagliptin group ranging from 0.58 ± 0.93 SD to 0.30 ± 0.30 SD, 0.45 ± 0.43 SD to 0.41 ± 0.39 SD respectively. This was of no statistical significance (p value = 0.265, 0.671 respectively) (Table 1).

Results of IL-6 in this study showed reduction in mean value of Sitagliptin group ranging from 136.32 ± 241.81 SD to 57.679 ± 78.55 SD (p value =0.314) but in case of Acarbose group there was slight increase in IL-6 levels with the mean value ranging from 120.01 ± 203.3 SD to 174.08 ± 492.1 SD .(p value=0.591) (Table 1).

At the end of three months there was no significant difference seen in the reduction of FBS (p value = 0.725), PPBS (p value = 0.600), HbA1C (p value =0.403), Plasma Insulin (p value =0.110), Insulin Resistance (p value =0.170), hsCRP (p value =0.451) IL-6 (p value = 0.408) on comparing the after values of Acarbose and Sitagliptin group.

DISCUSSION

It is a well known fact that, the risk of cardiovascular disorder is high in both type I and type II Diabetes Mellitus .In case of type I DM risk of CVD arise after some decades but in type II DM, it sets very early in the asymptomatic period of hyperglycemia and even by the time of diagnosis these patients are at potential risk. This is mainly due to the Insulin Resistance, which emerges at an early stage of type II DM. Obesity in diabetes along with inflammation leads to endothelial dysfunction and IR which then subsequently causes platelet aggregation, and all this process collectively leads to atherogenesis and cardiovascular disease ultimately. It has been proven that increase in the inflammatory markers would predict the risk of cardiovascular complications at the earliest.

Previous studies states that drugs like Metformin, Sitagliptin and Acarbose effectively reduces the inflammatory markers TNF-α, IL-6,

Table 1. Mean values of the test parameters

	Week 0 (baseline) mean ± SD	Week 12 mean ± SD	Mean difference	P value
BMI				
Acarbose	25.20±2.84	25.25±2.83	-.056+.79	0.796
Sitagliptin	27.02±4.64	26.32±4.81	0.69±1.04	0.033
FBS				
Acarbose	183.71±44.99	142.92±33.60	40.78±47.75	0.007
Sitagliptin	178.07±46.73	138.84±25.13	39.23±52.50	0.020
PPBS

Sitagliptin	136.32±241.81	57.67±78.55	78.64±269.97	0.314

hsCRP and NF-kB levels in diabetes patients and facilitate the prevention of endothelial dysfunction and atherosclerosis[15,20, 24,25]

In this study the results of BMI showed greater reduction in the Sitagliptin group with mean value ranging from 27.02 ±4.64 SD to 26.32 ± 4.81SD, p value = 0.033 compared to the Acarbose group. These were similar to the results of previous studies. [20]

Regarding the mean values of FBS, PPBS, HbA1c, Plasma Insulin, Insulin Resistance, both Sitagliptin and Acarbose combination groups showed good reduction in their mean value, which were again similar to the results of previous studies. [20, 22, 27].

Then mean levels of hsCRP at the starting of study in Acarbose and Sitagliptin groups were found to be 0.58 ±0.93 SD and 0.45 ± 0.43 SD respectively. At the end of the three months levels of hsCRP were reduced in both Acarbose and Sitagliptin groups to the mean value of 0.30±0.3 SD (p value= 0.265) and 0.41 ± 0.39 SD (p value= 0.671) (Table 1) respectively. Though there was greater reduction in mean values of hsCRP

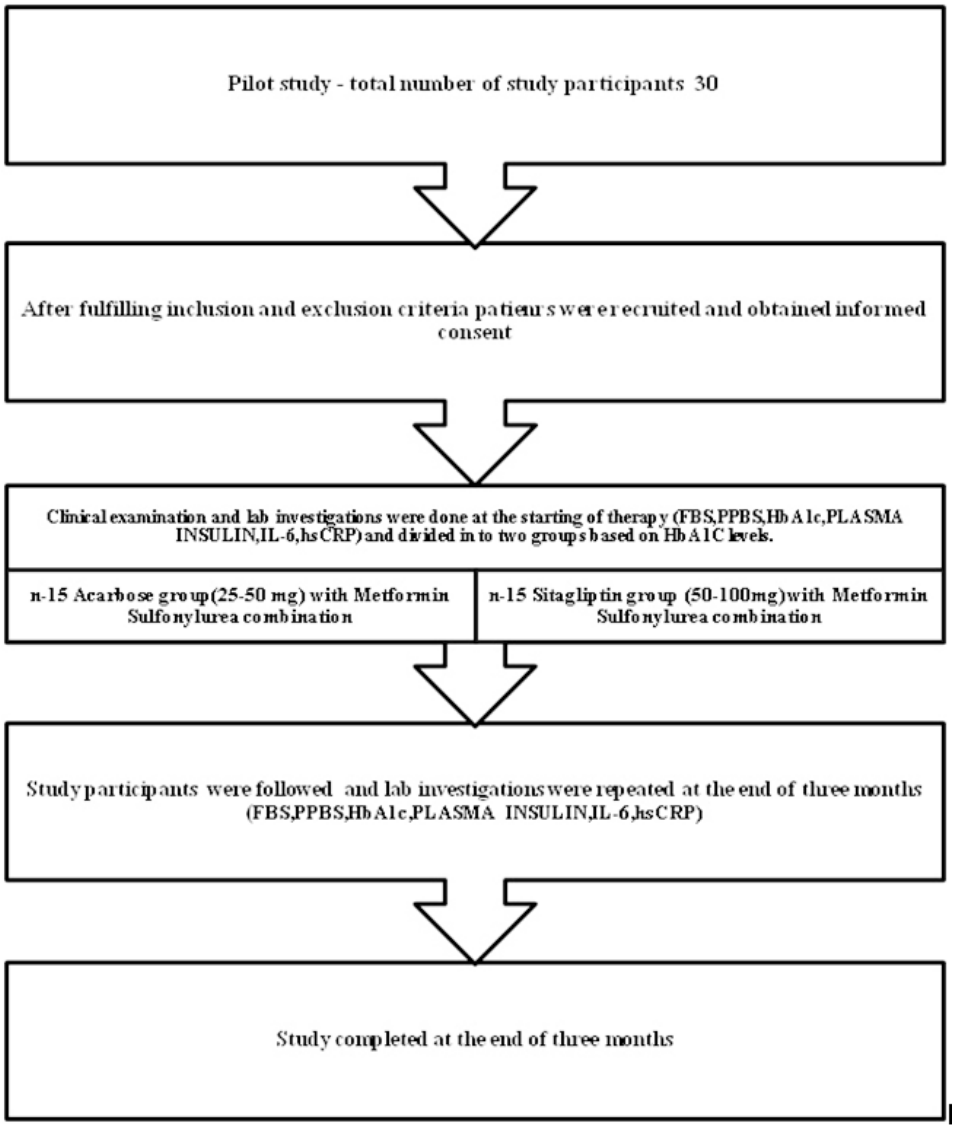

Fig. 1. Methodology of anti-inflammatory effect of oral hypoglycemic drugs

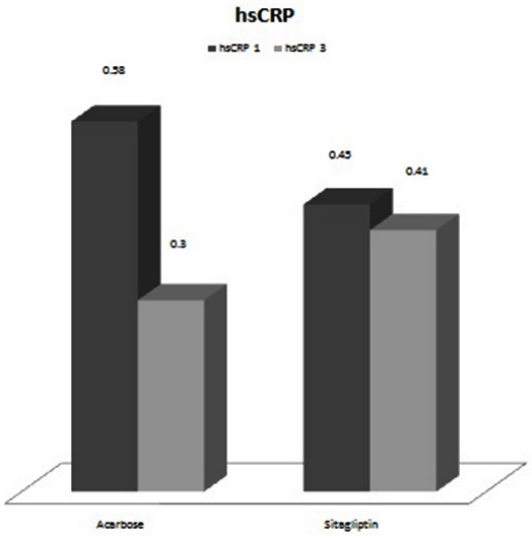

Fig. 2. hcCRP status in Acarbose and Sitagliptin groups at 1 month and at the end of 3 month

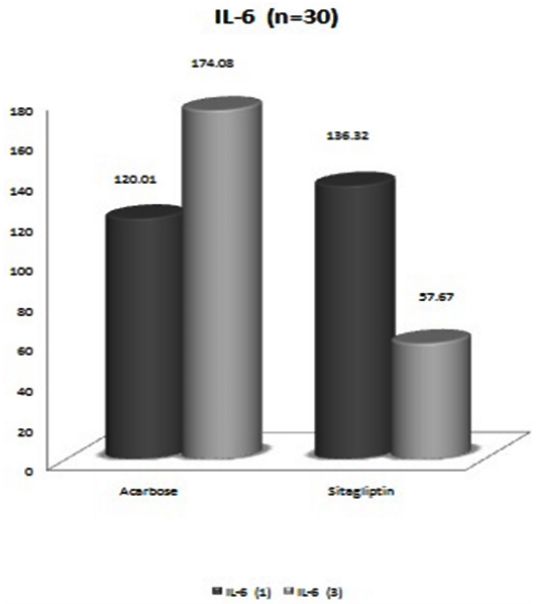

Fig. 3. IL-6 status in Acarbose and Sitagliptin groups at 1 month and at the end of 3 month

levels which were consistent with the results of previous studies [20, 25, 26] these results were not statistically significant. When the values of hsCRP were compared between Acarbose and Sitagliptin groups, at the end of the three months there were no statistical significant reduction in hsCRP values (p value=0.451).

Next inflammatory marker analyzed was the IL-6 levels. The mean values in the starting of treatment were 120.01 $\pm$ 203.3 SD in Acarbose group and 136.32 $\pm$ 241.81 SD in Sitagliptin group. At the end of the three months the mean values of IL-6 in Acarbose group was found to be increased to the mean value of 174.08 $\pm$ 492.1 SD but in Sitagliptin group it was found to be reduced to 57.69 $\pm$ 78.55 SD.When the before and after values of Sitagliptin group was analyzed, it showed reduction in the mean values of IL-6 levels at the end of the three months. But there was no statistical significance (p value =0.314) (Table 1).

When comparing the after values of IL-6 in Acarbose and Sitagliptin groups, greater reduction was seen in the Sitagliptin group after 3 months of therapy. Thus the findings in the study were consistent with the previous studies which showed the anti- inflammatory effect of Sitagliptin therapy. [20,21] But this is again not statistically significant (p value = 0.408).

Concerning the results of the anti-inflammatory markers in Sitagliptin treated group with metformin sulphonylureas combination showed a definite reduction in the mean values of both hsCRP, IL-6 levels after the three months treatment, but still it was not statistically significant. This may be due to less sample size, and the patients were followed only for 3 months. A long term follow up and a bigger sample size ismandatory to get a statistically significant results.Sitagliptin has proven to have a definite role in reducing chronic inflammation. Based on this study finding, fixed dose combination of Sitagliptin and Metformin might be helpful in preventing the progress of diabetes.

When the results of inflammatory markers in Acarbose group were analyzed and compared with previous studies,[22-24] Acarbose also reduced the inflammatory markers moderately in this study. This study showed a greater reduction in the mean value of hsCRP levels but not in IL-6, this might be because of small sample size, poor compliance of patients and the patients were followed only for 3 months. Hence long term follow up and large sample size may be required to see the reduction in the inflammatory markers and the role of these drugs in the insulin resistant states. During the

study period no adverse reactions were noted among the study participants.

CONCLUSION

This study demonstrated the additive anti-inflammatory effect of Sitagliptin, and Acarbose as these groups of drugs are now in trend and commonly been prescribed either as base line therapy or as add on therapy based on the HbA1C values. When such anti inflammatory property is pronounced with Sitagliptin, it can be sure that addition of Sitagliptin with Metformin will be a beneficial combination at the initial therapy to the patients in preventing the progression of diabetic related cardio vascular complications[26]

Limitations

In this study the patient sample size was small and the study duration was 3 months which is again one of the limitations to assess the anti-inflammatory effects of these drugs on long term effects. Hence long term follow up and bigger sample size may be mandatory in future to get the statistically significant reduction in the inflammatory markers.

ACKNOWLEDGEMENT

We express our sincere thanks to Dr. Saravanan and Dr.SujithKumar (Medicine department, PSGIMSR.) and Dr. Suresh (Endocrinology dept. PSGIMSR) for their help in the execution of this study. We also like to thank the study participants for their cooperation to complete this study

ABSTRACT

Introduction: During the past few decades, the drugs from natural products have gained importance in the field of medicine. Many plants and their products exhibit marked pharmacological activities. Benincasa Hispida and Lagenaria siceraria fruits are one of those important natural plants which are used in the treatment of various disorders. The present study was designed to analyze the antioxidant property of fresh juice and dry powder preparations of *Benincasa hispida* and *Lageneria siceraria* fruits in inhibiting cellular stress by chemical testing and DPPH assay. **Materials and Methods:** Fresh fruits were obtained from the local market and washed thoroughly in the running water. Then the dry powder and fresh juices of *Benincasa hispida* and *Lagenaria siceraria* were made by using hot air oven at 60 degree Celsius made and used for DPPH assay and chemical testing of Phenolic and Flavonoid compounds. **Results:** Only dry powder of *Benincasa hispida* fruit showed positive for both phenolic and flavonoid compounds. In *Lagenaria siceraria*, both dry powder and fresh juice revealed positive only for flavonoid compounds. In DPPH assay, dry powder preparartions of *Benincasa hispida* and *Lagenaria siceraria* proved better free radical scavenging activity compared to their fresh juice forms. **Conclusion:** Enhanced antioxidant property of *Benincasa hispida* and *Lagenaria siceraria* dry powders possess good therapeutic potential and can be useful as an effective antioxidant in clinical use of various diseases.

KEYWORDS: Antioxidant property, Dry powder, Fresh juice, *Benincasa Hispida*, *Lagenaria Siceraria*.

INTRODUCTION

The fruit of *Benincasa hispida*, commonly called as ash guard, belonging to cucurbitaceae family. Scientific studies disclose its anti-inflammatory, diuretic, anti-Alzheimer, antidiarrheal, antiulcer, anorectic, antihistaminic activities and its antioxidant activity.[1,2] Several studies have shown the antioxidant property of Benicia *hispida* fruit in various forms of its extraction (ethanol, methanol).[3]

Lageneria siceraria commonly called as Bottle guard is a rich source of vitamin B & C and used by the cardiac patients to prevent atherosclerosis. It is an edible fruit and has got many medicinal values. Many studies in the past have shown the antioxidant property of *Lagenaria siceraria* in different forms of its extraction (ethanol, Acetone).[4,5] No studies have analyzed the antioxidant property of fresh juice and dry powder preparations of *Benincasa Hispida and Lagenaria Siceraria* fruits.

Since these fruit are edible, easily available, and have got lot of medicinal values, it becomes essential to see their antioxidant property in fresh juice and dry powder forms.

AIM

To analyze the property of fresh juice and dry powder preparations of *Benincasa hispida* and *Lageneria siceraria* fruits in inhibiting cellular stress by chemical testing and DPPH assay.

MATERIALS AND METHOD

The fresh fruits were obtained from the local market and washed thoroughly in the running water. Then under sterile condition seeds were removed and the pulp of the fruits were cut into pieces and weighed. After weighing, both the fruit pieces were grinded separately and filtered using sterile cloth to extract juice from both the fruits. From this half quantity of the juices were used for dry powder preparations and the remaining were stored for chemical test analysis in the refrigerator. For dry powder preparation, both the juices were measured and filled in

the separate bowls and kept in hot air oven at 60 degree Celsius under sterile condition till all the water content of the juices get evaporated and the fine particles get settled. Now the settled powder particles were been dried, collected and weighed again. Finally, the dry powder and the fresh juice of both the fruits were used for the chemical testing and DPPH assay.

Chemical Testing[6]

Detection of phenolic compounds

a. Ferric chloride test: Juice and the dry powder forms of *Benincasa hispida* and *Lagenaria siceraria* were added to 5% FeCl3 reagent. Formation of deep blue colour was not appeared in juice and dry powder preparations of both fruits.

b. Lead acetate test: Juice and the dry powder forms of *Benincasa hispida* and *Lagenaria siceraria* were added to 10% lead acetate solution and mixed. Formation of white precipitate was present in dry powder preparation but not in the juice of *Benincasa hispida*. Whereas, in *Lagenaria siceraria* white precipitate was not present in both dry powder and juice forms. Thus the test was positive only for the dry powder preparation of *Benincasa hispida.*

Detection of flavonoids

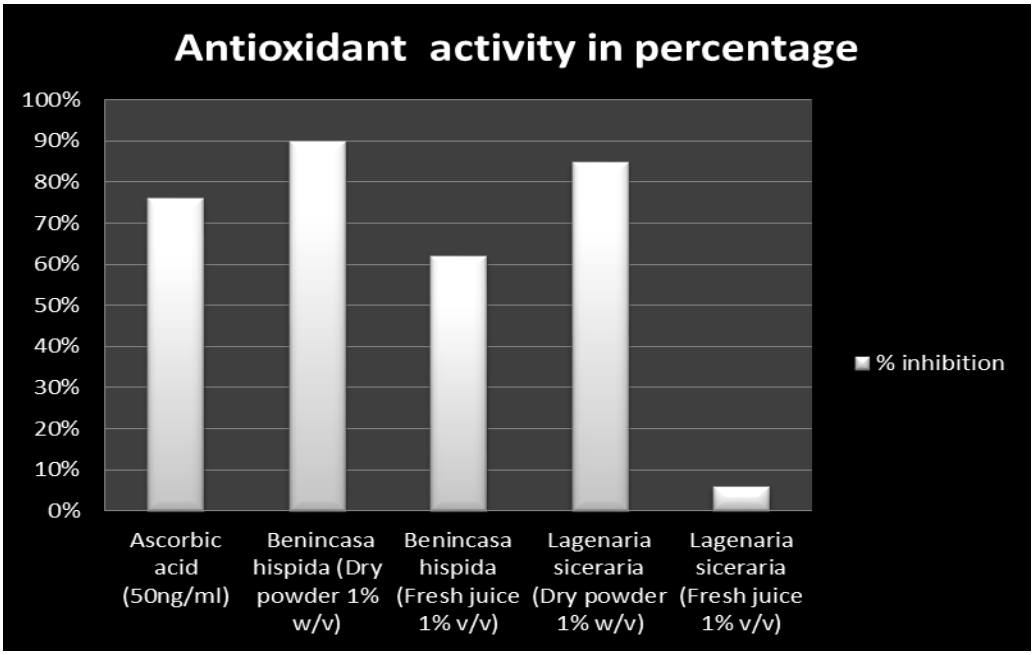
a. Aqueous sodium hydroxide test: The Juice and the dry powder forms of *Benincasa hispida* and *Lagenaria siceraria* were treated along with aqueous NaOH solution. Formation of yellow-orange colour was not found in juice but present in dry powder preparation of *Benincasa hispida* and the test was found to be positive in both juice and the dry powder preparation of *Lagenaria siceraria.*

b. H2SO4 test: The Juice and the dry powder forms of *Benincasa hispida* and *Lagenaria siceraria* were added to concentrate H2SO4 and observed for the formation of orange colour. Only the dry powder preparation of *Benincasa hispida* was found to be positive for the presence of flavanoids and not in the fresh juice form. In *Lagenaria siceraria,* the test was positive in both juice and the dry powder preparation.

Table No. 1: Results of the chemical testing.

		Phenolic compound		Flavonoids	
Sr.No	**Test substances**	**Ferric chloride test**	**Lead acetate test**	**Aqueous sodium hydroxide test**	**Sulphuric acid test**
1	*Benincasa hispida* Fresh juice	-	-	-	-
2	*Benincasa hispida* Dry powder	-	+	+	+
3	*Lagenaria siceraria* Fresh juice	-	-	+	+
4	*Lagenaria siceraria* Dry powder	-	-	+	+

DPPH Assay



The percentage of antioxidant activity (AA %) of fresh juice and dry powder preparation of *Benincasa hispida* and *Lagenaria siceraria* were assessed by DPPH free radical assay. The dry powder and the fresh juice of *Benincasa hispida* and *Lagenaria siceraria* were prepared in 1% w/v and 1% v/v solutions. The samples were reacted with the stable DPPH radical in an ethanol solution. The reaction mixture consisted of adding 0.5 mL of samples (Dry powder and Fresh juice), 3 mL of absolute ethanol and 0.3 mL of DPPH radical solution 0.5 mM in ethanol. When DPPH reacts with an antioxidant compound, which can donate hydrogen, it is reduced. The changes in color (from deep violet to light yellow) were read [Absorbance (Abs)] at 517 nm after 100 min of reaction using a UV VIS spectrophotometer. The mixture of ethanol (3.3 mL) and sample (0.5 mL) served as blank. The control solution was prepared by mixing ethanol (3.5 mL) and DPPH radical solution (0.3 mL). Reference standard compound being used was ascorbic acid 50 ng/ml. Lower absorbance of the reaction mixture indicated higher free radical scavenging activity.[7,9] Percentage inhibition was calculated by,

DPPH scavenging effect (%) = A0 - A 1 / A0 × 100.

Where A0 was the Absorbance of control reaction and A1 was the Absorbance in presence of test or standard sample. (Control =0.856).

Table No. 2: Absorbance and % inhibition of DPPH assay.

Samples	Absorbance	% inhibition
Ascorbic acid (50ng/ml)	0.206	76%
Benincasa hispida (Dry powder 1% w/v)	0.088	90%
Benincasa hispida (Fresh juice 1% v/v)	0.322	62%
Lagenaria siceraria (Dry powder 1% w/v)	0.131	85%
Lagenaria siceraria (Fresh juice 1% v/v)	0.808	6%

"Fig. 1: Antioxidant activity of fresh juice and dry powder preparations of *Benincasa hispida* and *Lageneria siceraria* in percentage."

DISCUSSION

In this study, the dry powder of *Benincasa hispida* showed positive for both flavonoids and phenolic compounds by the chemical testing. These results were similar to the studies which showed the presence of flavonoids and phenolic compounds in the methanolic fruit extract of *Benincasa hispida*.[10] In DPPH assay, dry powder of *Benincasa hispida* revealed 90% inhibition of free radical scavenging activity compared to its fresh juice preparation which was about 62%. In the previous DPPH assay studies of *Benincasa hispida* proved that the maximum antioxidant activity was found to be in the methanolic extract compared to the alcoholic extract.[1,3]

In this study, both the dry powder and the fresh juice of *Lageneria siceraria* showed positive for flavonoids and negative for phenolic compounds by the chemical testing. These results were similar to the studies which showed the presence of flavonoids in the ethanolic fruit extract of *Legenaria siceraria*.[11] In DPPH assay, dry powder of *Lageneria siceraria* showed 85% inhibition of free radical scavenging activity compared to its fresh juice preparation which was about 6%. In the previous DPPH assay studies of *Lageneria Siceraria* showed that the maximum antioxidant activity was found to be in the acetone extract compared to the alcoholic extract.[4,5]

CONCLUSION

In this study, both the chemical testing and DPPH assay showed maximum antioxidant activity in the dry powder preparations of *Benincasa hispida* and *Lageneria siceraria* compared to their fresh juice preparations. The result of enhanced antioxidant property of *Benincasa hispida* and *Lagenaria siceraria* dry powder possess good therapeutic potential and can be clinically useful as an effective antioxidant in various disease conditions after appropriate preclinical studies and clinical trials.

A study comparing cognitive function assessment in type-2 diabetes mellitus using Rowland Universal Dementia Assessment Scale and Mini Mental State Examination

S Shanmugapriya, N Dhandapani[1], T Saravanan[1]

Abstract:

BACKGROUND: Diabetes mellitus is a metabolic disorder which can predispose to cognitive impairment. It is important to screen diabetic patients for cognitive dysfunction in the routine clinical management. Our study aimed at comparative evaluation of commonly used cognition assessment tools such as Mini Mental State Examination (MMSE) and Rowland Universal Dementia Assessment Scale (RUDAS) in diabetes patients.

METHODS: The study was conducted as a prospective case–control design in a tertiary care teaching hospital from March to October 2015. After obtaining written informed consent, the data on demographic details, duration of diabetes, and glycemic control marked by glycated hemoglobin were recorded. A total of 101 previously diagnosed type-2 diabetes patients and an equal number of age-, gender-, and literacy-matched controls without diabetes were administered the MMSE and RUDAS cognition scales in a one-to-one interview by a trained diabetic educator who was blinded to the groups.

RESULTS: The study revealed that there was a significant difference in cognition scores between the diabetic patients with short duration (<5 years) and those with a longer history of diabetes (≥5 years) only in the MMSE scale using independent sample *t*-test ($P = 0.018$), unlike the RUDAS in which the difference was insignificant ($P = 0.235$). Similarly, there was also a significant correlation between glycemic control and cognition scores in the MMSE ($P = 0.03$), but not in the RUDAS scale ($P = 0.083$).

CONCLUSION: MMSE scale has been proved to be advantageous over the RUDAS as a screening tool for cognition assessment in diabetes patients.

Keywords:

Cognition score, diabetes duration, glycemic control, screening

Introduction

Diabetes mellitus is a metabolic disorder due to dysregulation of glucose homeostasis. The world prevalence of diabetes in adults has been predicted to increase from 285 million in 2010 to 439 million by 2030.[1] It is well established that diabetes is associated with significant morbidity, including neurological disability. Although it is known that diabetes can lead to cognitive deficits in the long term, elucidation of the effects on the central nervous system is still incomplete, unlike other complications such as nephropathy, retinopathy, and peripheral neuropathy. It is estimated that in 2010, 35.6 million people lived with dementia worldwide, with numbers expected to almost double every

20 years, to 65.7 million by 2030 and 115.4 million by 2050.[2] In addition to this, the scenario of type-2 diabetes predisposing to and accelerating cognitive impairment would further increase the burden of disease. With increasing prevalence of type-2 diabetes in India, the magnitude of cognitive impairment that the disease contributes to and the factors affecting should be studied.

Studies from various populations have consistently shown that diabetes is associated with cognitive deficits and dementia; both in elderly and younger patients.[3] Various pathophysiological mechanisms have been proposed. A process similar to that of peripheral neuropathy such as alterations in Na^+K^+ATPase activity and the ensuing reduction in myoinositol and sorbitol metabolism has been suggested. These may trigger biochemical abnormalities at the neuronal level, resulting in structural and functional changes, primarily in the white matter.[4] Chronic hyperglycemia, atherosclerosis, and hemodynamic changes may lead to microinfarcts which in turn to cognitive impairment. Diabetes-induced microvascular changes, such as disruption of the blood–brain barrier, and the resultant derangement of neurovascular coupling could be partly related to cognitive dysfunction.[5-7] Hyperglycemia may also be directly toxic to the neuron, leading to its degeneration[8] and consequentially the hippocampal as well as global atrophy.[5] Thus, diabetes is considered as one of the important contributory factors in the development of cognitive deficits.

Undiagnosed cognitive impairment can lead to reduced health status,[9] implying that screening for cognitive deficits should be an integral part of patient management in diabetes. Among the neuropsychological tests for dementia, the Mini Mental State Examination (MMSE), devised by Folstein *et al*., is one of the most widely used tools for the assessment of cognitive impairment.[10] The Rowland Universal Dementia Assessment Scale (RUDAS) is yet another screening test, designed as a multicultural cognitive assessment scale relatively unaffected by gender, education, and first language, as it can easily be converted for implementation in the local community.[11] Although there are studies comparing the accuracy and reliability of these two scales in geriatric population with and without dementia,[12-15] a thorough literature review reveals a paucity of studies directly comparing the two in a diabetic population. Hence, our study aimed at evaluating the effectiveness of the two scales as tools in assessing the cognitive decline in type-2 diabetes patients by comparing the correlation of cognitive score with the glycemic control and duration of diabetes.

Methods

This was a single-center, hospital-based case–control study conducted by collecting data from study participants from March to October 2015. Approval from the Institutional Human Ethics Committee was obtained before the start of the study.

Inclusion criteria

All patients willing to give consent, both males and females aged between 30 and 60 years with previously diagnosed type-2 diabetes mellitus (case) and without diabetes mellitus (control), with or without hypertension were included for the study.

Exclusion criteria

Patients with type-1 diabetes, stroke, alcohol intake or smoking habits, total blindness in both eyes, or complete loss of hearing in both ears; and patients who were previously diagnosed with and were known case of mental retardation, psychiatric disorders, and psychoactive drug use in addition to pregnant and lactating women were excluded.

The sample size calculation was done using "Epi tools," with a prevalence of 7% which was based on the previous data, and desired precision of 0.05 at 95% confidence interval revealed the sample size estimate of 101.

After obtaining written informed consent, the data on age, sex, literacy, current fasting and postprandial blood glucose (done by enzymatic reference method with hexokinase), and glycated hemoglobin (HbA1c) values (done by immunoturbidimetry), along with history on duration of diabetes and duration of hypertension were collected. The study was conducted on a sample of 101 diabetic cases and 101 non-diabetic controls matched for age, sex, and literacy to ensure homogeneity of the sample and to avoid bias in the results, owing to these parameters. In this study, patients who exhibited the ability to both read and write the colloquial language and/or English were included as literates.

MMSE and RUDAS scales were administered in a one-to-one interview with the study participant by a trained diabetic educator who was blinded to the group to which the patient belonged to. MMSE tested global cognition function with items assessing orientation, word recall, registration, attention, language abilities, and visuospatial ability and was scored out of 30. As per the MMSE scale, 21–23, 11–20, and ≤10 scores were indicative of mild, moderate, and severe cognitive dysfunction, respectively, while a score of 24 or higher was considered normal.[10] According to the recommendations of Crum *et al*., the MMSE scores were corrected for the literacy status. Based on these criteria, a score <24 was considered as impaired cognition for literates and that <22 for illiterates.[16] RUDAS scale measured memory, gnosis, praxis, visuospatial skills, judgment, and language. The maximum RUDAS score

[Downloaded free from http://www.ijhas.in on Tuesday, August 14, 2018, IP: 192.168.30.162]

was 30, for which the recommended cut point ≤22 was used to indicate cognitive impairment.[11]

Statistical analyses was done using Pearson's correlation test to analyze the correlation between mean MMSE/RUDAS score with parameters such as duration of diabetes and glycemic control. Student's *t*-test was used to identify significant difference in the mean scores between cases and controls based on age, sex, literacy, and comorbidity.

Results

The data were entered into Excel and analyzed using SPSS version 19. Among 101 cases, 4% had mild and 1% had moderate cognitive dysfunction using MMSE, whereas cognition deficit was identified in 5% cases using RUDAS. 1% controls, according to RUDAS score, had cognitive impairment while MMSE scoring revealed that 3% controls had cognitive dysfunction which was mild.

The baseline characteristics of age, sex, and literacy in both groups were matched [Table 1]. There were a higher proportion of females in both the case and the control group, with a male to female ratio of 36:65. Percentage of literates was high (94%) in both groups. The cases were arbitrarily categorized based on the observed HbA1c value as those with good control and poor control. An HbA1c value of 8.5% was taken as the cutoff value; those with <8.5% were included in the good control group and those with HbA1c values ≥8.5% were grouped as poor controllers of glycemic level. 44.6% of cases had good control, while 54.4% were included in the poor control group. The mean score was found to be less in patients who had HbA1c level ≥8.5% using both the scales. An independent sample *t*-test showed that the mean difference between the scores of patients with good and poor control was statistically significant in MMSE scale ($P = 0.046$), while in RUDAS scale, the mean difference was not statistically significant ($P = 0.372$) [Figure 1].

Cases in our study population were divided into those with duration of diabetes <5 years and those with ≥5 years history of diabetes. Accordingly, it was found that 60.4% cases had <5 years of diabetes history and the rest had ≥5 years duration. The mean scores were found to be less in people who had diabetes ≥5 years using both scales and was statistically significant in MMSE scale ($P = 0.018$) but not in RUDAS scale ($P = 0.235$) [Figure 2]. Furthermore, using Pearson's correlation test, a statistically significant negative correlation between duration of diabetes and cognitive levels ($P = 0.015$) in addition to a significant positive correlation between glycemic control and cognitive score ($P = 0.03$) was detected in testing with MMSE scale in the diabetes patients. In contrast, no significant correlation between duration of diabetes or glycemic control with cognitive dysfunction was evident while using RUDAS scale [Table 2].

In both MMSE and RUDAS scales, an independent sample *t*-test revealed that there was no statistically significant difference between the cases and controls in both categories of <50 years of age and those with ≥50 years. The difference in cognition level between the cases and controls in the two gender groups was similarly tested using independent sample *t*-tests, and it was found that there was no statistically significant difference in the mean scores based on gender using either of the scales [Table 3]. Another significant observation was that the mean score of females, in both cases and controls, were lower than that of males, even though the difference was not statistically significant, except in the diabetic group assessed using RUDAS scale, wherein the mean score

Table 1: Baseline characters of study population

Parameters	Mean±SD	
	Cases, 101 (diabetic)	Controls, 101 (non-diabetic)
Age	49.75±7.1	49.57±7.0
Sex (%)		
Male	36 (35.6)	36 (35.6)
Female	65 (64.4)	65 (64.4)
Literacy (%)		
Literate	6 (5.9)	6 (5.9)
Illiterate	95 (94.1)	95 (94.1)
MMSE	28.09±2.3	28.01±2.13

[Downloaded free from http://www.ijhas.in on Tuesday, August 14, 2018, IP: 192.168.30.162]

of females was significantly higher than that of males [Figure 3].

It was found using Student's *t*-test that the illiterates had a mean score lower than that of the literates, though a statistically significant difference was observed only with the MMSE scale (P = 0.001) but not in the RUDAS scale (P = 0.085). Ninety-five percent of the study population were literates, and this precluded performing a between-group analysis for cases and controls [Figure 4].

An independent sample *t*-test revealed that there was no statistically significant difference between the mean scores of cases and controls with hypertension. Similarly, there was no statistically significant difference between the mean scores of those with diabetes alone and those with diabetes and hypertension in the case group using both MMSE and RUDAS [Table 4], indicating that coexisting hypertension did not significantly affect cognition score in patients with type-2 diabetes.

Table 2: Correlation of duration of diabetes and glycemic control with cognitive levels using Mini Mental State Examination and Rowland Universal Dementia Assessment Scale

Scale	Parameter	Correlation value	*P*

MMSE = Mini Mental State Examination, RUDAS = Rowland Universal Dementia Assessment Scale, SD = Standard deviation

Discussion

The MMSE is a cognitive scale used for detecting cognitive impairment. Having developed in the West, it has serious limitations due to cultural and educational

	Diabetes only	27.91±2.152		

MMSE = Mini Mental State Examination, RUDAS = Rowland Universal Dementia Assessment Scale, SD = Standard deviation

bias.[16,17] It is one of the commonly used tools for cognitive assessment consisting of 11-item testing with sensitivity of 87% and specificity of 82%.[18] The RUDAS is a newer screening test developed in Australia. It is a brief six-item screening test which is short and easy to administer. It is claimed to be culturally and educationally unbiased and developed in view of application in multicultural setting.[11,12,19] It assesses body orientation, praxis, drawing, judgment, memory, and language. It has the additional advantage of being capable of assessing the impairment in executive function. With a cutoff score of 23/30, it has 88% sensitivity and 90% specificity.[11,18]

It has been well proven that age, in addition to ethnicity and education, is an important factor affecting the MMSE score. In our study, there was no statistically significant difference in the mean score between patients aged above and below 50 years. In a study done using MMSE scale, there was no quantitative difference in cognition scores above and below 70 years of age, but a significant difference between diabetic and non-diabetic patients was detected.[3] Their result indicated that in diabetic patients, diabetes could be a greater risk factor for cognitive impairment than age. However, our study results did not replicate such a significant difference between cases and controls in both the age groups studied [Table 3]. The reason attributable to this inference is that most of the earlier studies were done in a population with higher mean age,[5,20] but our study included a much younger population and that may also account for the lower percentage of cognitive deficits detected. A similar result has been demonstrated in a study with middle-aged diabetic population.[4]

The prevalence of diabetes is higher in men than women, but there are more women with diabetes than men.[21] In our study sample, the proportion of females was much higher than the males. Using MMSE, the males scored higher than females though not statistically significant and this was in concordance with earlier studies.[3] Assessed using RUDAS, the female cases scored significantly higher than male cases, but such an observation was not seen in the control group and the reason for the result could not be explained.

Our study demonstrated that the magnitude of the difference in the mean score between literates and illiterates was significantly higher in the MMSE score as compared to the RUDAS scale, indicating that our study has also proven that RUDAS scale is free of educational barrier as described in the previous studies.[11,12] However, former studies done in Thailand and South Indian Malayalam population showed that cultural, linguistic, and education barriers were not fully overcome with the use of RUDAS scale.[13,15]

The cutoff values for glycemic control and duration of diabetes have been chosen arbitrarily and do not depend on the conventional cutoff adopted internationally for the management of clinical condition. The reason being that the duration of diabetes and the glycemic control beyond which cognitive dysfunction occurs, in comparison to other complications of diabetes, is less defined and less well understood. Hence, using the same clinical cutoff criteria used for management would obviously result in false-negative correlation. In the diabetic population studied, the association of mean cognition score with the glycemic control marked by HbA1c level was found to be statistically significant, in addition to a significant positive correlation which was evident only in the MMSE but not the RUDAS scale. Our study thus reflected the results obtained in few previous studies which have highlighted the positive association between poor glycemic control and poor cognition using MMSE,[22,23] but no such correlation detected using RUDAS.[24] Another study done in middle-aged adults with type-2 diabetes has demonstrated that there is predominantly psychomotor slowing with poor metabolic control, even though learning, memory, and problem-solving skills appear to be largely intact in such patients.[4] On the contrary, few other studies have established that the magnitude of glycemic control does not have significant correlation with the cognitive score using MMSE scale.[3,25,26] The potential explanation for the contradictory results between correlations of cognitive dysfunction with glycemic control is that only the recent HbA1c values representing short-term control were included in most analyses and not the time trend in HbA1c, indicative of long-term control as the measure to categorize patients with good and bad glycemic control.

Evaluating the association between the duration of diabetes and cognitive scores revealed a significant negative correlation. Those with a longer duration (≥5 years) of diabetes exhibited a lower mean score than those with shorter duration of diabetes (<5 years)

[Downloaded free from http://www.ijhas.in on Tuesday, August 14, 2018, IP: 192.168.30.162]

using the MMSE, but not with the RUDAS. Our results were consonant with results obtained in few similar studies.[3,22,25,27] Thus, most studies have proven a definitive correlation between cognitive decline and duration of diabetes than with glycemic control.

In addition, our study has shown that there was a statistically significant difference neither between the mean score of cases with and without hypertension nor between the scores of hypertensive cases and controls using both scales. Literature evidence states that although hypertension alone may not be associated with significant cognitive decline, along with diabetes, it increases the risk of cognitive impairment.[28]

With enormously increasing prevalence of diabetes and diabetes being an important risk factor for cognitive impairment, it is the need of the hour to incorporate cognitive assessment in the routine management of diabetes patients. Ours is the first study that compared MMSE with RUDAS head-to-head in a diabetic population, and the study has proved that MMSE has a definitive advantage over RUDAS for screening diabetes-induced cognitive deficit. In patients with type-2 diabetes, increase in memory deficits with reduction in psychomotor speed and reduced executive function are strongly supported by the findings of earlier studies though there are also other cognitive domains such as verbal fluency, complex motor function, attention, and recall which are shown to be negatively affected. Hence, it is clear that diabetes indeed has composite neurocognitive effects, rather than a single one and difficulty in diagnosis of such multiple neurocognitive function deficits is well recognized.[29] RUDAS tests the executive function unlike MMSE, yet RUDAS failed to demonstrate statistical significance which could be potentially attributed to the relatively high rate of intrasubject variability which is inherent to cognitive testing, thus impairing its ability to identify executive function deficits, especially those which are mild.[29]

In our study, the actual differences in the mean scores between those with good and poor glycemic control (0.91) and those with shorter and longer duration of diabetes (1.11) in the MMSE were small despite achieving statistical significance. Since score differences in the range of 2–4 or greater in MMSE are necessary to conclude a clinically relevant difference, the clinical significance of our interpretation has to be guarded and requires further investigation involving a larger sample size.

Another limitation of the study is that a large proportion of participants were literates and this could be a potential source of bias in interpreting the results. Hence, we recommend that the effectiveness of MMSE scale between literates and illiterates should be compared in a diabetic population before it can be emphasized that the MMSE scale is best suited for screening cognitive deficit in routine clinical examination of diabetic patients for early identification of cognitive impairment.

Conclusion

Our study has truly delineated that cognition deficits based on MMSE scoring correlates with the magnitude of glycemic control as well as the duration of diabetes. The results signify that in the general population, screening for dementia may preferably be done with RUDAS scale, given the higher sensitivity, specificity and particularly as it is efficient to overcome the literacy barrier in a multicultural multi-linguistic population like the one in India. However, in type-2 diabetes patients, it is the MMSE scale that has been proved to be useful in detecting early cognitive impairment, especially in patients with poor glycemic control and longer history of diabetes.

Abstract

Purpose: Drug use prescribing indicators advocated by the World Health Organization (WHO) are important tools for assessing the degree of polypharmacy, use of generic medicines, and to evaluate if there is inappropriate use of antibiotics or parenteral medications besides estimating the adherence to the essential drugs list. This study aimed to assess the WHO prescribing indicators in prescriptions given at the medical outpatient department (OPD) in a private medical college hospital in South India.

Materials and Methods: The study was done prospectively from patients when they presented for consultation at the medical OPD at our tertiary care center. Prescriptions were randomly chosen to be analyzed for the WHO prescribing indicators from September 2016 to April 2017.

Results: A total of 700 prescriptions were analyzed and the average number of drugs per prescription was 2.955 ± 1.32. 32.57% of prescriptions had fixed drug combinations and a similar value of 36% was obtained for prescriptions containing more than one drug for the same indication. Amongst the prescribing indicators, generic prescribing was appallingly low (6.42%). In contrast, antibiotic prescribing and prescription of injections showed an appreciably rational trend with 15.42% and 8.14%, respectively. Furthermore, the prescription of the drugs enlisted in the essential drugs list was determined to be 90.67%.

Discussion: The need for increase in generic prescribing and augmenting the adherence of prescriptions to the essential drugs list has been identified. This can be accomplished by multimodal approach that includes regulatory changes, conducting educational programs directed at attitudinal change among current doctors and imparting modifications in medical curriculum so as to inculcate the culture of abiding by the best prescription practices among budding doctors.

Conclusion: This study has delineated the requisite for pertinent changes in current prescribing trends in a tertiary care teaching private colleges.

Keywords: Generic drugs, polypharmacy, prescribing indicators, rational prescribing

INTRODUCTION

Evaluation of drug prescription pattern is an important aspect of patient care, which also serves as a measure of the quality of care provided. A recent systematic analysis has ascertained that prescribing quality is a dimension requiring constant evaluation.[1] The rational use of drugs is imperative for an effective and efficient health-care system. However, irrational drug use, considered as a global menace

is especially prevalent in the developing countries due to irrational prescribing, dispensing, and administration of medications.[2] Such irrational prescribing is unethical and greatly decrease the standard of drug therapy in addition to resulting in widespread health hazards such as increased incidence of adverse effects, drug interactions, and emergence of drug resistance, especially with antimicrobial therapy.[3] The World Health Organization (WHO) has reported that more than half of all medicines are prescribed, dispensed, or sold inappropriately.[4]

Prescription pattern monitoring studies are tools for assessing the prescribing, dispensing, and distribution of medicines prevailing in a particular locale. The main aim of such studies is to facilitate rational use of medicines.[5] The drug use indicators have been developed by the WHO in coordination with international network for rational use of drugs as an endeavor to measure the extent of rational prescribing.[5,6] According to the WHO, core drug use indicators are divided into three categories, namely, the prescribing indicators, patient care indicators, and the quality of care indicators. These are highly standardized indicators which do not need national adaptation. Although they do not measure all aspects of drug utilization which require intensive methodologies, extensive and varied sources of data, the core drug use indicators provide a simple tool for quickly and reliably assessing a few critical aspects of pharmaceuticals use in health care.

The drug use indicators collected in a cross-sectional survey or measured at different points in time to assess the change in performance are typically measured within a defined geographic or administrative area, either to describe drug use at a given point in time or to monitor changes over time. This study was designed to assess the drug prescribing practices at the medical outpatient department at our tertiary care center which is a teaching medical college hospital, using the five WHO prescribing indicators which include the average number of drugs per patient encounter, percentage of drugs prescribed by generic name, percentage of encounters with an antibiotic prescribed, percentage of encounters with an injection prescribed, and percentage of drugs prescribed from essential drugs list or formulary.[6] These WHO indicators would be instrumental in identifying the degree of polypharmacy, extent of generic prescribing, whether usage of antibiotics and parenteral medications are appropriate besides estimating the adherence to the essential drugs list.[6,7]

Treatment of diseases by the use of essential drugs, prescribed by their generic names, has been emphasized by the WHO and the National Health Policy of India. It has been highlighted that the prescription monitoring studies are imperative to bridge the areas such as rational use of drugs, pharmacovigilance, pharmacoeconomics, pharmacogenetics, and evidence-based medicine.[5] In India, it is currently essential to conduct studies on prescribing patterns in every state and utilize the data generated by such studies to improve the quality of patient care with the primary aim of promoting rational use of drugs.

Appraisal of the WHO prescribing indicators in a private health facility is less common compared to public sector hospitals. Moreover, the level of health care, wherein this study is undertaken adds to its significance. Unlike most Indian studies, the current study is aimed to analyze the entire list of prescribing indicators advocated by the WHO in a teaching medical college hospital. In such a scenario, not only are the prescribers and patients but also the medical students from one of the stakeholders who imbibe the culture of rational prescribing. Thus, this study would throw light on deficiencies which require appropriate and sustained interventions to avoid being carried onto the next generation.

Noteworthy, most studies encompass prescription monitoring of a particular group of drugs such as antiepileptics, antimicrobials, antiasthmatics, and antihypertensive drugs[5] rather than evaluating all the prescribing indicators irrespective of the diagnosis like our study, which would enable capturing a wider picture of the current trends. Medicine is an ever-evolving science and it is important to understand that conducting such prescription monitoring studies periodically as a measure to ensure rational drug use is imperative.

MATERIALS AND METHODS

The study protocol was approved by the Institutional Ethics Committee (Approval number: 16/261), The research was conducted as a cross-sectional study in the outpatient medical department (OPD) of our tertiary care teaching hospital in South India. Based on the WHO guideline of including at least 600 patient encounters, we chose a sample size of 700. This study was done prospectively from the patients when they presented for consultation at the OPD after obtaining a written informed consent. Prescriptions were randomly chosen to be analyzed for the WHO prescribing indicators over 8 months from September 2016 to April 2017. Two well-trained clinical pharmacists were involved in collecting data on prescribing indicators. Each prescription was regarded as single-patient encounter for calculation of the required parameters. Prescriptions of patients attending medical OPD and treated on outpatient

basis for their ailments were included irrespective of the comorbidities. Data were collected on the demographic details of age, gender, diagnosis, and the treatment prescribed which were mentioned in the prescription. The prescribing indicators were studied in accordance to the standard guideline advocated by the WHO.[6]

1. Average number of drugs per encounter: Average was calculated by dividing the total number of different drug products prescribed, by the number of encounters surveyed. Whether the patient actually received the drugs was not considered relevant in calculating this indicator
2. Percentage of drugs prescribed by generic name: percentage was calculated by dividing the number of drugs prescribed by generic name, by the total number of drugs prescribed and expressed as a percentage
3. Percentage of encounters with an antibiotic prescribed: Percentage was calculated by dividing the number of patient encounters during which an antibiotic was prescribed, by the total number of encounters surveyed and expressed as a percentage
4. Percentage of encounters with an injection prescribed: percentage was calculated by dividing the number of patient encounters during which an injection was prescribed, by the total number of encounters surveyed, multiplied by 100
5. Percentage of drugs prescribed from essential drugs list or formulary: percentage was calculated by dividing the number of products prescribed which were on the essential drugs list or local formulary, by the total number of products prescribed and multiplied by 100.

RESULTS

The data were entered in Microsoft Excel 2007 and analyzed as frequency distributions and percentages to assess the prescribing indicators. A total of 700 prescriptions were analyzed over 8 months from September 2016 to April 2017. The demographic distribution of patients mirrored a rising trend with increasing age as a higher proportion of patients (295) were 60 years and above (42.1%). Among the rest, those aged 40 years and above were 36.7% (257) and 21.2% (148) were <40 years. Both males and females were almost equal in proportion with 357 males and 343 females. Diagnosis were multiple and diverse. Hence, categorization into communicable and non-communicable diseases showed that majority (68.6%) had non-communicable diseases contrary to those with communicable diseases (31.4%). It was found that a total number of 2069 drug products had been prescribed in the 700 patient encounters, and thus, the average number of drugs per prescription was 2.955 and the standard deviation was 1.32. Moreover, the median number of drugs per prescription was 3, which unlike the mean, would not be unduly influenced by the outliers. Overall, the study revealed a higher value for this indicator than the reference standard [Table 1]. Analyzing the patient encounters lacking the data for specified variables, it was found, 647 (92.42%) prescriptions did not have any generic names, whereas only 17 patient encounters lacked at least one drug from essential drugs list. It was evident that 84.57% prescriptions did not have any antibiotics and likewise, a high percentage of 91.85% did not have any injections prescribed.

It was interesting to find that among the 2069 drug products prescribed, the highest percentage (10.95%) of prescribed drugs were supplements which ranked first followed by the antidiabetic, antiplatelet, hypolipidemic, and anti-hypertensive drugs, whereas the overall percentage of antibiotics prescribed was only 15.42%, and hence lower in comparison to the former groups of drugs [Table 2].

The number of prescriptions with fixed drug combinations was 228 accounting for 32.57% [Figure 1]. The most common one being prescribed was analgesic combination (paracetamol with ibuprofen followed by tramadol with paracetamol) for pain relief. A similar value of 36% (252 out of 700) was obtained for prescriptions containing more than one drug for the same indication. Interestingly, prescriptions analyzed showed that patient encounters with two drugs (27.73%) were equal in proportion to those that included three drugs (27.28%) accounting for a total of 55% prescriptions falling under either of these two categories. An analogous high percentage (23.98%) was also recorded for prescriptions with four drugs in the treatment regimen [Figure 2].

With respect to generic prescribing, this study recorded a very low percentage of 6.42% indicating that current prescribing pattern of clinicians favored prescribing by

Table 1: Comparison of the World Health Organization prescribing indicators observed with standard reference range

Indicator	*n*	Average/percentage (SD)	Standard reference range/optimal value
Average number of drugs per patient encounter	2069	2.955 (1.32)	1.6-1.8
Percentage drugs prescribed by generic names	133	6.42% (0.34)	100%
Percentage patient encounters with an antibiotic	108	15.42% (0.38)	20.0%-26.8%
Percentage patient encounters with an injection	57	8.14% (0.27)	13.4%-24.1%
Percentage drugs from essential drugs list	1876	90.67% (1.31)	100%

SD=Standard deviation

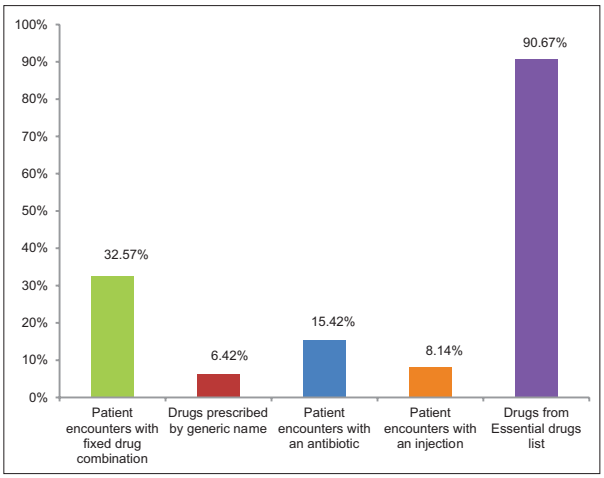

Figure 1: Measured percentages of prescribed fixed-drug combinations and the World Health Organization prescribing indicators

Table 2: Frequency distributions of commonly prescribed drugs

Name of the drug groups commonly prescribed	Name of drugs commonly prescribed	Sum (%)
Antidiabetic drugs	Metformin	161 (7.78)
Antiplatelet drugs	Aspirin	52 (2.51)
NSAIDS	Paracetamol	86 (4.15)
Supplements	Calcium and Vitamin D3	60 (2.89)
	Iron and folic acid	112 (5.41)
	Multivitamins and folic acid	55 (2.65)
Antiulcer drugs	Pantoprazole	99 (4.78)
	Ranitidine	73 (3.52)
Antihypertensive drugs	Amlodipine	36 (1.73)
	Telmisartan	21 (1.01)
Antibiotics	Levofloxacin	10 (0.48)
	Trimethoprim + sulfamethoxazole	8 (0.38)
	Azithromycin	7 (0.33)
	Amoxicillin + clavulanate	7 (0.33)
	Cefpodoxime proxetil	6 (0.28)

NSAIDS=Nonsteroidal anti-inflammatory drugs

brand names rather than using the generic ones. The percentage of patient encounters in which an antibiotic was prescribed was only 108 (15.42%) [Figure 1]. The highest prescribed antibiotic was levofloxacin followed by co-trimoxazole with azithromycin, amoxicillin-clavulanate, and cefpodoxime proxetil being next to the quinolone and the sulfomethoxazole-trimethoprim combination which were widely prescribed at our center during the study period [Table 2]. The most common indication for the antibiotic use was found to be a variety of respiratory infections ranging from pharyngitis, sinusitis to pneumonia.

About 8.14% of patient encounters had an injection being prescribed, and an overall 90.67% of adherence to essential drugs list was evident [Figure 1].

DISCUSSION

It is well known that the indicators of prescribing practices measure the performance of health-care providers in several key dimensions related to rational use of drugs. The indicators were assessed in our study based on a sample of 700 patient encounters that took place at the OPD in our hospital. The data that were collected prospectively by analyzing the prescriptions demonstrated that in our teaching hospital, the average number of drugs prescribed per encounter was 2.955. Comparison to the standard range advocated by the WHO for this indicator which estimates the degree of polypharmacy revealed that the measured average was much higher than the reference range of 1.6–1.8 considered as ideal.[6] This is also reflected in the high percentage of fixed drug combinations prescribed in addition to the use of combination of different drugs for a single indication in one patient encounter. In a similar study done in Goa,[8] the average number of drugs prescribed was 1.8 which was found to be lower than our finding and that obtained in other Indian studies on prescribing indicators by Upadhyay *et al.* (3.76) and Raj *et al.* (4.98).[9,10] In contrast, similar studies of drug use pattern in other countries such as Sudan (1.4), Zimbabwe (1.3), and Ethiopia (1.9)[11] have shown that the average number of drugs per encounter estimated in our study was higher.

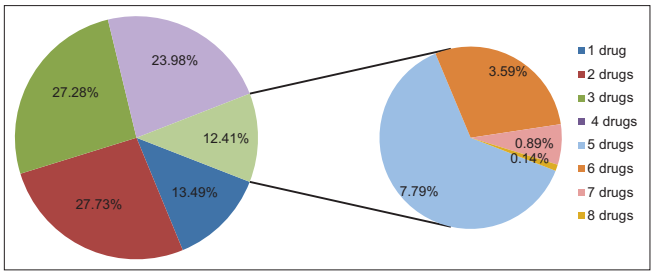

Figure 2: Percentage distribution of number of drugs in the prescriptions

The high average number of drug products per prescription exceeding the WHO reference range is demonstrative of a high degree of polypharmacy prevalent in our study locale. The reasons that could be attributed to this is the change in the epidemiological trend of rampantly increased prevalence of non-communicable diseases such as diabetes, hypertension, dyslipidemia, and coronary artery disease which are often coexistent contributing to the need for treating multiple disease entities in the same patient simultaneously.[12] Concomitance of such cardiometabolic conditions in a single patient further entails the requisite for prescribing more than a single drug for a given clinical indication which is often resistant to treatment in the face of multiple diseases presenting concurrently. Our study also stands testimony to this fact since a high proportion of participants (68.6%) had the diagnosis of non-communicable disease with diabetes ranking highest with 34.4%

Another rationalization for the high percentage of polypharmacy lies in the fact that currently there is a demographic shift with an increase in the aging population in our country.[13] This epidemiological transition is further responsible for perpetuating the current scenario prevailing. About 42.1% of the study population also was aged >60 years signifying that the greater proportion of aged population contributed to the high polypharmacy.

However, the high prescription rates for supplements recorded in our study remain unjustified and arise from two important factors potentially contributing to the irrational prescribing practice. First, the influence of pharmaceutical industries which vigorously promote supplementary products among doctors by providing biased information supporting the need for prescribing such products. Second, patients misconceptions on the health-promoting effects of supplements resulting in their persuasion and demand for such products in their prescriptions. However, the best approach toward such patients is to educate them rather than giving in to their false ideations.[3]

The percentage of drugs prescribed by generic name in our study was 6.42% which is too low compared with the standard derived to serve as ideal, which is 100%.[6] Wang *et al*. found that higher the doctor's education and training experience, the proportion of drugs that they prescribed by generic names showed a decrease.[14] Moreover, attitudinal differences have also been shown to exist among consultants in low- and middle-income countries compared to those in high-income countries.[15]

The likely explanation for the low percentage of generic prescribing could be due to repeated and persuasive promotion of the propriety products by pharmaceutical companies and in certain instances, clinicians are compelled to concede to the insistence of affluent patients demanding innovator drugs for treatment.[16] Another plausible cause for this stems from the presumed belief among a subset of prescribing physicians that the bioavailability differences between generic and brand drugs could adversely affect the therapeutic outcomes.[17] Such prejudices could unfavorably affect the tendency of prescribing generic drugs. Finally, the role played by industries in hindering generic prescribing by offering financial perks to prescribers cannot be underestimated.[18] Literature evidence states that generic prescribing is better in public centers in comparison to that in private sector hospitals.[16]

It is important to increase awareness on generic prescribing considering the high treatment costs incurred by the practice of prescribing by brand names. Nicolosi and Gray investigated the cost impact of generic and proprietary prescribing among chronic disease patients in South Africa and their findings indicated that "all generics were more than 40% cheaper, per defined daily dose per month, than the brand version."[19] An analysis of facility-based medicines price data from 17 countries by Cameron and Laing,[20] found that an average of 9%–89% could be saved by switching from brand to generic equivalents. Shift in the trend favoring generic prescribing is warranted and this can be implemented by an integrated approach of training the medical students who are future prescribers on the pharmacoeconomic significance of this practice in addition to conducting continuing medical education programs for clinicians with the focus of alleviation of their apprehension on bioequivalence regarding the use of generic drugs. Moreover, a variety of strategies have been recommended by experts to overcome the barriers to genetic prescribing and the most vital of these include enforcing statutory obligations, setting clear guidelines for generic prescribing, and legally de-incentivizing prescribing by propriety name.[21]

Interestingly, we found that the number of antibiotics prescribed (15.42%) as well as the number of encounters with an injection (8.14%) was low, indicating a positive trend toward reduction in indiscriminate use of antibiotics and unnecessary injections. An obviously rational prescribing pattern is noted for both these indicators in our tertiary care center. Noteworthy, our study duration was 8 months, and hence, the study would not have comprehensively captured the seasonal variation in antibiotic prescription pattern due to differential incidence rates of infections at different times of the year.

About 90.67% of drugs prescribed conform to the WHO essential drugs list which is lower than that obtained in other studies in India (99.6%), Tanzania (96%), and South Ethiopia (96.6%), whereas higher in comparison to that in countries like Nepal (88%). This could be attributable to the lack of sensitization of the prescribers and lack of rules enforced to mandate prescribing from the essential drugs list. Akin to generic prescribing, this indicator also has been demonstrated to vary between the private and public sectors[22] indicating the need for the practice of prescribing from essential drugs list to be more widely adopted especially in private sector hospitals.

One of the strengths of the study is that it was done prospectively using the patient prescriptions attending the OPD rather than the data being collected retrospectively from case records which is often the design adopted in prescription pattern studies as it is much easier to

collect information from patient records. In addition, the prospective design of this study positively ensures eliminating duplication of data, while retrospective analyses cannot be claimed to be completely devoid of bias such as exclusion of incomplete data from poor record keeping unlike prospective evaluation.

A major limitation of our study is that it was done in a single center which is a private medical college hospital with limited sample size, and hence, the data cannot be extrapolated to other centers lacking similar characteristics like public or government hospitals and health-care centers.

This study implies the need for implementing interventions such as programs, workshops, and symposia to impart awareness on rational prescribing among the medical fraternity. Thus this research has not only identified the pitfalls in current prescription practices, but in addition, has recommended the potential solutions to weed out irrational prescribing trends encountered.

CONCLUSION

Our study on prescribing indicators has clearly delineated that the prescribing practices for antibiotics and injections are appropriate and rational; conformity to essential drugs list is considerably good, though scope for improvising is certainly evident. However, the degree of polypharmacy is higher than the standard. Generic prescribing is also an element that needs to be vastly improved on. Therefore, appropriate measures to reduce polypharmacy and increase generic prescribing by clinicians have to be implemented by the administrative team and policymakers to ensure rational and safe prescribing.

Comparison of the Effects of Zonisamide and Flupirtine on Paclitaxel Induced Peripheral Neuropathy in Rats

BHUVANESWARI KRISHNAMURTHY[1], PRASHANTH ASHOK KUMAR[2], ABILASH SATHYANARAYANAN[3]

ABSTRACT

Introduction: Many peripheral and central causes lead to neuropathic pain disorders. Effective treatment of neuropathic pain is not completely manageable and hence, it becomes necessary to evaluate the application of Zonisamide as a sodium channel and T-type calcium (Ca^{+}) current inhibitors and Flupirtine by activation of potassium (K) channel through N-methyl-D-aspartate (NMDA) receptor inhibition in the treatment of neuropathic pain.

Aim: To analyze the analgesic effect of Zonisamide and Flupirtine in paclitaxel induced neuropathic pain model in rats by hot plate and cold allodynia test.

Materials and Methods: Total of six groups of animals, each with six rats were given with single intraperitoneal (i.p.) injection of 1 mg/kg of paclitaxel on four alternate days (day 0, 2, 4, and 6). Drugs Zonisamide (50 mg/kg daily for group 2, 100 mg/kg daily for group 3, Flupirtine (10 mg/kg, daily for group 4, 20 mg/kg daily for group 5) and Gabapentin daily for group 6 were administered in the dosages per group from days 0 to 7. Nociceptive tests were done for all animals on days 0, 7, 14, 21, 28 to assess the pain threshold. Student's t-test was used to analyze the statistical significance.

Results: In our study, on the 21st day of testing we observed that 100 mg/kg dosage of Zonisamide group has shown a significant increase in reaction time suggesting analgesic effect. Prominent increase in the reaction time was also observed that on day 14 of testing, both the Gabapentin and Flupirtine groups showed an earlier analgesic effects when compared with the Zonisamide group.

Conclusion: Zonisamide and Flupirtine showed anti-nociceptive activity in the Paclitaxel model of peripheral neuropathy compared with the standard treatment of Gabapentin.

Keywords: Analgesic action, Effect of ion channels, Neuropathic pain, Reaction time

INTRODUCTION

Neuropathic pain is a disabling condition affecting about 7-8% of the population [1]. The Health Related quality of life for individuals with neuropathic pain is rated low compared to those with coronary artery disease, diabetes mellitus and recent myocardial infarction [2]. Opioid analgesics have a role in the treatment of neuropathic pain, but they have been questioned in regard to their safety profile. This is especially important in treatment of the elderly who have an increased prevalence of neuropathic pain [3,4]. In a country like India, with an estimated 62 million people living with diabetes mellitus, treatment of neuropathic pain effectively is important [5]. The first line treatment for neuropathic pain includes Gabapentin, Anticonvulsants, Topical Lidocaine and Capsaicin - they have achieved a total treatment satisfaction of only 50% according to one study done in diabetic patients [6]. Thus, it becomes necessary to evaluate the application of other drugs in the treatment of neuropathic pain.

Flupirtine is a centrally acting, non-opioid, NMDA receptor antagonist that causes analgesic effect by opening Kv7 potassium channels. It is effective in alleviating several types of pain especially chronic musculoskeletal pain and post-surgical pain [7]. It has been demonstrated that Flupirtine has significant analgesic property in several animal pain models including in diabetic neuropathic pain model, carrageenan-induced hyperalgesia and ciguatoxin induced pain in rats [8,9].

Zonisamide is an antiepileptic drug that has been tried previously for the treatment of chronic pain with inconclusive results [10]. It has been evaluated in the Streptozotocin induced Peripheral Neuropathy model previously and has shown to have an effect in reducing the pain induced [11]. In the published literature, it was found that Flupirtine provided significant pain relief in patients with small fiber neuropathy within a week when the other first line drugs like gabapentin and pregabalin have failed. Furthermore, studies have shown it to be useful in neuropathic pain only in conjunction with opioids and there isn't any literature evidence with head-head comparison of the drug with the currently available first line drugs [12]. In a recent review in Cochrane library on Zonisamide in neuropathic pain, there was only one study done on 25 patients with painful diabetic neuropathy (13 in Zonisamide vs 12 in placebo) which showed that three out of 11 responders had ≥50% reduction in pain intensity which may be due to one of its diverse mechanisms of action. There was no study directly comparing the effect the drug with that of the first line drugs [13].

Since, the data available regarding the modulation of pain in the Paclitaxel-induced neuropathic pain in rat model, by Zonisamide and Flupirtine is insufficient this study evaluated Zonisamide and Flupirtine for their pain relieving effects in the Paclitaxel Model of Peripheral Neuropathy in rats.

MATERIALS AND METHODS

This experimental study was carried out after obtaining ethical clearance from the Institutional Animal Ethics Committee of PSG Institute of Medical Sciences and Research, Coimbatore, India during May 2014 to July 2014.

All the animals were procured from the Animal House at the Institution. All the groups were housed in different cages with the male and female rats separated. They were allowed to acclimatize to the ambient temperature, following with they were tamed before each injection to facilitate easy handling.

Paclitaxel Model of Peripheral Neuropathy in Rats

Paclitaxel induced peripheral neuropathy in rats has been evaluated as

a robust model for studying the antinociceptive effects of various drugs [14, 15]. This model involves administration of single intraperitoneal (i.p.) injection of 1 mg/kg of paclitaxel on four alternate days (0, 2, 4, and 6). The volume of injection is kept constant at 1 mL/kg. This model typically presents sensory neuropathy on the 14th day.

Test Groups

This consisted of six groups of animals, each with 6 wistar rats (weight 200-250 g). Three male and three female in each group.

Group-1: Paclitaxel alone

Group-2: Paclitaxel + Zonisamide 50 mg/kg

Group-3: Paclitaxel + Zonisamide 100 mg/kg

Group-4: Paclitaxel + Flupirtine 10 mg/kg

Group-5: Paclitaxel + Flupirtine 20 mg/kg

Group-6: Paclitaxel + Gabapentin

Nociceptive tests were done for all animals on days 0, 7, 14, 21, 28 to assess the pain threshold.

The dosages of drugs were chosen based on the previous published literature in similar rat models [8,9]. In these studies the dosages considered included 50 mg/kg, 100 mg/kg, and 150 mg/kg of orally administered Zonisamide. These were found to be the optimum dosages in which there was a significant analgesic effect obtained.

Drugs Zonisamide, Flupirtine and Gabapentin were administered everyday orally in the dosages as per the group from days 0 to 7.

Outcome Parameters

Hot plate test: The hot plate test involves placing the rat in a transparent glass cylinder on a preheated plate at 55°C. After 60 minutes of corresponding test drugs administration, per group rats were placed on hot plate to measure the latency period with cutoff time 60 seconds was allowed to each animal to prevent injury. The time duration of latency is the time interval between placing the rat on the hot plate and the time for the rat to perform two behavioural components, namely, paw licking and jumping. The average latency time period in different groups was 17-21 seconds [Table/Fig-1]. Both of these responses are supra-spinal integrated responses [16,17].

Cold allodynia test: This was performed by immersing the tip of the tail in cold water at four degrees. The time taken for a withdrawal reflex is the time of latency considered. A cut of latency of 20 seconds was kept to avoid any injury [18,19]. Both the tests were done for all the animals on days 0, 7, 14, 21, and 28.

STATISTICAL ANALYSIS

Data obtained from the study were entered in SPSS software version 19.0. Student's t-test was done to analyze the statistical significance.

RESULTS

Paclitaxel-induced neuropathy was seen on day seven by Hot plate test and on day 14 by cold allodynia test. Decrease in latency was observed in hot plate and cold allodynia tests and it was persisted till 28 days in the control group. No other abnormal behavioural response was seen.

Hot Plate Test

Latency period was significantly delayed for the paclitaxel group on Day 7 (p=0.01) and Day 14 (p=0.01) whereas Gabapentin treated group, both Flupirtine treated groups 10 mg/kg (p=0.02) showed significant delay in latency time on day 14. However, Zonisamide showed significant delay (p=0.02) in latency time only for the dose 100 mg/kg on the day 21 compared to Gabapentin and control groups [Table/Fig-1].

Cold Allodynia Test

The latency time for a reaction is reduced in the paclitaxel group significantly from day 14 (p=0.01 and still reduction seen on day 28 (p=0.02) when compared to Day 0. Also, there was a significant delay in reaction time in the 100 mg/kg Zonisamide group (p=0.02) on Day 14, Gabapentin group (p=0.01) and both the 10 mg/kg (p=0.01), 20 mg/kg (p=0.01) of Flupirtine groups and showed delay in latency time for a reaction in on day 14 [Table/Fig-1].

DISCUSSION

The Paclitaxel induced peripheral neuropathy model in rats has shown to be an established indicator which mimics neuropathic pain in humans. It has been used to evaluate the neuropathic effect of other anticonvulsants [5].

The results show that neuropathic pain was induced by the 14th day from the starting of Paclitaxel in group 1, identified by the decrease in latency time. This is in keeping with the Paclitaxel model of

peripheral neuropathy. On examining the difference in groups, we find that the Gabapentin group showed delayed latency period from day 14, i.e., less neuropathic pain. This cements the proven potent analgesic effect of Gabapentin [10].

In our study, on the 21st day of testing we observed that the group with the 100 mg/kg dosage of Zonisamide has shown a significant increase in reaction time suggesting analgesic effect.

Similar prominent increase in the reaction time was observed for the Gabapentin and both the Flupirtine groups earlier, on day 14 of testing, showing that Gabapentin and Flupirtine act producing earlier analgesic effects when compared to the Zonisamide group. Thus, in our study both Zonisamide and Flupirtine produce analgesic effects comparable to the established Gabapentin.

Zonisamide, an anticonvulsant, has different mechanism of action, one of which includes inhibition of the T-type Calcium channels [20,21]. These channels have been studied and they have been implicated in the modulation of chronic pain [22]. They are emerging targets for treatment of neuropathic pain [23]. Lercanidipine, an antihypertensive, also acts via modulation of the T-type Ca^{++} channels in the body. This drug has been shown to be effective in treating neuropathy in this Paclitaxel model [19]. Previous studies have shown that Zonisamide has a potential ability to treat neuropathic pain [24]. There is literature on evaluation of the analgesic property of Zonisamide on chronic pain models [25]. On the other hand, a recently published Cochrane analysis has shown that Zonisamide has not been efficacious enough to advocate routine use in the treatment of peripheral neuropathy [10].

Flupirtine is a K(V) seven channel activator with GABA-A receptor modulating action [26]. It has central nervous system activity causing analgesic effects [27]. Flupirtine has not undergone extensive clinical trials but there is evidence of analgesic activity as shown in previously evaluated animal pain models [28]. One study has demonstrated its analgesic activity on prostate bone metastasis in rats [29]. Flupirtine has also been studied previously in combination with an Opioid in Streptozotocin Induced Peripheral neuropathy model in rats showing analgesic properties [9]. There had been no published reports of the analgesic effects being evaluated in the Paclitaxel model.

Gabapentin has been evaluated extensively in the treatment of peripheral neuropathy and has been placed as one of the first line drugs used in the treatment of peripheral neuropathy [30].

Zonisamide and Flupirtine showing anti-nociceptive activity in the Paclitaxel model of peripheral neuropathy, evaluated alongside a treatment standard of Gabapentin, provide robust evidence of their analgesic activity.

Gabapentin is used as a first line drug in patients with neuropathic pain. Since, many of these patients have comorbidities it becomes vital to choose a drug that has minimal adverse reactions [31]. Gabapentin is associated with adverse reactions such as sedation, nausea and vomiting, which makes it cumbersome to use in debilitated patients [32]. The other drugs which have been used in neuropathic pain including opioids and sedatives have significant adverse effects [33].

Flupirtine has a unique mechanism of action and studies have shown that it causes a anti-nociceptive action without producing sedation [9]. Flupirtine has also shown to have neuroprotective and muscle relaxing properties [34,35]. Further since Zonisamide and Flupirtine are non-opioid drugs and tolerance does not develop in most cases they have minimal abuse potential [36,37]. Flupirtine has also shown shown to be effective in refractory neuropathic pain [38].

LIMITATION

In this study only two methods (cold allodynia, hot plate) of evaluation were used. A nerve conduction study would have given better results.

Further only two doses of Zonisamide have been tested. Other dosages to evaluate the most effective dosage have to be evaluated.

CONCLUSION

Zonisamide and Flupirtine, thus can be used as adjunctive drugs and reduce the dose related side effects of conventional therapy. They also work by a different, novel mechanism of action when used for the treatment of neuropathic pain, making them a potential choice for complementary therapy.

Thus, further studies evaluating the antinociceptive property of Zonisamide and Flupirtine in humans may further their usage in pain pathways.

Questionnaire

ABSTRACT

Background: Clinical audit is based on the concept of quality assurance in health care. It is important for all health care providers especially specialists and consultants to be aware of the principles governing clinical audit in addition to the methods in conducting such an audit.
Objectives:
- To assess the knowledge and attitude of medical postgraduate students on clinical audit.
- To evaluate the effectiveness of an interventional program conducted to educate the principles and methods of conducting clinical audit to medical postgraduates.

Methods: The study was done in 92 postgraduate medical students in our institute using a pre-test and post-test questionnaire, evaluating their knowledge on different perspectives of medical audit and also assessing the change in their attitude towards audit after an educative interventional program. The questionnaire consisted of 13 knowledge questions and 3 attitude questions. Each question was scored and the overall maximum score was 35.
Results: The mean post-test score (24.45 ± 3.21) was significantly higher than the mean pre-test score (16.18 ± 3.41) using paired *t*-test ($p < 0.001$) indicating that the educational intervention was effective in improving the understanding of the candidates on clinical audit.
Conclusion: It is imperative for all medical postgraduates to realize the importance of clinical audit in addition to acquiring the skill of conducting a meaningful and successful clinical audit. Attainment of such a competency can be achieved through planned repeated interventions and help usher in an era of best quality of patient care.

1. Introduction

It is important for all clinicians to realize the growing importance of the clinical audits. A clinical audit is considered as an integral part of the clinical practice. It is a quality improvement process that seeks to improve patient care and outcomes.[1,2] Evaluation of patient outcomes in the field of medicine have been conducted since as early as 1853.[3] The aim of the clinical audit process is to ensure adequate quality of care in the management of patients. With the current day and age of advanced medical care, it is crucial to review and constantly improve the standard of care provided. This requires sustained efforts in the unrelenting strive towards providing the best possible quality of care to patients.

The "Quality Initiative" considered forerunner of clinical audit, was launched by the Royal College of General Practitioners in 1983 to define specific objectives for patient care and monitor the extent to which those objectives were met.[4] Later, the National Institute for health and Clinical Excellence (NICE) published the paper "Principles for Best Practice in Clinical Audit", which defined clinical audit as "a quality improvement process that seeks to improve patient care and outcomes through systematic review of care against explicit criteria and the implementation of change".[2]

Hence it is necessary to understand and be familiar with the underlying principles and methods in conducting a clinical audit. This is especially important from the perspective of the medical

post-graduate who is not only the future specialist and consultant but an important stakeholder in ascertaining whether quality care is offered to all patients in a particular health care unit. It is therefore essential for all medical postgraduates in various disciplines to have first-hand knowledge of clinical audit. It is also being increasingly recognized by the academic sectors that postgraduates should be trained to conduct clinical audit conceptualizing it as an essential component of evidence based medicine.[5,6]

Accordingly, our study was designed to assess the knowledge of postgraduate students on the principles and methods of clinical audit in our tertiary care teaching hospital and also to evaluate the effectiveness of an interventional training program in medical audit which was conducted specifically with the objective of sensitizing and imparting knowledge on how to conduct a clinical audit.

2. Materials and methods

The study protocol was approved by the institutional human ethics committee before the start of the study (Approval Number: 13/289). The study was done prospectively in a tertiary care teaching medical college hospital using a pre-test and post-test questionnaire that was validated by a team of three experts from the hospital clinical audit committee and institutional quality control committee. After obtaining a written informed consent, the questionnaire was administered to the postgraduate students at the beginning and at the end of an educational program on how to conduct clinical audit by audit experts. The questions framed evaluated the knowledge and attitude of medical postgraduates about clinical audit before and after the program. The data was collected from the participants of two consecutive programs conducted in two successive years. Each participant attended only one of the two consecutive sessions. The questionnaire consisted of 16 questions out of which 13 were knowledge and three were attitude questions.

2.1. Statistical analysis

The questions were scored and statistical difference in the mean pre-test and post-test score was analyzed using paired *t*-test. The results of the survey was also analyzed qualitatively and expressed as frequency distribution of percentages.

3. Results

A total of 92 postgraduates participated in the study. The study which was done at a single centre in two consecutive years involving two different batches of 2nd year postgraduates from various specialties, 39 students participated in the first year and the remaining 43 in the next successive session in the following year.

The first question on the need for an audit evoked diverse array of responses both in pre and post-test. The four options which were included were (1) audit has to be an integral part of clinical practice, (2) done to evaluate adverse patient outcomes, (3) as academic program in medical education and (4) administrative evaluation of patient care. Though all the four choices may be apparently appropriate, doing an audit as a mere administrative evaluation is unjustified as the objective of any clinical audit is betterment of patient care, based on which, the first three options are considered the correct responses. At the end of the session, it was observed that about 60% had clearly excluded administrative evaluation though only 20% of them had acquired complete knowledge on the need for clinical audits in contrast to only 8% who were aware of this before the program as made obvious by pre-test analysis. It was apparent that the term 'audit' had been deeply entrenched with the belief of being a tool for administrative evaluation, as made evident from a statistical comparison of pre-test and post-test scores ($p = 0.904$) (Table 1).

Answering the question on types of clinical audit which can be standard based, adverse occurrence screening or critical incident monitoring and peer reviewed, only 50% in the pre-test agreed that all three were indeed the audit types while the post-test revealed that 82.6% accepted "all the above" as the appropriate response.

In assessing the understanding of the students on the types of evaluation, design of the audit and the stages in the audit cycle, it could be demonstrated that there was definitive acquisition of knowledge on these aspects of audit based upon the increase in percentage of the responders opting for the correct answer in the post-test when compared to the pre-test (Figs. 1 and 2).

On the ethics approval perspective, a shift in the responses favoring the need for ethics committee approval before publication of the results (54.3%) rather that at the beginning of the audit (9.8%) was evident in the post-test, contrary to the impression of most students in the pre-test that ethics committee's approval had to be obtained before the start of an audit (59.8%). A considerable increase in the proportion of participants who indicated that there

Design	1.52 ± 0.85	1.96 ± 0.29	−0.43 ± 0.82	<0.001
Steps in audit cycle	0.44 ± 0.83	1.82 ± 0.56	−1.38 ± 1.01	<0.001
Ethical approval process	0.53 ± 0.79	1.42 ± 0.69	−0.89 ± 1.02	<0.001
Who can conduct audit	3.64 ± 0.97	3.87 ± 0.61	−0.22 ± 1.01	0.034
Who can make recommendations	1.28 ± 1.05	1.63 ± 1.06	−0.34 ± 1.50	0.029
Tool for prioritizing topic	0.61 ± 0.92	1.24 ± 0.97	−0.63 ± 1.14	<0.001
Defining aims	0.93 ± 1.00	1.52 ± 0.85	−0.58 ± 1.09	<0.001
Criteria selection	0.54 ± 0.89	1.35 ± 0.94	−0.80 ± 1.15	<0.001
Standard definition	0.76 ± 0.97	1.50 ± 0.87	−0.73 ± 1.35	<0.001
Commonest method involving service users	0.58 ± 0.49	0.78 ± 0.41	−0.20 ± 0.56	0.01
Audit is not research	0.51 ± 0.50	0.91 ± 0.28	−0.40 ± 0.51	<0.001
Professional responsibility	0.71 ± 0.45	0.82 ± 0.38	−0.11 ± 0.50	0.041
Achievement of same performance level as in research indicates lag in quality	0.20 ± 0.39	0.26 ± 0.44	−0.06 ± 0.48	0.203
Overall score	16.18 ± 3.41	24.45 ± 3.21	−8.28 ± 4.02	<0.001

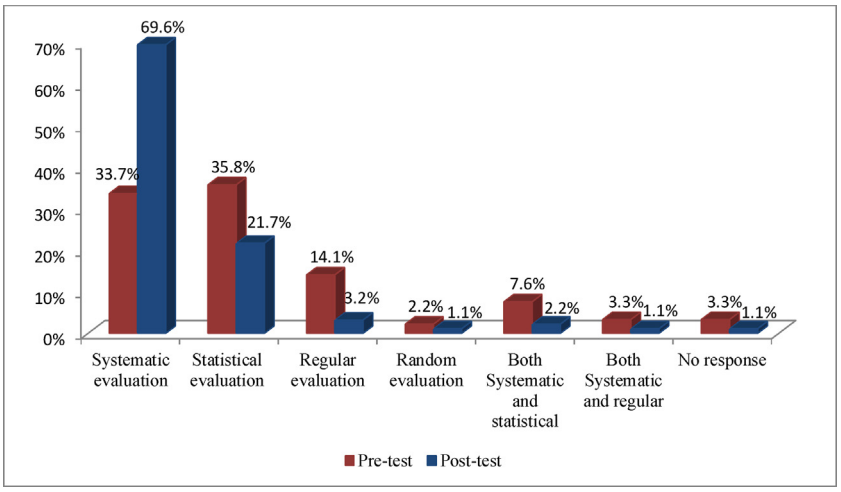

Fig. 1. Percentge of responses to types of evaluation for structure, processes and outcomes of care in clinical audit.

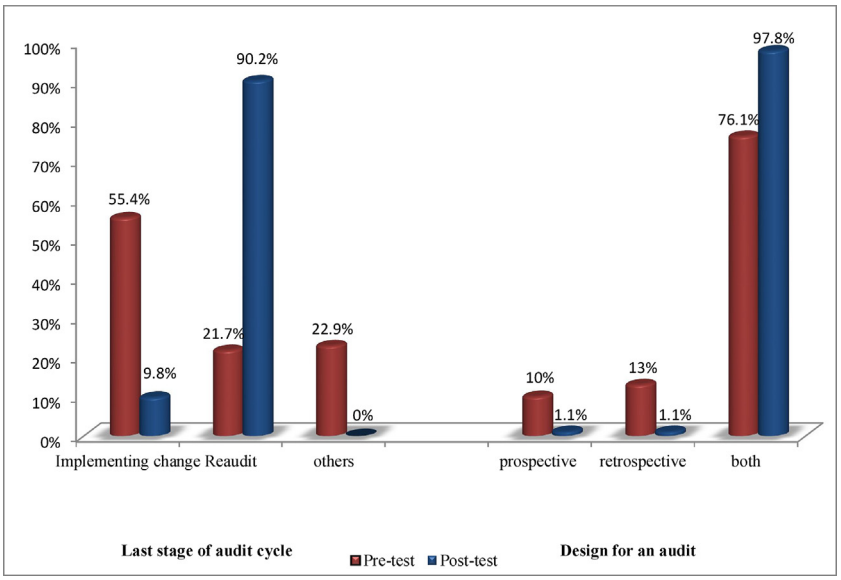

Fig. 2. Percentage of responses to steps in an audit cycle and the design for an audit.

was no need for ethics approval for the conduct of a clinical or therapeutic audit was also noted in the post-test (33.7%).

Appraisal of the postgraduate students' knowledge on who can conduct an audit and who can make recommendations based on an audit result, drafted as two separate questions made it evident that the session had enlightened 97.8% on the fact that any medical professional including an administrator can conduct an audit whilst the question on recommendation which was structured as dual correct response one, namely the PI (principal investigator) and the hospital audit team, only 5.5% responded with completely correct answer in contrast to 72.8% who had chosen only one of the correct responses at the end of the session though it was obvious that there was an increase in the percent of single correct response compared to the pre-test results (59.8%).

Knowledge on the tool for prioritizing the audit topic showed an increase, demonstrated by the rise in percentage of students opting the right response in the post-test (69.6%) compared to the pre-test (30.4%) (Fig. 3). Likewise their understanding on defining the aims, criteria selection and comprehending the standard revealed augmentation, manifested by selection of the correct choice indicating an improved knowledge on these concepts by large majority of participants (Fig. 4).

Attitude questions patterned on yes/no response ascertained that the students considering audit as yet another research was high before the program (40.2%) but they were able to discern the difference between an audit and research subsequent to the intervention (91.30%). In addition, a high proportion of participants were able to appreciate that auditing forms part of their professional accountability at the end of the program (82.6%). However, it was clear that the study subjects had not undoubtedly understood that failure to achieve the same performance level as that in research was often not possible in unselected patient populations in a practical clinical scenario; only 60.9% had chosen the right response in the post-test (Fig. 5).

Evaluating the candidates' knowledge on the commonest method of audit involving patients, 85.9% rightly agreed that it was satisfaction survey in the post-test contrary to only 57.6% who were in favor of it in the pre-test. Each question was scored with maximum total score being 35. A paired *t*-test was done to assess if the difference in mean score for post-test (24.45 ± 3.21) was statistically higher compared to that of the pretest (16.18 ± 3.41)

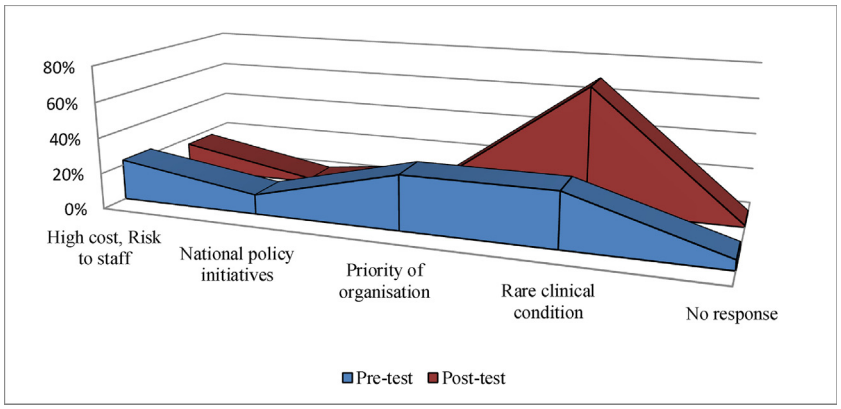

Fig. 3. Frequency distribution of responses to "the tool for prioritizing the topic for audit are all except" expressed in percentages.

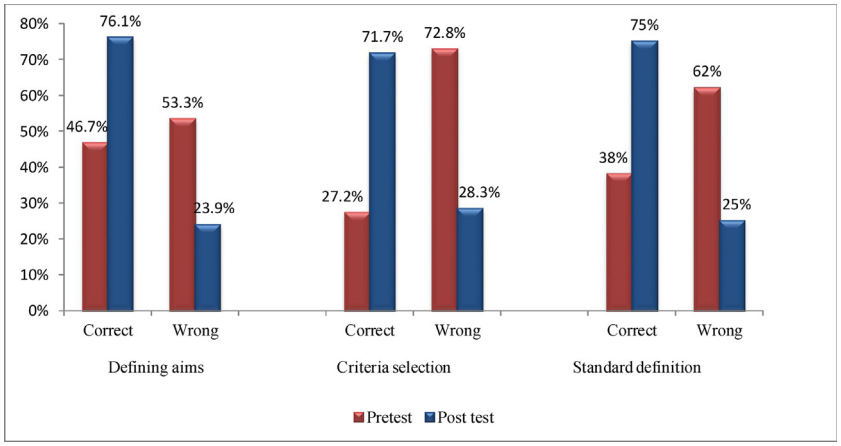

Fig. 4. Frequency distribution of the percentage of correct and wrong responses to the parameters of aims, criteria and standard in an audit.

and it was found that a statistically higher ($p < 0.001$) mean post-test score was achieved (Table 1).

4. Discussion

This study involving 92 postgraduate students in a tertiary care teaching hospital revealed that the knowledge and understanding on the principles and concepts were quite limited as was evident from the pretest analysis. However the planned intervention in the form of an educational session was effective in conveying the basic fundamentals regarding clinical audit to the participants. This was discernible from the statistically greater mean score attained in the post-test compared to the pre-test (Table 1).

In analyzing the individual components, it was demonstrable that elements such as types of audit, types of evaluation, design and stages, ethics committee approval for an audit were well comprehended by the participating candidates following the intervention. Likewise their understanding on the prioritizing tool,

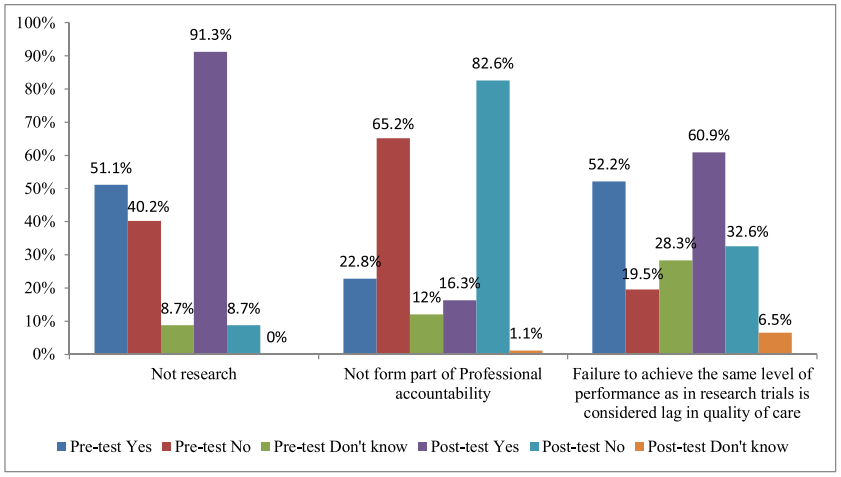

Fig. 5. Percentage distribution of responses to the attitudinal aspects of an audit.

defining aims, criteria selection and the meaning of standard showed statistically significant improvement ($p < 0.001$). A fairly good knowledge was also gained on who can conduct ($p = 0.034$) and who can make recommendations following an audit ($p = 0.029$). The participants were able to appreciate the role played by the PI in making recommendations proved by the shift in the choice of responses from the hospital audit team in the pre-test to the PI in the post-test.

An equal magnitude of improvement was not seen in the understanding on the need for an audit because a considerable majority of participants, despite the program, erroneously believed that the conduct of clinical audit was purely on administrative motive; this was made obvious by the post-test score on this element (Table 1). Also, their attitude towards achieving the same performance level as in research to ensure the best quality of care was rather unaltered (Fig. 5). Such misbelieves and misconceptions seem to be deeply rooted signifying the need for repetitive and sustained measures such as continuing medical education programs, symposia and workshops in clinical audit to enable better understanding as well as need for an attitudinal change towards such clinical audit facets.

Introspecting on the need for such programs targeting the medical postgraduates reveals that this measure not only provides a good learning experience but also would ensure ready involvement of these future consultants in the quality improvement process, as rightly pointed out by Walshe that the outcomes of an audit depend on 'who did it and how it was done'.[7] In addition, enhanced understanding of the audit concepts would pave the way for weeding out the lack of commitment, poor record keeping and inadequate data entries which are the deterrents in the path of quality improvement. Assuming the role of audit lead to facilitating teamwork are the positive attributes that would stem from the in-depth knowledge thus gained. It would not be an exaggeration to say that incorporating the competency of participation in medical audit as a module in postgraduate medical curriculum would be a step forward in implementing evidence based medicine in clinical care, since it is understandable that practicing medicine does not merely stop with updating on current research evidence of best practice but being able to show that such new standards of care is achieved in one's own practice through the clinical audit findings. Thus postgraduate training should encompass clinical audit which is considered as an integral part of clinical governance, for ascertaining the best clinical care to patients.[8]

5. Conclusion

This study has highlighted that educational programs on clinical audit with the objective to impart knowledge and improve understanding of the principles, concepts and methods should be designed and conducted for the postgraduate medical students of diverse specialties for enabling them to acquire the skill of conducting clinical audit which would ensure sustained quality control in patient care.

Knowledge and Attitude Towards the Translation of Medical Research to Clinical Benefit Amongst Researchers in A Tertiary Care Hospital

S SHANMUGAPRIYA[1], DEENA SANGEETHA[2], RAMALINGAM SANKARAN[3]

ABSTRACT

Introduction: One of the primary goals of any biomedical researcher should be practical applicability or the translation of scientific discoveries to clinical care. Research that lacks potential for translation contributes to ineffective use of resources, time and manpower. Hence, it is important for researchers to be aware that the clinical significance should not be forgotten in the quest for a significant p-value.

Aim: To assess the knowledge of researchers in ascertaining the practical applicability of his/her own research, to ascertain their motives in planning research and to evaluate the attitude of researchers towards the ethics of doing research that is less likely to translate into clinical benefit.

Materials and Methods: This cross-sectional study was conducted at a tertiary care medical college hospital in South India. Teaching faculty from clinical, pre and para-clinical departments were administered a questionnaire which included 14 questions. The questionnaire consisted of five knowledge and nine attitude questions. The responses were analysed qualitatively and expressed as frequency distributions.

Results: A total of 60 researchers were included and given the questionnaire. The respondent rate was 32 (53.3%). Only 3 (9.4%) were completely aware of "translational research" while about 11 (34.4%) knew that research done by pre & para-clinical sciences could be both basic and translational. Also, 17 (53.1%) of participants were willing to do research that did not result in either immediate or direct clinical benefit. A small minority of 4 (12.5%) admitted that the focus of their research was to achieve statistical significance. About 10 (31.3%) of researchers surveyed and felt that research offered an opportunity for free treatment to patients and 5 (15.6%) felt that therapeutic misconception was acceptable.

Conclusion: This study identified the gap between knowledge and understanding of the practical applicability of research and its ethical perspectives amongst researchers and hence, indicates the need for increasing awareness on the importance of assessing the translatability of one's research.

Keywords: Clinical significance, Ethics, Practical applicability, Statistical significance

INTRODUCTION

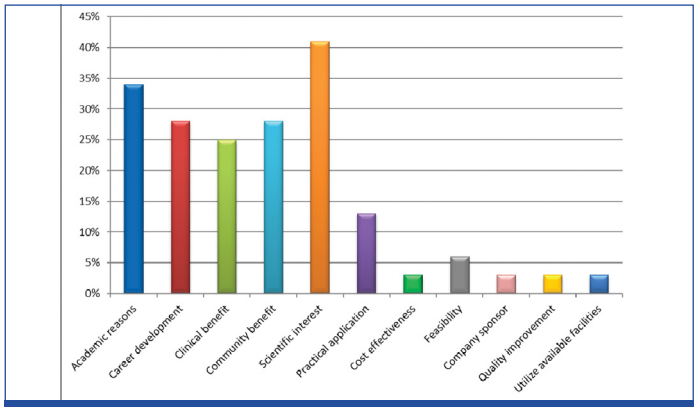
In the current era, there is a substantial increase in the number of researches done and published. The current system of publication in biomedical research provides a distorted view of the data generated [1]. There is too much focus on statistical significance, with parameters more important than statistics fading into oblivion [2]. The primary goal of any biomedical researcher should be practical applicability which refers to the translation of the scientific discoveries to clinical care [3]. Translational research refers to transfer of knowledge from bench to bedside [4].

Biomedical research tends to be skewed as most data generated are positive and mushroom around a particular topic at a particular point in time [1]. When a researcher looks to find solutions for his or her own clinical problems, research is done with a practical end point in view. However, when there is no room for this, research tends to lose quality.

Improper study designs waste resources and generate results that are not strong enough to translate to clinical practice. Small effect sizes are chosen to generate statistical significance more readily [5]. However, statistical significance is not the same as clinical significance and this tends to be forgotten in the quest for a 'significant' p-value [2]. From an epidemiologist's perspective, the relevant question is whether the study's hypothesis is true i.e. the probability of the hypothesis being greater than 0.05? For clinicians, the relevant question is whether a particular strategy can be followed in an individual patient or a subset of similar patients [6].

We believe that it is also unethical to expose the patient or healthy volunteer to any risk, however, small or theoretical, if it does not have the potential to benefit him and/or society. So, this study was designed to evaluate the knowledge of the researchers in assessing the practical applicability of his or her research in future patient care. Secondly, the study also aimed to ascertain the motives of the researcher towards doing research and to evaluate the attitude of the researcher towards the ethics of doing research which is less likely to translate into clinical benefit.

MATERIALS AND METHODS



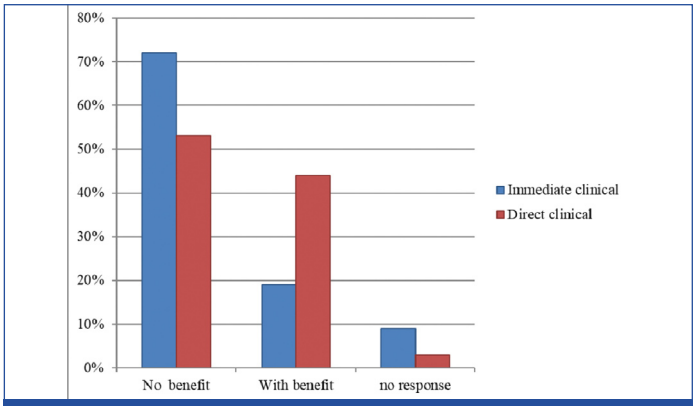
This cross-sectional study was done after the approval of Institutional Human Ethical Committee (Approval number: 13/250) for six months from November 2014 to April 2015. Teaching faculty of our tertiary care and teaching hospital in Coimbatore, South India was surveyed with a questionnaire to evaluate their knowledge on assessing the practical applicability of their research and their attitude towards the ethics of research lacking the potential for translation. The study participants recruited were teaching faculty who had involved in research while postgraduates, residents and faculty who had not done any research were excluded.

The questionnaire consisted of 14 questions, of which five were knowledge questions and the remaining were attitude questions. The questionnaire was drafted to be self-administered and it was validated by a team of three members who were researchers belonging to the three levels namely, Assistant professor, Associate professor and Professor; thus representing three different strata with reference to both the quantum and experience in research. Reliability analysis done using SPSS software revealed a cronbach's alpha value of 0.797. After obtaining a written informed consent from each participant, the questionnaire was administered. The responses were qualitatively analysed and expressed as frequency distribution of percentages. Detailed statistical analysis was deferred to enable meaningful expression and lucidity of inferences from the qualitative data.

RESULTS

Out of 60 researchers, who were included for the study and given the questionnaire, only 32 responded by returning the completed questionnaire. Out of 32 teaching faculty who participated in the study, 16 (50%) were Professors, 8 (25%) Associate Professors and 8 (25%) were Assistant Professors. The rest either returned an unfilled questionnaire or failed to give it back. Thus, the respondent rate for the study was 32 (53.3%) and the reasons offered by most for non-participation was lack of time and interest.

There were varied qualitative responses from the participants to the first question on three motives for research. The research intentions were categorized based on the responses specified into 11 categories. It was found that majority had indicated scientific interest 13 (40.6%) and academic endeavours which



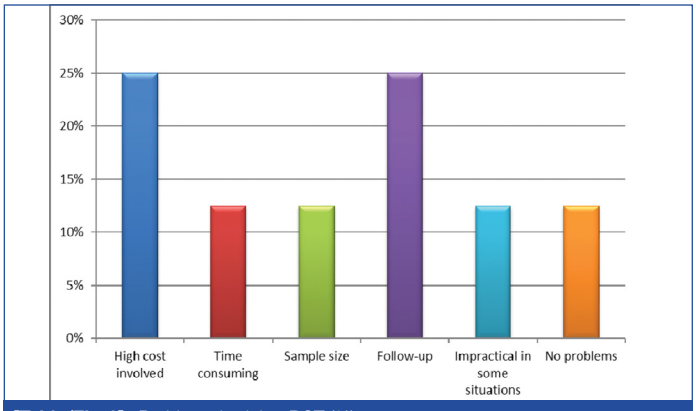
[Table/Fig-1]: Motives indicated for research (%).

included guideship responsibilities, interdisciplinary research, or mandatory involvement in clinical audits 11 (34.4%) as the driving forces in their research involvement [Table/Fig-1].

It is fundamental for the researchers to be familiar with the term "translational research" which denotes translating knowledge from basic sciences to clinical studies as well as translating clinical trials to everyday practice. On this perspective, it was found that the understanding of what translational research means was incomplete; 24 (75%) of participants were partially aware in contrast to mere 3 (9.4%) with complete knowledge about this term. The rest were totally unaware of translational research indicated by their lack of response.

In addition, assessment of the knowledge on research done in preclinical and paraclinical departments, structured as a dichotomous true/false question, revealed that only 11 (34.4%) of participants were aware that research done in pre and para-clinical sciences could be both basic and translational.

Also, 17 (53.1%) of participants were willing to do research that did not result in direct clinical benefit and 23 (71.9%) of them



[Table/Fig-2]: Attitude towards doing research and its clinical benefit (%).

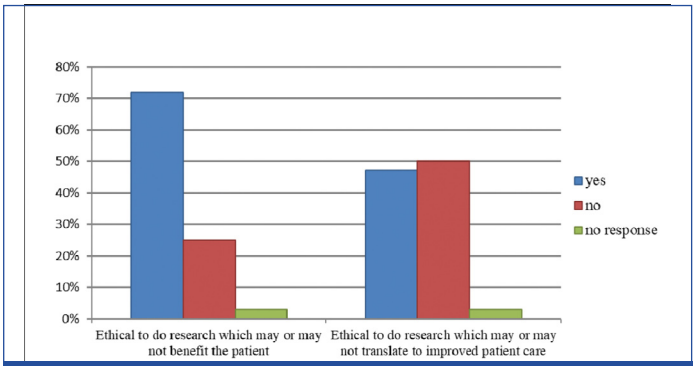
opined that their research would not have immediate clinical benefit [Table/Fig-2]. In appraising the attitude of the researchers towards the outcome of testing their hypothesis, a small minority of about 4 (12.5%) admitted that the focus of their research was to achieve statistical significance whilst the rest ascribed that their primary aim in research was to confer greater importance to the clinical significance 10 (31.3%), practical applicability 11 (34.4%) while 7 (21.9%) were in favour of analysing the results irrespective of the statistical significance.

A couple of knowledge questions on sample size and Randomized Clinical Trial (RCT) design revealed that 24 (75%) were aware that smaller the sample size in a study, more likely the research findings cannot be relied upon. On the other hand, the remaining 8 (25%) were unaware of the fact that the sample size could influence the research outcome, out of which 1 (3%) had opted not to answer the question on sample size.

An estimate of only 8 (25%) had the experience of being involved in a RCT and only to this fraction of the study population was the question regarding experiential knowledge on the problems faced during the RCT was directed. The difficulties that they had enumerated included cost, time, achieving the required sample size, follow up of the participants and the impracticality of

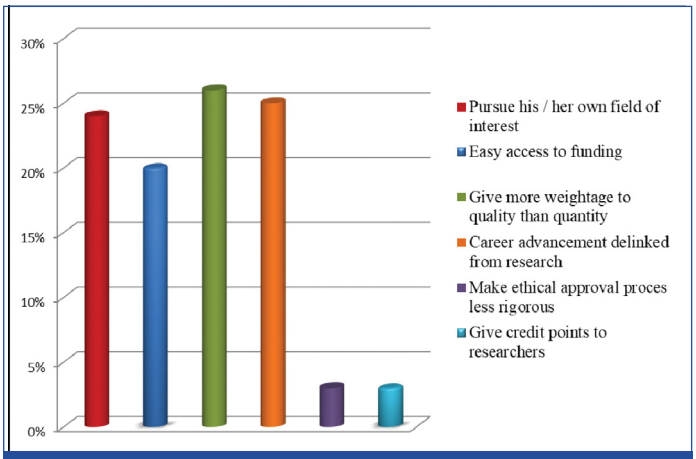
[Table/Fig-3]: Problems in doing RCT (%).

addressing certain hypothesis using RCT design. Amongst these responses, cost and follow-up issues ranked highest with 25% each [Table/Fig-3].



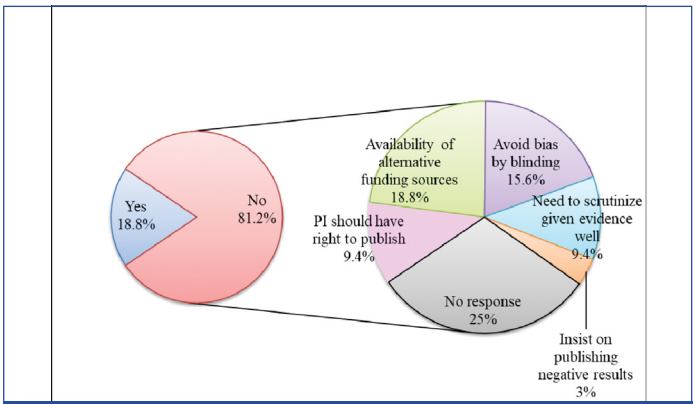
In assessing the attitude of those not having done any RCT 24 (75%), the reasons offered by a greater percentage of participants were that RCT design was not applicable to their research 3 (12.5%) and that they were apprehensive on the difficulties in the conduct of a randomized study 3 (12.5%) whilst 4 (16.7%) revealed that they had not such an opportunity. Two (8.3%) attributed it to practical constraints. The rest indicated lack of motivation.

A rating scale to assess the frequency with which the researchers evaluated the practical application of their research, before



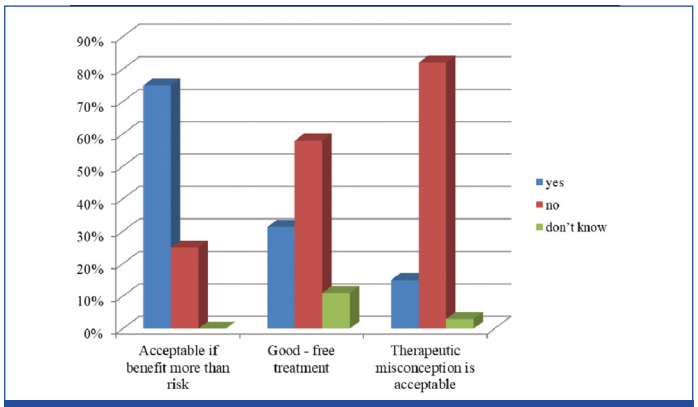
formulating their hypothesis demonstrated that 11 (34.4%) did so "always" and an equal percentage admitted that they did such an evaluation "most of the times."

Interrogating on the ethical aspects, 23 (71.9%) researchers divulged that it was ethical to do research which may or may not directly benefit the patient. Surprisingly, 15 (46.9%) agreed that it was ethical to do research which may or may not translate to clinical benefit [Table/Fig-4].



A large majority of study participants 25 (78.1%) opined that the current "publish or perish" situation was unhealthy for translational research. A valid list of strategies identified for improving translational research which most voted for, were

[Table/Fig-4]: Attitude towards research ethics (%).



[Table/Fig-5]: Strategies to improve translational research (%).

[Table/Fig-6]: Research in collaboration with drug companies is always healthy (%).
PI - Principal Investigator

to give greater significance to quality than to the quantity of research, allowing one to pursue his/her own interest, delinking research from carrier progression and enabling access to easy funding [Table/Fig-5].

Twenty five (81.2%) were convinced that research in collaboration with drug companies was unhealthy due to a variety of reasons [Table/Fig-6]. Those who felt otherwise 6 (18.8%) did so because such collaboration enabled research, offered funding source, provided easy compensation and facilitated achieving a larger sample size. Twenty four (75%) opined that research which attributed some risk to an individual research subject or a group of research subjects was acceptable only if the possible benefit

[Table/Fig-7]: Questions regarding attitude towards certain aspects of research (%).

to the community was large. It was shocking to discover that 10 (31.3%) felt that clinical research offered an opportunity for free treatment to patients who enrolled themselves in the trial and 5 (15.6%) felt that therapeutic misconception was acceptable [Table/Fig-7].

DISCUSSION

Translation of basic medical research refers to the transfer of new understanding of disease mechanisms gained in the laboratory into clinical care [4]. Though, there are studies on various perspectives of translational research, ours is the first study done to assess the knowledge and attitude of researchers towards translational value of their research findings. The study has brought out that there is only incomplete understanding on translational research and in addition, a high percentage of study subjects were unaware that research in pre and para-clinical departments could be both basic and translational.

It is important for all academic researchers to be aware of "translational research" terminology [7] as they are one of the important stakeholders who are committed not only in identifying and confirming novel concepts through appropriate research, but are also involved in validating the potential of new discoveries to translate to clinical application and improving therapeutic outcomes, thereby culminating in better patient care [8].

In spite of the fact majority of participants have indicated scientific interest as the motive for research, an equally high percentage have revealed that their research endeavours, was part of the academic requirement and was on account of career advancement [Table/Fig-1]. Linking career advancement with the number of publications is indeed a double edged weapon since it motivates the basic scientists and clinicians to undertake more research, thereby promoting research activities; however, the same may not always be true from a translational perspective. This is reflected by a high proportion of study participants disfavouring the "publish or perish" standpoint prevailing as it is unhealthy for translational research.

Clinical evidence of efficacy relies on the dissemination of research results, usually by publication in medical journals which is a critical step that would impact further progression of the research findings [9]. A recent review identified 101 articles published in six top basic science journals which had an apparent promise for development as a major clinical application and yet

only five of these promising advances has been licensed for clinical use over a period of 20 years; out of which only one had created a major impact on medical practice. Three quarters of the promised interventions from basic science papers do not proceed to randomized trial. The article also reported that the strongest predictor of moving to randomized experimentation was industry involvement in the original basic science publication [10].

Science is subject to great uncertainty. An empirical evaluation of the 49 most-cited papers on the effectiveness of medical interventions, published in highly visible journals in 1990–2004, showed that a quarter of the randomized trials and five of six non-randomized studies had already been contradicted or found to have been exaggerated by 2005 [11].

The plethora of scientific information gained through research, promoted largely by academic requisite for career advancement, coupled to limited venues for publication (journals with sufficiently high impact) are factors which deter research in the translation path. Moreover, the current system of publication further perpetuates the publication bias [1]. The more extreme, spectacular results indicating large treatment effects are preferentially published as is evident from the paucity of negative data which are more difficult to get published [12]. The abundance of positive findings published in scientific journals marks the tell-tale effect of selective publishing which not only hampers translation of research findings but also questions the discriminating value of the statistical significance [12-14].

In-depth knowledge of the researchers on the sample size and the relevant design for the research hypothesis is warranted. A study done analysing 215 two arm parallel group RCT of superiority with a single primary outcome published in six high impact factor general medical journals between 1st January 2005 and 31st December 2006 revealed that 5% of reports did not have any sample size calculation and the difference between the sample size reported in the article and the replicated sample size calculation was greater than 10% in 30% of the 157 reports that gave enough data to recalculate the sample size [15]. Thus, every component of a RCT is important for its success; if the design or sample size is inappropriate, then the results of the study will be unreliable, however, well the study is conducted [16].

As it has been rightly highlighted by many participants, there are a number of constraints for conducting RCT which is considered as the gold standard for interventional studies. Apart from implementation issues, complexity involved in understanding the level of clinically meaningful improvement, the expected variation of improvement in the sample, high dropout rates during follow-up are other disadvantages which hinder the choice of RCT design by researchers [17].

The study has made it obvious that researchers are apprehensive about industrial collaboration despite some advantages like the easy access to funding for the conduct of the trial, alleviation of difficulties in providing compensation, use of high quality methods [18] and potential for publication in high impact journals [19]. Nevertheless, industry funding and collaboration in trial design, data collection and analysis have been found to be associated with an increased likelihood of reporting a positive primary outcome and decreased prospect of reporting of trial limitations. Collaborative trials more commonly use surrogate primary endpoints which may, in part, explain why these trials are more likely to have positive primary outcomes [20]. Thus, our results signify that researchers are concerned with interference and influence of the study results and its dissemination by the sponsoring company.

Yet another remarkable finding established is that there is inadequate understanding on the ethical concepts of research as well. Though, ethical challenges for translational research remains the same as clinical research, it should be realized that considerable difference do exists as clinical research is regarded to be ethically distinct from medical care, while translational research emphasizes the links between the two, showing how both need to be grounded in the ethics of doctor-patient relationship [3]. Thus, there is requisite for a different approach towards translational research ethics which reaches farther beyond the research ethics and medical ethics [21]. This study has implied that it is clearly essential to impart ethical concepts to researchers to augment their understanding on ethical principles governing research.

LIMITATION

The major limitation of this study was the small sample size and limited experience of the researchers in RCT designs or trials with industry collaboration. A multi-centric design involving a large sample size from different tertiary centers and medical colleges across India will enable to capture a broader picture of the challenges to translational research.

CONCLUSION

The study has delineated the need for rigorous implementation of educative programs for all researchers to enhance their understanding on the significance of ensuring the practical applicability or translatability of research in addition to improving their knowledge on ethical perspectives. Ultimately, research should be aimed at finding solutions to the everyday clinical problems inorder to have a greater practical end point in view.

Abstract

A simple, sensitive and reproducible ultra-performance liquid chromatography (UPLC) method has been developed and validated for simultaneous estimation of polychlorinated biphenyl (PCB) 77 and PCB 180 in mouse plasma. The sample preparation was performed by simple liquid–liquid extraction technique. The analytes were chromatographed on a Waters Acquity H class UPLC system using isocratic mobile phase conditions at a flow rate of 0.3 mL/min and Acquity UPLC BEH shield RP_{18} column maintained at 35°C. Quantification was performed on a photodiode array detector set at 215 nm and PCB 101 was used as internal standard (IS). PCB 77, PCB 180, and IS retention times were 2.6, 4.7 and 2.8 min, respectively, and the total run time was 6 min. The method was validated for specificity, selectivity, recovery, linearity, accuracy, precision and sample stability. The calibration curve was linear over the concentration range 10–3000 ng/mL for PCB 77 and PCB 180. Intra- and inter-day precisions for PCBs 77 and 180 were found to be good with CV <4.64%, and the accuracy ranged from 98.90 to 102.33% in mouse plasma. The validated UPLC method was successfully applied to the pharmacokinetic study of PCBs 77 and 180 in mouse plasma.

1 | INTRODUCTION

Polychlorinated biphenyls (PCBs) are a chlorinated class of chemicals that are divided into 209 congeners grouped across 10 homologs (US-EPA, 1989). They are emerging as persistent pollutants in the environment although their production has been restricted in many countries owing to their high lipophilicity and ubiquitous nature (UNEP, n.d.). Two such biphenyl congeners, viz. PCB 77 and PCB 180, have contrasting and unique physicochemical and toxicological characteristics. PCB 77 is a coplanar dioxin like tetra-chlorobiphenyl congener, while PCB 180 is a nondioxin-like congener with greater lipophilicity. PCB 77 is low chlorinated congener (Agency for Toxic Substances and Disease Registry, 2000), whereas, PCB 180 is heptachlorobiphenyl with more chlorination of biphenyl nucleus (Viluksela, Heikkinen, van der Ven, Rendel, & Roos, 2014). Since PCB 77 is planar with a small dihedral angle (Dasary, Saloni, Fletcher, Anjaneyulu, & Yu, 2010), it is an endocrine disrupter. Moreover as it is non-*ortho*-substituted dioxin-like congener, it is unique among endocrine disrupters, and also forms polar hydroxylated metabolites (Grimm et al., 2015). PCB 180, on the other hand, is not an endocrine disrupter as it lacks dioxin activity and is more lipophilic (Maisano et al., 2016; Matthews & Dedrick, 1984; Saija et al., 2016). This congener forms reactive metabolites in addition to hydroxylated compounds (Grimm et al., 2015). In summary, PCB 77 and PCB 180 differ from a toxicological perspective – PCB 77 is a low chlorinated neurotoxic endocrine disrupter that is more polar than the other congener, PCB 180, which is a high chlorinated nondioxin-like lipophilic persistent pollutant. PCBs and other chlorinated compounds can be estimated by isotope dilution high-resolution gas chromatography–mass spectrometry in tissues (Sather, Newman, & Ikonomou, 2003). PCBs can also be estimated in other matrices like air samples (Muir & Sverko, 2006), aroclor standard mixtures (Pietrogrande, Benvenuti, & Previato, 2000), rat liver microsomes (Zhai, Wu, Lehmler, & Schnoor, 2013), groundwater samples (Letcher, Li, &

ABBREVIATIONS: PCB, polychlorinated biphenyl

Chu, 2005) and blood plasma (Mathews, 2014) by various gas chromatographic detection techniques.

Most studies on PCB 77 concentrations in environmental and biological samples have used gas chromatographic techniques with detection methods including mass spectrometry (Eske et al., 2014; Ghosh et al., 2010; Wang et al., 2013) and nonspectrometric methods (Brieger & Hunter, 1993; Chu et al., 1995). Studies employing PCB 180 as the analyte of interest have evaluated its concentrations in matrices using gas chromatography with electrochemical detector (ECD) detection (Bogdevich & Cadocinicov, 2001; Cossu, Ledda, & Chessa, 2013; Tian et al., 2016; Viluksela et al., 2014). Only one study (Dmitrovic, Chan, & Chan, 2002) which has evaluated both the congener serum levels has employed GC–MS. To date, there are only a handful of studies that have employed liquid chromatography for assessment of PCB concentrations (Mathews, 2014; Pietrogrande et al., 2000). None of these studies have assessed PCB 77 and PCB 180, congeners with toxicological significance and uniqueness, simultaneously, in a cost-effective and time-efficient manner employing UPLC or HPLC.

In this study, we report such a method development and validation for PCB congeners, viz. PCB 77 and PCB 180 using a novel ultra-high-performance liquid chromatographic method for simultaneous estimation of these two PCB congeners in mouse plasma samples. We have optimised a cost-effective and time-efficient method of routine estimation of these congeners in plasma samples. Additionally, one of the objectives of this study is to estimate the pharmacokinetic parameters of these congeners in plasma, after occupational exposure in mouse using a whole body inhalational chamber.

2 | MATERIALS AND METHODS

2.1 | Chemicals and reagents

The reference standards of PCB 77, PCB 180 and PCB 101 (IS) were purchased from Sigma-Aldrich, India. Acetonitrile and methanol of HPLC grade was purchased from Sigma-Aldrich, India. Methyl *tert*-butyl ether of HPLC grade was obtained from Himedia, India. Ultrapure water (18.2 MΩ cm) was obtained from a MilliQ water purification system from Millipore (Milford, USA). All other chemicals used were analytical grade.

2.2 | Animals

Thirty-two Swiss albino mice were procured from PSG animal facility and quarantined. All animals were housed in standard housing conditions with ambient light–dark cycle (10:14 h) and environment (temperature of 24–26°C) with feed and water *ad-libitum*. The animals were weighed and grouped into cages randomly. All mice were females with 18–25 g body weight. The mice were acclimatized in the animal house for 3 days followed by acclimatization in the laboratory for 2 days. Prior approval for the study was obtained from the Institutional Animal Ethics Committee. All experiments were carried out as per regulatory guidelines like the Organisation for Economic Co-operation and Development (EU), Committee for the Purpose of Control and Supervision of Experiments on Animals (India) and Indian Council for Medical Research Guidelines for Biomedical Research (India).

2.3 | Instrumentation and chromatography conditions

The UPLC instrument consisted of a Waters Acquity H class UPLC system equipped with a quaternary pump and 96-vial autosampler coupled with a diode array UV detector (Waters, Milford, MA, USA). The chromatographic separation was performed on an Acquity UPLC BEH C_{18} column from Waters (2.1 × 100 mm; 1.7 µm). The column temperature was set at 35°C and the autosampler was kept at 15°C. The mobile phase was composed of a mixture of acetonitrile (85%, *v*/v) and water (15%, *v*/v) at a flow rate of 0.3 mL/min. Before analysis the mobile phase was filtered through a 0.22 µm membrane filter and degassed by ultra-sonication. A 5 µL injection of each sample was loaded onto the system and total analysis time was 6 min. The diode array detector (DAD) was set at 215 nm. The sampling needle was washed with 300 µL of strong wash (ACN–water, 65:35) to reduce carry-over and 300 µL of weak wash (ACN–water, 30:70). Data acquisition was done using Empower 3 software version 1.0 (Waters, USA).

2.4 | Preparation of stock and working standard solution

PCB 77 and PCB 180 stock solutions of 1 mg/mL were prepared by dissolving suitable amounts of the single drug in methanol. Mixtures of stock solutions of PCB 77 and PCB 180 (100 µg/mL) were prepared in methanol. The IS stock solution of 200 µg/mL was prepared in methanol. The stock solutions of PCB 77, PCB 180 and IS were stable at 4°C for 1 month. Further dilution was made in methanol–water (50:50, *v*/v) to produce working stock solutions for the calibration standards and quality control (QC) standards. The IS working solution (5 µg/mL) was prepared in methanol–water (50:50 *v*/v). Calibration curve samples were prepared in drug-free mouse plasma with the appropriate mixture of working solution of PCB 77 and PCB 180 on the day of analysis. All the samples were stored together at −80 ± 10°C until analysis.

2.5 | Sample preparation

Sample preparation was carried out by the liquid–liquid extraction procedure. Into a 100 µL of aliquot of plasma, 10 µL of IS working solution was mixed for 30 s on a spinix vortex shaker (Tarsons, India). To this, 3.0 mL of *tert*-butylmethylether was added and this was vortex mixed for 5 min. This was centrifuged at 10,000 rpm for 5 min at 4°C on an Eppendorf 5810R centrifuge (Eppendrof AG, Hamburg, Germany). The clear supernatant organic layer (2.5 mL) was transferred into 5 mL polypropylene tubes and evaporated to dryness at 35°C using a nitrogen evaporator (Turbovap®, Biotage, USA). The residue was reconstituted in 100 µL of the mobile phase, vortex mixed for 1.0 min and centrifuged at 10,000 rpm for 5 min. Finally, 90 µL of the clear supernatant was transferred into glass micro-vials and 5 µL was injected onto the UPLC system for analysis.

2.6 | Method validation

The method was validated for selectivity, specificity, recovery, linearity, accuracy, precision and stability using US Food and Drug Administration guidelines (US DHHS et al., 2001) for the assay in plasma.

2.7 | Carry-over and limit of quantification

Carry-over effect was assessed by injecting the highest calibration standard just before blank plasma. The limit of quantitation (LOQ) was defined as the first point of the calibration standard with lowest concentration (signal-to-noise ratio ≥ 10:1) that can be calculated with an acceptable precision and accuracy.

2.8 | Selectivity and specificity

The selectivity of the method was assessed by analyzing pooled drug-free mouse plasma injected at the beginning of the validation and the potential interferences at the LC peak region for analytes and IS were investigated. At least four out of six lots should have a response <5 times the lower limit of quantitation (LLOQ) level response in the same matrix.

2.9 | Recovery

The recoveries of PCB 77 and PCB 180 were assessed by analyses of the three various concentrations (30, 500 and 2250 ng/mL) whereas the recovery of the IS was determined at a single concentration of 5 µg/mL. Recovery was calculated as the extracted spiked plasma peak area response compared with the response obtained for neat standard solution at equivalent concentrations by liquid–liquid extraction process. The analytes responses from the extracted samples at known concentrations were compared with responses of un-extracted standards.

2.10 | Linearity

Linearity was evaluated by linear regression analysis with the use of working standard solutions and spiked plasma samples containing the drugs of interest at different concentrations within the range 10–3000 ng/mL for PCB 77 and PCB 180. The calibration curves were constructed by plotting the ratio of the peak area of each analyte to the peak area of internal standard vs the nominal drug concentration. The slopes and intercept were calculated with least square linear regression analysis of the data with the use of a $1/x^2$ (x-concentration) weighting factor. The acceptance criteria for each back-calculated standard concentration were ±15% deviation from the nominal value except at the LLOQ, which was set as ±20% (US DHHS et al., 2001).

2.11 | Accuracy and precision

The validation method evaluations of the accuracy and precision in the experiments were performed with four independent series (including ruggedness) in plasma. The intra- and inter-day assay accuracy and precision were estimated by analyzing six replicates containing analytes at three different QC levels, that is, 10, 30, 500 and 2250 ng/mL. Accuracy represents the closeness of agreement between the mean values obtained from the series of measurements by the method and the actual value. The accuracy should be within 85–115% of the nominal value, except at the LLOQ, where it should not deviate more than 20% (US DHHS et al., 2001). Precision represents the closeness of agreement among a series of measurements obtained from multiple samplings and was estimated with variances of repeatability (intra-day variances) and intermediate precision (sum of intra-day and inter-day variances). The precision should not exceed ±15% relative standard deviation (RSD), except for the LLOQ, where it should be within ±20% of RSD (US DHHS et al., 2001).

2.12 | Stability

Stability tests were performed to evaluate the stability of analytes in plasma samples under different conditions. The bench-top stability study assessed the stability of analytes in plasma at room temperature for 9 h, whereas a post-preparative stability study assessed the stability of analytes in the treated samples (autosampler stability for 24 h at 15°C) at low (30 ng/mL) and high (2250 ng/mL) QC concentration. Freeze–thaw stability was determined after three freeze and thaw cycles and long-term stability was determined by testing QC samples stored at −80°C for 30 days.

2.13 | Pharmacokinetic study

Animals were exposed to PCB 77 and 180 via inhalation at a dose of 4 mg/m^3 in water for 6 h in a whole body inhalation chamber. Blood samples (150 µL) were obtained using lithium tubes with heparin, using retro-orbital venipuncture at 0.0 (before exposure) followed by 2.0, 4.0, 6.0, 8.0, 12.0, 24.0, 36.0 and 48.0 h after the initiation of exposure. Whole blood samples were centrifuged at 3500 rpm for 10 min and plasma was separated and stored at −80°C until use. The areas under the plasma concentration–time curve (AUC_{0-inf} and AUC_{0-t}) were used to estimate maximum plasma concentration and time taken to reach this concentration (C_{max} and T_{max}) using trapezoidal rule. The half-life of elimination ($T_{1/2}$) was determined using linear regression with sum of least squares method. WinNonlin software 5.1 was used to calculate the pharmacokinetic parameters by noncompartmental model (Pharsight Corporation, CA, USA).

3 | RESULTS AND DISCUSSION

3.1 | Optimization of the chromatographic conditions

We optimised a reverse-phase liquid chromatographic method for simultaneous estimation of PCB 77 and PCB 180 in mouse plasma samples using diode array detection. LC method development was carried out focusing on achieving sufficient resolution of target drugs and endogenous interferences in matrix within a short run time. The method is novel and additionally has certain unique advantages over previously used methods for quantification of chlorinated biphenyl pollutants. First this method has optimum sensitivity in determination of PCB levels in mouse plasma with sparse samples. Adequate specificity has also been

demonstrated in this method for detection of PCB 77 and PCB 180 using an internal standard which has intermediate chemistry.

The method was developed and optimized using a mobile phase with simple composition and a reverse-phase column. The mobile phase and solvent usage are cost-effective compared with the gas chromatography employed elsewhere, and the run time is less time consuming such that a number of samples can be estimated quickly in the prescribed time duration. The method is also simple and can be used for rapid estimation of these congeners in plasma samples during experimental sampling procedures. Finally, the fact that this is one of the first reports of a rapid simultaneous method that has been developed and successfully optimized for quantification of two distinct PCB congeners in plasma cannot be overemphasized.

3.2 | Carry-over and limit of quantification

No carry-over was observed when the highest calibration standard was analyzed just before the blank plasma. This indicated that flow through needle configuration of the injector and the washing step of the column at the end of the chromatography separation were adequate to remove potential residues of the analytes. The LOQ on the calibration curve was 10.0 ng/mL for all of the compounds and the signal-to-noise ratio in plasma was ≥10.

3.3 | Selectivity and specificity

Selectivity was evaluated by comparing the chromatograms of pooled plasma and pooled plasma spiked with IS with analytes (10 ng/mL) and IS. A kinetic study sample was obtained after 4.0 h of inhalation at a dose of 4 mg/m^3 (PCB 77 and PCB 180). As shown in Figure 1, no interfering peaks from endogenous compounds were observed at the retention times of analytes and IS. The total chromatographic run time was 6 min.

3.4 | Recovery

Liquid–liquid extraction technique gave adequate recovery and clean samples. The results of the evaluation of neat standards vs plasma extracted standards were estimated for PCB 77 and PCB 180 (30, 500 and 2250 ng/mL) and the mean recoveries were 90.10 ± 1.34 and 89.51 ± 1.52%, respectively. The recovery of IS at 5 µg/mL concentration was 87.11 ± 2.70%.

3.5 | Linearity

The calibration curves exhibited excellent linearity with regression correlation coefficient (r^2) >0.996 over the concentration range of 10–3000 ng/mL for all of the drugs in mouse plasma. The standard calibration curve had a consistent reproducibility over the standard concentrations across the calibration range. A typical regression equation was prepared by determining the best fit of peak-area ratio (peak area analyte/peak area IS) vs concentration, and fitted to $y = mx + c$ using a weighting factor ($1/x^2$). The lowest concentration with the RSD <20% was taken as the LLOQ and was found to be 10.0 ng/mL for the PCB 77 and PCB 180. The percentage accuracies observed for the mean of back-calculated concentration for four calibration curves for the entire drugs were within 96.10–102.50%.

3.6 | Accuracy and precision

Accuracy and precision of the method evaluated intra-day (repeatability) and inter-day (intermediate) for mouse plasma for all of the drug samples are summarized in Table 1. The intra- and inter-day precisions were <4.64% and the accuracy ranged from 98.90 to 102.33% at all levels. All of the values were within the accepted range and the method was accurate and precise.

3.7 | Stability

The stabilities of PCB 77 and PCB 180 in mouse plasma were investigated under a variety of storage and process conditions, in plasma at room temperature for 9 h, in the autosampler for 24 h at 15°C, after three freeze–thaw cycles and after long-term storage at −80°C for 30 days, and are summarized in Table 2. The results indicated that PCB 77 and PCB 180 were stable under the conditions described above.

3.8 | Applicability of the validated method

In this study, we report a rapid simultaneous liquid chromatographic method for quantifying PCB 77 and PCB 180 in mouse plasma. For

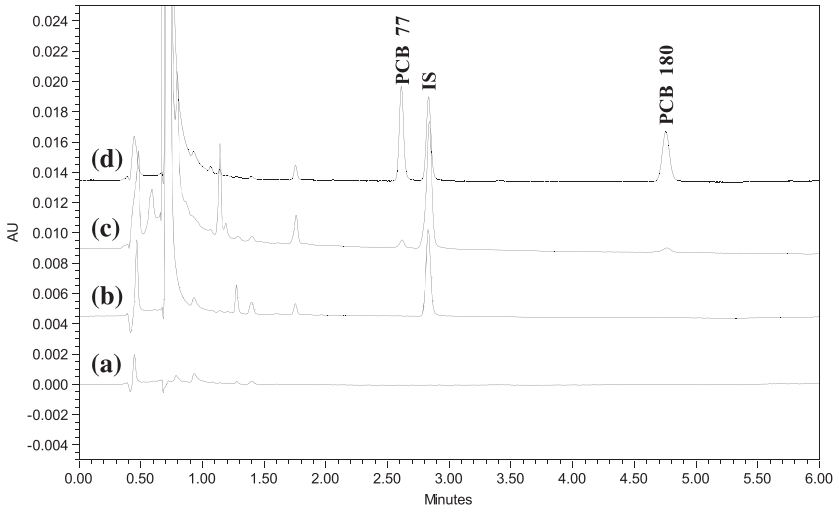

FIGURE 1 Representative UPLC chromatograms of polychlorinated biphenyl (PCB) 77, PCB 180 and IS in mouse plasma. (a) blank plasma sample; (b) blank plasma sample spiked with IS; (c) blank plasma spiked with analytes (10 ng/mL) and IS; and (d) pharmacokinetic plasma samples collected from mice at 4.0 h time point following inhalation exposure to PCBs

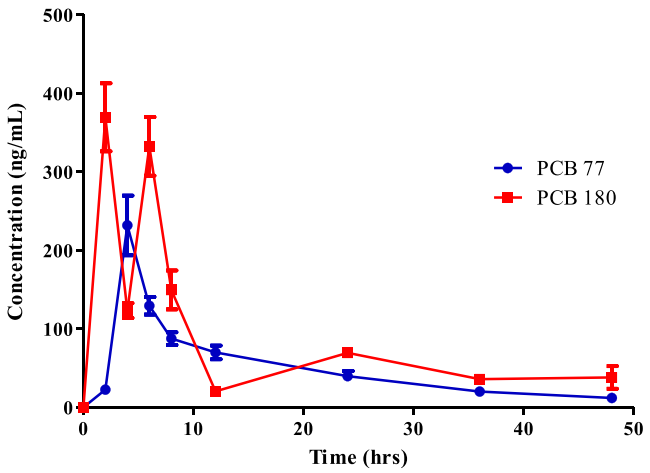

FIGURE 2 Mean plasma concentration–time profile of PCB 77 and PCB 180 in mouse plasma after inhalation of PCBs at 4 mg/m^3 dose

PCB 77, the AUC_{0-inf} was 2640.37 ± 300.92 ng h/mL, as compared with 4855.76 ± 733.19 ng h/mL for PCB 180. Similarly, the AUC_{0-t} was 2387.12 ± 280.64 ng h/mL for PCB 77 which is less than the value of 3761.24 ± 375.65 ng h/mL obtained for PCB 180. The C_{max} for PCB 77 was 231.76 ± 37.90 ng/mL. The C_{max} for PCB 180 was greater as compared with that of PCB 77, which was 369.47 ± 43.24 ng/mL. The T_{max} for PCB 77 was 4 h, which was twice that for PCB 180. The half-life of elimination of PCB 77 from plasma was 14.11 ± 1.94 h, which was less than the value obtained for PCB 180, i.e. 19.34 ± 7.26 h. The profile of mean plasma concentration of PCB 77 and PCB 180 vs time is shown in Figure 2.

4 | CONCLUSION

A simple, sensitive, and reliable UPLC method has been developed and validated for simultaneous determination of PCB 77, and PCB 180 in mouse plasma. This UPLC method has significant advantages, including good resolution between peaks and adequate extraction recovery with shorter chromatographic run time. The current method has been optimized for estimation of PCB congeners of diverse chemical properties, with high precision and accuracy. It is also highly cost and time effective, while not compromising the recovery and yield. We have developed a quick and reliable method to estimate PCB congeners in mouse plasma samples, which could be applied in regular measurement of these pollutants in occupational hazard risk assessment. Finally, this method is comparable to if not better to gas chromatographic methods reported previously, in terms of analytical validity and practicability.

ABSTRACT

***Introduction*:** Many students in the II MBBS curriculum find difficult to learn Pharmacology. II MBBS students do not have many opportunities to observe the clinical effects of the drugs as they read about, making learning experience largely theoretical. To improve the learning experience and to facilitate recall by providing an opportunity to observe the clinical effects of drugs using simulation a practical way of teaching method in Pharmacology would improve student understanding of the role of drugs in a given clinical scenario and it would improve their prescription writing skills. ***Methods*:** 29 II MBBS students attended a lecture class on drugs used in bronchial asthma and underwent a pre-test, followed by demonstration of management of acute exacerbation of bronchial asthma in a simulation model, in smaller groups. Later, their individual management of the simulated patient was assessed by observation & they were asked to write a prescription for maintenance therapy for their patient. A post-test was conducted one month later. ***Results*:** All students improved their post-test scores, and this was especially marked in those who had scored less than 50% in their pre-test. 70% of students were able to revert bronchospasm within 15 minutes and all students wrote a correct prescription for maintenance therapy. ***Conclusions*:** Thus, simulation mode of teaching improved the learning skill and outcome, with an added advantage of knowing to interpret clinical data to select the appropriate drugs to solve the clinical problem.

KEYWORDS: Bronchial asthma, II MBBS learning, novel pharmacology practical method, novel teaching method.

INTRODUCTION

Undergraduate medical students learn Pharmacology through regular lectures and few types of practical methods. Even though they have early clinical postings in various clinical departments to observe /understand the basic concepts like history taking, value of interpretation of lab reports to the related clinical situation and treatment given, there is less chances to observe and interpret /visualize various effects of drugs other than animal experiments, Computer assisted learning, video based teaching, problem based teaching /learning which are used currently in traditional method as an informative session to improve their

knowledge. This many time overload the students with more information with knowledge gain and may or may not be creating interest in students to practice reflective thinking and better understanding.**(1,2)** Hence, to understand pharmacology in the 2nd professional MBBS program, to acquire good prescription writing skill, the undergraduate MBBS students need some exercises with application based assessment example - learning with need for writing correct , effective prescription individually than making them to recall theory and writing in a paper as simple practical assessment. . In present scenario, students need imagination and memorizing skills, since majority of the assessment in II MBBS program is recall type and do not have much scope for rational thinking.

Pharmacology is a science in the MBBS Curriculum where students are given a complete knowledge of drugs and their role in therapeutics. They are expected to write a complete and rational prescription for any given condition at the end of the year. Teaching is primarily lecture-based and students do not have many opportunities to observe or visualize the effects of the drugs. **(1, 2)** As part of our continuous commitment to improve quality, to observe and interpretation of drug effects in a realistic model like simulation would positively influence the undergraduate medical students self learning habits and enable them to learn therapeutics effectively during MBBS training to value the rational prescription skills**.(3,4,5)**
Simulation, when used as an adjunct in the II MBBS lecture-based program helps the students to bridge the theory –practice gap. **(6)** Hence we planned this study to evaluate the use of simulation as a teaching method in Pharmacology. Our objectives were to investigate if the use of SimMan 3G high fidelity manikin, a wireless human patient simulator represents an average-size adult patient useful in teaching core skills like airway, breathing, cardiac, and circulation management with attached patient monitor that displays vitals, labs, and X-ray. This high fidelity manikin is effective in recognizing, identify drugs and dose with programmable response as simulation based learning environment a practical teaching method to improve student understanding of the role of drugs in a given clinical scenario with specific route and dose of administration and whether it would improve their prescription writing skills.

MATERIALS AND METHODS:

The study was conducted at the Department of Pharmacology and Centre for Clinical Simulation and Research, in a private Medical College after obtaining ethical approval from the Institutional Human Ethics Committee.

A. *Pre and Post-test model*

Second MBBS student volunteers (n=30) were participated in this observational study after signing written informed consent using one group pre and post-test model. All students were listened to a preliminary lecture class on the Pathophysiological approach to the pharmacotherapy of bronchial asthma and the management of acute exacerbations of chronic asthma. They were provided with learning material and after a month, were asked to attend a pre-test, a short test with multiple choice questions on the management of acute exacerbation of bronchial asthma and the interpretation of clinical parameters related to assessment of severity of the exacerbation. After the pre-test, smaller groups of student participants were taught the management of acute exacerbation of bronchial asthma, with stepwise therapy according to the severity of symptoms in a simulation model. They were assessed individually, within a month of their demonstration exercise, by observation of their

management of acute exacerbation of bronchial asthma in the simulation model (NAEP guidelines, ERP-3, 2007 Bethesda US).**(7)** This was followed by post-test with the same pre-validated multiple choice questions, one month later. Learning outcome of each student, who had voluntarily participated in this study with variable learning potential was compared before and after the simulation method of learning.

*Methodology for SimMan 3G High fidelity simulator way of learning **(8)***

To determine whether the students would be able to select and administer the appropriate drug/s to relieve bronchoconstriction in an acute exacerbation of chronic asthma model using SimMan 3G – High Fidelity simulator with in ½ hour to 1 hour, the following methodology (Figure -1) was used.

B. *Learning assessment after exposure to Simulation Model*

I- *Quantitative Assessment*:

A questionnaire was administered to each student after he/she completed the exercise on the simulation model. The first part of the questionnaire was for quantitative assessment, and questions were meant to assess the students' practical knowledge gained through their performance in the asthmatic simulation model. Students were asked to name the drug that had the fastest onset of action and its route of administration. They were also asked to write a prescription-on-discharge for maintenance therapy of the patient they had managed in the simulation model. A Questionnaire with three questions was used in this study mainly to know how the students were able to tackle the problem given to them using problem solving ability in simulation method, with an intention to rate the difficulty level of this simulation method by the students. Parameters like interpretation of the clinical investigations like PO_2, HR, RR etc, to choose the drug to reduce the symptoms based on the clinical parameters, to select and apply appropriate drug with route to reduce symptoms using pathophysiological approach were incorporated in the questionnaire. All the students were requested to rate this parameters with likert scale where 0 is no difficulty level, 1 is 20% difficulty and 5 is 100% difficulty. This is to check the friendliness of simulation technique students were asked to rate their difficulty in solving various aspects of the clinical problem they had encountered.

II -*Qualitative assessment:*

The students were asked to describe their opinion in learning through this mode of teaching and whether it improved their ease of recollection of pharmacological principles through a questionnaire. They were asked to describe the barriers to learning, if any, in the simulation mode of teaching and to rate their confidence in handling a similar clinical situation.

RESULTS:

Out of 30 volunteers students, 29 students completed the study and were included in statistical analysis. One of them dropped out as she was unable to attend the initial pre-test. 29 students completed the study and were included in statistical analysis. The pre-test and post test scores on comparison by paired-t test showed a statistical significance (P=0.001) with SPSS version 19.

There was improvement in post-test scores compared to pre-test scores and this improvement was especially marked in those students who had scored less than 50% in the pre-test (Figures 2 , 3 & 4). The vast majority of students (70%) were able to revert bronchospasm

in the acute asthma model in SimMan-3G in less than 15 minutes by timely and appropriate intervention with drugs. Only 10% of students required more than 20 minutes (Figure 5).

Quantitative Analysis

Most of the students found it very easy to interpret clinical parameters as part of the management of bronchial asthma in the simulation. Only 13% (n=4) of the study participants (n=29) felt a difficulty level of 20%. Almost all students were able to correctly identify the drug for producing effective bronchodilation with immediate improvement in oxygen saturation in the simulation model. Only 7% (n=2) of the study participants failed to identify an appropriate bronchodilator. All the students were able to write a correct prescription for 10 days maintenance therapy after discharge of the simulated patient, and all of them were able to write the correct dose and route of drug administration.

Qualitative Analysis

All the student participants were asked to answer few open ended questions to assess parameters like any barrier to choose drugs, able to give appropriate prescription for maintenance therapy, simulation mode of learning whether improved their confidence, facilitate recollecting pharmacological principles, able to solve clinical problem using simulation. All the student participants were able to confidently manage the clinical scenario through this learning method and felt that it was easy to clinically apply the pharmacological principles of each drug used. All the students were also confident of giving an appropriate prescription for maintenance therapy after managing the acute exacerbation of asthma and did not encounter any barriers in the choice of appropriate drugs. Simulation improved the student's self-confidence and helped them to recollect the pharmacological principles and apply these principles rationally in therapeutics.

DISCUSSION:

We had carried out a questionnaire-based survey to understand the efficacy of our teaching methods in the students' ability to apply their theoretical knowledge of the pharmacological concepts of drugs in clinical application. We surveyed II MBBS, Final MBBS (end of course) and CRRI (end of internship) to analyze if the training imparted during the Pharmacology course was sufficient for clinical application of pharmacological concepts, according to their current requirement. We identified the need for an active teaching method to enable students to think, apply and reinforce their prescription-writing skills. Because this simulation based exercise is related with assessment and students has commitment to solve given clinical situation using simulation surprised us, that students would have an improved learning experience if they were given the opportunity to observe the clinical effects of drugs in a simulated environment and that this would improve their self-learning and practical skills.**(3,4)**. Present medical undergraduate curriculum-pharmacology teaching under MCI guidelines, facilitate medical students to require good prescription skills with the knowledge on pharmacoeconomics, effective dose calculation, value of drug interactions, appropriate selection of drugs with appropriate Pharmacotherapeutic reasoning, adverse drug reaction(ADR) impact in clinical setup and the need to report ADR to Pharmacovigilance centre, importance of rational use of medicine in clinical practice (RUM) through practical's and in theory classes. Even though all the students are taught and assessed with suitable assessment method, how many students are really carrying the core principles of

pharmacology to clinical practice is not clear and difficult to judge.**(5)**

Pharmacotherapeutic knowledge can be suitably kindled with case based discussion, problem solving exercises to improve the quality of RUM and to develop good prescription writing skills during undergraduate training program. Unless there is an active demonstration of these training, students may tend forget these practical concepts before they become trained medical professional to undergo internship with minimum theory knowledge. **(5)** Majority of the practical pharmacological assessment are carried out in writing like recall, except very few exercises with OSPE format, may be one of the factor which can induce lack of importance about the applied aspect of the subject pharmacology by the students.

In this study, when students were assessed with pretest after routine theory class on bronchial asthma with pathophysiological way of approaching the disease, to provide good clinical care with clinical Pharmacotherapeutic knowledge, students were scored less than 50%(Figur2-IA), but the same set of students expressed better assessment after witnessing the clinical problem through simulation and the students' scores were more than 50% (Figur2-IA) clearly exhibits the need of clinical way of leaning pharmacology in undergraduate curriculum.**(5)** This might improve the value of learning pharmacology to self-improve good prescription skills during medical undergraduates training.

Simulation provides more chances to create realistic scenarios and to undergo training, retraining with many times possible. But with patients, medical undergraduate students have little limitation to provide treatment and allowed to observe the treatment procedures, which may not improve the real skill or competency expected to treat the similar clinical situation. Even they make mistakes during problem solving skills training, it's correctable and with their own pace students can work with simulated patients which is not possible with real patients. These type of training will help the student to develop required skill personally whether real patients available or not. Though this model is very expensive and need special preparation, training and time consuming, when it's used as a learning tool to visualize drug effects during undergraduate training program will definitely improve the quality of training and competencies like problem solving, decision making and interpersonal, drug selection, prescription writing skills expected in the medical undergraduate training.

This study also demonstrated that, pharmacology can be learned in a realistic way using simulated patients not only for one clinical reason but also when there is a change in patient based information's or monitoring the patients vitals for achieving the treatment goal effectively with rationale prescription/ selection of drugs which in turn to value the students responsibility as a future physician. This may motivate the students to learn pharmacology in a systematic way by reading the text books appropriately not only with motive to pass university exam purpose but also equip personally with pharmacological knowledge to solve clinical problems with good drug selection /application skills. by reading text book appropriately.**(6)** In this study after managing the simulated asthma patient, students were also asked to name the drug with the fastest action in relieving bronchospasm, with its route of administration, based on their experience in the simulated patient, to rate their difficulty in choice of drug and in understanding the clinical parameters used to assess the severity of the clinical problem of the simulated patient and students comfort level (quantitative and

qualitative assessment) revealed students improved organizational skills to solve the given simulated patient problem.**(6)**

Initially 30 students volunteered to participate in the study, but one withdrew. There was a significant improvement in post-test scores for all participants (Figures 3 and 4), but this improvement was especially marked in those students who had scored less than 50% in the initial pre-test (Figure 2). Overall 70% student participants were able to revert bronchospasm within 15 min and 30% took more than 15 min (Figure 5). This method of study closely followed *Kirkpatrick's four levels of assessment* of students learning through simulation method. **(9)**

Level 1: *Assess the simulation training and participant's reaction:*

Initial theory class followed by observing the simulated patient, responsibility to select appropriate drugs in suitable route of administration to reduce the seriousness of the problem with well appreciated learning environment by all the students (Qualitative Analysis)

Level 2: *Improvement in knowledge*. Comparison of pretest and posttest scores (Figures 2, 3 & 4) after students were exposed to simulation , a method to self understand the clinical importance of the given clinical problem solving attitude showed a remarkable shift in the learning outcome in both poor and good performers alike. When pre and posttest scores were compared for poor performers alone, the scores had almost doubled (Figure 2) expressed the need of clinical way of learning pharmacology will provide better understanding of the subject than by memorizing all the Pharmacotherapeutic concepts.**(2)**

Level 3: *Behavioural change or knowledge application in a clinical setting:*

By answering open ended questions, all the student participants were confident, able to recollect pharmacological principles in the applied format as per the situation or clinical requirement and were able to give a correct prescription (Qualitative analysis).

Level 4: *Impact of simulation training in terms of result*:

Simulation mode improved the learning skills (qualitative analysis) and outcome in terms of marks /knowledge gained (Figures 2, 3 and 4) with an improvement in interpretation of clinical data related to clinical scenario (integrated approach) to select the appropriate drugs to solve the clinical problem (Figure 5).

Studies express that if students are provided with an opportunity to learn in a simulated environment, their learning experience is improved. When they are given an opportunity to observe the clinical effects of the drugs they read about, both their self-learning and their practical skills improve, as a result of moving the students' emotions associated with learning in a positive direction.

High fidelity simulation adopted in this study depends on the type of outcome to be achieved with respect to student's level of learning.(10) This study facilitated the 2nd professional MBBS student participants to understand and interpret the effects of anti-asthmatic drugs using SimMan 3G – High Fidelity stimulator.

This study also exhibited similarity with *Kolb's learning cycle* and professional competency in learning process as an outcome (Figure - 4, 5) by:

a) Students experienced the actual medical problem (acute exacerbation of chronic asthma model) given to them through simulation method

b) Students were able to explore the reasons for the observed clinical problem through recall of their theory exposure

c) Students were able to recall their knowledge to interrelate and execute plans to stop/ overcome the problem exposed to them through simulation

d) Students were able to apply solutions to overcome/limit the clinical problem given to them using simulation method.

CONCLUSION:

Hence, this study clearly exhibited the positive role of simulations on changing learning outcome in MBBS professional teaching and training process and showed an improvement in knowledge gained after simulation (Figure 4) with their learning objective.**(10,11)**Through this study, simulation mode of teaching and learning environment has proved a definite influence on the student mindset for self -learning and kindled interest to teach/learn the subject effectively to achieve the long term goal of clinical application of pharmacological science in undergraduate medical students training. Small sample size of the study participants and questionnaire (quantitative analysis) which is not prevalidated were the limitations of this study.

ACKNOWLEDGMENT:

We express our sincere thanks to the management of PSG Institutions for providing the infrastructure with SimMan 3G High fidelity simulator. Our heartfelt gratitude to the MCI Nodal Centre, Christian Medical College, Vellore, TamilNadu, for their guidance in the design of this project. We also thank the II MBBS student volunteers, The Dean and PSG IMS & R and Hospitals, Centre for Clinical Simulation and Research Lab, Dr. Breetha, of PSG IMS&R, for their help in the execution of this study.

ABSTRACT

Knowledge regarding use of medicine to school teachers is an important component of the overall health care delivery system of any country. School teachers need to be aware of rational use of medicines because health education provided by them may have an immediate effect on students, their parents and also to the community. This study is aimed to evaluate the medication practices of school teachers in Coimbatore including the both city and rural areas. It is a Cross sectional study using a preformed questionnaire conducted from October 2014 to January 2015 among 400 school teachers working in both government and private schools in Coimbatore (urban and rural areas). After IHEC approval, permissions from the school authority were obtained. Written informed consent was obtained from the participants. Through preformed study Questionnaire data was collected from the participants and results were analyzed. Among the voluntarily participated participants it was found 86.5% follow doctor's advice for their personal ailments and nearly 76% of teachers do not visit physician for basic complaints. About 44.5% give medications to children without doctor's prescription or advice. Around 73% had agreed upon the importance of full course of medicines as per the prescription. This study revealed a wide gap in the knowledge of health habits and medication practices, which can be overcome in future with personal or group discussion in the form of workshop to alleviate the doubts in their minds, since we understand that teachers are the best medium to disseminate the concept of rational use of medicines to the society.

Keywords: Knowledge, Medication practices, School teachers.

INTRODUCTION

Appropriate use of medicines plays an important role in clinical practice. Both the health professionals and the public need to be aware of the rational drug usage and the consequences of inappropriate or irrational use of medicines having ill effects on health. Almost half of all medicines are used irrationally all over the world according to WHO. Globally up to 80% of illness episodes are self-treated with modern pharmaceuticals[1].This can have severe outcomes like drug resistance, adverse drug reactions, prolonged illness and even death. Lack of access to medicines and high financial cost are some of the common reasons particularly found in developing countries like India.

Knowledge regarding use of medicine to school teachers is an important component of the overall health care delivery system of any country[2]. School teachers need to be aware of rational use of medicines because health education provided by them may have an immediate effect on students, their parents and also to the community. This study is aimed to evaluate the medication practices of school teachers in Coimbatore including the both city and rural areas.

The World Health Organization has defined Rational Use of Drugs as follows: "Patients receive medicines appropriate to their clinical needs, in doses that meet their own individual requirements, for an adequate period of time, and at the lowest

cost to them and the community" [3]. Irrational use of medicines includes overtreatment of a mild illness, inadequate treatment of a serious illness, misuse of anti-infective drugs, over-use of injections, self-medication of prescription drugs and premature interruption of treatment[4].

People have several reasons for irrational use of medicines like lack of knowledge or skills, unrestricted availability of medicines, overwork of health personnel, inappropriate promotion of medicines and profit motives from selling medicines. There are twelve core interventions by WHO to promote more rational use of medicines and public education is one among them. Without sufficient knowledge about the risks and benefits of using medicines and when and how to use them,

People will often not get the expected clinical outcomes and may suffer adverse effects. This is true for prescribed medicines, as well as medicines used without the advice of health professionals[3].

Children spend a considerable part of their life in school exposed to a variety of environmental, physical, emotional and social influences. School is the place where the child learns how to interact, behave with others and to give and accept respect and the school teachers are the one who are creative, caring, dedicated, determined and have the ability to shape up the students to shine as a responsible person in the community. As teachers play an important role in educating their students and are regarded as learned and respected persons in local communities it is important that they have proper knowledge about medicines[5, 6]. This knowledge can be transferred to their students, their parents and members of the community.

A study done in Kuwait among school children found that self-medication among adolescents shown to be high and teachers considered teaching their students about the proper use of medicines so important that it should be included in the national curriculum of health education[7]. Similarly, another study done in Poland illustrated that appropriate informational devices implemented in primary and secondary schools could play an influential role in reducing the strain of community-acquired infections. The resource improves knowledge about microorganisms, hygiene and antimicrobial agents, and can be targeted at pupils, teachers and parents[8]. A pre-post comparison of a community intervention in Nepal has also shown the seriousness and gain of educating school teachers and their impact on students[9]. Another questionnaire based study done before and after

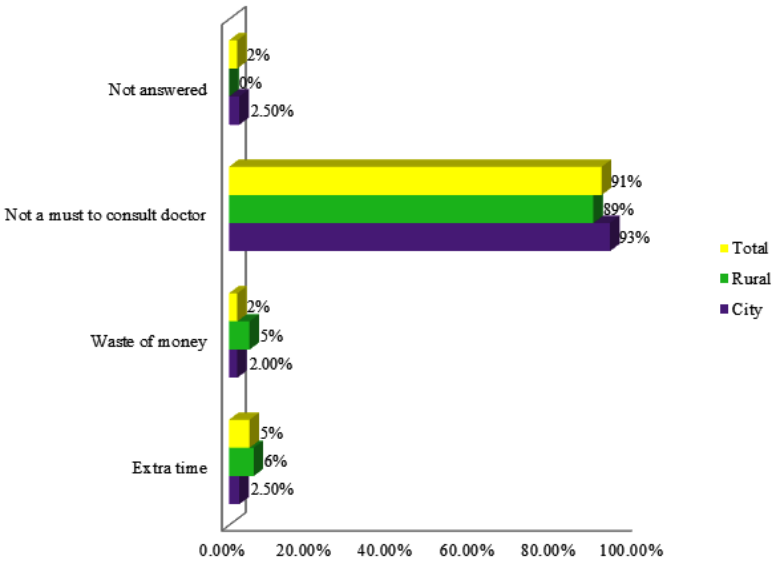

Fig. 1: Reasons for not visiting doctor for basic complaints

the educational intervention in Nepal regarding the knowledge, attitude and practice towards medicines among school teachers showed overall improvement in total scores post-intervention [10]. Similarly a study done among literate consumers in Dehradun found the habitual stocking of medicines, awareness regarding the expiry period of medicines and their self-perception in usage of medicines in addition to the doctor's advice[11].

In developing countries like India where the morbidity and mortality rates are high, awareness on rational medication usage is necessary to the society. At schools students are taught different subjects including topics like human body, health and nutrition, environmental health and personal hygiene. Teachers who teach the students should have at least a basic knowledge in using medicines which can be transferred to students and through them to parents and the community.

Table 1: Knowledge of school teachers in percentage for the given questionnaire

S.No	Questions	City (%)		Rural (%)		Total (%)	
		Yes	No	Yes	No	Yes	No
1	Do you visit doctor for a basic complaint (eg. headache, body pain)?	22	78	27	73	24	76
2	Do you purchase medicines from pharmacy without a doctor's prescription?	19	81	11	89	15	85
3	Do you follow the instructions given by the doctors / pharmacists to use drugs appropriately (eg. antacids in empty stomach)?	88.5	11.5	84.5	15.5	86.5	13.5
4	Would you agree purchasing full course of medicines as a must as per the prescription?	71	29	74.5	25.5	73	27
5	Do you have the habit of checking expiry date before intake of medicine?	97.5	2.5	94.5	5.5	96	4
6	Do you give adult medications to children?	6	94	2	98	4	96
7	Do you use the same prescription given by the doctor for a particular health complaint once again without consulting him?	35	65	26	74	31	69
8	Do you have the habit of using your family member's medications for your health complaints?	10.5	89.5	13.5	86.5	12	88
9	Are you regularly maintaining first aid box in school?	93.5	6.5	97	3	95	5
10	Do you have the habit of giving medications to children without doctor's prescription/advice? (Eg. fever-paracetamol, pain-buprufen, cough-cough syrup, diarrhea-oral rehydration powder)	48	52	41	59	44.5	55.5
11	Have you shared fellow staff member /family members with your medicines?	19.5	80.5	16.5	83.5	18	32
12	Do you have the habit of stocking medications at home to use in case of emergency?	66	34	64.5	35.5	65	35

Coimbatore is the second largest city in Tamil Nadu state in India which is surrounded by the Western Ghats and known for its pleasant climate. It is credited as the "Manchester of South India" due to its cotton production and textile industries. Coimbatore has a population of 1,601,438 with an average literacy rate of 82.43%[12].Though the city is known for its traditions; heavy industrialization has resulted in the growth of trade unions. There are various ethnic groups settled here as a result of increased economic growth and job opportunities. So this study is planned to evaluate the medication practices of school teachers in the city and rural areas of Coimbatore.

Aim & objective

To evaluate the medication practices of school teachers in the city and rural areas of Coimbatore.

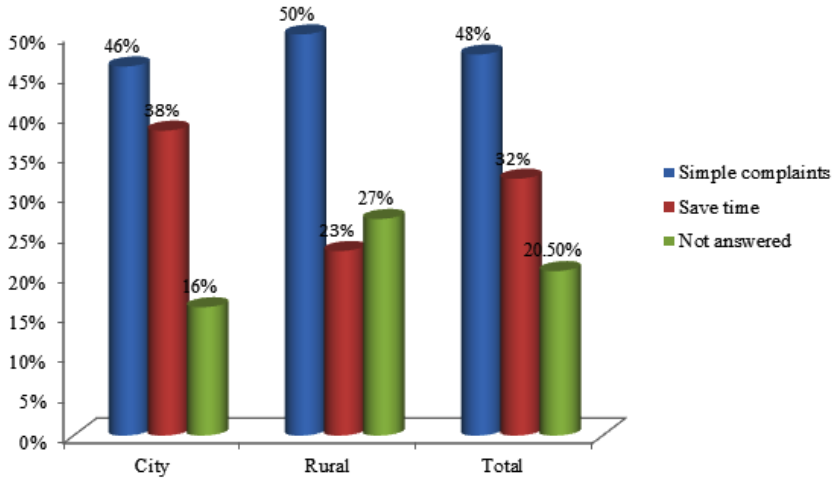

Fig. 2: Purchasing medicines without prescrption - Reasons

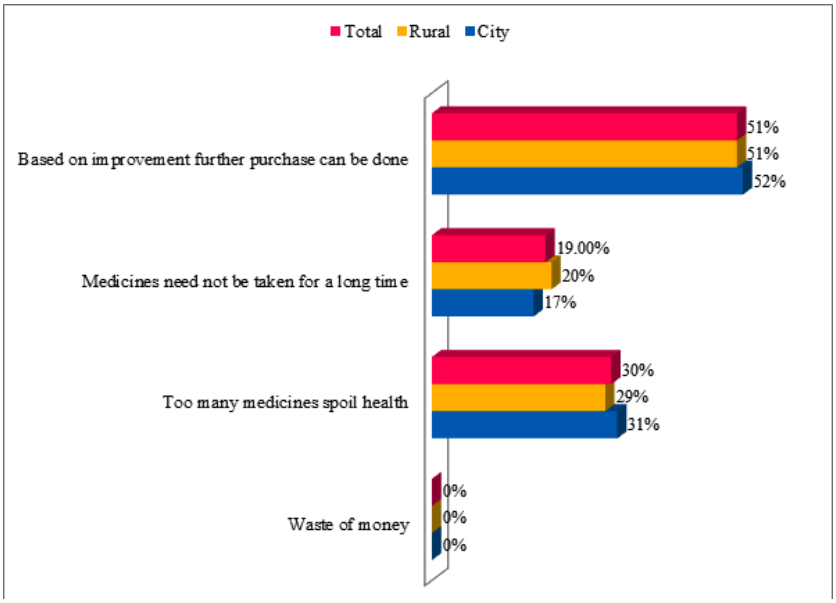

Fig. 3: Reasons for not purchasing full course of medicines

Methodology

A Cross sectional study was done using a preformed questionnaire during the period of October 2014 to January 2015. There were four hundred school teachers working in both government and private schools situated at urban and rural areas of Coimbatore district voluntarily participated in this study.

After getting approval from IHEC, then. Permissions from School management were obtained. Written informed consent from the participants and the Questionnaire was filled by them. Finally, the results were analyzed in percentage (frequency distribution) and the study was completed.

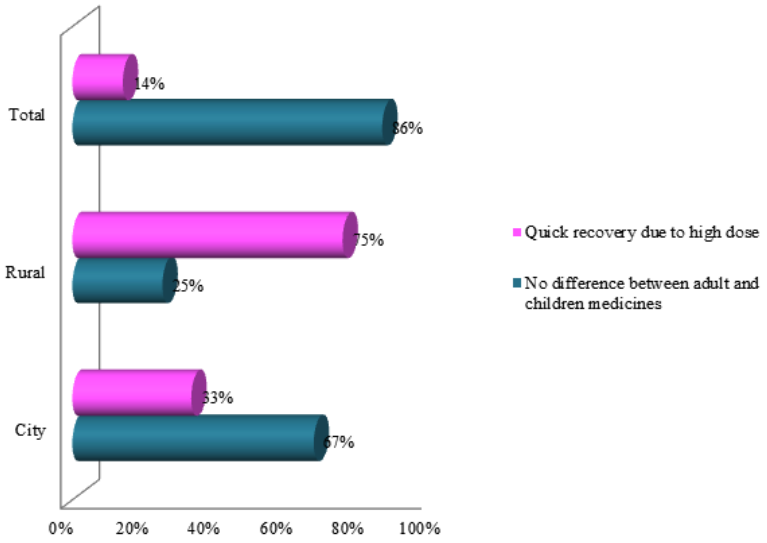

Fig. 4: Reasons for giving adult medications to children

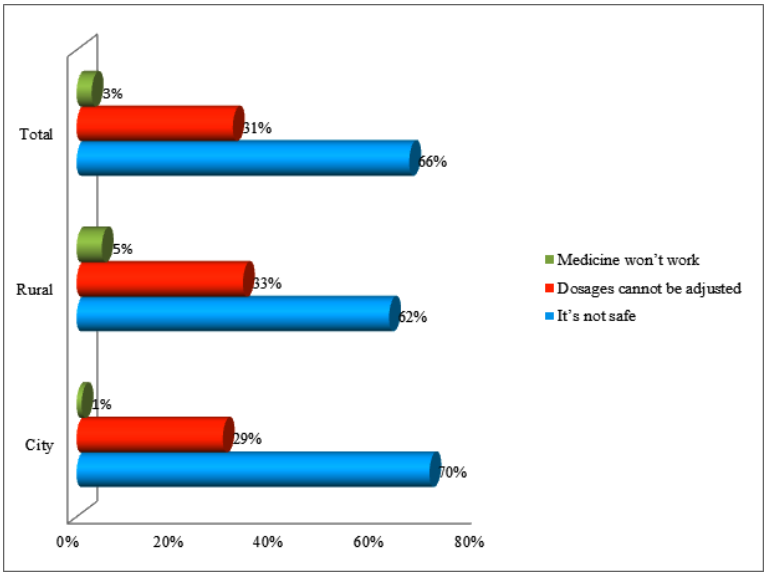

Fig. 5: Reasons for not giving adult medications to children

RESULTS

Among the School teachers who voluntarily participated in this study, we found 86.5% follow doctor's advice for their personal ailments. However, nearly 76% of teachers does not visit physician for basic complaints. About 44.5% give medications to children without doctor's prescription / advice. Around 73% agree the importance of full course of medicines as per the prescription. (Table 1)

DISCUSSION

This cross sectional study using a preformed questionnaire was done to evaluate the medication practices of school teachers in the city and rural areas of Coimbatore district. Over 400 school teachers working in both government and private schools including primary, middle and higher secondary schools in Coimbatore district after obtaining permission through proper channel from the school management participated in the study. The teachers were given a brief explanation about the study and after obtaining informed consent they were asked to fill up the questionnaire.

In this study only 22% from city, 27% from rural areas visit doctor for basic complaints (Table.1) and most of them (93%) consider that it is not necessary to visit doctor for simple / basic complaints (Fig.1).

Around 81% from city and 89% from rural areas said that they won't purchase medicines without doctor's prescription (Table.1)[11]. About half of the study population said that they purchase medicines without prescription for minor or simple complaints. Others have mentioned that it takes lot of time to consult a doctor and in order to save time they purchase by themselves (Fig.2).

Most of the school teachers from both city (88.50%) and rural (84.50%) areas have said that they follow the instructions given by the doctors / pharmacists to use drugs appropriately [eg. taking antacids in empty stomach] (Table.1).

In this study around 71% of school teachers from city and 74.50% of school teachers from rural area (Table.1) purchase full course of medicines as per prescription given by the doctor. Remaining

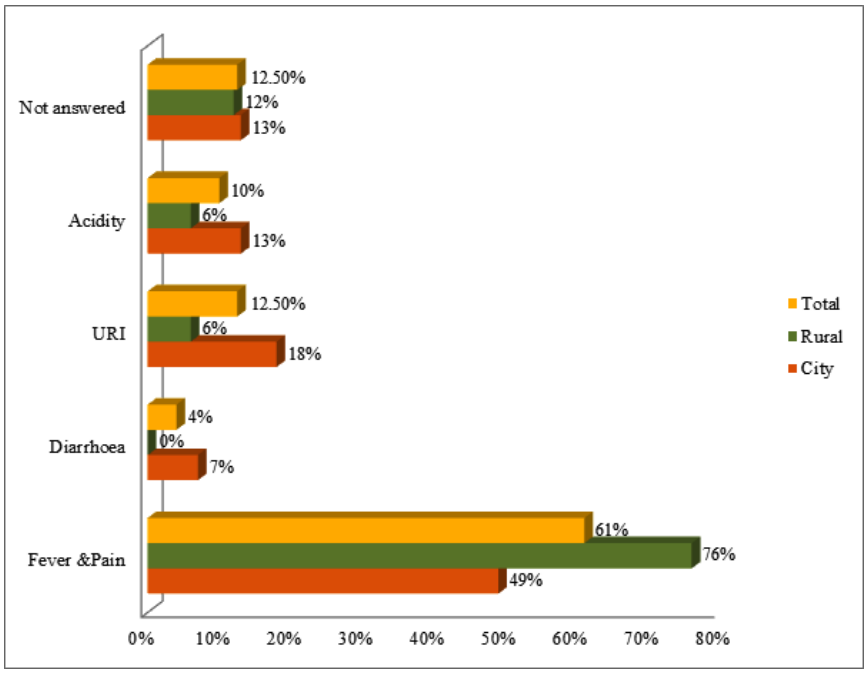

Fig. 6: Health problems for sharing your medicines with others

teachers have answered that based on improvement of symptoms further purchase could be done (around 50%), some teachers answered that medicines need not be taken for a long time and others said that too many medicines would spoil their health (Fig.3).

Among the 400 school teachers, around 96% (97.50% from city and 94.50% from rural areas) have answered that they would check the expiry date before intake of medicine (Table.1).

Most of the teachers participated in the study answered that they would not give adult medications to children (Table.1). The most common reason was that it is not safe to give adult medicines to children (70% in city % 62% in rural area) followed by dosages cannot be adjusted for children and medicines given for adult won't work for children (Fig.5). Very few teachers answered that they give adult medications to children because there is no difference between adult and children medicines and quicker recovery occurs due to high dose as given for adults (Fig.4).

Around 35% from city and 26% from the rural areas have answered that they use the same prescription again and again for getting the drugs from pharmacy without consulting a doctor (Table.1).

Only 10.50% from the city and 13.50% from rural areas use their family members medications for their health complaints (Table.1).The reasons they have mentioned for using their medicines were that they use only for simple complaints or they have similar complaints as them. Most of them did not use their family members' medicines as they considered them to be not safe or they have different health complaints not related to them.

Regarding the maintenance of first aid box in the schools, around 93.50% from the city and 97% from the rural areas have answered that they regularly maintain the first aid box in their schools (Table.1).

In this study it was found that almost half of the school teachers (48% from city and 41% from rural) give medications to children without doctor's advice or prescription (Table.1).

Regarding sharing of their medicines with the staffs or family members, only about 19.50% from city and 16.50% from rural areas share their medicines with others (Table.1). They mainly used to share medicines for fever, pain, acidity, diarrhea and respiratory infections (Fig .6).

In this study it was found that around 66% from city and 64.50% from rural areas were stocking medications at home (Table.1).Only some of the teachers have mentioned the drugs that they stock at home. They used to stock analgesics, cough syrups, antacids and anti diarrheal medications.

CONCLUSION

From the above results it was found three fourth of school teachers practice self-medication for basic complaints and one third teachers share their medicines with family members. Nearly half of participants administer medicines to their children without a prescription

This study revealed wide gap in the knowledge of health habits and medication practices, which can be overcome in future with personal / group discussion in the form of workshop to alleviate the doubts in their minds, since we understand that teachers are the best medium to disseminate the concept of rational use of medicines to the society.

Received: 01 May 2017, Revised and Accepted: 25 May 2017

ABSTRACT

Objectives: Agomelatine is a novel melatonin (MT) receptor agonist at MT 1 and 2, serotonin receptor antagonist and an effective chronobiotic agent. The study was designed to evaluate the effects of agomelatine on body weight and food intake in restraint stress model in adult Swiss albino mice.

Methods: After the approval of Institutional Animal Ethics Committee, 40 male Swiss albino mice were randomly divided into four groups of 10 animals each; two were treatment groups which received 25 mg/kg (low dose) agomelatine, 50 mg/kg (high dose) agomelatine, standard group given trazodone and the control group administered the vehicle (1% hydroxyethyl cellulose [HEC]) intraperitoneally for the last 14 days in the 3 weeks study period. Chronic restraint stress was given for 4 hrs per day for all groups starting from day 0 to 21.

Results: Using paired t-test, both 12 hrs ($p=0.011$) and 24 hrs ($p<0.001$) food intake in the high dose agomelatine group were significantly increased. Between groups using ANOVA test showed a statistically significant increase in food intake for this group when compared to the control group. Unlike the low dose agomelatine group ($p=0.205$), the mean body weight in the group treated with high dose agomelatine revealed a statistically significant rise compared to that of the control ($p=0.001$) in ANOVA test.

Conclusion: High dose agomelatine was effective in antagonizing the body weight lowering effect of restraint stress in addition to amelioration of reduced food intake. The study has potentially brought out the additional therapeutic benefit of agomelatine in improving the altered feeding and body weight changes when used in the treatment of the depression.

Keywords: Agomelatine, Body weight, Food intake, Satiety, Circadian rhythm.

INTRODUCTION

Depression is a common illness worldwide, with an estimated 350 million people affected; constituting a major portion of mental health disorders [1]. A meta-analysis reported that the worldwide prevalence rate of depressive disorders in elderly population between 4.7% and 16% with a comparatively higher prevalence of 21.9% in India [2]. A study conducted in North India has shown that the prevalence of depression in the elderly was high even in a rural community with an estimate of 14.4% [3]. Hamilton Rating Scale for depression states that key features of depression include weight loss and reduced appetite [4]. Core symptoms according to diagnostic and statistical manual of mental disorders-V also includes eating too much/little. Moreover a U-shaped association between body weight and depression has been described [5].

Agomelatine is a novel melatonin (MT) receptor agonist at MT1 and MT2 receptors, serotonin receptor 5-hydroxytryptamine ($5HT_3$2C) antagonist and an effective chronobiotic agent. It is found to be an effective antidepressant and an anxiolytic agent [6,7]. It has also been proved to improve sleep in a depressed patient by synchronizing the circadian rhythm [7].

Agomelatine, in addition to being a chronobiotic agent, has been shown to be effective in restraint stress induced depression in animal models [8]. Chronic restraint stress induces depressive-like behavior by increasing immobility time in the forced swimming test and cognitive deficit by producing memory impairment in the object recognition testing in animal models [9]. Restraint stress also affects the food intake and body weight of the animals [10]. There is a paucity of studies evaluating the effects of agomelatine on body weight and food intake in depression. Therefore the study was designed to evaluate the effects of agomelatine on body weight and food intake in restraint stress (immobility induced) model in adult Swiss albino mice.

METHODS

The Institutional Animal Ethics Committee approved the protocol of the study (Approval number: 241/2014/IAEC). Adult, male Swiss albino mice weighing 25-40 g and aged 5-10 months were housed in constant ambient temperature under 12 hrs light, 12 hrs dark cycle. They were group housed as 3-4 mice per cage in polypropylene cages. Pellet diet and tap water were provided *ad libitum*. The animals were randomly allocated into four groups of 10 mice per group.

- Group 1 - (treatment Group 1) low dose agomelatine was administered - 25 mg/kg/day
- Group 2 - (treatment Group 2) high dose agomelatine was administered - 50 mg/kg/day
- Group 3 - (standard group) trazodone 10 mg/kg/day
- Group 4 - control group given 1% HEC.

The vehicle HEC is cellulose derived hydrophilic polymer [11]. The test, standard and vehicle (1% HEC) were given intraperitoneally (single dose per day) to the animals in the respective groups for the last 14 days in the 3 weeks period. Chronic restraint stress was given for 4 hrs per day starting from day 0 to day 21 for all groups.

The body weight and food intake (both 24 hrs and 12 hrs dark phase) were measured at 0, 7, 14, 21 days in each group [12]. After acclimatizing to individual housing for12 hrs, food intake namely the 24 hrs and 12 hrs dark phase food intake were measured by keeping pre-weighed amount of food in each of the cages, in which the animals

were individually housed and measuring the left-over food at the end of light phase (12 hrs) and dark phase (12 hrs). An accurate measurement was made by returning the spilled food at the bottom of the cage before measuring the weight of left-over food. Each animal was weighed and the body weight was recorded before the measurement of food intake on 0, 7, 14, and 21 days (Fig. 1).

RESULTS

All data ware entered into excel and analyzed using SPSS software version 19. At baseline, a one way ANOVA test done showed that there was no significant difference in either the body weight (p=0.08) or the food intake, both the 12 hrs (p=0.53) and 24 hrs (p=0.05) in the four groups of animals indicating that there was no significant difference at baseline among the animals which were randomized to the four groups.

The food intake, both 12 hrs and 24 hrs in both the treatment groups (low dose and high dose) as well as the standard trazodone group showed an increase when compared between the 7th day intake and 21st day intake demonstrating the effects of drug treatment (Figs. 2 and 3). Using paired t-test, both 12 hrs (p=0.011) and 24 hrs (p<0.001) food intake in the high dose agomelatine group were found to be significantly increased. In addition, between groups analyses using ANOVA test showed a statistically significant increased food intake only in group 2 treated with high dose agomelatine when compared to control, but not the other two groups (Table 1).

A paired t-test done at the end of 7 days showed that there was a statistically significant reduction in weight in Groups 1-3 (Fig. 4) which were subsequently treated with low dose agomelatine, high dose agomelatine and trazodone respectively. The reduction in weight was induced as a result of the chronic restraint stress in this animal model.

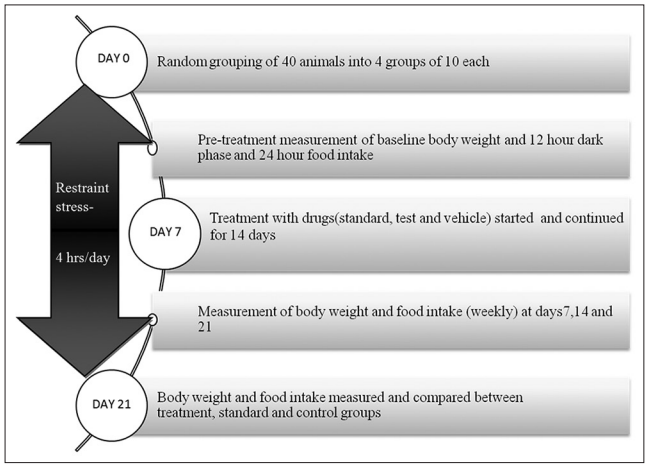

Fig. 1: Methodology of the study

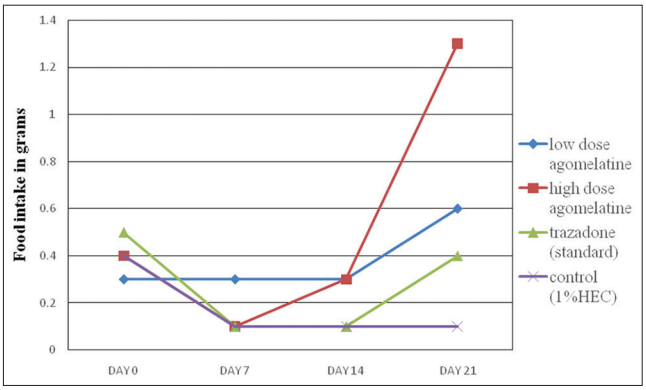

Fig. 2: Comparison of 12 hrs mean food intake among groups

A paired t-test between the body weight measurements on day 7 and day 21 was done to detect a statistically significant change in mean body weight when agomelatine/trazodone was given along with the restraint stress. The low dose agomelatine group showed a statistically significant reduction in body weight (p=0.026). However, using ANOVA test, the changes in mean body weight were not significant in the groups which were treated with low dose agomelatine or trazodone compared to the control group (Fig. 4 and Table 1). The rise in mean body weight in the group treated with high dose agomelatine (p=0.001) when compared to control, was statistically significant indicating that agomelatine at 50 mg/kg was effective in antagonizing the body weight lowering effect of restraint stress. This was also mirrored in the statistical analysis of food intake between the three groups done at the end of 21 days (Table 1).

DISCUSSION

Agomelatine is a MT receptor agonist, serotonin receptor 5HT2C antagonist and an effective chronobiotic agent. It has been found to be an effective antidepressant and an anxiolytic [6]. Agomelatine synchronizes the circadian rhythm and also ameliorates stress-related changes like depressive symptoms by modulating the cytoskeleton micro tubular dynamics and synaptic markers such as brain derived neurotrophic factor in amygdala and hippocampus [13,14]. Agomelatine antagonizes serotonin 2C receptor which is an important mediator of satiety [15]. It is well established from studies conducted earlier that restraint stress model in mice induces depression such as state in addition to the reduction in body weight and food intake by altered expression of food related genes like decreased ghrelin and increased Pro-opiomelanocortin [16,17].

A statistically significant increase in food intake was demonstrated only in the group treated with high dose agomelatine when compared

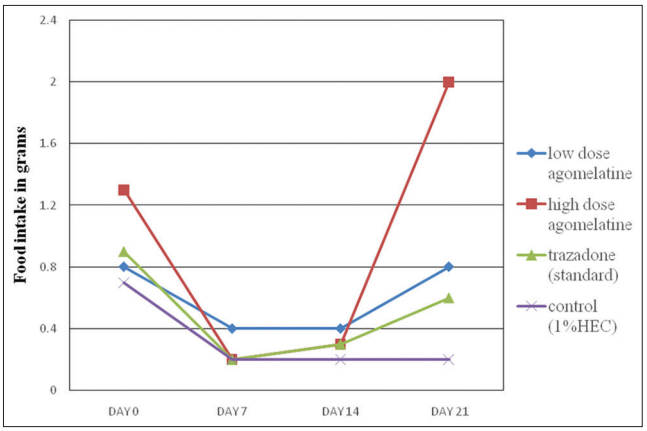

Fig. 3: Comparison of 24 hrs mean food intake among groups

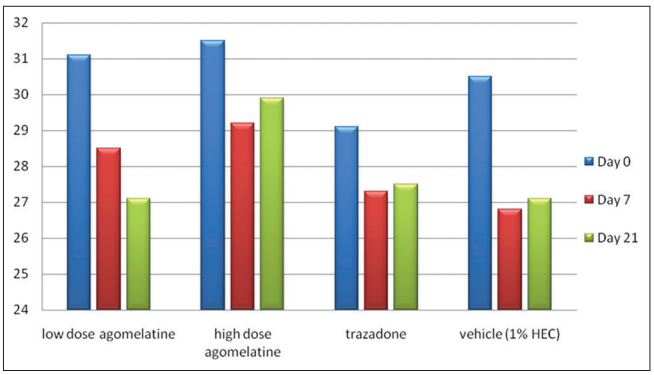

Fig. 4: Comparison of body weight (grams) among groups

Table 1: Between-groups analysis using one-way ANOVA

Groups	12 hrs food intake		24 hrs food intake		Body weight	
	F statistic	p value	F statistic	p value	F statistic	p value
Group 1 (low dose agomelatine)	7.091	0.073	7.606	0.140	10.051	0.205
Group 2 (high dose agomelatine)		0.000		0.000		0.001
Group 3 (trazodone)		0.275		0.321		0.176

to control, but not in groups which were treated with low dose agomelatine and trazodone (Table 1). This has confirmed that though there was an increased food intake evident in all the three groups, it was the high dose agomelatine which has significantly increased the food intake higher than that of the control group at the end of the treatment period, thereby effectively neutralizing the effect of restraint stress on the body weight. This also explains why the high dose agomelatine group had mean body weight significantly higher compared to that of control in contrary to the low dose agomelatine and trazodone groups.

The reasons for the effects of agomelatine on body weight and food intake are twofold. The first being the antidepressant activity of the drug, responsible for the therapeutic effect on the animals in depression-like state induced by chronic restraint stress which secondarily has led to the changes in body weight and improved food intake in the stressed animals. Second, this can be explained as due to the agomelatine's action at the serotonin receptor 5HT2C, which is a serotonin receptor subtype that is involved in normal satiation following a meal. Agomelatine antagonizes the 5HT2C receptor, and thereby it interferes with the satiety, increasing the food intake in the treated animals. The effect was well manifested in the group treated with high dose agomelatine. In contrast, the low dose agomelatine group did not show a similar response which probably could have been due to inadequate dosage to demonstrate such effects on weight and food intake. Thus, this study has delineated the effects of agomelatine on food intake and body weight when used as an antidepressant.

CONCLUSION

This study highlights the additional therapeutic benefit of agomelatine in the treatment of depression as it improves the altered feeding and body weight changes. The study clearly indicates the role of agomelatine in normalizing food intake and body weight in depressed patients with weight loss from poor feeding. These beneficial effects can be explained by its synchronizing action on circadian rhythm and antagonism of 5HT2C receptor, an important mediator of satiety.

Abstract

Background: Achievement of goals of rational use of medicine (RUM) in the community is not possible without participation of community pharmacists. Pharmacists must know that they are the main tool to educate and spread information on rational use of medicine in the community. This background enabled this study to observe the knowledge, awareness and attitude of the community pharmacists towards the rational use of medicine. Aim and Objectives were to assess the knowledge and awareness among community pharmacists about rational drug use in and around Coimbatore.

Methods: It was a cross sectional observational study using a preformed questionnaire. Study participants were 215 Community Pharmacists (those are registered pharmacist running standalone pharmacy stores not affiliating to any institutions /hospitals/not a part of a large chain of stores) inside (115 Pharmacist) and around (100 Pharmacist) Coimbatore city. Questionnaire was given to them and results were analyzed and expressed in percentage at the end of the study.

Results: Comparing the awareness about RUM in the community pharmacists in and around Coimbatore was found with the results which was almost equal or less in terms of dispensing medicines without prescription, issuing medicines to outdated prescription, educating the public about ADR etc.

Conclusions: This study ensure the need of the community pharmacist participation for the development of a clear educational policy on promoting rational use of medicine involving all segments of health care system to ensure the community benefit and safety.

Keywords: Attitude, Awareness, Knowledge, Rational use of medicine, Pharmacist

Introduction

Rational uses of medicines (RUM) play an important role in clinical practice. The clinicians, pharmacists and the public should have an idea about rational use of medicine to prevent adverse drug reaction due to inappropriate use of medicine which will produce ill effects on health. The goal in rational use of medicine can be achieved only by participation of community pharmacists. The pharmacists form the bridge between the clinicians and patients. The reach of the pharmacists is extensive both in the community and hospital.

Community pharmacists are the first contact with public in terms of many common illnesses. Public have faith and confidence in community pharmacists because they were belonging to the same location and can be easily approached. Pharmacists in rural areas educate the patients about their illness and even guide them which clinician to consult for their illness. Its beyond medicine supply, community pharmacists have cordial relationship with the public. Community pharmacists form the key in unlocking the patient's ignorance towards rational use of medicine. In western world, it is documented that appropriate pharmacy practice by the pharmacist will lead us to reach the goal in rational use of medicine.

World Health Organization has described RUM as "The meaning of rational use of medicine is that the patient gets appropriate medicine according to their clinical needs, in doses needed for their requirements for an adequate period and at a reasonable cost for both the patient and their community."

In a publication done by WHO only the rules and regulations of RUM was enumerated. Very few studies were conducted among the pharmacists. This study emphasises the vital role of pharmacists in concept of rational use of medicine and provide necessary education to them. Many pharmacists are aware of the consequences of irrational use of medicine. Pharmacists must know they are the main tool to educate patients about advantages of rational use of medicine.[1]

In another study, the participants were general practitioners and community pharmacists with patients diagnosed as upper respiratory infection where general practitioners were better than the pharmacists in concept of using antibiotics when compared to the pharmacists.[2]

One study was done with 756 community pharmacists. The pharmacists lacked public concern and were not keen about the RUM concept. The main reason for this was their diversities in education, influence by the management to get attached to drug policies and finally the most important was the financial needs.[3]

The patients must educate about various drugs, drug interactions and adverse effect due to irrational use of medicine. In another study 66% pharmacists explained ADR, 41% checking prescription validity, 87% maintains professional relationship, 12% consult other pharmacist and 81% explaining medicines effects.[4]

This was the first study to compare community pharmacists in urban and rural area of Coimbatore.

Objectives

1. To assess the knowledge and awareness among community pharmacists about rational drug use in and around Coimbatore.
2. To know the dispensing attitude of community pharmacist regarding rational drug use.

M□□□□□□□

The design of this study was 1 year, non-interventional, a Prospective cross sectional observational study was initiated using a preformed questionnaire.

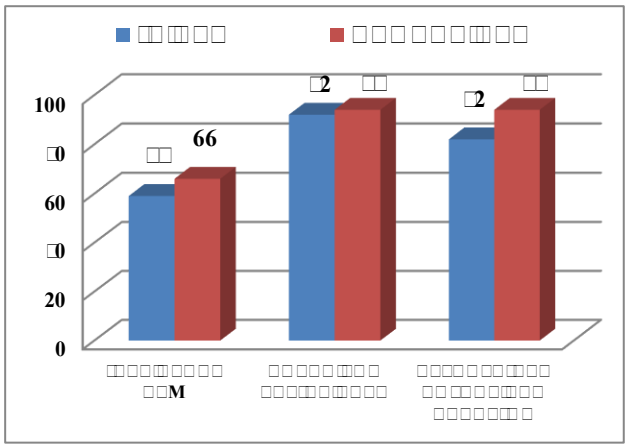
Inclusion criteria

Community Pharmacists (those are registered pharmacist running standalone pharmacy stores not affiliating to any institutions /Hospitals/not a part of a large chain of stores).

Exclusion criteria

Pharmacists in nursing home, chains of pharmacy stores, multispecialty hospitals, and medical college hospitals, Government hospitals were excluded from this study.

After obtaining written informed consent, 215 Community Pharmacists (115 Pharmacist - inside Coimbatore city) and (100 Pharmacist outside Coimbatore city) were participated in this study. Study period was from October 2014 to February 2015. Questionnaire was filled by the study participants, and then the results were analyzed and expressed in percentage at the end of the study.



□□□□□□□

Comparing the knowledge, awareness and attitude about RUM of both the groups of pharmacists in Coimbatore was done. While comparing the knowledge about RUM in community pharmacists in and around Coimbatore, was found to be 59% and 49% respectively (Table 1).

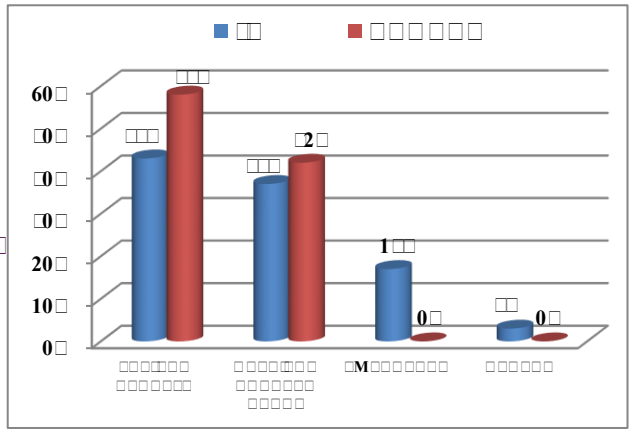
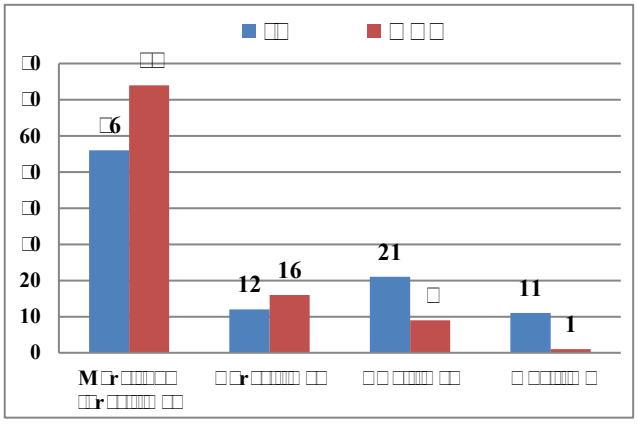
Observed any injections related ADR (injection abscess, hepatitis etc)	2	98	1	99

Community pharmacists were dispensing medicines without prescription was 65 % in Coimbatore and was 80% around Coimbatore. The reasons for dispensing medicines without prescription by both groups were compared and the major reason identified was patient's request (Figure 1). 6% of community pharmacists inside Coimbatore city are dispensing medicines without prescription because of emergency. Community pharmacists in and around Coimbatore were issuing drugs over the counter and the percentage was 38 % and 41 % respectively and 3 % had other reasons for dispensing medicines without prescription.

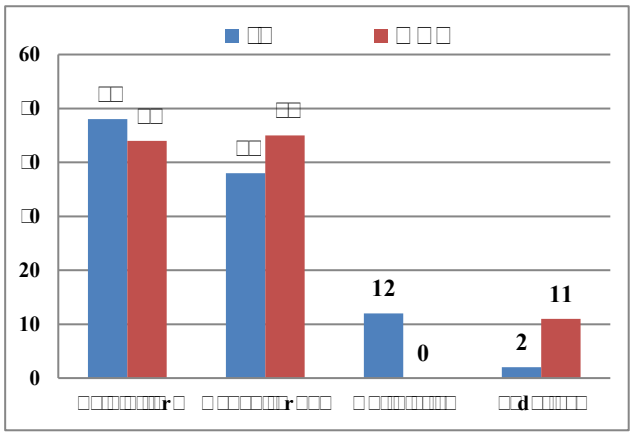


The next comparison between the community pharmacists were those issuing medicines for old prescriptions, which was72 % and 81 % respectively. (Table 1) The number of times medicines issued for the old prescriptions was analysed (Figure 2). About 56% and 74 % of community pharmacists in both the groups are dispensing medicine for the old prescription more than once. Some community pharmacists in and around Coimbatore are issuing medicine for the old prescription only once around 11% and 1% respectively.

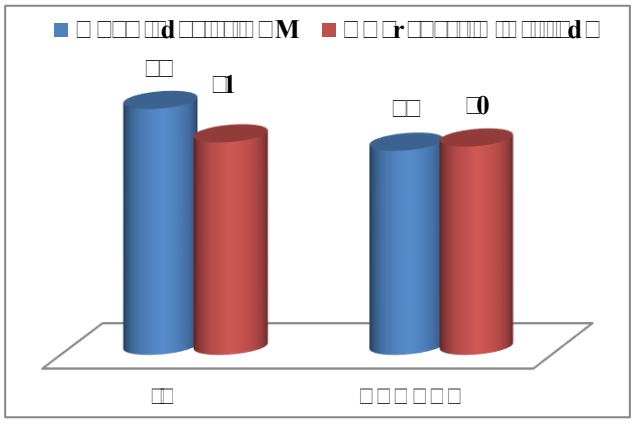


There was a comparison between the two groups whether these pharmacists were provided alert to the public about the ill effects of drugs. Community pharmacists in and around Coimbatore were all most equal in giving alert to the public about the ill effects of drugs (70%-80%) (Table 1) when compared to international study [4] this study showed a good indicator.

Regarding the Pharmacovigilancereduction program, whether the community pharmacists in and around Coimbatore guided the patients to report the ADRs was found to be almost equal around 65%-75% (Table 1).



A RUM concept of dispensing medicine for appropriate dosage and duration were compared between the two groups of the community pharmacists in and around Coimbatore was found that 82% and 51% of community pharmacists in and around Coimbatore respectively were dispensing medicines in appropriate dosage and duration (Table 1).



92%-94% of in and around Coimbatore Community pharmacists were checking expiry date before dispensing the drugs (Table 1) compared to an international study

which was 41%.[4] This study could not observe any injection related ADR in both groups. Patients repeatedly requesting to issue medicine without any prescriptions were 49% and 71% respectively (Table 1). Medicines which were given repeatedly without prescription were pain killers and it was 45-50% in both the groups. Cough syrups were the second commonly issued medicine with repeated request by the patients which was around 35-45% in both the groups. The community pharmacists in Coimbatore were expressed that 12% of patients are repeatedly requesting to issue antibiotics, while community pharmacists around Coimbatore report that 11% of patients are repeatedly requesting to issue sedatives. The number of patients repeatedly requesting to issue sedatives in Coimbatore is only 2% (Figure 3).

Discussion

This study was the first kind study India which tried to assess the knowledge, attitude and awareness of community pharmacists in and around Coimbatore (metro population city) towards rational use of medicine. Community pharmacies are the part of the healthcare system throughout the world. Community pharmacists act as a first-line treatment source for most of the population diversity in their distribution and setups make them an easily accessible. Community pharmacists are a quick source of advice, referral, dispensing medicines and information to the patient's. The way drugs are procured, stored and dispensed and the information given by the dispensers indicates the quality of their practice leading to rational or irrational use of medication.

This study found that only around 55% of community pharmacists have the idea about RUM (Table 1). A similar study was done in another country found that community pharmacists lacked awareness and knowledge about RUM.[5,6]

While comparing the reasons for issuing drugs without prescription, in this study majority of the community pharmacists were issued the medicines at the patient's request and also, they issued medicines over the counter without prescription (Figure 3). In an international study it was expressed that no need for the prescription for chronic and CNS diseases and also they were dispensed medicines without prescription because patient asked for the drug by name.[6]

This study found that community pharmacists dispensed medicines for old prescriptions. A similar finding was seen in another study, where medicines were issued for old prescriptions for months.[7]

In this study it was found that the number of community pharmacists provided alert to the public about the ill effects of drugs was 79% and 69% respectively in and around Coimbatore. There was a study expressing that only 40-50% community pharmacists provide alert the public about the ill effects of drugs.[8]

In another study it was found that community pharmacists guiding patients to report ADR was deficient.[4,9] But in this study, it was found that community pharmacists guiding patients for possible ADRs was 79% - and 69% and provided guidance to report ADR 72% and 69% respectively in and around Coimbatore.

It was found that, 82% and 51% of community pharmacists in and around Coimbatore was dispensing medicines in the appropriate dosage and duration. But a study done in another country had found that 97% of community pharmacists were dispensing antibiotics irrationally.[6]

In this study, it was confirmed that, almost all the community pharmacists check expiry date before dispensing the drugs and only 1.3% were enquired and observed ADRs related to injection.

This study also bring out that, the community pharmacists issued medicine without demanding prescriptions was 35% and 20% in and around Coimbatore compared to another international study which had expressed about the

patients repeated request to issue medicine without any prescriptions.[10]

Knowledge and attitude of the community pharmacists on drug safety and related aspects could greatly influence their dispensing behavior and thereby positively contribute to the patient safety. Majority of the community pharmacists had low acceptable knowledge on drug safety related aspects for specific drugs and a good number of them were not aware of certain practical aspects.[11]

In many places it was observed that, the practice of irrational drug use like self-medication, antibiotic prescribing, and sale of less-than-prescribed quantity of drugs specially antibiotics, and finally poor drug storage practices. Global research provides the evidence that it's possible to improve and regulate the practice of community pharmacists through a combination of interventions, education to achieve the goal of promoting RUM. Changing their knowledge and practices would be a slow, difficult and challenging procedure, but if the intervention once done it efficiently improves the skills even in the most resource-deprived settings.

Educational interventions with interactive training sessions if provided would be useful in improving prescribing practices of the community pharmacists like proper drug storage, record-keeping, reading doctor's prescription, medication counselling, discouraging sale of antibiotics without prescription, promoting quality dispensing of medicine etc may improve the practices in a possible way through appropriate and repeated interventions which are sustained.[12] There is a compelling need for the development of a clear policy on promoting rational use of medicine involving all segments of health care system such as physicians, community pharmacists, drug companies and government agencies. This will ensure that rational use of medicines which will benefit the community can be achieved.[12]

There is a definite need for the development of a clear educational policy on promoting rational use of medicine involving all segments of health care system such as physicians, community pharmacists, drug companies and government agencies to ensure that rational use of medicines benefits in the community.[12] Community Pharmacist require continues educational services like frequent update, scientific meeting, creating and providing good communication activities with physicians, training pharmacy staffs, adhering treatment principles, RUM practices, skill development opportunities, technical support, and pharmacy education may reduce the gap between health care system and community.[13,14]

□□□□□□□□□

The World Health Organization has recognized few factors like patient demands, drug advertising etc as limitations towards achieving rational use of medicine based on various research evidence. If an appropriate intervention applied in the needy area may be helpful to improve RUM practices in the community where the pharmacist's services are very important segment in the health care system of many countries.

Abstract

Background: Urinary tract infection (UTI) is one of the most common bacterial illnesses and hence one of the most important indications for antibiotic treatment. Current knowledge of the common organisms implicated in causing UTI in the local community and surveillance to monitor the changes in susceptibility of uropathogens are imperative to ensure appropriate therapy. The study objectives were to assess the proportion of UTI caused by each of the common urinary pathogens, to study the antibiotic drug sensitivity patterns by analyzing the culture and sensitivity reports and to identify the drugs which would be potentially favourable candidates for empirical therapy in the study locale.

Methods: This hospital based cross sectional study was done by collecting the data from case records of patients who attended OPD or were admitted with diagnosis of UTI during the study period.

Results: *Escherichia coli* was the single most important cause of UTI, accounting for 70% of the infection among the studied subjects, amongst which 55% was extended spectrum beta-lactamase producing organisms. A pattern of increased susceptibility to higher antibiotics like ertapenem, tigecycline and decreased sensitivity to fluroquinolones was evident. In addition, nitrofurantoin was found to be one of the antibiotics to which most of the organisms were susceptible (85%) favouring its use in empirical therapy of UTI.

Conclusions: The pattern of accentuated susceptibility to higher antibiotics in the face of declining trend in the sensitivity to commonly used antibiotics necessitates promoting awareness on the need for rational prescribing of antibiotics among clinicians.

Keywords: Antibiotics, Culture and sensitivity, *Escherichia coli*, Urinary tract infection

Introduction

Urinary tract infections (UTI) remain one of the commonest infections diagnosed in out-patients and hospitalized patients. An in-depth knowledge on antimicrobial susceptibility pattern is essential for appropriate therapy, particularly with increasing resistance resulting from repeated use of the same antibiotic.[1] It is also essential to be aware of the changing patterns of antibiotic resistance in a locale.[2] Published data may not always represent the scenario prevailing in a particular location as the studies done elsewhere could vary in the pattern of microorganisms involved in causation, their sensitivity and resistance to different antibiotics which in turn depends on the antibiotic prescribing pattern in that region. This indicates that there is a need for studying the existing antibiotic sensitivity patterns in the local population.[3] Resistance significantly varies by region and the highest antibiotic resistance has been observed in developing countries. Similarly a significant rise in resistance over time is seen in studies reporting on community acquired *E. coli* UTI.[3]

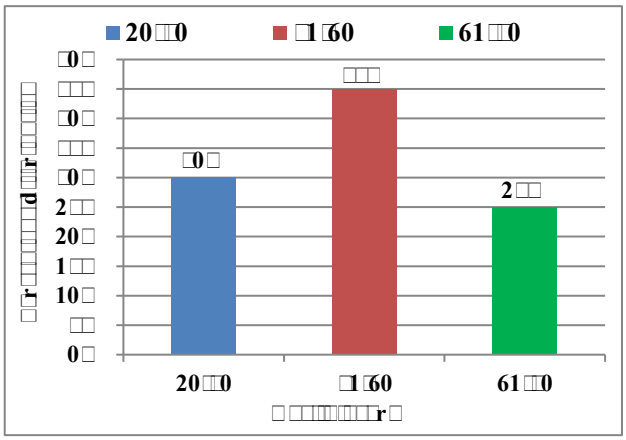
Hence this study was designed to evaluate the drug sensitivity patterns to some of the commonly used antimicrobials in UTI like the beta lactams, fluroquionolones and aminoglycosides. In addition, the

antibacterial drugs commonly used in UTI like nitrofurantoin, cotrimoxazole were also studied for the sensitivity patterns. Thus, the study was done to provide an insight into the drug sensitivity patterns of common urinary pathogens to antibiotic therapy by analyzing the culture and sensitivity reports.

Our study was designed to identify the proportion of UTI caused by each of the urinary pathogens prevalent in the study locale and the likely drug candidates with the potential of being used as empirical therapy in community acquired pathogens by evaluating their sensitivity pattern, thereby enabling identification of the drugs which can effectively be used in the management of UTI.

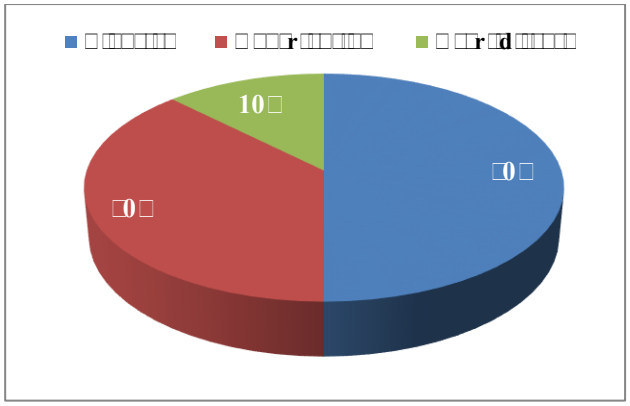
M□□□ □ □□□

This was a hospital based study done at a tertiary care teaching hospital after the approval from Institutional Human Ethics Committee. The study was a cross sectional one, done using case records. The data from case records of the patients who attended OPD or admitted with diagnosis of UTI during the study period were included for the study based on inclusion and exclusion criteria.



The data from the case records of adult patients above the age of 20 years, of both sexes, diagnosed with UTI were included for the study. Patients with asymptomatic bacteriuria, those with complicated UTI, upper UTI or known malformations, paediatric and pregnant patients, immunocompromised patients like patients with HIV, on corticosteroids or immunosuppressant therapy, organ transplant recipient were excluded.

The culture and *in vitro* sensitivity testing report data were collected in addition to demographic data, co morbid conditions, symptoms and duration of symptoms and drug therapies. In addition, data on history of hospitalizations, catheterizations and frequency of recurrences were also obtained from the case sheets. Also, the details recorded on the review date regarding cure or continuing symptoms, repeat culture reports, if any, was made note of from the case record.



□□□□ □□□□

A total of 20 patients whose case records indicated that they had been diagnosed with UTI were included for the study. All these patients were urine culture positive. In our study 30% of patients were in the age group 20 -40 years and a large majority of about 45% were in the age group of 41-60 years and 25% of the patients were aged 61 -80 years (Figure 1). Male female ratio in our study population was 65:35.

Catheterization was done in 20% of the study subjects. The duration of catheterization was variable with one patient having a history of prolonged catheterization of 12 days. Concomitant renal disease was found in a high proportion of the UTI patients. Amongst the studied population, 10% had renal failure, 10% nephritis and 5% pyelonephritis with renal calculi. One patient manifested with lupus nephritis as she was a known case of systemic lupus erythematosis. One patient was a case of neurogenic bladder. About10% patients had presented with concomitant prostatitis and a similar 10% with UTI had history of recurrent episodes (Figure 2).

cefaperazone in combination with sulbactam and the next highest being piperacillin tazobactum combination with 45% and a slightly lower percentage of 40% was recorded for amoxicillin clavulanate (Figure 7).

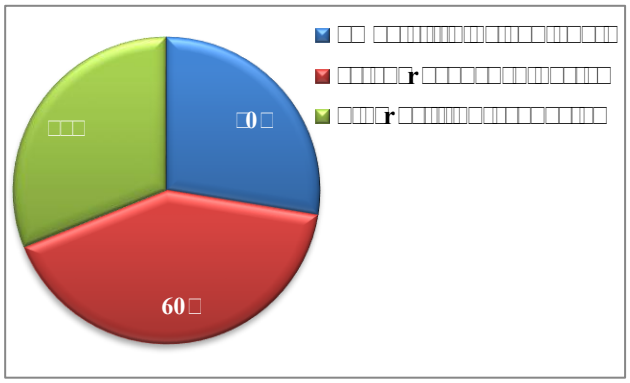

Figure 7. Pie chart showing the percentage of sensitivity of the organisms to the antibiotics in the amino-penicillin group

Amino-penicillins

The aminopenicillins were one of the drug groups studied for bacterial sensitivity apart from ureidopencillins in the penicillin group of beta-lactam antibiotics and among the two amino-pencillins used commonly, organisms showed a marginally higher sensitivity to ampicillin (20%) as compared to amoxicillin (10%).

Cephalosporins

In the cephalosporin group, cefaperazone in combination with sulbactum was the antibiotic to which most organisms (60%) were sensitive. Apart from it, the other cephalosporins found to be useful in 10 -20% of infections based on culture and sensitivity pattern are cefepime, ceftriaxone, cephalothin and cefuroxime respectively with 30%, 20%, 15% and 10%. It was evident that sensitivity for the first and second generation was lower in comparison to third and fourth generations of cephalosporins (Figure 8).

Carbapenems

Among carbapenems, greatest sensitivity was recorded for ertapenem (70%) (Figure 9).

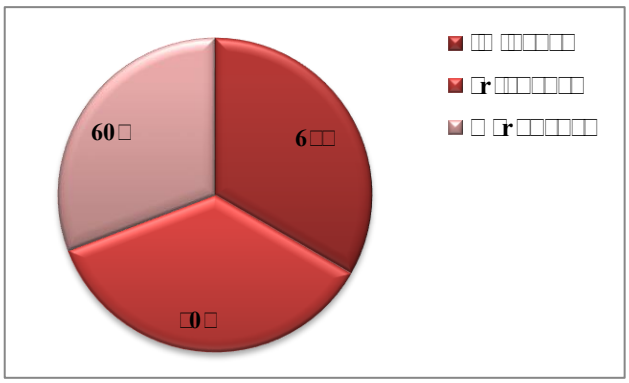

Figure 9. Pie chart showing the percentage of sensitivity of the organisms to the carbapenem group of antibiotics

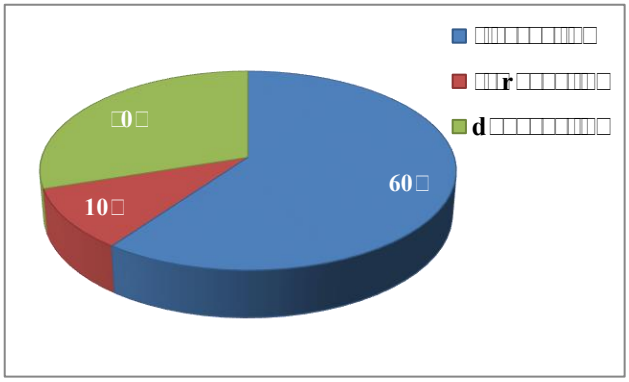
Tetracycline and glycylcycline

Tigecycline was found to be the antibiotic to which 60% of the organisms studied were susceptible to and it matched that of cefaperazone combined with sulbactum in achieving the same percentage of sensitivity (Figure 10).



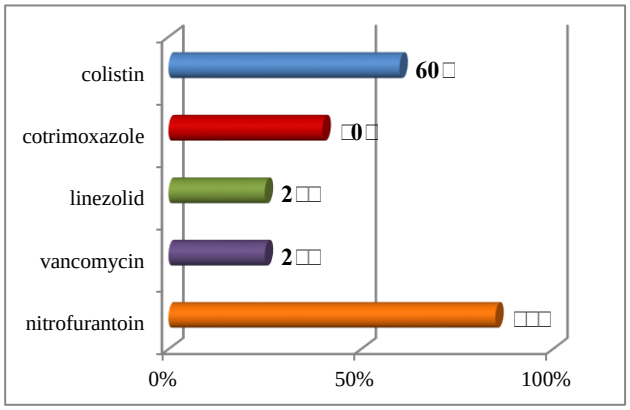


Figure 10. Pie chart showing the percentage of sensitivity of the organisms to the tigecycline and cefaperazone sulbactam combination

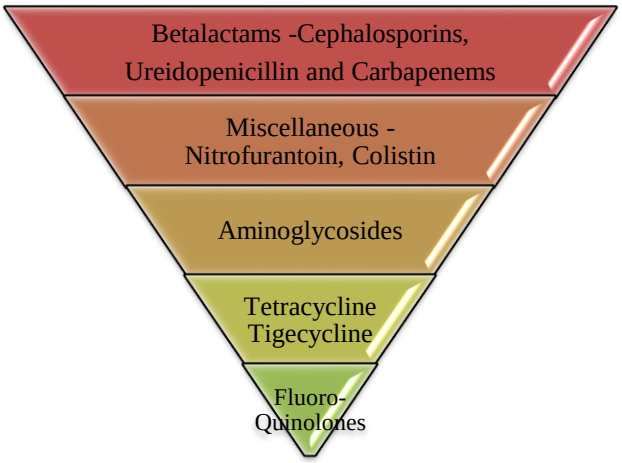

Miscellaneous antibacterials

Interestingly, 85% of the cultures showed sensitivity to nitrofurantoin. Also, colistin was another antibiotic found to have similar percentage of sensitivity comparable with tigecycline and cefaperazone sulbactam combination. Sensitivity to cotrimoxazole was 40% and that for vancomycin and linezolid, with 20% each (Figure 11).

The pattern of antibiotic sensitivity of the UTI causing organisms was analyzed. Comparing the various drug groups with differential sensitivity percentages, the highest *in-vitro* sensitivity was to the beta lactam group followed by nitrofuantoin and colistin of the

miscellaneous antibacterial group and the least sensitivity was demonstrated by the fluoroquinolones (Figure 12).

Discussion

Urinary tract infections (UTI) is the most common infection experienced by human after respiratory and gastrointestinal infections, accounting for 8.6 million visits (84% by women) in 2007 in the United States.[4,5] UTI is said to occur more commonly in females than in males; in males it is uncommon, but often associated with structural abnormality.[6] But in our sample, we found a greater percentage of males than females.

The highest co-morbidity noted in our study population was diabetes and hypertension. Diabetes plays a definitive role in increasing the occurrence of UTI because of the changes in immunological function and thereby increasing the susceptibility to UTI. Studies have demonstrated that the epidemiology of urinary tract infections (UTIs) among men and women with diabetes is similar to the epidemiology of those without diabetes with women having greater risk than men.[7] However, the bacteriology and antibiotic susceptibility patterns also do not, in general, differ from those without diabetes.[7,8] Our study results are well in line with these findings. In addition, a study has revealed that the virulence factors of *E. coli* affecting the diabetic individuals also remains the same as in the general population.[8]

Worldwide, the most frequent etiology is *Escherichia coli* and this is also reflected in our study results.[9] However the sensitivity and resistance patterns of *E. coli* strains causing UTI varies considerably between regions and countries.[10] In this study, we found that most *E. coli* isolated in culture were susceptible to cefaperazone-sulbactum, ertapenem, tigecycline, nitrofurantoin, colistin and amikacin. Among these nitrofurantoin and colistin are the drugs administered orally and the rest have to be administered by parenteral route. Interestingly, we found a decreasing sensitivity to fluoroquinolones which have been regarded as one of the first line drugs in UTI and therefore rampantly used which consecutively would have lead to a high degree of fluoroquinolone resistance in our population.

The study highlights the increasing trend of resistant Gram negative organism in culture necessitating the need for higher antibiotics. A study has highlighted that among tetracyclines, tigecycline has best in vitro susceptibility against ESBL producing Gram negative rods.[11] Likewise, a high cure rate, both clinical and microbiological has been recorded for ertapenem also, particularly for ESBL infections.[12] The indiscriminate use of such higher antibiotics like ertapenem and tigecycline will foster development of drug resistance, further complicating the management of urinary tract infection.

The vicious cycle wherein widespread use of newer antibiotics leading on to the organisms developing resistance to them and that in sequence, further necessitating the development of newer antibiotics ultimately results in difficult to treat infections. Such a situation can be overcome by implementing rational prescribing practices like the use of lower antibiotics with limited spectrum to which the organism is susceptible rather than resorting to prescribe higher antibiotics with a wide spectrum.[13]

This study has clearly delineated the emphatic role of nitrofurantoin in urinary tract infections. Our findings are in concordance with currently emerging trend in the use of nitrofurantoin as a key oral antibiotic option in the treatment of acute uncomplicated cystitis due to multi-drug resistant Gram negative bacilli causing UTI.[14] Studies also have acknowledged that the efficacy of nitrofurantoin for the empirical treatment is supportable from a public health perspective in an attempt to decrease uropathogen resistance.[15] Thus the current scenario based on drug sensitivity justifies the use of nitrofurantoin in the empiric management of UTI, not only due to the high susceptibility of *E. coli* to nitrofurantoin and the ease of oral administration but also owing to the fact that it lacks

cross-resistance with commonly prescribed antibiotics for UTI. However, nitrofurantoin is contraindicated in renal disease since most of it is really excreted.

Limitation

The limitation of the study is the small sample size. A larger study with a larger sample is needed to confirm the drug sensitivity pattern of UTI causing organisms in the study locale established through our study results.

□□□□□□□□□

The study highlights that *E. coli* contributes to the majority of the urinary tract infections diagnosed in our tertiary care hospital. In addition, the current drug sensitivity pattern signifies the need for higher antibiotics and this mandate implementing strategies of rational prescribing to avert forging resistance to these agents also. Nitrofurantoin, with good activity against a high percentage of the cultured organisms causing UTI, rationalizes its use for empirical treatment of UTI.□

Abstract

Background: Asafoetida is an herbal food supplement that has numerous peripheral pharmacological actions. Its central nervous system effects have not yet been completely elucidated in both animals and human participants. The study focuses on deciphering the effects of this Herbaceutical with that of Donepezil and vitamin C in mouse models of short term novelty object recognition memory and open field test.

Methods: The study was conducted in two stages - a pilot stage which assessed the most effective dose of asafoetida on cognition, followed by a post-pilot study phase wherein its effects at that dose were compared with those of Donepezil and vitamin C. Novelty Preference Test (NPT) on y-maze and Open field test on Open field box were used to evaluate the effects of the formulation on memory and motor activity in mice.

Results: A dose of 400mg/day of asafoetida orally was found to improve memory significantly in comparison to 200mg/day in mice. Asafoetida showed a greater potency in improving memory than Donepezil and vitamin C. After 11 days of daily treatment with Asafoetida commercial powder, more than fifty percent of the mice showed an increase in recognition index of 0.7-0.8 as compared to 0.55 at baseline.

Conclusions: Asafoetida powder has nootropic efficacy in mouse model - this has to be explored mechanistically and pharmaceutically to enable the psychopharmacological characterization of the active principles and its pharmacological effects in the central nervous system.

Introduction

Asafoetida is a commercial form of dried latex extracted from the tap root of *Ferula asafoetida linn*. Plant, that is used in some countries as food supplement and flavouring agent. Although it has been widely used in Chinese and Indian medicine systems for thousands of years, its pharmacological effects have yet to be completely elucidated.

Different mechanism for augmentation of cognitive deficits exist in different pathophysiological states and disease- for example, Donepezil is a cholinesterase inhibitor which improves memory even in severe cognitive impairment seen in dementia by increasing acetylcholine levels in the cortical regions of the brain.[1] Other mechanisms have also been proposed, including antioxidant actions of vitamins and minerals on free radicals and glutamate excitotoxicity prevention.[2] We propose to evaluate for the first time, the mechanism of nootropic action of a commercial preparation of the oleoresin of Ferula spp., although few studies have addressed the research question in other ways. For example, studies on its amnesia reversal in galactose and sodium nitrate induced deficits in rats and assessment of its cognitive effects using passive avoidance tests have been published with positive evidence of its central

actions, although it has widespread effects in both preclinical and clinical models peripherally.[3,4]

The most commonly evaluated active principle of this herb is ferulic acid.[5] For example, it contains sesquiterpenes, coumarins and sulphur-rich components and phenolics including ferulic acids.[6-8]

The present study aims to evaluate the most efficacious dose of asafoetida's nootropic effect and then to compare its cognitive effects with two probe drugs acting by different mechanisms viz., vitamin C and donepezil. This has been accomplished using a two-phase study evaluation approach.

M□□□ □ □□□

Animals

Prior animal ethics committee approval was obtained from the Institutional Animal Ethics Committee (IAEC) for thirty Swiss albino mice. After procurement from breeder and quarantine, these thirty mice were housed in groups of six, after separating them into two divisions, the first randomly selected twelve mice for pilot stage and the remaining eighteen mice for the post pilot efficacy study. The first twelve mice were initially acclimatized in the laboratory and then randomly reallocated after one week into two cages for the pilot study execution.

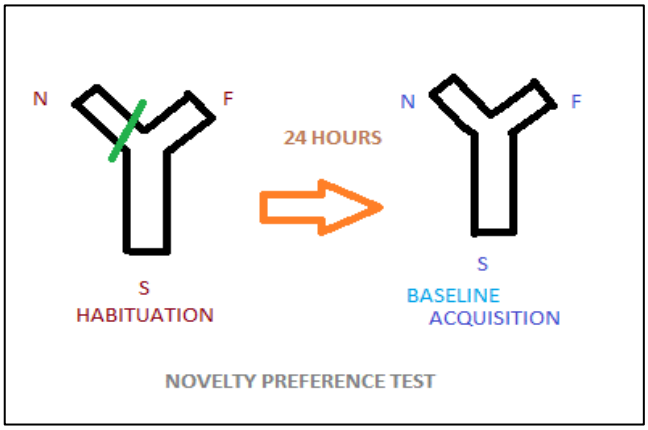
Drugs

Commercially available asafoetida powder is obtained and dissolved in water and administered by oral gavage in mice daily till a specific criterion is met with. Donepezil tablets are ground and dissolved in water and administered by intraperitoneal syringes daily. Vitamin C is obtained as tablets and dissolved in aqueous solvent for oral gavage (pH = 7.0). The specific efficacy criterion is that treatment is continued in all groups till at least 50% of one either group exhibits a 50% improvement in baseline NOR index earlier.

Drug treatment

The study comprised of two phases - an initial pilot phase and a second efficacy phase. The objective of the pilot study phase was to ascertain the more effective of two doses of asafoetida for meeting a predefined criterion of cognitive improvement, along with the standard drug Donepezil. The objective of the next phase was to compare the cognitive improvement of asafoetida with two standard drugs acting by different mechanism, using surrogate behavioural markers.

The mice in the first cage were administered 200mg/kg/day of a commercial preparation of asafoetida powder in solution by oral gavage, whilst the other cage mice were given the same formulation at a dose of 400mg/kg/day. Each mouse was also co-administered Donepezil 2mg/kg/day intraperitoneal, till at least 50% of the rodents given either combination exhibited a 15-20% improvement in novelty recognition indices from baseline. At this cut-off, treatment was stopped in both groups and an interim analysis was performed to ascertain which of the two doses is more potent in improving novelty object recognition memory on a y-maze.



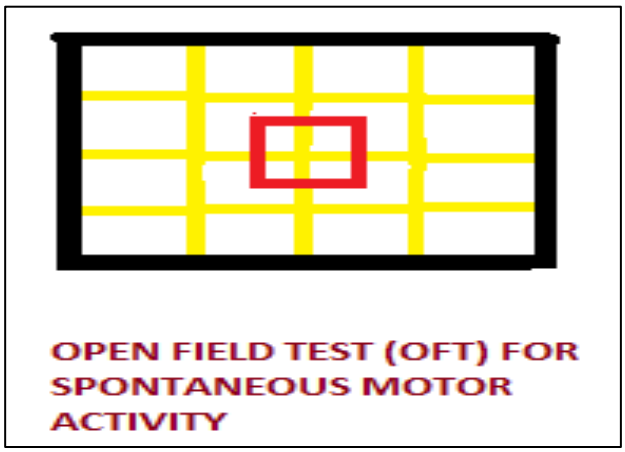
The efficacy study phase was executed using eighteen mice which, after acclimatization, were divided into three groups - first group received Asafoetida 400mg/kg/day, the second group mice were administered Donepezil 2 mg/kg/day intraperitoneal, and the six mice of the third group were given vitamin C 125mg/kg/day (pH = 7.0) orally.

The Y-Maze

The y-maze novelty preference test using the elevated y-maze for mouse evaluates short term spatial novelty-object recognition (NOR) memory. The elevated y-maze consists of three arms in a horizontal plane that is elevated from the floor by 50 centimetres. The three equally long arms are placed at 120° to each other, separated by a triangular central platform. Each arm measures about 100 centimetres. In length and is enclosed by walls whose height is about 50 centimetres. One of the arms has a provision for closure at the junction with the central platform, with a guillotine door - this is the Novel (N) arm. The other two arms which do not have such doors are the Start (S) and the Familiar (F) arms. The NOR index calculated from the number of arm entries of a single mouse (NAE) into each arm, with ¾ths of its body inside that arm, is as follows:

$$NOR\ INDEX\ (\%) = \frac{NAE\ (N)}{NAE\ (N) + NAE\ (F)} \times 100$$

$$Familiarization\ index = \frac{NAE\ (F)}{NAE\ (S)} \geq 1.0$$



□□□r □l □□□ □□□□ M□□□□□ □□□□□□□□r □□r □□□□□□□□□□□□ □□ □□□ □r □□□□□□□□□ □□□□ □□□□□□r□ □□□ □□□□□□□□□□□d □□□□□□□□□□□□□□□ □□ d □□r □□□□□□r □□r □□□□□□□ □□d □□□□□□□□□□□□□□□r □□□□□□□

The level of NOR memory acquisition and retention is directly proportional to the above index. The rodents are allowed to explore all three arms freely for 8 minutes in the y-maze followed by four successive habituation trials, in which the novel arm is closed. The habituation trials are meant for the rodent to familiarize with the familiar arm with novel arm closed. Thirty minutes after drug treatment, each animal can explore the novel arm relative to familiar arm, after placing it in the start arm for 5 minutes. NOR index is then measured for each animal (Figure 1).

The open field test

The open field box measures spontaneous motor activity (SMA) in rodents.[4] It is a cubical box measuring 90 cm^3 volume with an arena or floor, that is divided into 16 smaller yellow-bordered squares (Figure 2). The central portion of this arena is marked by a similar red-bordered square. The whole arena is divided into 4 white-bordered quadrants for purposes of software-acquisition of activity trials. The Open Field test measures SMA activity in 3-minute trials per mouse. The SMA index as a measure of motor activity is calculated as follows:

$$SMA\ INDEX = \frac{\sum Peripheral\ yellow\ square\ entries}{\sum Central\ red\ square\ entry}$$

Elevated plus maze: The Elevated Plus Maze (EPM) is a plus like maze used to assess effects on interventions on anxiety like behaviour (Figure 3). It consists of four arms, two of which are enclosed on all three sides by walls. The other two arms which are on opposite end of the maze are not enclosed by walls. The whole maze is elevated on the ground at a height of 50cm. The transfer latency is the time the mouse takes to move from the open arm to the enclosed arm in a single daily ninety second trial. Additionally, the ratio of open to enclosed arm entries was also calculated as a measure of anxiolytic index.

The study design (Figure 4) is such that the more potent of two doses of asafoetida (with donepezil) is chosen based on greater / earlier nootropic activity followed by an efficacy phase, that aims to compare this dose of asafoetida with vitamin C and Donepezil-induced activities on y maze.

Statistical analysis: All statistical analysis was performed using Graphpad Prism v 4.0 and SPSS v 16.0. Analysis of variance (1 way and 2 way) with post hoc Bonferroni test and Pearson correlation along with Levenne test were performed for hypothesis testing.

□□□□□□□□

There was a statistically significant difference between the groups as determined by one-way ANOVA after 7 days ($F(3,21) = 3.581$, $p = 0.031$) and after 14 days of drug treatment ($F(3,21) = 7.996$, $p = 0.001$). A post hoc Bonferroni test with Y Maze Recognition index as the dependent variable across all groups of both phases taken together revealed a statistical significance between control

and high dose asafoetida group (p = 0.002). The improvement with high dose (400mg/kg/day) asafoetida was noted in 10 days of treatment even earlier compared to Donepezil in the efficacy study phase. After 11 days of daily treatment with Asafoetida commercial powder, more than fifty percent of the mice showed an increase in recognition index of 0.7-0.8 as compared to 0.55 at baseline. A two-way ANOVA for determination of factors affecting the repeated measures of Y maze NOR Index revealed statistical significant for the influence of both days of exposure (p <0.0001) and drug treatment (p = 0.007). Pairwise group comparison across all four treatment groups revealed significant interaction of drug treatment over days – for example Asafoetida high dose was more nootropic than Donepezil on days 10 and 11, and vitamin C on day 11, in the Bonferroni test (Figure 5).

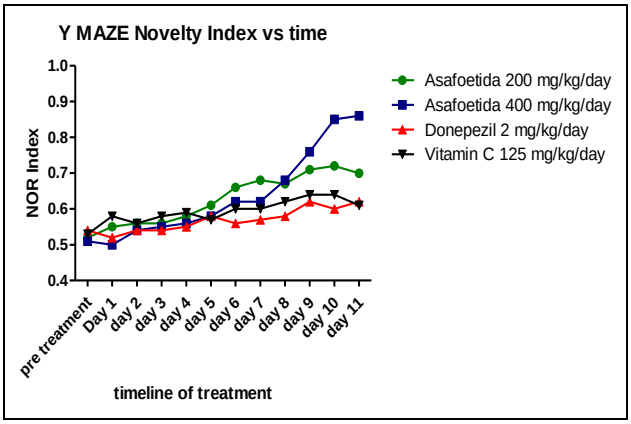

Figure 5: Y maze NOR index vs time in days for Asafoetida, Donepezil and Vitamin C treated groups

The one-way ANOVA of open to enclosed arm entries on the EPM revealed statistical significance between Donepezil and high dose Asafoetida group (p = 0.017, 95% CI: -137.17 to -7.16), with the mean ratios greater in the asafoetida 400 mg/kg/day group (p = 0.024), as revealed by a Bonferroni test. The percentage of open to enclosed arm entry ratios on days 7 and 14 across all the groups did not yield statistical significance using Levenne test (p>0.05).

Intergroup comparison of the ratio of peripheral to red square ratios on open field on days 7 and 14 across all the treated groups revealed no statistical significance using 1-way ANOVA (p>0.05). Also, the number of red and peripheral square entries on open field test on days 7 and 14 did not yield significant differences among all groups.

The Pearson correlation coefficient between y maze recognition index and the ratio of peripheral to central square entries on open field showed significant correlations on day 7 (R^2 = 0.8), but not on day 14, and both the correlations were statistically insignificant. A similar result was obtained for correlation between recognition index and transfer latency.

DISCUSSION

A novel effect of Asafoetida on spatial memory on y-maze which was earlier and greater than even Donepezil has been reported in this study. The mechanism of cognitive improvement seems to correlate more with cholinergic pathway improvement with Donepezil than with vitamin C effects. Also, this nootropic effect of Donepezil was higher at high dose with minimal motor and anxiogenic side effects as noted by results of open field and elevated plus maze tests.

Vitamin C exerts neuroprotective effects after its transport into neurons through sodium-dependent ascorbate transporters.[1] Donepezil is a cerebroselective acetyl-cholinesterase inhibitor that increases neurogenesis in the central nervous system, especially the hippocampus, and improves cognition.[2]

Although only a couple of studies exist to prove asafoetida nootropic effects,[3,4] our study reports that it affects spatial memory with minimal motor and anxiety adverse effects, which parallels more with Donepezil mechanism than antioxidant pathway, from the recognition indices parallelism.

Derivatives of sesquiterpenes are known to have chemo preventive effects in cancers and coumarins have anticoagulant activity. [5-7] Ferulic acid have also been used to improve haemostatics during silk weaving.[8,9] Phenolic acids which includes about half a dozen chemicals in Ferula spp. possess emotional improving and antidepressant activities. However, its effects in the central nervous system on higher cognitive properties have not been deciphered and evaluated completely.

Limitations

A small sample size and absence of biochemical confirmation; but it will serve as a pilot study for enabling further studies on this important nutraceutical.

ABSTRACT

To compare the effectiveness of vitamin B12 and folic acid in comparison to N-acetylcysteine (NAC) as hepato-protective agent against liver damage in experimentally induced acute acetaminophen toxicity in Sprague dawley rats. 18 male Sprague dawley rats were randomly divided into three groups of six each. Group A was administered NAC, group B - vitamin B12 and group C - folic acid intraperitoneally one hour after an acute over-dosage of acetaminophen 3mg/kg. After 48 hours, 1.5 ml of blood was withdrawn and the animals were sacrificed for histopathological examination of liver. The mean AST and ALT of vitamin B12 group did not differ statistically from that of the NAC group. The folic acid group had higher mean AST though not statistically significant whilst the mean ALT was significantly higher compared to NAC group. The reduction in the mean ALP and GGT with vitamin B12 showed statistically significant reduction whereas the folic acid group did not. Histopathology of liver revealed that the tissue architect was totally disturbed with portal tract appearing hemorrhagic and congested in addition to centrilobular necrosis in the folic acid group. In vitamin B12 group, the architecture of tissue was preserved with only mild inflammation. Vitamin B12, unlike folic acid has proved to be an efficacious hepato-protective agent in animal model of acute acetaminophen toxicity.

Keywords: Acetaminophen toxicity, Folic acid, Vitamin B12, Liver enzymes, Histopathology.

INTRODUCTION

Acetaminophen or paracetamol is one of the commonly used non-steroidal anti-inflammatory drugs. Though considered as safe analgesic-antipyretic, an overdose can lead to hepatotoxicity. Each year in the United States, approximately 6% of adults are prescribed acetaminophen doses of more than 4 g/day and 30,000 patients are hospitalized for acetaminophen toxicity.[1] Acetaminophen overdose is clinically significant as it is the most common cause of drug-induced liver failure.[2] Liver

injury occurs in 17% of adults with unintentional acetaminophen overdose.[1]Acute tubular necrosis is yet another manifestation of acute acetaminophen toxicity and it can occur either isolated or along with hepatotoxicity.[3]

N-acetylcysteine (NAC) is used as the treatment of choice for acetaminophen overdosage.[4, 5] Intravenous and oral formulations of NAC are available for the treatment of acetaminophen overdose. Though the current standard of care involves NAC, the use of this drug has many adverse effects like allergy, anaphylaxis, angioedema, bronchospasm.These reactions are dose-dependent and preceded by release of histamine. Hypotension can occur due to the vasodilatory effect and in severe cases, there can be consequent oliguria which may lead on to the issue of pre-renal pathology for an acute renal failure.[6]Animal studies and previous case reports strongly suggest that massive NAC overdose can cause cerebral edema and seizures.[7]

Though it has been well established that NAC can reduce mortality in acute overdose toxicity of acetaminophen, it is important to understand that the risk of adverse reactions to NAC do exists as is the risk of its overdosage.[6, 8] Noteworthy, the preparation of NAC for intravenous administration is quite complex.[6] Cases of iatrogenic NAC overdose have been reported in literature and it is important as this could even lead to death of the patient due to progressive hemolysis, thrombocytopenia and acute renal failure.[6, 7]

A high incidence of more than 60% patients treated with NAC has been reported to develop ADR.[8] Vitamin B12 and folic acid have been demonstrated to possess hepato-protective effect in other models of liver injury. Though one animal study indicating the effectiveness of folic acid in liver injury induced by acetaminophen has been reported in literature,[9] there are no studies evaluating the protective role of vitamin B12 in this animal model and in addition, this is the first study comparing the hepato-protective activity of vitamin B12 with folic acid in experimentally induced acute acetaminophen toxicity in rats in order to identify the potentially less toxic alternative to NAC by evaluating the effects of vitamin B12 and folic acid on liver enzymes and histopathology of liver tissue in comparison to that of NAC.

MATERIALS AND METHODS

The institutional animal ethics committee approved the protocol of the study (Approval number: 289/2015/IAEC). 18 Adult, male Sprague dawley rats weighing 200-300g were housed at constant ambient temperature in 12hr light, 12hr dark cycle. They were group housed as 3 animals per cage in polypropylene cages. Pellet diet and tap water were provided *ad libitum*. The animals were randomly allocated into the following three groups of 6 rats per group.

Group A: 6 rats in which acetaminophen at a dose of 3g/kg was given and NAC at a dose of 150mg/kg once after 1 hour of acetaminophen toxic dose.
Group B: 6 rats in which acetaminophen at a dose of 3g/kg was given and vitamin B12 at a dose 10mg/kg once after 1 hour of acetaminophen toxic dose.
Group C: 6 rats in which acetaminophen at a dose 3g/kg was given and folic acid 8mg/kg administered once after 1 hour of acetaminophen toxic dose.

The animals are weighed and the drugs were orally gavaged based on the body weight. 48 hours later, 1.5ml of blood was collected from the tail vein of the rats and liver function test (LFT) was performed. Quantitative analyses of liver enzymes namely, aspartate-aminotransferase (AST) or serum glutamic-oxaloacetic transaminase (SGOT), alanine-aminotransferase (ALT) or serum glutamic-pyruvic transaminase (SGPT), alkaline phosphatase (ALP) and ã-glutamyl transpeptidase (GGT) were performed. The values of these enzymes thus estimated were indicative of the severity of liver damage and were statistically analyzed.

All the rats were then sacrificed and liver specimens were taken, fixed in 10% formaldehyde and embedded in paraffin. Sections were cut from the tissue blocks, mounted on slides, and stained with Van Gieson's stain. They were examined under microscope for liver cell damage and disruption of normal architecture. [Figure1]

Statistical analysis: The data was entered in Excel and analyzed using SPSS software version

19. Comparison of the mean of liver enzymes was done using one-way analysis of variance (ANOVA) followed by Fisher's least significant difference (LSD) test. The difference between the groups was considered statistically significant if $p<0.05$. Histopathological changes between groups were qualitatively analyzed.

RESULTS

The mean AST (260.2 ± 54.7) of vitamin B12 group was lower compared to that of the group which received NAC with mean AST (319.8 ± 57.6) and though the mean ALT for vitamin B12 group (114.3 ± 32.4) was higher than that of NAC

Table 1: Comparison of liver enzymes between groups using one way ANOVA

Parameter	Between groups comparison	Mean difference	p value
AST	Groups A and B	59.667	0.103
	Groups A and C	-30.167	0.393
ALT	Groups A and B	-27.167	0.348
	Groups A and C	-207.333*	0.000
ALP	Groups A and B	119.167*	0.001
	Groups A and C	-378.000*	0.000
GGT	Groups A and B	-0.400	0.372
	Groups A and C	-1.650*	0.002

*The mean difference is significant at the 0.05 level.

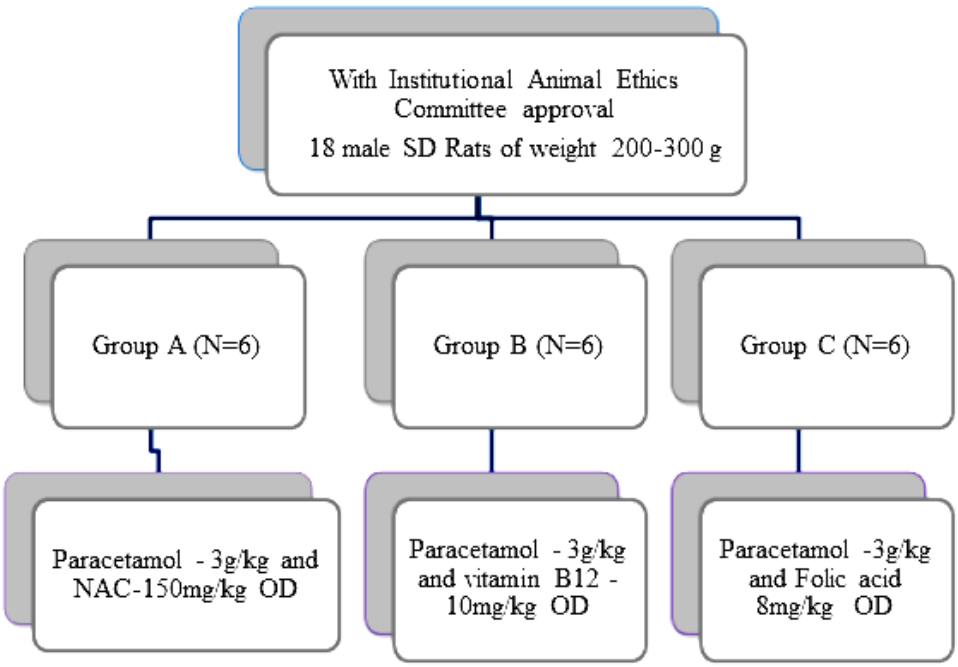

Fig. 1: Methodology

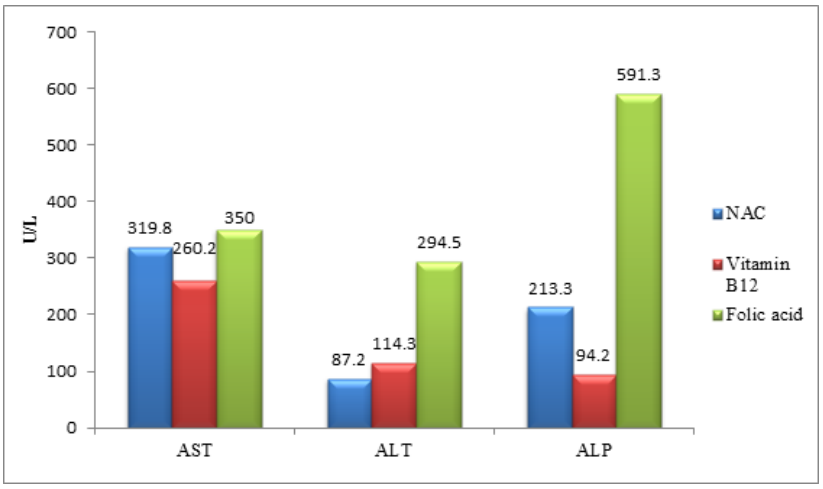

Fig. 2: Comparison of mean AST, ALT, ALP between groups

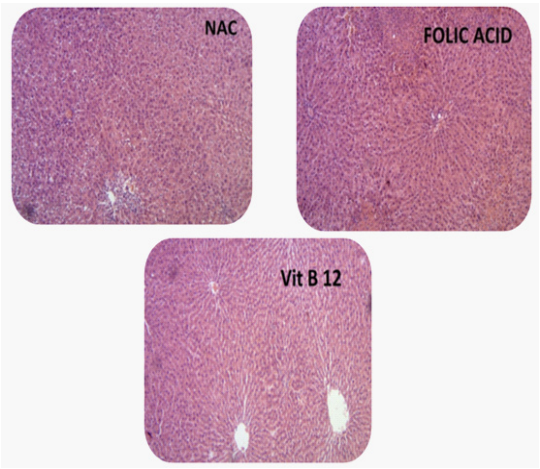

Fig. 3: Histopathology picture of the study groups

group (87.2 ± 41.5), [Figure2] the difference was not statistically significant by ANOVA with *post-hoc* LSD test either for AST (p=0.103) or ALT (p=0.348) between the two groups. [Table1]

On the contrary, folic acid group demonstrated a higher mean AST (350 ± 65.4) and mean ALT (294.5 ± 65.5) than NAC group. Comparison of the folic acid group with the group that received standard NAC treatment using ANOVA revealed that there was no statistical significance for the difference in the mean AST (p= 0.393) unlike that for mean ALT (p< 0.001). In addition, the vitamin B12 group had a significantly lower AST with mean difference of -89.8 ± 34.3 (p= 0.019) as well as for ALT with mean difference of -180.2 ± 28.0(p< 0.001) when compared to the group given folic acid. [Figure2 and table1]

Interestingly, there was a statistically greater reduction in mean ALP for vitamin B12 (94.2 ± 61.2) compared to NAC group (213.3 ± 48.2) whereas folic acid group (591.3 ± 44.8) had a statistically higher mean ALP (p< 0.001) indicating that folic acid did not demonstrate ALP reduction analogous to vitamin B12. [Table1]

Though mean GGT was slightly higher for the vitamin B12 group (1.18 ± 0.77) compared to the NAC group (0.78 ± 0.68), there was no statistical significance (p=0.372) for the difference in the mean values. However GGT for folic acid group (2.43 ± 0.79) mirrored the ALP wherein there was a statistically significant higher mean GGT (p=0.002) observed for folic acid group compared to the NAC group. [Table1]

Histopathological examination of the liver specimens revealed interface hepatitis, focal hepatic necrosis and thinning of sinusoidal plate in group A. In contrast, the group which received folic acid demonstrated tissue architect being totally disturbed with portal tract appearing hemorrhagic and congested in addition to centrilobular necrosis. Group B or vitamin B12 group had the architecture of tissue preserved with only mild inflammation. [Figure3]

DISCUSSION

This animal study has brought out the effective lowering of the liver enzymes by vitamin B12 in acute acetaminophen toxicity. The protective efficacy of vitamin B12 in reducing the liver damage after acetaminophen overdose is also evident from the histopathological changes observed in the study. It has been well established that acetaminophen induced liver damage causes centrilobular necrosis associated with a marked increase in AST, ALT activity.[10, 11, 12] Also, the increase in serum ALP activities is supported by the findings of earlier studies that, acetaminophen overdose is also accompanied by an increase in ALP activity due to hepatocellular injury. [10, 13] The reactive oxygen species-sensitive transcription factor namely nuclear factor-kappaB (NF-kappaB) is said to play a vital role in genesis of acetaminophen induced hepatotoxicity[12] and it has been reported that oxidative stress mediated by the metabolite N-acetyl-P-benzoquinone-imine (NAPQI) is considered to be the main cause of hepatic injury which involves depletion of cellular ATP, reduced Ca^{+2} ATPase activity with increased cytosolic Ca^{+2} levels, apoptosis and lipid peroxidation mediated by reactive oxygen species associated with a concomitant increase in AST, ALT, ALP.[14,15] It has also been hypothesized that reactive oxygen species induced lipid peroxidation generates peroxynitrite, a powerful oxidant and nitrating agent. Peroxynitrite can consequentially modify cellular macromolecules, aggravating mitochondrial dysfunction and ATP depletion, thus leading to cellular necrosis in hepatocytes and sinusoidal endothelial cells.[16]

The effectiveness of vitamin B12 parallels that of NAC since there is no significant difference in the mean AST, ALT and GGT values between the two groups [Table1]. In addition, the reduction in mean ALP was statistically greater for the vitamin B12 group than the NAC group. In comparison, folic acid did not demonstrate a similar effectiveness either in reduction of raised hepatic enzymes or reversal of histopathological changes induced by acute administration of high dose acetaminophen. [Figue3] This is in contrast to an earlier study which indicated lowering of liver enzymes and improvement in hepatocellular damage histopathologically following administration of folic acid in acetaminophen induced toxicity in rats. Folic acid, though has plausible hepato-protective effect attributed to its property of eliminating the changes that are related to the oxidative stress such as lipid peroxidation and oxidative DNA damage, [9, 17] our study did not replicate a similar efficacy and this can be ascribed to a lower dose of acetaminophen for induction of toxicity in the previous studies and disparity in the time duration of blood withdrawn for estimation of liver enzymes. Such hepato-protective property of folate supplementation regimens after induction of liver toxicity using either chromium in rabbits or folate deprivation with copper exposure in rats have been reported in literature.[18, 19] The contradiction in findings between different studies probably stems from the fact that there is some inherent variation in the pathways and diversity in the intensity of oxidative stress induced by different models.

On the other hand, our study has delineated a significant hepato-protective effect of vitamin B12 demonstrating its efficacy in acute acetaminophen toxicity rat model.[Table1 and Figure3] The potential mechanisms contributory to this beneficial effect is the ability of vitamin B12 to maintain the sulphydryl level under oxidative conditions despite lack of radical scavenging property.[20] Moreover, vitamin B12 has been shown to protect rat primary hepatocytes from hepatotoxin-induced cell death in *in-vitro* experiments.[20] Evidence suggests that the activity of glutathione reductase is significantly lower in B12 deficient liver[21] and that the interaction between vitamin B12 and glutathione could protect against disease related to vitamin B12 deficiency.[22] The presence of cobalt complex in vitamin B12 has been shown to effectively inhibit the hepatic inflammation and fibrosis.[20] Besides, protective effect of vitamin B12 in experimental liver injury by carbon tertrachloride[23, 24] has been well documented in literature wherein the beneficial effect has been primarily hypothesized as owing to the improvement in mitochondrial integrity and this could be another contributory factor in the hepato-protection in acetaminophen toxicity amelioration also.

CONCLUSION

This study highlights that vitamin B12 exhibits significant hepato-protective effect and hence can be considered as a potential therapeutic

agent, alternative to N-acetyl cysteine in acute acetaminophen over dosage after appropriate human trials.

ACKNOWLEDGEMENT

We acknowledge Dr.Pavithra and animal house technicians for their support in the conduct of the study.

Abstract

Background: Previous studies on *Momordica charantia* (MC) (bitter gourd) have shown the inhibition of NF-κβ and Leukotrienes expression in many inflammatory pathological conditions. Based on ist anti-inflammatory action this study aimed to Identify MC fruit dry powder (MCp) and MC fresh juice (MCj) action on airway inflammation in Guinea Pig model and also to find out the presence of alkaloids and flavonoides.

Methods: 18 adult Guinea pigs of both sexes (excluding mating animals) were randomly divided into three groups with six animals in each namely Montelukast, MCj and MCp groups respectively. They were given with OD oral administration of concerned drugs for 1 -7 days. 6 control animals were exposed to 2% histamine aerosol for 120 seconds using histamine chamber prior to treatment with Montelukast, MCj and MCp to observe the normal Pre-Convulsive Dyspnea (PCD) in seconds. After six hours of daily OD oral dose of test drugs administration, all the groups' were exposed to 2% Histamine aerosol one by one for 120 sec on day1 & 7 to observe PCD. The MCj and MCp were also tested with chemical assay, TLC to confirm the presence of alkaloids, flavonoides.

Results: ON DAY 1 and 7: MCj and MCp showed significant decrease in PCD occurrence and it is statistically significant compared to the control. PCD blocking action of MCj group was effective in DAY 1. TLC and Chemical Assay were not supportive for bronchodilator action.

Conclusions: MCj and MCp have promising preventive role in asthma. This study had expressed the positive protective role of *Momordica charantia* in asthmatic condition based on its known anti-inflammatory action.

Keywords: Guinea pig, *Momordica charantia*, Pre-convulsive dyspnea

Introduction

Asthma is a controllable chronic inflammatory disorder of the airways with high difficulty to cure completely.[1] Long term use of anti-inflammatory drugs is the treatment of chronic asthma. Most potent and consistent anti-inflammatory agent available is Corticosteroids and it's not free of adverse effects even in the inhaled form.

As a result, there is continuous search for an alternative especially from natural sources. *Momordica Charantia* (bitter gourd), a common edible vegetable, is known traditionally to possess medicinal values.[2,3] Many studies had confirmed the anti-inflammatory property of *Momordica Charantia* with cytokine inhibiting activity.[4,5] It inhibited the expression of inflammatory genes like IL-1,IL-2,IL-6,IL-8,TNF-α and Matrix Metallo Proteinases (MMPs) in animal studies.[6] Like Montelukast a Leukotrienes receptor antagonist used in asthma, *Momordica Charantia* fruit also inhibits NF-Kβ expression.[7]

Very few animal studies were done on its anti-inflammatory property utilizing the prostaglandins and inflammatory cytokine inhibition by *Momordica Charantia.* So far, no study has been done to prove its anti-inflammatory effect in asthma. Hence this study has

aimed to understand the bronchodilator property of *Momordica Charantia* as an agent to reduce airway inflammation in a whole animal model using Montelukast as a comparative standard.

M□□□□□□□

Method I: Animal study-histamine induced bronchospasm in guinea pig model

Animal which used for the study were adult guinea pigs with weight 400-700gram of both sex excluding animals used for breeding.

Period of the study was 15 days to 2 months including animal selection.

Total number of animals were 18 as 3 groups with 6 animals in each.

Study parameters were PCD (Pre-convulsive Dyspnea) per 120 seconds.

Histamine chamber with nebulizer instrument was used with standard technique to apply.

Momordica fruit dry powder and fresh juice

Momordica Charantia was bought from local farm after getting botanical certification. Then it was used to prepare fresh juice and dry powder after removing seeds.

Fresh juice

Fresh juice was prepared by using fresh 500gram of *M. Charantia* unripe fruits. Then it was cut into small pieces after removal of the seeds. These fruits were crushed with a commercial blender and juice was obtained after filtration through soft muslin cloth.

Dry powder

500gram of *M. Charantia* unripe fruits were cut into small pieces after removal of the seeds. These pieces were allowed to dry in hot air oven at 60 degrees for 24 hrs.[8] Once the fruit pieces were dried enough, they were made into fine powder using blender. Powder thus prepared was passed through a sieve and fine particles was obtained and stored in air tight containers.

IAEC

The animals were maintained at ambient temperature 25±2^{0}C and 55% relative humidity. The Institutional Animal Ethics Committee of PSG and IMSR approved the study and the study was conducted strictly with guidelines of ICMR and CPCSEA. 6 animals out of 18, randomly selected to observe the control values for PCD per 120 seconds. Control was exposed to 2% Histamine aerosol for 120 seconds.[7] These values were compared with Montelukast, MCp (*Momordica Charantia* dry powder) and MCj (*Momordica Charantia* fresh juice) exposure to understand the protective effect on histamine induced Bronchospasm.

If any animals showed severe bronchospasm in any of these groups were immediately exposed to normal air and Inhalational corticosteroid + salbutamol aerosol using nebulizer to revert the histamine induced bronchospasm. After completion of the study, all the animals were observed for a period of 1 week in their own environment with the normal water, food for any reactions.□

Method II

A. Chemical analysis for alkaloid material[9]

Detection of alkaloids

Dry powder and Fresh Juice were dissolved individually in dilute Hydrochloric acid was heated for 30 min, allowed to cool and filtered.

- Mayer's Test: Filtrates were treated with Mayer's reagent (Potassium Mercuric Iodide).
- Wagner's Test: Filtrates were treated with Wagner's reagent (Iodine in Potassium Iodide).
- Dragendroff's Test: Filtrates were treated with Dragendroff's reagent (solution of Potassium Bismuth Iodide).
- Hager's Test: Filtrates were treated with Hager's reagent (saturated picric acid solution).
- Marquis test was performed with both dry powder and fresh juice.[10]

1 drop reagent made up of 8-10 drops (approx. 0.25ml) of 37% formaldehyde solution to10 ml of glacial acetic acid. Then added 3 drops of concentrated sulfuric acid

Results are present in Table 4.

- Chen-Kao Test: Test for ephedrine and pseudoephedrine.[10]
  - Reagent 1: Added 1 ml of glacial acetic acid to 100 ml of water (=1% (v/v) aqueous acetic acid solution).
  - Reagent 2: Dissolved 1 g of copper (II) sulphate in 100 ml of water (=1% (w/v) aqueous CuSO4 solution).
  - Reagent 3: Dissolved 8 g of sodium hydroxide in 100 ml of water (=2N aqueous sodium hydroxide solution).

Procedure

Placed a small amount (1-2 mg of powder, or 1-2 drops of a liquid) of the suspected material in a depression on a spot plate.

- Added 2 drops of Reagent 1.
- Added 2 drops of Reagent 2 and then added 2 drops of Reagent 3 and stirred. Results were shown in Table 5.

B. Thin layer chromatography[11]

MC Dry powder and fresh juice were subjected to thin layer chromatography (TLC) with silica gel F254 plates using Chloroform-Methanol solvent was used and the extract showed spots on Merck silica gel (MSG) pre-coated TLC plate of thickness of about 0.2mm.

The plates were saturated in chromatography tank and spots were detected following drying of the solvent. Band of separated fractions was detected under UV light. The retention fraction (Rf) of each fraction or band was calculated and recorded.

Statistical analysis

Analysis was done by comparing the before and after values, and also between groups student t- test was done for comparing before and after values, whereas ANOVA was used in comparing between all three groups. Analysis was done using SPSS version 19.

On day 1

MCj and MCp were showed significant decrease in PCD occurrence and it was statistically significant compared to the control. MCj group PCD blocking action was significant, when all the three groups were compared (Table 1, 2 and 3).

Table 1: Mean PCD inhibition in control and after 120 minutes in MC powder and juice treated groups

Mean PCD inhibition	120 minutes
Control	61.10±9.74
Day 1	79.16±16.21
Day 7	87.35±21.16
Momordica dry powder (MCp)	
Control	61.10±9.74
Day 1	93.47±12.36
Day 7	93.47±10.52
Momordica fresh juice (MCj)	
Control	61.10±9.74
Day 1	73.46±16.48
Day 7	100.00±0.00

On day 7

MCj and MCp showed significant decrease in PCD occurrence statistically, compared to the control. TLC and chemical assay were not supportive for bronchodilator action (Table 1, 2, 3).

Table 2: Comparison between control and day 1 and day 7 in MC powder and juice treated groups

		't'	
PCD (Pre convulsive dyspnoea)			
Montelukast	Control and day 1	2.225	0.077
	Control and day 7	2.521	0.053
	Day 1 and day 7	0.955	0.383
MC powder	Control and day 1	4.187	0.009
	Control and day 7	5.194	0.003
	Day 1 and day 7	0.000	1.000
MC juice	Control and day 1	2.733	0.041
	Control and day 7	7.950	0.001
	Day 1 and day 7	3.176	0.034

Table 3: Comparison between MCj and MCp in day 1 and day 7

Day 1	MCj is significant over MCp	P =0.037
Day 7	No Significance between all 3 groups	P >0.05

Table 4: Chemical tests for alkaloid and ephedrine

1. Mayer's test	Positive	Positive
2. Wagner's test	Positive	Positive
3. Dragendroff's test	Negative	Negative
4. Hager's test	Positive	Positive

Table 5: Chemical tests for ephedrine and pseudoephedrine by *Marquis* reagent

Ephedrine	Pale yellow	-	-
Pseudoephedrine	Pale yellow (greenish	-	-
Norephedrine	Pale yellow (brownish)	-	-
Norpseudo-ephedrine	Yellow (brownish)	-	-
Norpseudo-ephedrine	Yellow (brownish)	-	-
N-methylephedrine	Brownish red		
Chloropseudo-ephedrine	no change	-	-

- Chemical tests: Test for alkaloid and ephedrine were revealed in tabulation (Table 4, 5).
- Chen-Kao test: Test for ephedrine and pseudoephedrine11 - Both dry powder and fresh juice didn't show violet color positive reaction.

Thin layer chromatography[11]

- Solvent System: Chloroform-Methanol (9:1) Detection at UV: 366nm.
- Color of bands: Reddish spots

Results were shown in the Table 6 and Table 7.

which proved that the dry powder of *Momordica Charantia* was effective in delaying PCD in Histamine exposed guinea pigs significantly.

MCp group's were compared for the difference between PCD on Day 1 and Day 7. The mean PCD was found to be 93.47±12.36 on Day 1 against 93.47±10.52 on day 7. This was not statistically significant with P value of 1.000 as there was not much difference in the average value of PCD.

MCj group were compared the baseline Day 1 control value the mean was found to be 73.46±16.42 which was more than the control mean of 61.1%. Also this difference in PCD was statistically significant with P value of 0.041 which shows Fresh juice was effective in delaying PCD. MCj group compared for the Day 7 values, the mean was found to be 100.00±0.00. This too was statistically significant with P value of 0.001. This proved that the fresh juice of *Momordica Charantia* was significantly effective in delaying PCD in Histamine exposed guinea pigs.

MCj group compared for the difference between PCD on Day 1 and Day 7, the mean PCD was found to be 73.46±16.42 on Day 1 against 100.00±0.00 on day 7. This was statistically significant with P value of 0.034 which justifies Momordica was effective in both short term and long-term management.

Further analysis of both study groups of Momordica dry powder and fresh juice with student t-test. On day 1 in dry powder group the mean was found to be 93.47±12.36 and in fresh juice group it was found to be 73.46±16.42. This was statistically significant with P value of 0.038; which showed the dry powder was better on Day 1 of treatment with quick response. On day 7 in dry powder group the mean was found to be 93.47±10.52 whereas in fresh juice group it was 100.00±0.00. This was not statistically significant as both groups had similar protective effect on day 7. The average was more in fresh juice group compared to the dry powder group on day 7.

When ANOVA was used to analyze the difference between the groups, (Table 2) on Day 1, MCp was significantly better than MCj with P value of 0.037 whereas it was not statistically better than Montelukast. On day 7, there was no statistical significance between all 3 groups since all were effective in abolishing PCD occurrence.

These results showed that, there was a significant improvement in both groups of *Momordica* after starting treatment, whereas there was no much difference between groups. It's a pilot study and each group strength was six may be the limitation of this study.

Momordica charantia had been extensively studied for various metabolic, antihypertensive and its role in Diabetes with its anti-inflammatory background and not much significant reference for the direct effect of MC on smooth muscle activity.[12-15]

[illegible]

This study had expressed the positive protective role of *Momordica charantia* in asthmatic condition based on its known anti-inflammatory action. Further, MC both dry powder and fresh juice protecting role on histamine aerosol induced bronchospasm as an anti asthmatic action may be explored and proved in clinical situation using suitable models to ensure the usefulness and effectiveness in chronic asthma treatment compared to standard care of management in future.

[illegible]

Authors would like to thank PSG Institutions Management for providing the infrastructures including financial assistance to proceed and complete this study. Authors thank the Dean, PSG IMS and R and Hospitals, The Principal, PSG College of Pharmacy for their kind technical support to complete this study. Also thank all the technicians, lab assistants of Department of Pharmacology PSG IMS and R for their countless help in performing this Research.

ADR monitoring centre

ABSTRACT

Objectives: The study was aimed to evaluate the completeness of suspected adverse drug reaction (ADR) forms in order to identify the areas lacking complete information, to assess the proportion of the ADR forms received with incomplete data and to evaluate the completeness score of the individual case safety reports.

Methods: This cross sectional study was done as an audit using data in the ADR forms collected and Individual Case Safety Reports (ICSRs) submitted in VigiFlow in the previous two years from January 2015 to December 2016 at our ADR Monitoring centre (AMC).

Results: The total number of ADR forms audited was 1650. Seriousness, action taken and outcomes and concomitant drugs were three areas identified to be lacking complete information. The mean completeness score was 0.95 for 2015 and 0.97 for 2016, indicative of a high completeness score of the ICSRs uploaded in Vigiflow maintained by the AMC.

Conclusion: The audit has analyzed various parameters of ADRs reported for completeness and has demonstrated that, though some improvement in completeness of reporting is evident in the year 2016 compared to 2015, there is an obvious need for increasing the awareness on reporting of ADRs with complete information amongst reporters.

1. Introduction

Adverse drug reactions (ADRs) are inevitable consequences of pharmacotherapy. It is well known that all drugs carry the potential to produce both desirable and undesirable effects. No drug is absolutely safe under all circumstances and ADRs can occur even if a drug is correctly selected and dosed [1]. It has been reported that the number of patients dying because of adverse effects of drugs per year has increased up to 2.6-fold from the past [2]. Moreover, rates of hospitalization of patients and polypharmacy have increased the risk of ADRs. Thus, it becomes challenging for the physician, health care providers, World Health Organization (WHO) and pharmaceutical industries to address the problem of ADRs. Documented details are required to identify the ADRs in patients.

Pharmacovigilance plays a very important role in the surveillance of adverse drug reactions. Adverse drug reactions are documented in suspected ADR reporting forms [issued in India by Indian Pharmacopeia Commission (IPC) at National Coordination Centre (NCC), Ghaziabad] under the Pharmacovigilance program of India (PvPI) which strives towards ensuring drug safety in patient care [3,4]. ADR monitoring centres (AMC) play a vital role in the collection and follow up of ADR reports. Currently there are 197 AMCs functioning across India [5]. They are responsible for collecting the adverse reaction information and reporting it to the IPC, functioning under the Ministry of Health, Government of India. The ADR information is in turn forwarded to the WHO and the online database, VigiFlow provides the platform for reporting the ADR data [6]. Hence reported information in the ADR forms plays a vital role in the interpretation of drug reactions and the ensuing drug safety measures implemented.

Incomplete reporting of essential data is a very important factor that hinders effective interpretation of the ADR forms. Hence ensuring completeness of the ADR forms plays an indispensible role in success of Pharmacovigilance program. The recommendation by PvPI is that the reporter has to ascertain entering the information on patient's initials, age, gender and weight, date on which the suspected reaction appeared, description of event, name, dose, dosing frequency, the route of administration of the suspected medicine and concomitant drugs including the details

on batch number, expiry date and the indication for the use of the medication. In addition similar data on vaccines and biological products, de-challenge and re-challenge results, causality assessment, relevant laboratory investigations, relevant past medical history and action taken for the ADR are required to be filled in while reporting [5]. Missing information or incomplete data is a deterrent not only in analyzing the ADR reports and assigning causality but also affects the quality of information that serves as the source of input for the international database [7,8].

The vigiGrade completeness score is a numerical score assigned to each individual case safety report (ICSR) entered in VigiFlow based on the completeness of information provided. The maximum score is 1 for each complete report calculated from the information provided according to a structured algorithm. Based on the algorithm, a field score is assigned to specific data fields, such as patient gender, indicating whether the field has been filled or not. In addition to the field scores, scores for pieces of information derived from multiple fields is generated. The completeness score is calculated for each drug- ADR combination separately and the mean of these scores is the Report Completeness Score. Reports with overall score >0.8 out of 1 are considered well documented [9]. Overall, only one report in eight provides the desired level of information, but much higher proportions are observed for individual countries [7,8].

Hence this study was done to evaluate the completeness in suspected ADR reporting forms to identify the areas lacking complete information, to assess the proportion of the ADR forms received with incomplete data and to evaluate the completeness score in the ADR forms reported over the past two calendar years 2015 and 2016 at our AMC.

2. Materials and methods

After the approval of the institutional human ethics committee (Approval number:17/010, dated 13th January 2017), the study was done as a cross sectional one using data in the ADR forms collected over the previous two years (January 2015 to December 2016) at the ADR monitoring centre in our tertiary care teaching hospital in Coimbatore. The audit was done as a retrospective record based study during January to March 2017. All the ADR forms from January 2015 till December 2016 and likewise all ICSRs submitted in VigiFlow and stored as soft copy during the same period were analyzed for the completeness score in accordance to the guideline provided by vigiGrade.

The areas lacking complete information were analyzed under ten categories namely report title, source (name, qualification), patient information (patient age, sex, initials), seriousness, free text (laboratory investigation & past medical history), outcome, drug details, action taken, indication and concomitant drugs.

Percentage of forms with incomplete information in each of the parameters analyzed from ADR reporting forms were recorded. The parameters showing a considerable difference in the percentages observed in the year 2016 compared to that in 2015 was analyzed for statistical significance using the Z test- social science statistics software and p value <0.05 was considered significant.

The completeness score of each ICSR reported in both years were calculated using the formula $C = \pi^{n}_{i=1}((1\text{-}w_i) + (w_i{*}f_i))$ where, C is the Completeness score, i is the Field included in the score, w_i is the Field weight and f_i is the Field score, n is total number of Drug-ADR combination [8,9]. The mean completeness score for the two years were estimated.

3. Results

All Suspected ADR forms submitted to the ADR monitoring centre from January 2015 to December 2016 were audited. The total number of audited forms were 797 from the year 2015 and 853 from the year 2016 accounting for a total of 1650 ADR forms. The report title was complete in all the ADR forms in both years and hence 100% complete. The source of the report was analyzed for two sub-parameters which included the name of the reporter and secondly, the qualification of the reporter. Name of reporter was complete in all the forms and thus 100% complete. On the other hand, qualification of reporter was incomplete in 274 (34%) forms out of 797 in the year 2015 and 226 forms out of 853 in the year 2016 accounting for 26% incompleteness. (Table 1)

Patient information which encompassed the details on patient's age, sex and initials was complete in 100% forms in both years. Seriousness was not filled in a considerable proportion of the ADR forms. 296 out of 797 forms were incomplete contributing to 37% incomplete seriousness data in 2015 and 252 out of 853 forms accounted for 29% of incompletion in 2016. It was found that a total of 92 serious ADRs in 2015 and 135 in 2016 were reported. Free text data analyzed which included the relevant laboratory investigation results and past medical history was found to be 100% complete in both the years. (Table 1)

The outcomes column was incomplete in 56 out of 797 forms in 2015 and 40 out of 853 in 2016 amounting to a fraction of 7% and 4% in 2015 and 2016 respectively. The other parameters audited were drug details such as name of brand, dose, route and frequency of administration. 45 out of 797 forms were incomplete in 2015 attributing 5% being incomplete as against 2% (18 out of 853 forms) in 2016. (Table 1) The area most frequently incomplete was frequency and route of administration.

Action taken column was incomplete in majority of the forms; in 2015, 581 out of 797 forms accounting for 72% and comparatively, a lower value of 42% (364 out of 853 forms) were revealed to be incomplete in 2016. In addition, 6% (52 out of 797

Table 1
Percentage of incomplete forms in the years 2015 and 2016.

Year	2015 n = 797			2016 n = 853		
Parameter	Complete	Incomplete	Percentage of Incomplete forms	Complete	Incomplete	Percentage of Incomplete forms
Report title	797	0	0%	853	0	0%
Source	523	274	34%	627	226	26%
Seriousness	296	501	37%	601	252	29%
Patient information	797	0	0%	853	0	0%
Free text	797	0	0%	853	0	0%
Outcome	741	56	7%	813	40	4%
Drug details	752	45	5%	835	18	2%
Action taken	216	581	72%	489	364	42%
Indication	745	52	6%	850	3	0.30%
Concomitant drug	783	14	1%	841	12	1%

forms) in 2015 and a meager 0.3% (3 out of 853 forms) in 2016 were found to lack the indication. (Table 1) In the concomitant drugs information, only 14 out of 797 forms were incomplete amounting to 1% in 2015 and an exactly equal one percentage (12 out of 853) were identified to be incomplete in the reported forms in 2016. (Table 1)

A detailed breakup of ADRs from various departments could not be done since specific mentioning of the department is not mandated in either the ADR form or for the entry in Vigiflow. Hence we did not include it as a criterion for assessing completeness. However all ADRs reported were drug related and no AEFI (adverse event following immunization) were reported to our AMC.

We estimated the statistical significance of the mean change in percentage of incomplete forms with respect to the parameters namely source, seriousness, outcome, drug details and action taken which had a considerable difference in the values obtained for 2015 and 2016. Analysis was done using the Z test- social science statistics software revealed that the reduction in percentage of incompleteness were not significant for the parameters- source ($p = 0.186$), seriousness ($p = 0.197$), outcome ($p = 0.307$) and drug details ($p = 0.218$) whilst p value for the action taken was statistically significant. (Fig. 1)

The mean completeness score was 0.95 for 2015 and 0.97 for 2016 implying that a high completeness score of the ICSRs uploaded in VigiFlow was maintained by the AMC.

4. Discussion

Amongst the 1650 forms audited, a high degree of completeness was maintained with reference to the report title and patient information. With regards to the source which represented spontaneous reporting from the clinicians, the Pharm D interns and Pharmacology postgraduates, the majority of incomplete forms on qualification of the reporter were from the postgraduates of Pharmacology. This lack of complete information could be attributed to the fact that they were known to the department of Pharmacology functioning as the AMC, which could have precluded them from giving complete information on qualification. However, the incomplete reporting with respect to the source has shown a decline of 8% in 2016 (26%) compared to 2015 (34%) though the difference was not statistically significant ($p = 0.186$)

It is noteworthy that a lack of clarity exists among the reporters in labeling an ADR as serious or not. It is possible that most of the reporters are unfamiliar with assessing the seriousness of the reaction. Categorizing those reactions that can prolong the hospital stay which is one of the seriousness indicators, cannot be easily discerned, as in a practical clinical scenario, it is difficult to attribute whether the reaction itself or the disease *per se* was responsible for the extended hospital stay of the patient. It was found that the ADR forms were complete in seriousness data when the reaction was definitely a life threatening one like the anaphylaxis. Also, a significant finding was that a notable improvement in the percentage of seriousness data entry in the forms in 2016 was evident compared to 2015, though the difference was not statistically significant.

100% completeness in free text information was illustrated based on the audit and with reference to the drug details; potential for improvement was delineated especially with the frequency and route of administration. Outcomes parameter referring to the recovery information can be rather considered as a grey area due to lack of follow up information regarding the patient's status as recovery may take much longer and often beyond the date of reporting [10].

The action taken with regards to the changes in the regime of the offending drug was not stated in a high proportion of the ADR forms reported. Nevertheless, the information on how the reaction was treated was indicated in majority of the forms. The action taken column in the ADR forms had to be filled with the data on whether the suspected drug was withdrawn or the dose increased/changed/reduced. In such situations, wherein the offending drug

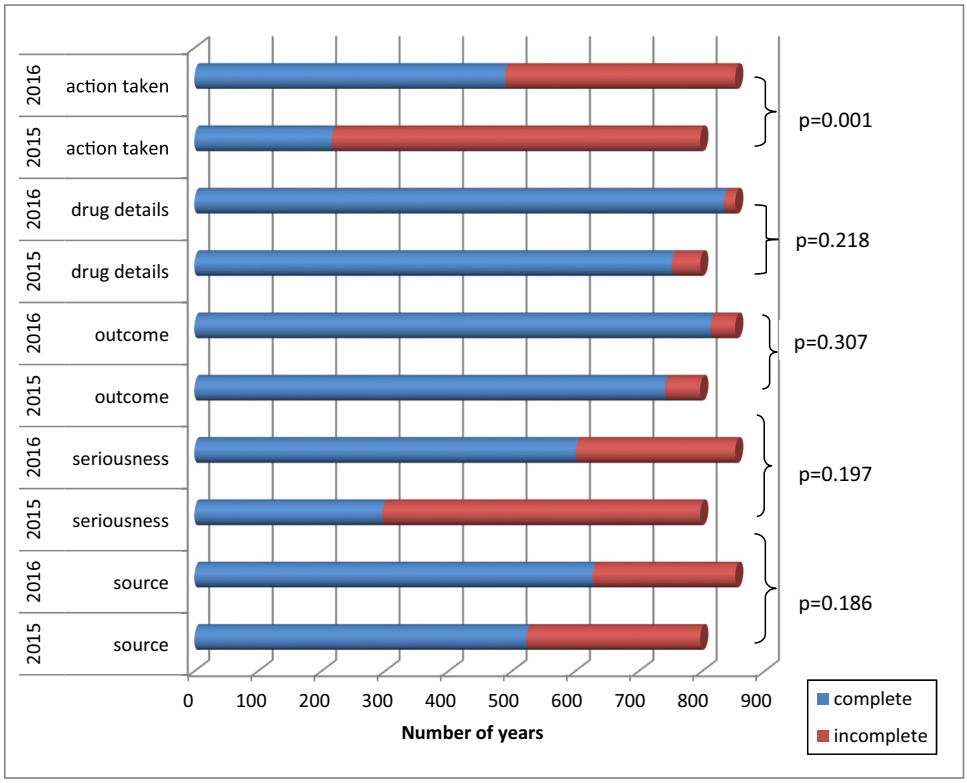

Fig. 1. Comparison of parameters showing difference in percentage of completeness in the years 2015 and 2016.

had been withdrawn or dose modification done, it was obviously mentioned in the form. On the contrary, if the suspected drug was continued in the same dosage despite the reaction, the column on action taken was left incomplete indicating the reporter's attitude of not attaching significance to that information or unwillingness to reveal it. In such cases, the option of "not applicable" which needs to be chosen remained unselected and this could be deciphered from the fact that the "date stopped" column of the suspected medication was also left blank simultaneously. Remarkably, a statistically significant improvement in the action taken data ($p = 0.001$) was demonstrated in the forms reported in 2016 compared to that in previous year denoting gradually increasing awareness about pharmacovigilance among health care professionals [9,11].

A meager percentage of reporters have failed to specifically mention the indication for which the offending drug was administered. This might have resulted from the attitude that the indication of the particular drug for a given diagnosis is widely known. The indication columns were obviously better filled in forms reported in 2016 (0.3%) in comparison to 2015 (6%). Nonetheless, this large variation precluded testing for statistically significance which could not be performed due to the very small value of 0.3%.

The list of concomitant drugs was largely complete in both years and this apparently high percentage is due to the standard operating procedure followed by the AMC personnel to retrospectively collect the information on concomitant drugs, if missing/incomplete either from the consultants or case records [10]. This information is imperative for a meaningful causality analysis and therefore the completeness of concurrently administered drugs information is ensured by the AMC workforce to the maximum extent possible.

Interestingly, we found that ADRs to newer drugs reported were primarily for the anti-diabetic drugs (voglibose, vildagliptin) and cardiology related drugs namely ticagrelor (antiplatelet), lercarnidipine and cilnidipine (antihypertensive drugs). In addition, certain chemotherapeutic drugs like tigecycline, the antifungal drug- caspofungin and antifibrotic drug – pirfenidone used for idiopathic pulmonary fibrosis were among other newer drugs to be implicated in causing ADR. This is quite reflective of the trends in use of new drugs indicating the prompt use of such newly discovered agents for treatment of clinical conditions like diabetes, hypertension and heart disease.

It is important to furnish complete data on the ADR reported in order to ensure the utility of the data for patient safety. The study which was conducted as an audit has highlighted the areas with a definite scope for improvement. Seriousness, action taken, outcomes and concomitant drugs are four such critical areas identified. The major setback in the seriousness entry is lack of certainty on the part of reporters in assigning the seriousness category. This can be improved by periodic contact programs educating them on the various criteria for deciding the seriousness of the reaction report. The completeness of information on action taken and outcomes can be improved if there are ways to ensure the reporter contacting the AMC personnel to share the follow up information. The study has also brought out the need for increasing the awareness amongst reporters that a comprehensive list of concomitant drugs is essential for causality assessment. This can be emphasized through appropriate education programs and providing feedback to the reporters [12–14].

A high completeness score of the ICSRs had been maintained by the AMC. A similar value of 0.94 was recorded in a study for ICSRs received by IPC during July 2011 to September 2014 [9]. This is primarily owing to the programming of VigiFlow software which is designed such that the mandatory columns are filled before submission through appropriate pop up message alerts and stepped data entry which consequentially averts low scoring of ICSRs submitted.

Key message

The trend of increasing awareness on pharmacovigilance is evident from the audit and a definite scope for further improvement has also been identified. Initiation of appropriate programs in view of inculcating the culture of ensuring completeness in ADR reporting amongst healthcare professionals will be instrumental in improving the quality of reported data.

5. Conclusion

The audit has analyzed various parameters of ADRs reported for completeness and has demonstrated that there is increasing awareness on reporting of ADRs with complete information as is evident from the progress in completeness of reporting in 2016 compared to 2015. This can be further improved by structured educative programs with objectives targeting achievement of 100% complete reporting with respect to all the parameters. This would envision an era of best practices for ensuring patient safety.

ABSTRACT

Objective: Low molecular weight heparin (LMWH) is an indirect thrombin inhibitor used clinically as an anticoagulant for thromboprophylaxis of patients at risk of deep vein thrombosis. The study was done to assess the magnitude of rise in serum potassium after administration of low molecular weight heparin comparing enoxaparin with dalteparin and to evaluate the frequency of clinically significant hyperkalemia in the population studied.

Methods: The study was done as a prospective non-randomized observational study in a population of 32 patients started on heparin for thromboprophylaxis for deep venous thrombosis, pulmonary thromboembolism or stroke.

Results: A statistically significant elevation in serum potassium was seen in patients treated with LMWH ($p = 0.007$). The magnitude of rise in potassium was significantly higher in enoxaparin ($p = 0.008$) than the dalteparin group ($p = 0.447$). A clinically relevant hyperkalemia of>5 mEq/l was seen in 25% of the population studied. Other important associations detected from the study were that the advancing age and increasing dose could be potential risk factors contributory to an accentuated rise in serum potassium which may culminate in clinically significant hyperkalemia.

Conclusion: The study has highlighted that the likelihood of rise in potassium levels during LMWH therapy necessitates monitoring of serum potassium.

INTRODUCTION

Heparin is a parenteral anticoagulant that acts as indirect thrombin inhibitor and is extensively used for treatment and prophylaxis of several thromboembolic conditions in clinical practice. Heparin is a heterogeneous mixture of sulfated mucopolysaccharides whose biologic activity is dependent upon the endogenous anticoagulant antithrombin. Antithrombin inhibits clotting factor proteases, especially thrombin (IIa), IXa, and Xa by forming equimolar stable complexes with them.

Hyperkalemia is an electrolyte abnormality associated with the use of heparin therapy in patients. It is a condition wherein the serum potassium is elevated above the normal range (Normal: 3.5–5 mEq/l). The incidence of heparin-induced hyperkalemia in hospitalized patients is estimated to be 1-10% [1]. The risk of heparin-induced hyperkalemia is increased many folds in patients with renal insufficiencies and in the elderly population [2]. Thus it is important for the physician to be aware of this complication and ensure appropriate monitoring of serum potassium levels during heparin therapy.

Unfractionated heparin (UFH) has a high molecular weight in the range of 5000–30,000 Daltons. In contrast, low molecular weight heparin (LMWH) is shorter chain fractions which inhibit activated factor X with a lesser effect on thrombin than the UFH. LMWH is as efficacious as UFH with more predictable therapeutic effect and lesser adverse effects. LMWH offers many advantages such as weight-based dosing, lower frequency of injections, eliminating the need for laboratory monitoring in addition to a decreased risk of heparin-induced thrombocytopenia and osteoporosis. Therefore LMWH preparations are more commonly used in the current clinical scenario.

Heparin therapy can induce hypoaldosteronism by inhibiting the enzyme involved in the synthesis of angiotensin ll receptors in the adrenal gland. This, in turn, produces natriuresis and hyperkalemia. Heparin can produce hyperkalemia within 4-7 d of beginning treatment [3]. The risk of hyperkalemia is increased in patients with chronic renal failure, diabetes mellitus, and elderly people [2]. While most physicians are aware of heparin-induced thrombocytopenia, heparin-induced hyperkalemia is less commonly recognised [4].

Though there are many case reports on unfractionated heparin-induced hyperkalemia in literature, there are very few prospective studies evaluating the effect of LMWH on serum K^+ levels. Therefore our study was designed to evaluate the frequency of occurrence of a heparin-induced increase in serum K^+ levels in hospitalized patients receiving LMWH for thromboprophylaxis. We chose to compare the change in K^+ electrolyte levels due to enoxaparin with that of dalteparin as enoxaprin and dalteparin are the two commonly used low molecular weight heparins in patient care.

MATERIALS AND METHODS

This was a hospital based prospective open-label, non-randomized study. The institutional human ethics committee (IHEC) approved the protocol of the study. (Approval number: 13/361). The study was done in 32 patients started on low molecular weight heparin in our tertiary care teaching hospital. Patients who were admitted and started on LMWH, either enoxaparin or dalteparin were included for the study, based on inclusion and exclusion criteria.

All patients, aged>30 y, both males and females with normal baseline potassium value and started on low molecular weight heparin, either enoxaparin or dalteparin for thromboprophylaxis in ICU or inpatient care were included for the study after obtaining a written informed consent. Patients with chronic renal insufficiencies or altered renal function tests, on pre-existing potassium supplementation or receiving drugs which can increase K^+ level like spironolactone, ACE inhibitors, angiotensin receptor blockers, NSAIDS including cyclooxygenase 2 inhibitors, trimethoprim, amiloride, triamterene, pentamidine, nafamostat, renin inhibitors, digoxin and related glycosides, mannitol, beta-blockers, succinylcholine and other drugs known to alter the potassium levels

were excluded by a detailed evaluation of the list of concomitant drugs. Children, pregnant and lactating women were also excluded from the study. In addition, patients whose baseline potassium value was not estimated or missing were not included in the study.

After obtaining a written informed consent, data on demographic details, the diagnosis, the indication for heparin, other co-administered drugs and the serum electrolyte levels were obtained. The baseline K^+ level was collected from the case record of the patient. Another K^+ level estimation was done at the end of day 4 of starting heparin. Blood collection was done meticulously by a trained lab technician using standard venipuncture technique; taking care to avoid tourniquet, fist-clenching, inappropriate needle diameter, excessive force during aspiration and other maneuvers which could result in hemolysis or falsely elevated potassium values. Potassium estimation was done in the biochemistry laboratory by ion selective electrode method using potentiometry. Any documentation of symptoms pertaining to hyperkalemia during heparin therapy recorded in the case record was also noted. Data regarding the patients who developed clinically significant hyperkalemia requiring a change in therapy or other measures taken control the hyperkalemia was also collected. The data collected was entered into Excel and statistical analysis was done using SPSS software version 19.

Table 1: Baseline demographic data of the participants

S. No.	Parameter	Measured values
1	Mean Age	58.5 y
2	Male female ratio	14:18
3	Patients treated with LMWH	32
4	Patients treated with Enoxaparin	17(53%)
5	Patients treated with Dalteparin	15(47%)

Table 2: Paired t-test to compare the means of the serum potassium before and after administration of heparin across different age groups

Groups (n= no of patients)	Serum potassium level (mEq/l)				Paired difference of before and after values		p-value
	Before		After		Mean	±Standard deviation	
	Mean	±SD	Mean	±SD			
31-60 y (n=13)	3.87	0.436	4.20	0.794	-0.329	0.526	0.065
61-80 y (n=19)	3.83	0.736	4.13	0.669	-0.295	0.430	0.015

n=32; Data expressed as mean±SD

RESULTS

A total number of 32 patients participated in this study. The mean age of the study participants was found to be 58.5±14.5 y (table 1). About 59% of the patients were in the age group between 61-80 y and the rest (41%) were 31-60 y aged. The occurrence of serum potassium elevation, according to the study, was found to be significantly higher in the patients of 61 to 80 y age group, unlike the 31-60 y age group subjects in whom the rise in potassium level after treatment was not statistically significant (table 2).

Amongst the study participants, 44% were males and 56% were females (table 1). Among the patients started on low molecular weight heparin therapy, around 53% received enoxaparin while 47% of patients received dalteparin (fig. 1). The mean potassium level done at the end of 4 d after starting treatment with low molecular weight heparin, showed a demonstrable increase compared to baseline and a paired t-test revealed a statistically significant difference (p = 0.007) in the serum potassium before and after treatment with heparin (fig. 2).

Considering the change in serum potassium levels in the enoxaparin-treated group and the group treated with dalteparin, it was observed that both groups had a definite increase in the mean potassium levels after commencing treatment. However, it was found using paired t-test that a statistically significant increase in the serum potassium level was demonstrable only for the enoxaparin group (p =0.008), but not for the dalteparin group (p = 0.447) (table 3).

In addition, a correlation between increases in serum potassium with that of the dose administered could be identified for both groups as shown in the graphical representations fig. 3, 4.

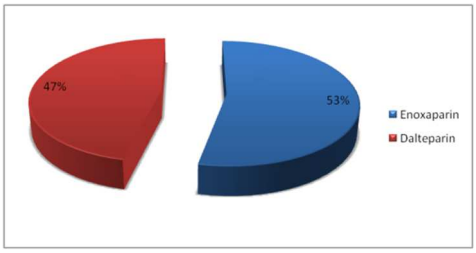

Fig. 1: Frequency distribution of the patients started on low molecular weight (enoxaparin, dalteparin)

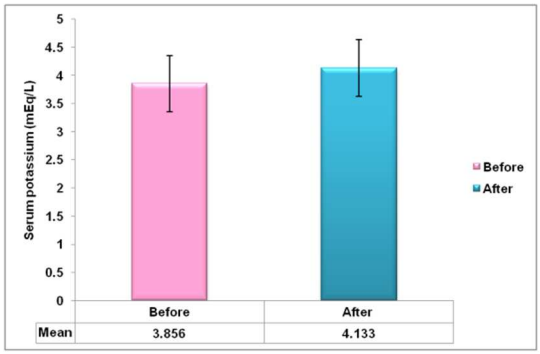

Fig. 2: Serum Potassium expressed as mean±SD before and after treatment with low molecular weight heparin

Table 3: Paired t-Test to show the statistically significant difference in the serum potassium values before and after treatment

Groups (n= no of patients)	Serum potassium level (mEq/l)				Paired difference of before and after values		p-value
	Before		After		Mean	±Standard deviation	
	Mean	±SD	Mean	±SD			
LMWH (n=32)	3.89	0.667	4.12	0.707	-0.232	0.391	0.007
Enoxaparin (n=17)	3.81	0.556	4.10	0.602	-0.292	0.396	0.008
Dalteparin (n=15)	4.06	0.31	4.16	0.332	-0.106	0.373	0.447

Data expressed as mean±SD

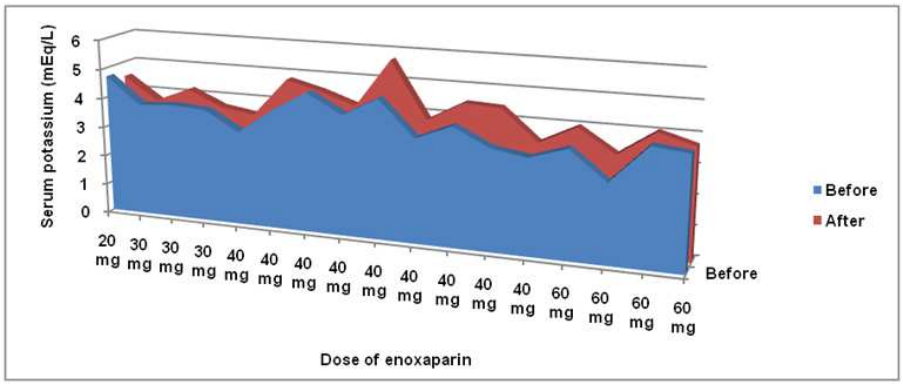

Fig. 3: Chart representing the rise in serum potassium levels across various doses of enoxaparin

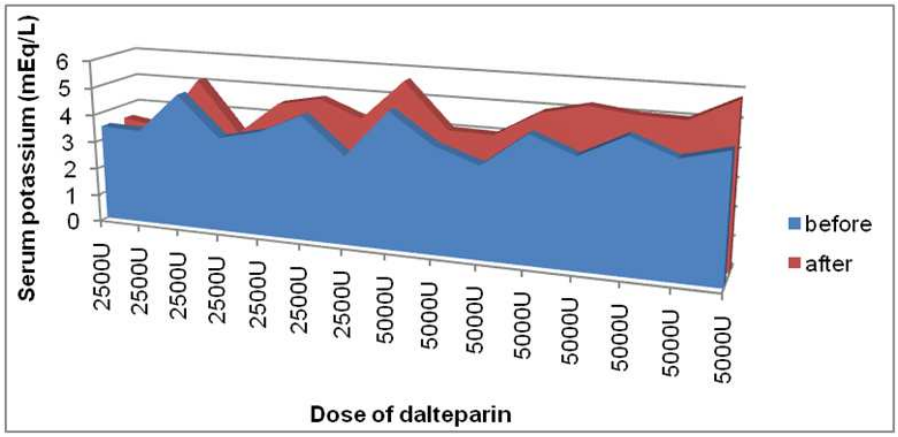

Fig. 4: Chart representing the rise in serum potassium levels across various doses of dalteparin

Clinically relevant hyperkalemia (more than 5mEq/l) was noted in 8 (25%) patients out of the 32 participants. Among these patients, 5(16%) were treated with dalteparin and 3(9%) were in the group treated with enoxaparin (fig. 5). Though around 1/4th of the patients in the study manifested with clinically relevant hyperkalemia, none of them was symptomatic or needed any specific measures to correct the electrolyte abnormality.

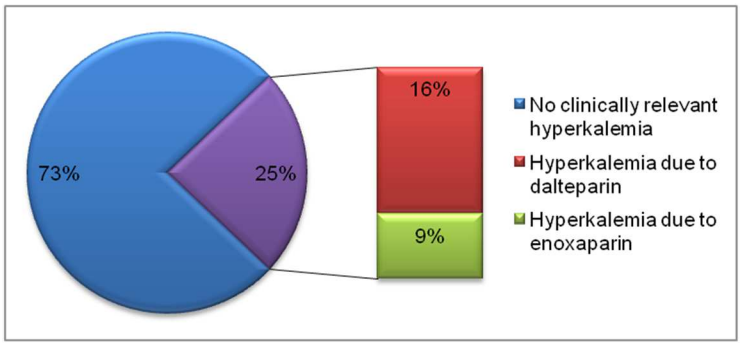

Fig. 5: Chart representing the frequency of patients who developed clinically significant hyperkalemia (>5 mEq/l)

DISCUSSION

In our study done in 32 patients started on low molecular weight heparin, there were 46% aged 31-60 y whereas a larger proportion of patients, ie, 59% were in the age group of 61-80 y. This emphasises that there is an increased risk of thromboembolic disease as the age advances. This has been demonstrated in earlier studies. [5, 6] This is probably attributed to the increase in the prevalence of the risk factors for thromboembolic diseases with ageing.

In addition, it was established through the study results that increasing age is also associated with an increased risk of hyperkalemia with heparin therapy. This is evident from the statistically significant increase in serum potassium in the 61-80 y age group (p = 0.065), but not in the age group of 31-60 y (p= 0.015) (table 3). The male-female ratio was 14: 18 indicating that a higher number of female patients had received heparin therapy during the study duration. Noteworthy as most of the female patients who participated in the study were in the postmenopausal age group but none of them was on any hormonal treatment.

Using paired t-test, a statistically significant rise in serum potassium was demonstrated in the study population treated with LMWH (p = 0.007). In the current clinical scenario, UFH has been largely replaced by the LMWH. This is quite understandable, particularly since there are plenty of advantages for LMWH over UFH like equal efficacy, increased bioavailability, and less frequent dosing. Also, monitoring of activated partial thromboplastin time is not required. It has been well brought out in this study that the low molecular weight heparin is also implicated in increasing the serum potassium levels like UFH.

The primary mechanism of heparin-induced hyperkalemia has been well established and it is due to suppression of aldosterone synthesis. This is mediated by a reversible effect on aldosterone through blockade of an enzymatic step in the synthesis and also the angiotensin II receptors in the adrenal gland. The most important mechanism of heparin-induced hypoaldosteronism involves a reduction in both number and affinity of angiotensin II receptors in the zona glomerulosa. Prolonged administration of heparin causes a marked reduction in the width of adrenal zona glomerulosa thereby leading to hyperkalemia and natriuresis. This reversible suppression of aldosterone occurs within a few days of initiation of therapy and is independent of either the anticoagulant effect or the route of administration. It has been reported that reduced aldosterone levels may be evident as early as 4th day of initiation of heparin therapy [3]. Thus LMWH has effects similar to that of UFH on aldosterone [7, 8] and hence LMWH is also associated with increasing the risk of hyperkalemia in treated patients. This has also been brought out by our study result which is well in concordance with previous studies reported in the literature [9, 10].

It was found that among the LMWH, enoxaparin (53%) was more commonly used than dalteparin for thromboprophylaxis (47%). The definitive reason for this cannot be offered, especially because an extended literature search has shown multiple studies and metanalyses comparing UFH with LMWH, but head to head comparisons of the different LMW heparins are few in number and these have claimed similar compliance, health status, deep venous thrombosis, and bleeding rates with both [11] while some studies have brought out that switching patients from enoxaparin to dalteparin was cost-effective [12]. However the DETECT trial has established the hypothesis that dalteparin 5,000 units subcutaneous (SC) daily may not be clinically non-inferior to enoxaparin 30 mg SC twice daily for venous thromboembolism prophylaxis in high-risk population and until an adequately powered, prospective noninferiority trial is performed, enoxaparin is supported by level 1 evidence and should be the prophylactic agent of choice [13].

In our study, a statistically significant increase in the potassium level was seen only in the group treated with enoxaparin (p = 0.008) but not the dalteparin group (p = 0.447). Though the study infers a statistically higher risk of serum potassium elevation with enoxaparin in comparison to dalteparin, this cannot be translated to a definite clinical significance with certainty owing to two reasons. First is the lack of sufficient sample size and secondly, on account of the remarkable finding that a higher proportion of patients in dalteparin group (15%) had clinically relevant hyperkalemia (>5 mEq/l) compared to 9% in the enoxaparin group. An explanation for more number of patients manifesting hyperkalemia in the dalteparin group is probably due to the higher mean baseline value (4.06±0.31) compared to that of enoxaparin group (3.81±0.55). This is in accordance to a study which has shown that baseline potassium level reflects pretreatment aldosterone level and hence its value has a predictive role for assessing the susceptibility to develop hyperkalemia [10].

Interestingly, the results of the study also revealed an association of a larger rise in potassium levels being associated with higher doses of both the low molecular heparins studied. This is substantiated by the fact that the higher doses of enoxaparin 40 and 60 mg produced a greater elevation of serum potassium levels as compared to the lower doses of 20, 30 mg and this observation was replicated in the groups on dalteparin 2500U versus 5000U as well (fig. 3,4). Thus the adverse effect is found to be dose dependent and the possible explanation of this observation stems from an accentuated aldosterone suppression by higher doses of heparin leading to an augmented rise in serum potassium levels.

Thus the study has clearly delineated that significant elevation of serum K+is seen in patients treated with low molecular weight heparin and that the magnitude of the rise in potassium to clinically relevant hyperkalemia (>5mEq/l) occurs in approximately one-quarter of the patients studied. This signifies the need for adequate monitoring of the serum K+while on LMWH for thromboprophylaxis.

The limitation of the study is the small sample size. Therefore it is recommended that the study results have to be confirmed in larger trials in order to enable extrapolation of the results to the larger patient population treated with heparin clinically.

CONCLUSION

The study has highlighted the magnitude of changes in potassium levels in patients receiving low molecular weight heparin for thromboprophylaxis. In addition to the known risk factors like renal failure and concurrently administered drugs, the study has made it evident that advancing age and increasing dose could potentially contribute to the development of hyperkalemia with low molecular weight heparin therapy. Thus the study results help the clinicians to potentially predict the patients likely to experience this electrolyte disturbance; stratify their risk and manage them appropriately.

Background: To assess the attitude of second year medical students towards the teaching Principles in Pharmacology didactic lecture classes.

Methods: It was a descriptive epidemiological and questionnaire based study. Second year students who were attending pharmacology lecture classes for a period of one month (nearly 8 lectures) were given questionnaire and ask to fill it by assessing the theory classes which was conducted throughout that month. Each question was graded with mark and finally total score was converted to 50 marks. Five-level Likert's criteria were used to analyze few questions in the questionnaire. Data were analyzed by frequency distribution.

Results: Out of 115 students who attended the questionnaire session, 61% students were having a very good and better attitude towards the faculty talking Pharmacology lecture classes and remaining students have a few lacking areas in the teaching mode which should be analyzed.

Conclusions: Students have good attitude towards the faculty taking didactic lectures and the lacking areas can be future improved by efficient planning of interactive and interesting lecture methods for the usefulness of students as well as the teacher.

Keywords: Attitude, Second year medical students, Pharmacology lectures

Pharmacology is the study of drugs. In pharmacology teaching will be a combination of lectures and practical sessions.[1,2] Lecture is a traditional and didactic method of teaching. It is the most common method of teaching which is used to provide knowledge and information to a vast number of medical students but there is negligible student involvement in these types of teaching process.[3] Medical teachers are working hard to implement diverse teaching techniques to educate medical students who were formerly thought only by blackboard and slide projectors. Now day's audio visual aids such as power point have been used as one of the newer methods. The optimum use of audio visual aids is essential for their learning. Traditional didactic lecture is an inactive method in nature and less effective as compared with active learning methods, such as problem-based learning. However, a well-efficient lecture remains one of the most powerful ways to integrate and provide information from numerous sources on scientific topics.[4,5] Hence this study aims to analyze student's attitude towards the medical education teaching skills and methods.

Aim of the study was to evaluate the attitude of second year medical students towards the teaching principles in Pharmacology didactic lectures.

Objectives

- To evaluate students' perception regarding the motivation, teaching, communication and linguistic aspects of the faculty during the lecture classes.
- To evaluate the effectiveness of teaching with regard to content and teaching methods.

- To analyze students' level of satisfaction about the faculty with respect to teaching, insisting on newer concepts, including research ideas.
- To know whether introduction, objectives, summary, take home message of a particular topic are covered by the faculty during the lectures.

M□□□□□□□

Pharmacology topics by pharmacology teachers to 2nd year MBBS students for a period of one month in 8 lecture classes.□

Inclusion criteria

- Second MBBS students who give consent to participate in my research study
- Second MBBS students who are present during the questionnaire study

Exclusion criteria

- Second MBBS students who are not giving consent to participate in the study
- Second year MBBS students those who are absent during the questionnaire Study
- All other MBBS students in the college excluding second year MBBS students
- Partially filled or unfilled questionnaire even after giving consent

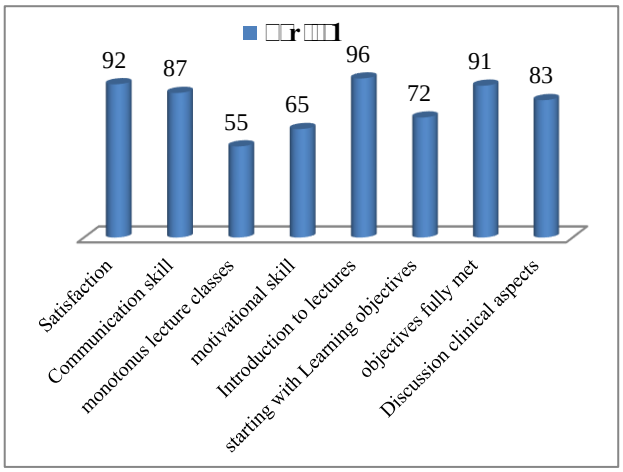
Type of study was descriptive epidemiological study.

Duration of the study was one month from 1st July 2015 to 31st July 2015.

Study tool□□

Feedback assessment form

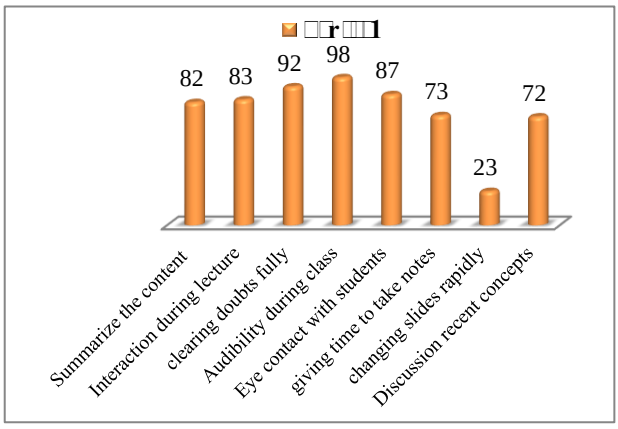
Study was carried out at Department of Pharmacology, Private Medical College, Coimbatore.



A total of 145 students studying second year MBBS from a private medical college was included in the study. Informed consent was obtained and the study was conducted by providing a planned questionnaire for assessing the attitude of medical students towards professional teaching skills and methods. An assessment was set with a maximum of 50 marks to evaluate the students' attitude towards facilitator and the presentation. Each question was graded with mark and finally total score was converted to 50 marks and no negative marks were awarded to questions unanswered. Five-level Likert's criteria were used to analyze few questions in the questionnaire.[6] Based on the marks obtained, the attitude of students towards faculty was classified into 6 categories. Later the data were analyzed followed by tabulation of results and interpretation was done.

Statistical analysis

Data were analyzed statistically using frequency distribution



□□□□□□□□

96% of students said that faculties give introduction to the lectures in an interesting manner, 92 % said that they were satisfied with the teaching methods and 91% said that the objectives of the classes were fully achieved (Figure 1).

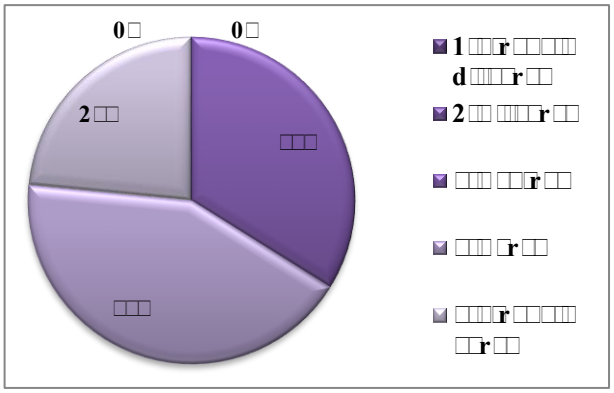
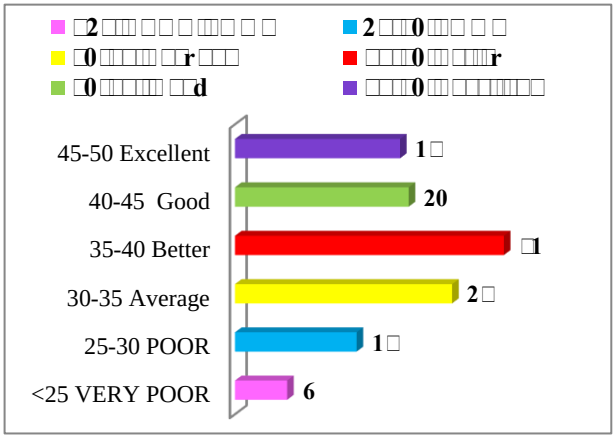
98% of students suggest that all faculties should be student friendly, 63% suggested providing teaching material one week before the class so that they can read the concepts in better way (Figure 3).





In students' aspect 85% told that they ask doubts in the class, 70% of the students said that they take notes during class (Figure 4).

Out of 115 students who attended the questionnaire session,61% students were having a very good and better attitude towards the faculty talking Pharmacology lecture classes and remaining students have a few lacking areas in the teaching mode which should be analyzed (Figure 5, 6 and 7).

Discussion

Out of 145 second year medical students, only 115 students participated in the research study by filling the questionnaire after giving informed consent. Around 100% students have told that the teachers were punctual to lecture classes. 96% of students accepted that the faculty gave introduction, stressed upon learning objectives and reinforced at the end of the class after summarizing. 92% of students were satisfied with the faculty teaching. This satisfaction is important because it shows that at least half of the student's population tries to understand the concepts. 91% of students had stated that the objectives of the class were completely met. 65% was satisfied with the faculty's motivation skills.

87% of students felt that the linguistic skills of faculty were good. 83% of students felt that the faculty gave enough clinical background concerned to the theory topic. These results showed that the faculties were efficient in disseminating the relevant concepts and that

they could also give real life examples for the clinical cases which would make a good impact on the topic by the students.[4]

83% and 92% of students said that the teaching staffs interacted and cleared doubts regularly during the lecture hours. Approximately 45% of students agreed that the teaching aids used by faculty were good. 87% of students told that faculties have good eye contact with them during lectures. 98% of students said that faculty teaching was clearly audible during the lecture. 73% of students felt the faculty had given enough time for taking notes. Students who took notes during the lecture regularly were found to be 77%. Earlier studies have also stated that in order to improve the understanding of the students and for their future referencing, enough time to take notes has to be given which will in-turn improve the learning skill of the students.[4]

Regarding pitfalls during teaching was that, 23% felt that the faculty changed the slides rapidly. 25% of students felt that the faculty could further improve the way of teaching. 55% of students felt that lecture classes were monotonus. In the previous studies, they have mentioned that breaking the monotony for every 20 minutes by directing questions towards the students and also by showing some slides unrelated to the theory topic (E.g. Vacation slides) will be helpful and prevent the students from getting bored.[7,8]

Merely 10% of students said that they come prepared for the theory classes. It is good to come prepared for the theory classes because they could understand the entire concepts clearly and also clarify the doubts in the theory class itself. 30% of students used to sleep occasionally during the class hours. It shows that faculties should take few more steps to make the theory classes much more interesting, as we discussed earlier by giving some real-life examples and by breaking the monotony.[4,7-9] 10% of students stated that they would play with mobiles during the lecture classes. Institutions should make some arrangements to restrict the mobiles at least during the academic hours so that the student's distractions can be reduced. It can also be minimized by modifying the theory class into active and interactive learning sessions which involves both the students and the teacher actively taking part in the teaching learning process.

Now considering the role of small group teaching and problem based learning etc., we can incorporate these methods in between the theory classes to make the topic much more interesting. Studies have also shown better results by use of these methods in teaching.[5,10,11]

Regarding the students' suggestions, 98% of the students wanted the faculty to be a friendly facilitator, so that they can easily approach the faculty whenever it's needed. Studies have also shown that by incorporating Postgraduates in Under graduates teaching program, it will improve the imparting of knowledge and learning skill in the students.[12] Merely 23% of students wanted the class to be taken purely in a black board. Black board teaching is necessary but still it wouldn't be completely sufficient to ensure that all scientific concepts to be effectively delivered through this approach. So we can also use Audio visual aids and hand models to describe the topic. 63% of students wished to get the teaching material one week before the class.15% of students suggested to keep short tests at periodic intervals.

Out of 115 students 70 (61%) students were having a very good and better attitude towards the faculty taking Pharmacology lecture classes. So instead of giving monotonus lecture classes alone, we can also incorporate multiple modes of teaching methods as we have discussed above to improve the knowledge and learning skills in the students.

□□□□□□□□□

From the results of the study conducted regarding the attitude of students towards the didactic lectures, it was found that overall students' satisfaction was good. However, faculty could further improve their skills in certain areas like motivating the students, communication skill, usage of needed teaching aids, interactive teaching class which include recent advances and discussion of clinical points. Regarding the suggestions of the students, they expect every faculty to be a friendly facilitator, in addition to periodic short tests to evaluate their understanding of the subject. Thus, continuous monitoring of faculty and student performance by means of assessment is mandatory.

The final expectation from every faculty in a medical college is to bring out a knowledgeable and skilful Indian medical graduate which is an achievable process. Suggestions from the students must be taken in to consideration to implement better teaching methods than before. This can be achieved by the efficient planning of interactive and interesting lecture methods for the usefulness of students as well as the teacher.

A Study of Bony and Cartilaginous Neck Structures in Deaths Due to Suicidal Hanging at New Delhi

Jegadheeshwararaj J[1], Thejaswi H T[2], Atul Murari[3]

[1]Assistant Professor, Department of Forensic Medicine and Toxicology, PSG Institute of Medical Sciences and Research, Coimbatore. Tamilnadu, [2]Assistant Professor, Forensic Medicine, PGIMER & Dr.RML Hospital, New Delhi, [3]Director, Professor, Dean, Lady Hardinge Medical College, New Delhi

ABSTRACT

The present prospective study was done at Lady Hardinge Medical College, New Delhi. In this study the incidences of the bony and cartilaginous injuries in 100 cases of deaths due to hanging were analysed with the gender, age, socio economic status, place of hanging, the type of suspension, the location of the knot, type of the knot, the type of hanging. 76(76%) of cases were males and the majority of the cases were from 21-30 age group, 94(94%) of the victims belonged to the low socioeconomic status, 97(97%) of the cases hanged themselves indoor, 2(2%) had committed suicide by hanging at their workplace, 81(81%) cases had complete type of hanging and 64(64%) had atypical type of hanging. In our study there were 42 (42%) cases had some injuries in their bony and cartilaginous neck structures. Hyoid bone fractures were found in 6(6%) cases, thyroid cartilage injury was seen in 39(39%) cases among which 3 cases had both hyoid and thyroid cartilage fracture in combination. All the above injuries occurred only in cases with complete type of hanging. The incidence of such injuries was more frequent in males who had typical and complete type of hanging.

Keywords: *Hanging, injuries, hyoid bone, thyroid cartilage.*

INTRODUCTION

Death due to hanging is a form of asphyxia caused with a ligature which encircles and constricts the neck, in such a manner that the weight of the whole or a part of the body acts as a constricting force. The external and internal findings in the neck in such cases are well documented. But for unknown reasons there are major variations in the bony and cartilaginous injuries reported in various studies. This study was undertaken to establish a strong correlation with the various factors that influence the pattern of injuries to the bony and cartilaginous neck structures in such cases.

MATERIALS AND METHOD

The study was done in 100 cases of suicidal hanging brought for medico-legal autopsies to the Department of Forensic medicine and toxicology, Lady Hardinge medical college, New Delhi. Only those cases with a well documented type of suspension, an intact ligature material were included in this study. A detailed history with photographs of the crime scene was mandated in the inclusion criteria. A standard autopsy procedure with special emphasis on the fine dissection of neck structures was done. Provided, cases only with evidential proven ante mortem injuries were alone considered in our study.

RESULTS

1. Among all the 100 cases of suicidal hanging, 76(76%) were males, 24(24%) were females.

2. The age groups ranged from 18-59 years, Majority of them (i.e. 60% of the entire study group) were from 21-30 years, 94(94%) of the victims were from low socio economic status, 97(97%) of the cases had hanged themselves indoors, 2(2%) of the cases had hanged themselves at their work place.

Corresponding author:
Thejaswi H T
Assistant Professor, Forensic Medicine, PGIMER & Dr. RML Hospital, New Delhi

3. Ropes were used as the ligature material in 52(52%) of the cases and others preferred saris, scarf, bed sheets, wires and plastic tapes.

4. 81(81%) cases had a complete type of hanging and 19(19%) of them were partially hanged.

5. In 36 (36%) cases the knot was at the nape of the neck thus constituting typical type of hanging. 64 (64%) cases had atypical type of hanging.

6. About 37 (37%) cases had contused sternocleidomastoid muscles. And the internal carotid artery showed transverse tears in 19 (19%) cases.

7. In 42 (42%) cases there were some injuries either in the hyoid bone or the thyroid cartilage only. Among which 3 cases had both hyoid and thyroid cartilage injury.

8. Unilateral fracture of greater horn of hyoid bone was present in 6 (6%) cases.

9. Fracture of the greater horn of thyroid cartilage was present in 39 (39%) cases, in which 33 individuals had unilateral fracture of the superior horn and 6 individuals had bilateral superior horn fractures.

10. The frequency of fractures in our study was higher among the males who were in the elderly age group and those who had a complete and typical type of hanging.

DISCUSSION

The present study was done to establish a strong correlation with the various factors that influence the pattern of injuries to the bony and cartilaginous neck structures in such cases.

With regard to the gender the male female ratio in our study was 3:1 with 76 (76%) and 24 females (24%). More than half of the males i.e. 38 out of 76 males and 4 out of 24 females had some injury in their bony and cartilaginous structures. Similar results were shown in other studies [1,2].

The age distribution ranged from 18 years to 59 years. Almost half of the cases were from 21-30 age groups. Various other studies also have reported the same age distributions [2,3,4]. The relations of the frequencies of fractures with respect to the gender and age distribution are as given (Table 1).

Table 1

In our study the fracture of the hyoid bone and the thyroid cartilage frequented in elderly aged victims.

There were 81 (81%) victims had a complete

Age	Total no. of cases n=100		No. of cases with fracture n=42	
	Males	Females	Males	Females
11-20	9	3	0	0
21-30	47	10	24	0
31-40	6	7	5	1
41-50	9	3	4	2
51-60	5	1	5	1
>60	0	0	0	0
Total	76	24	38	4

hanging and 19(19%) victims were partially hanged and with regard to the location of the knot there were 36 (36%) cases who had their knot on their nape of the neck thus constituting typical hanging. In 64 (64%) cases had atypical type of hanging among which 42 cases had their knot on the right side of the neck, 21 cases had their knot on their left side of the neck and one of the victims had the knot under the chin. 94% of the victims were from low socio economic status, 97% of the cases had preferred hanging indoors and 2% of victims had committed suicide at their workplace.

More than half of the cases 52% preferred ropes as the ligature material. Other ligature materials were chunni (a long scarf), sari and bed sheets. Similar findings are being reported in other studies[5,6].

The external and internal soft tissue findings were similar to other case studies reported [5,7,8,9].

In our study 42(42%) cases had some injury in their hyoid bone and thyroid cartilage. In our entire study there were 6 (6%) cases of hyoid bone fracture in their greater horn and 39 (39%) cases had their superior horn of thyroid cartilage fractured. No other bony injuries were detected on the neck.

With regard to the type of suspension all the injuries to the hyoid bone and the thyroid cartilage occurred only in those victims who had a complete type of hanging. And the incidence of such injuries was higher in those cases with typical type of hanging.

The frequency of the fracture with respect to the type of suspension and hanging are as given (Table 2).

Table 2

	Type of suspension		Total	Type of hanging		Total
	Complete	Partial		Typical	Atypical	
Total no. of cases	81	19	100	36	64	100
No. of cases with injury.	42	0	42	24	18	42

Thus the incidence of injuries to the hyoid and thyroid cartilage is highest in victims who had a complete typical type of hanging.

REVIEW OF LITERATURE

Regarding the frequency of the hyoid bone fracture Polson and Ghee[10] reported that hyoid bone fractures in 25% of their cases. Davidson and marshall[11] showed that 26.7% of their 101 cases had associated hyoid bone fracture. R.Clement et[12] al in their retrospective study claim that incidence of hyoid fracture is about 1% of their 206 cases. In India Sharma BR et al[13] and Th.Meera et al[14] had reported hyoid bone fractures in 21% and 3.5% of their case series respectively. Weintraub[15] stated that hyoid bone was fractured in a seventh of all hangings and a fifth of victims aged over 40 years, irrespective of the type of hanging. Interestingly, Hyoid bone fractures were never reported in 83 cases studied by VJM DiMaio[16]. Smith and Fiddes[17] also claimed that hyoid bone injuries never occurred in such deaths.

Fracture of superior horn of thyroid cartilage is the only cartilaginous injury in various studies. According to Polson and Ghee[10] fractures of superior horn of thyroid were found in almost 50% of their cases. Davidson and Marshall[11] showed that 26.7% of their 101 cases showed thyroid cartilage fractures. Eventually VJM DiMaio 12% of his 83 cases of hanging had fractures of thyroid cartilage[16]. Then Camps and Hunt[18] in their study claimed that the fractures of neck structures were directly related to the age of the individual. Luke et al[19], Simonsen J[20] and P.Betz et al[21] related the incidences of the neck injuries to the type of hanging. But Slobadan Nikolic[22] et al contradicted the above fact in their study. Suarez Penaranda[23] et al in their series of 228 cases correlated the bony and cartilaginous injuries to the gender and claimed that there were no correlation between the side of the fracture and the location of the knot. Bowen[24] in his retrospective series of 201 cases did not report any such injuries at all.

CONCLUSION

The present study shows that unilateral fracture in greater cornu of hyoid bone occurred in 6 out of 100 cases (6%). Hyoid bone fractures occurred exclusively in males who were aged more than 30 years of age. The hyoid bone fractures occurred only in complete type of hanging.

In our study fracture of the superior horn of thyroid cartilages were the only cartilaginous injuries found in 39 out of 100 cases (39%). Among these 39 cases 33 had unilateral and 6 cases had bilateral superior horn fractures. Thyroid cartilage fractures occurred more in males and exclusively in those victims who had a typical and complete type of hanging. The incidence of fracture of thyroid cartilage increased in elderly victims.

Conflict of Interest: The authors declare that there is no conflict of interest in this study.

Ethical Clearance: This study was cleared by the Institutional ethical committee as a dissertation topic at Delhi University.

ABSTRACT

For long time forensic investigators have considered Hyoid and laryngeal injuries as important findings in cases of deaths due to strangulation. Further the incidence of injuries to the neck structures in such cases being related to various factors like the age, gender, the type of the hanging based on suspension and the position of the knot are well documented. Our study highlights the impact of other crucial factors which are usually overlooked, but having strong association in the deaths due to strangulations in general and hanging in particular. The study was undertaken in Central Delhi in 100 cases of hanging, where we studied the association between the hyoid and laryngeal fractures with other variables like type of the ligature material used, the number of turns around the neck, the width of the ligature mark, the type of the knot (fixed/running noose), the duration of suspension and the Body Mass Index of the individuals. In our study 42% of cases had hyoid/laryngeal injuries. These injuries were more common in those who had used hard ligature material with more than one turn around their neck and with a broader ligature mark on their neck. Hyoid and laryngeal injuries were also more common in victims who had a running noose and a prolonged duration of suspension.

Keywords: *Hanging, ligature material, Number of turns, width of the ligature mark, type of knot, duration of suspension.*

INTRODUCTION

Death due to suicidal hanging is a major cause of death worldwide[1]. Hanging is a common method to commit suicide in India[2]. Investigating authorities consider the injuries in the hyoid bone and the laryngeal cartilages to be significant findings in such deaths. In our study, factors like the type of the ligature material (soft/hard), number of turns around the neck, the width of the ligature mark, the type of the knot (fixed knot/running noose), the duration of suspension (with evidential Postmortem findings) and the Body Mass Index of the individuals were compared and associated with the hyoid and the laryngeal injuries.

MATERIALS AND METHOD

This prospective study was done in 100 cases of suicidal hanging at Central Delhi, which were brought to Lady Hardinge Medical College for medico-legal autopsy. Only the cases which satisfied our mandated inclusion criteria i.e. A meticulous inquest with a well documented approximate time since suspension which correlates with the postmortem findings, photographs of the crime scene, an intact ligature material, weight of the body in kilograms and length of the body in centimeters (To calculate the body mass index), were taken up for analysis. A standard autopsy procedure with meticulous examination of neck structures was performed. The nature of the ligature mark (soft/hard ligature), the numbers of turns around the neck made by the ligature, the width of the ligature mark and the body mass index of the individuals were considered. The structured Performa was used for data collection.

RESULTS

1. In our study of 100 cases, the fracture of the greater horn of hyoid bone and fracture of the superior horn of thyroid cartilage were the only injuries found.

2. 42 cases had some injury in their neck structures. 39 cases had only thyroid cartilage fracture, 3 cases had only hyoid bone fracture among which 3 cases had both hyoid bone and thyroid cartilage fractures.

3. 50% of the victims who had used a hard ligature material like ropes, wires had injuries in their hyoid bone and laryngeal cartilages.

4. 46% among those who had multiple wraps around their neck showed some bony and cartilaginous injuries.

5. The incidence of Hyoid and cartilaginous injuries were greatest in those who had a hard ligature with more number of turns around the neck.

6. 56% of those victims who had a broader ligature mark had injuries in their hyoid bone and laryngeal cartilage.

7. Hyoid and laryngeal injuries were present in every two victims who had a running noose around their neck.

DISCUSSION

Incidence of injuries in relation to the type of the ligature material used and its number of turns around the neck:

The nature of ligature materials used was broadly classified into hard and soft type. 52 of them had a soft type of ligature material like blankets, chunni (a long scarf) and sari and 48 of 100 victims had a hard ligature material like nylon ropes, coir ropes, electrical wires and plastic tapes. Chunni was the commonest material used in 33 cases followed by the nylon rope in 29 cases. Similar results were shown by Jayprakash and Sreekumari[3], Sharma et al.[4]

Regarding the number of turns around the neck, 61 of 100 victims in our study group had only a single turn and 39 of them had more than one turn of ligature material around their neck. (Table. 1)

Table No 1: Incidence of fractures with respect to the Ligature material and the number of turns

S.No.	Type of ligature and no. of turns.	Total no. of cases.	No. of cases with bony or cartilaginous injury.
1.	Hard ligature with single turn.	21	9
2.	Hard ligature with more than one turn.	27	15
3.	Soft ligature with a single turn.	40	15
4.	Soft ligature with more than one turn.	12	3
Total		**100**	**42**

Conspicuously the incidence of fracture was highest in those who had a hard ligature with more than one turn around their neck. Similar results were reported by Sharma et al, that injuries were more frequent in victims who had tough materials as the ligature[5]. But Luke et al. in their study reported that there was no association of the fractures with the composition and number of wraps around the neck[6]. Paparo and Siegel in their study also did not find that the type of ligature had any role on the incidence of the fractures[7].

Incidence of fractures with respect to the width of the ligature mark:

The ligature mark was measured in all the cases. Based on the width of the ligature mark all the cases were grouped into narrow, medium and broad ligature marks. 18 cases had narrow ligature mark (<2cm), 38 cases had medium ligature mark (2-4cm) and 44 cases had broad ligature mark (>4cm). The incidence of fracture with respect to the width of the ligature mark is as given in the Table 2.

Table No 2: Incidence of fractures with respect to the width of the ligature mark

S.No.	Width of the ligature mark	Total no. of cases	No. of cases with bony or cartilaginous injury.
1.	Narrow (<2cm)	18	6
2.	Medium (2-4cm)	38	11
3.	Broad (>4cm)	44	25
Total		100	42

In our study 56% among those victims who had broader ligature mark had neck injuries. Similar results were shown by G.Feigin in his study and he related the neck injuries directly to the width of the ligature mark[8]. Luke et al. in their study did not derive any association with the width of the ligature mark[6].

Incidence of fractures with respect to the type of the knot:

87 cases had a fixed knot and 13 had a running noose around their neck. 35 cases out of 87 and 7 out of 13 cases had injuries in their neck bony and cartilaginous structures. Thus the incidence of the neck injuries was higher in victims who had a running noose (Table No. 3). Similar results were shown by Sharma BR et al. in their study[4].

Table No 3: Incidence of fractures with respect to the type of the knot:

S.No	Type of knot	No. of cases	No. of cases with bony and cartilaginous injury.
1.	Fixed knot	87	35
2.	Running noose	13	7
		100	42

Incidence of fractures with respect to the Duration of suspension:

An approximate duration of suspension was estimated from postmortem changes and the police inquest as mandated in our inclusion criteria. There were 24 victims who were suspended for 0-2 hours, 36 were suspended from 2-6 hours and 39 were suspended for more than 6 hours (Table No. 4).

Table No 4: Incidence of fractures with respect to the Duration of suspension:

S.No.	Duration of suspension (hours).	No. of cases	No. of cases with bony and cartilaginous injury.
1.	0-2	24	3
2.	2-6	37	9
3.	>6	39	30
Total		100	42

The study showed that the incidence of the fracture of the hyoid and the thyroid cartilage increased proportionately with the prolonged duration of suspension. Similar results were claimed in the study by I Morild which showed that higher frequencies of fractures were found in longer suspension time[9].

Frequency of the fractures with respect to the Body mass index of the victim:

The weight and length of the corpse was measured as the part of the autopsy procedure. BMI was calculated with the standard formula for all the victims (Weight in kg/Height in m^2). The BMI of the entire study group fell within the normal narrow range with an average of 23.5 kg/m^2 among males and 21.6 kg/m^2 among females[10]. Hence it was difficult to derive a definite cut-off point to relate the body mass index with the frequency of the neck injuries. R Clement et al. in their study related that the incidence of fractures increases with the weight of the individuals[11].

CONCLUSION

In our prospective study it was apparent that, the injuries to the hyoid bone and the neck cartilage

occurred more in the victims who used a hard ligature material with more number of turns around their neck with a broader ligature mark and a prolonged duration of suspension. Hence it is recommended that these factors which are usually overlooked may also be evaluated along with the other variables like the age, gender, type of hanging, location of the knot to make the forensic investigation complete. We have prepared a pro-forma containing checklist that can be used before conducting autopsy, so that the frequently overlooked factors can be avoided (Table No 5)

1. Name :
2. Age :
3. Gender:
4. Brief history:
5. Place of death:
6. When the person was last seen alive:
7. Time of the last meal:
8. Time of his last urination:
9. Time of recovery:
10. Time since suspension (Based on Post mortem findings):
11. Type of suspension (Complete/Partial):
12. Type of the knot (Fixed/Running noose):
13. Position of the knot (On the nape of the neck/ side of the neck):
14. Type of the ligature material (Hard/Soft):
15. Distance of the drop:
16. Number of turns around the neck (Single/more than one):
17. Width of the ligature mark on the neck (<2cm/ 2-4 cm/>4cm):
18. Length of body (cm):
19. Weight of the body (kg):
20. BMI (Weight in KGs/Height in M^2):

Pre-hospital delay
Acute ischemic stroke
Stroke education
Thrombolysis
Stroke response

ABSTRACT

Background: Pre-hospital delays contribute to late arrival for acute ischemic stroke (AIS) treatment in the emergency department and are an important barrier preventing people from receiving thrombolytic therapy. This study looked into the factors causing pre-hospital delay in a tertiary care centre in South India with the aim of identifying measures to decrease pre-hospital delay.

Methods: Consecutive cases of AIS from October 2018 to June 2019 were included. A structured questionnaire was used to collect data regarding demographic details, presenting symptoms, time of stroke onset and arrival, mode of transport and knowledge about stroke and thrombolysis. Pre-hospital delay was defined as $>$ 4 h (Considering our door-to-needle time of 30 min) between stroke onset or the time point of wake-up and the time of arrival.

Results: Overall, 505 patients were enrolled. Prehospital delay was observed in 352patients (69.7%). The median pre-hospital delay was 9.5 h. In the multivariable analysis, the odds of early arrival were increased in patients who perceived the initial symptoms as serious (OR: 45.57; 95%CI, 11.43–181.63), those with prior knowledge of stroke symptoms (OR: 4.64; 95% CI, 1.86–11.55), those using ambulance services (OR: 3.11; 95% CI, 1.39–6.95), and those developing hemiparesis (OR: 2.50; 95% CI, 1.25–4.97). The odds of early arrival were lower in those visiting their family doctor after the stroke (OR: 0.17; 95%CI, 0.05–0.51).

Conclusions: Modifiable factors related to stroke recognition and response behavior continue to cause significant pre-hospital delay in India. There is an immediate need for a strong education campaign focusing on stroke specific knowledge to decrease pre-hospital delay.

1. Introduction

India is a low middle-income country with a cumulative incidence of stroke ranging from 105 to 152/100,000 persons per year which is higher than that of high income countries [1]. We have an estimated adjusted prevalence rates of between 334 and 424 strokes per 100,000 persons in urban areas and between 84 and 262 strokes per 100,000 persons in rural areas [2]. When compared to the Western countries, Asian countries have greater mortality and morbidity from stroke than from coronary heart disease due to a higher prevalence of hypertension and a lower level of serum total cholesterol [3].

Many randomized and placebo-controlled multicentre studies have clearly shown that intravenous thrombolysis is an effective treatment for acute ischemic stroke (AIS) [4–6]. Thrombolysis is generally performed within 3·0 h to 4.5 h after the onset of symptoms in AIS and thus its effectiveness could be limited by this narrow therapeutic time window. The problem of underuse of thrombolysis is common in many countries as patients come late for consideration of this treatment resulting in pre-hospital delay (PHD). In a developing country scenario like ours, hurdles can be expected in the efforts to improve PHD. First, very little robust data is available addressing this issue in India [7–10]. Second, very few corrective measures would have been possible since India spends only 3.66% of its Gross Domestic Product (GDP) on healthcare [11].

We initiated this single centre study and aimed to look into the reasons of delayed arrival of patients with acute ischemic stroke and identify measures to decrease the delay.

2. Materials and methods

2.1. Setting

This study was conducted by our institute, PSG Institute of Medical Sciences and research, located at Coimbatore, Tamil Nadu. Coimbatore is a district in the state of Tamil Nadu occupying its western border with the neighboring state of Kerala. (Fig. 1) Coimbatore caters to around 3.5 million people which includes the local population and those from the neighboring districts of Tamil Nadu as well as the Palghat district of Kerala.

2.2. Standard protocol approvals, registrations, and patient consents

The institutional ethics committee approved the study protocol. Written informed consent was obtained from all the participants in the study. Data not published within the article will be shared by request from any qualified investigator.

2.3. Patients

All the patients who came to our Emergency medicine department (EMD) presenting with the symptoms of AIS between October 2018 and June 2019 were included in the study. All hemorrhagic and venous infarcts were excluded.

2.4. Data collection

The patients were subjected to detailed clinical examination on arrival by one of three on-duty neurologists enrolling patients into the study. The time when the patient noted the first neurological symptom of stroke was considered the time of onset. The time the patient was examined by a physician at the EMD (available round the clock in the EMD and hence no physician delays) was considered the time of arrival. The time gap between the time of onset and the time of arrival was taken as the onset-to-door time (OTD). In wake-up strokes, the time of awakening was considered the time of onset (last seen normal was not taken since the aim was to look into the pre-hospital delay) since that represents the time when one could possibly seek medical attention. The OTD time was categorized into $<$ 1 h, 1–3 h, 3–4 h, 4–6 h, 6–24 h and $>$ 24 h. Those who arrived within 4 h of the stroke onset were considered to have come within the window period (WWP) and the rest out of window period (OWP). The time of 4 h was taken considering the door-to-needle time of 30 min in our hospital. This treatment time is made possible by the dedicated stroke team aided by a dedicated CAT scanner situated close to the emergency room. A structured questionnaire was then completed by interviewing either the patient or the caregiver. This questionnaire was designed after reviewing similar studies and following consultations with the medical and neurological societies (Supplement 1) Patients were interviewed in the hospital wards by the three clinical pharmacists (SK, NS & AAS) who underwent an orientation to the questionnaire for 2 weeks. In case of difficulties caused by neurological deficits, the caregivers were interviewed. The interview was conducted in the local Tamil language within 24 h of admission to minimize the possibility of stroke education happening during the stay in the hospital. Except for some instances of late arrival in the night and lack of caregiver availability, the interview was completed within the first few hours of arrival.

The questionnaire had queries addressing various demographic details including age, gender, urban or non-urban living and whether they stay with family or friends. Education was categorized into those with college education ($>$12th) and those without ($\leq 12^{th}$). Information regarding prior knowledge of stroke symptoms and thrombolysis along with details of the mode of transport of the patient to our hospital was collected. Whether they visited their family doctor or the local hospital before coming to our centre was noted. Knowledge of stroke symptoms

b = N(%).

was assessed based on whether the patient could attribute the presenting symptom to stroke. Whether they perceived the initial symptoms as serious requiring urgent care was asked. The presence of previous stroke and family history of stroke was enquired into. The National Institute of Health Stroke Scale (NIHSS) was used to document the stroke severity. The stroke onset time was divided into day (8am–8 pm) and night (8 pm–8am). The circulation of brain, anterior or posterior which was predominantly affected, was noted with imaging assistance. We assumed that people staying within a 20-km radius from the hospital would be able to reach within the 4-hour window period and categorized them into groups staying within or beyond 20 km from the hospital. It takes more than an hour to cover the distance of 20 km in the busy Indian roads. This doubles during peak hours. Details of the clinical presentation including the various risk factors and clinical features at presentation were also noted.

2.5. Statistical analysis

Statistical package of social sciences (SPSS) version 24 was used to analyze the data. Descriptive statistics, mean and standard deviation were calculated for continuous variables whereas frequency distribution and percentage were used for categorical or ordinal variables. The variables were compared between people who came WWP and OWP using the Chi-square test to evaluate the statistical significance of associations. Statistical significance was set at $P < 0.05$. The significant variables identified by univariate analysis were further subjected to binary logistic regression analysis to identify significant predictors of prehospital delay.

3. Results

There were 505 patients who presented with AIS during the study period of six months. No patient opted out of the study. Demographic data of the patients is given in Table 1. A total of 309 patients (61.2%) were from Coimbatore. (Fig. 1**)** Majority of the remaining (163 out of 505 = 32.3%) was from the neighboring districts of Tirupur, Erode and Palghat from where the travelling time to our hospital can vary between 1 and 1.5 h. Ambulance services were utilized by 279 patients (55.2%) whereas the remaining came in private vehicles.

Overall 153 out of 505 patients came WWP of four hours (30.3%) whereas the remaining 352 (69.7%) came OWP. The mean time to reach the hospital after stroke onset was 14.6 h (median 9.5 h, range 30 min-36 h). The OTD of our patients is depicted in Fig. 2. Around 154 (30.5%) patients visited a nearby clinic or hospital before reaching our hospital of which 110 (21.7%) had done so within the window period of four hours. Only 22 (4.3%) of them could finally reach our centre WWP.

The results of univariate analysis are shown in Table 2. In the multivariable analysis, the odds of early arrival were increased in patients who perceived the initial symptoms as serious (OR: 45.57; 95%CI, 11.43–181.63), those with prior knowledge of stroke symptoms (OR: 4.64; 95% CI, 1.86–11.55), those using ambulance services (OR: 3.11; 95% CI, 1.39–6.95), and those developing hemiparesis (OR: 2.50; 95% CI, 1.25–4.97). The odds of early arrival were lower in those visiting their family doctor after the stroke (OR: 0.17; 95%CI, 0.05–0.51).

4. Discussion

Despite India keeping pace with the developed nations in terms of availability of advanced medical facilities, the proportion of our population getting access to thrombolysis remains low. The problem of PHD continues to be a major stumbling block as evidenced by the failure of nearly 70% of our study population to reach before 4 h. Four major modifiable factors and one non-modifiable factor were the major determinants of PHD. The modifiable factors were knowledge about stroke symptoms (stroke recognition), perception of urgency at stroke onset and use of ambulance services which facilitated early arrival and visit to family doctor which resulted in PHD (stroke response behavior). The non-modifiable factor was the development of hemiparesis which facilitated an early arrival.

The use of ambulances for transportation resulted in early arrival of our patients. Fifty five percent of our population were transported in the ambulances of the emergency response services of Tamil Nadu which is comparable to the 38–65% use of Emergency Medical Services (EMS) in the developed nations [12,13]. Use of EMS has been clearly shown to be crucial in reducing PHD [14,15]. From the time of its inception in 1985, EMS services have progressed slowly in India till they made a quantum leap in the last decade [16]. Ambulances were made available on calling a single number 108. The sub-optimal response time and unattended calls along with difficult access to rural areas are some of the issues with our EMS which could explain increased PHD of our patients despite good ambulance utilization. Similarly improper patient response (not calling EMS) and system response (non-availability) could be responsible for some of them resorting to private transport.

Patients who came WWP were more aware of the stroke warning signs and recognized stroke. Prior knowledge about stroke symptoms and thrombolysis has been shown to be an important determinant of early arrival to hospital in various studies [8,17]. In contrast to the knowledge of risk factors, knowledge about warning symptoms of stroke is less worldwide. Only 29% of our study population knew about warning symptoms. Knowledge about thrombolysis, was noted in eighteen percent of our study population which is an improvement over the previously reported knowledge of 0% in a population based study from Tamil Nadu and 2% among stroke patients in South India [18,19]. Of particular interest is the fact that despite this low percentage of patients who understood the signs and symptoms of stroke, the ambulance utilization remained high. This discrepancy is because many people in non-urban areas are necessarily dependent on ambulance services for emergency transport especially in the night. Their response though delayed would still be to call the ambulance.

People who perceived the symptoms as requiring urgent attention

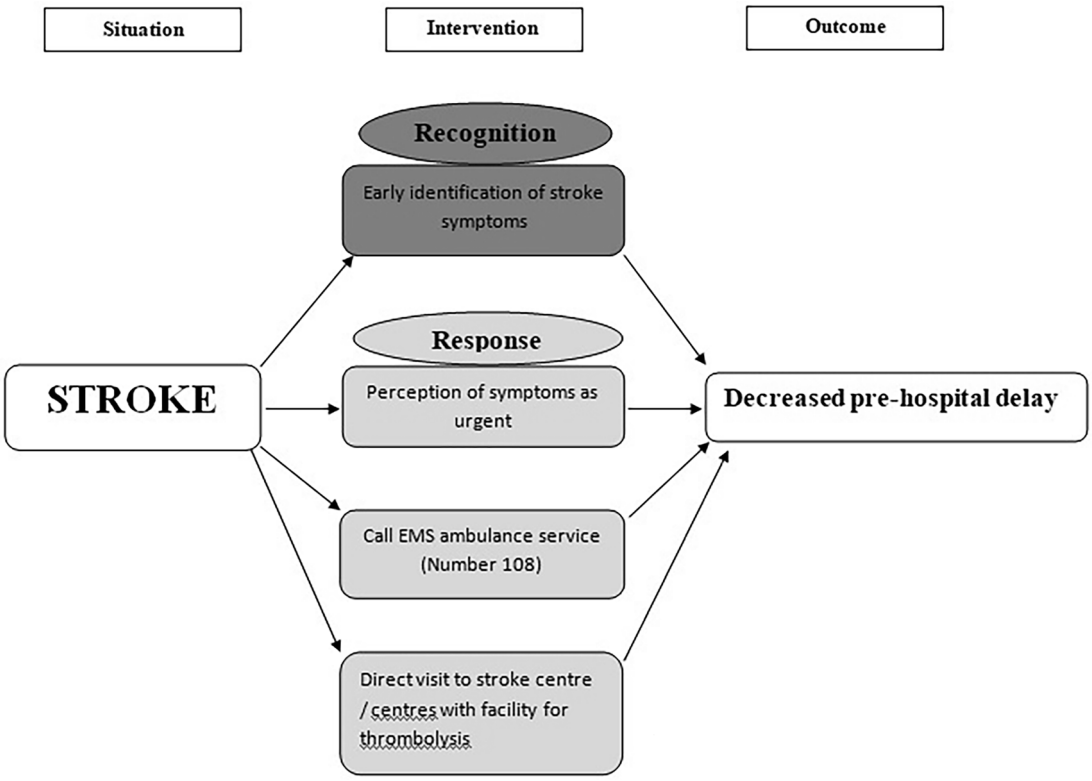

Fig. 3. Schematic diagram showing the suggested interventions to decrease pre-hospital delay.

could avoid PHD. Severity of stroke could be the clinical factor contributing to this perception since people with higher NIHSS score reached early. Even increased stroke awareness may not necessarily translate into a rapid response and early arrival to the hospital [20]. We found that a previous history of stroke was not associated with decreased PHD. Also, knowing somebody in the family with stroke was associated with increased PHD. That neither personal experience of stroke nor knowing somebody with stroke is capable of improving the response demonstrates the dissociation between knowledge and behavior [21]. In sharp contrast to the West, living together also did not help in improving PHD which reflects on the poor response behavior of the caregivers. Education campaigns across the world have failed to increase the emergency response of patients despite improving stroke awareness [22]. One reason could be the fading memory of the public as experienced by Canadian researchers who noticed that the benefits of increased awareness after a television based campaign lasted only for 5 months [23]. Self-efficacy is suggested as an important determinant of behavior and hence promotion of stroke recognition and response self efficacies could also help narrow the recognition-response gap [24].

Visit to the family doctor resulted in significant PHD. Similar observations have been made by other studies [10,20]. The health seeking behavior of our population includes visit to the nearby clinic or the family doctor who would decide the further course of treatment. Eighty eight patients (17.4%) missed out on the treatment opportunity of thrombolysis because of the time lost during local clinical visit. In a study conducted among 109 general practitioners (GPs) of Tamil Nadu, only 24% opted for thrombolysis as the best treatment for AIS and 17% were aware of the therapeutic time window for thrombolysis [25]. Hence there is an urgent need to educate them about stroke and thrombolysis. Since CAT scan facilities are currently available in both the private and Government sectors in rural Tamil Nadu, the local physicians can be encouraged to drip-and-ship the patient. Smartphone-based telestroke services can be arranged in a few clinics to facilitate the process. This was successfully implemented by the state of Himachal Pradesh [26]. Tenecteplase, after its recent approval in India for stroke thrombolysis can become a good option considering its lower cost and ease of administration. The GPs and their staff can discourage patients seeking appointment over phone for stroke symptoms from meeting them and advise them to contact EMS to reach the nearest centre with stroke treatment facilities.

Similar modifiable factors and increased PHD have been observed in the available studies from India [7–10]. They continue to be our bane preventing people from benefitting from thrombolysis. We need a strong public education campaign to address the modifiable factors and improve the PHD. The 'Act FAST' campaign launched in the UK in 2009 also served as a template for similar campaigns in other European countries [27]. The FAST-Television campaign in UK resulted in the remarkable fall in the PHD in 2009 which was sustained till 2013 [28]. Studies published from Europe on PHD after 2010 generally show median delay times of 1–3 h [29–33]. The European nations have benefitted by addressing the modifiable factors and brought down the median PHD below 3 h. The problems which remain are more of the non-modifiable ones like age and ethnicity, stroke related factors like severity, circulation involved, onset time and insurance related issues.

Our study has few limitations. First is the possibility of underestimation of the prevalence of PHD in a hospital based study because of selection bias. Many patients in the rural setup would not have ventured for treatment resulting in infinite delay. Second, is the possibility of recall bias due to unintentional reporting errors from the caregivers of patients.

5. Conclusion

Modifiable factors pertaining to stroke recognition and response behavior continue to cause PHD in India. The need of the hour is a strong patient education campaign to help recognize stroke and respond quickly and appropriately. We suggest the following interventions to improve recognition and response behavior as outlined in Fig. 3.

1. Patient education regarding warning symptoms of stroke.

2. The availability of dedicated ambulance services especially in the rural areas should be strengthened and the public should be informed to contact 108. People operating EMS services should also be educated periodically about the need to respond immediately in cases of stroke.
3. General practitioners should avoid appointments for people with symptoms of stroke. They should inform them about the nearest center with facilities and encourage them to call EMS.
4. Target practical aspects to facilitate a positive behavior in case of an acute stroke. The need for immediate attention irrespective of the perceived urgency based on stroke severity should be emphasized.

Abstract

Background: A variety of hematological manifestations are seen at every stage of human immunodeficiency virus (HIV) infection, and they often pose a great challenge in the comprehensive management of acquired immunodeficiency syndrome. Anemia is the most common hematological abnormality associated with HIV infection. The severity and the incidence of cytopenia are usually correlated with the stage of the disease and underlying immune status if interpreted cautiously, especially if the patient is on regular follow-up. The primary objective of the present study was to understand the spectrum of hematological abnormalities in HIV-infected patients, whereas the secondary objective was to evaluate the correlation of hematological abnormalities with absolute CD4 count and HIV viral load. **Materials and Methods:** The present cross-sectional descriptive study was conducted on 100 patients, aged 18 years and above, diagnosed with HIV infection and confirmed by Western blot or ELISA method. Both inpatients and outpatients at our tertiary care hospital were included in the study. **Results:** Individuals with high viral load and low CD4 count had a higher prevalence of anemia. There was a statistically significant and directly proportionate decrease in the absolute CD4 count as the hemoglobin levels decreased ($P = 0.004$). In the present study, normocytic normochromic blood picture and anemia of chronic disease blood picture were more prevalent among the study participants. Individuals with high viral load and CD4 count <200 cells/mm^3 had a higher rate of occurrence of coinfections. The correlation of absolute neutrophil count and thrombocytopenia with absolute CD4 count and HIV viral load was not statistically significant. **Conclusions:** Complete blood counts and peripheral smear observations were significantly correlated with high HIV viral load and lower absolute CD4 cell counts and therefore can be suggested as economical alternatives for the evaluation of the status of HIV disease stage and its progression.

Key words: Absolute CD4 count, anemia, cytopenia, hematological profile, HIV viral load

INTRODUCTION

A variety of hematological manifestations are seen at every stage of human immunodeficiency virus (HIV) infection/acquired immunodeficiency syndrome (AIDS), and they often pose a great challenge in the comprehensive management of AIDS. Hematological abnormalities and their complications are the most common causes of mortality and morbidity in HIV-infected individuals.[1] They hinder the treatment directed at HIV and the opportunistic infections and malignancies of AIDS. The hematological abnormalities have also been reported to augment the risk of bacterial infections and affect the quality of life.

Anemia is the most common hematological abnormality associated with HIV infection. This, in turn, is attributed to the abnormal cytosine expression and alteration in bone marrow microenvironment.[2] On the other hand, thrombocytopenia occurs by immune-mediated destruction of the platelets, in addition to inadequate platelet production. Other causes of cytopenia in these patients include treatment-related adverse events or secondary to the opportunistic infections or neoplasms or preexisting or coexisting medical issues. HIV-infected patients with cytopenia require bone marrow examination to determine the cause of cytopenia and also to direct appropriate therapy. The severity and the incidence of cytopenia are usually correlated with the stage of the disease.[1,3,4] These manifestations also reflect the underlying immune status if interpreted cautiously, especially if the patient is on regular follow-up. Hematological abnormalities can be the initial presentation of HIV infection. Patients might be asymptomatic due to the HIV infection and the reason for referral to a physician is usually the abnormal blood count or lymphoid disorders. By considering the possibility of HIV infection, there is an opportunity to diagnose and treat the patients earlier and prevent the transmission of infection. Hematological abnormalities might be the direct result of HIV infection or due to secondary infections, neoplasms, and side effects of the therapy. Early diagnosis and treatment for hematological abnormalities are key factors that contribute to reduction in the morbidity and mortality. Despite the availability of numerous reports on HIV in India, the focus on the hematological manifestations appeared to be limited. Most of the available data are from the West, which might not be directly applicable to the Indian population. Hence, the present study was conducted with the primary objective to understand the spectrum of hematological abnormalities in HIV patients among the Indian population, whereas the secondary objective was to evaluate the correlation of hematological abnormalities with absolute CD4 count and HIV viral load.

MATERIALS AND METHODS

The present cross-sectional study was conducted on 100 patients, aged 18 years and above, diagnosed with HIV infection and confirmed by Western blot or ELISA method. Written informed consent was obtained from all the participants who expressed their willingness to participate in the study. Both inpatients and outpatients at the institution (PSG Institute of Medical Sciences and Research) were included in the study. Patients who refused to give consent and did not have a complete profile of investigations were excluded from the study.

All patients were investigated with a complete hemogram that included estimation of hemoglobin level, red cell indices (mean corpuscular volume, mean corpuscular hemoglobin, and mean corpuscular hemoglobin concentration), red cell distribution width, total leukocyte count, differential leukocyte count, platelet count, reticulocyte count, and peripheral smear examination. Further to determine the cause of hematological abnormality, indirect bilirubin level, serum iron, total iron-binding capacity, fasting serum Vitamin B12, serum folic acid, stool occult blood, upper gastrointestinal endoscopy, colonoscopy, and bone marrow examination were done accordingly.

Statistical analysis

The data were analyzed using Microsoft Excel 2010 and Statistical Package for the Social Sciences version 19.0 (Armonk, NY: IBM Corp.). A predictive value of <0.05 was considered statistically significant.

RESULTS

Complete hemogram

In the present study conducted on 100 patients, 81 patients were treatment naive and 19 were on antiretroviral therapy (ART). Individuals with high viral load and low CD4 count <200 cells/mm^3 had a higher prevalence of anemia. Table 1 shows the comparison of absolute CD4 count and HIV viral load of groups of patients of varying hemoglobin levels. Individuals with high viral load and low CD4 count <200 cells/mm^3 had a higher prevalence of anemia. Severe anemia was noted in about 71.4% of individuals with CD4 count <200 cells/μL, 28.6% among CD4 count 200–500 cells/mm^3, and 26% among CD4 count >500 cells/mm^3 [Table 1]. There was a statistically significant and directly proportionate decrease in the absolute CD4 count as the hemoglobin levels decreased ($P = 0.004$).

Likewise, the comparison of HIV viral load in groups of patients of varying hemoglobin levels showed a statistically significant increase in the viral load as the hemoglobin levels decreased ($P = 0.000$). Severe anemia was noted in about 85.7% of individuals among HIV viral load >1000 copies/ml [Table 1].

In the present study, there were 81 treatment-naive individuals. Hence, the data analysis was done separately

[Downloaded free from http://www.ijstd.org on Wednesday, September 16, 2020, IP: 157.46.127.239]

for the treatment-naive patients. Treatment-naive individuals with high viral load and low CD4 count <200 cells/mm^3 had a higher prevalence of anemia. Severe anemia was noted in about 66.7% of individuals among CD4 count <200 cells/mm^3 and 33.3% among CD4 count 200–500 cells/mm^3. Severe anemia was noted in 83.3% of participants with HIV viral load >1000 copies/ml. Severe anemia was not reported in treatment-naive patients with CD4 count >500 cells/mm^3 and HIV viral load <200 copies/ml [Table 1]. The differences observed in hemoglobin count in treatment-naive patients between different groups of HIV viral load (P = 0.000) and absolute CD4 count (P = 0.008) were statistically significant.

Comparison of platelet count and absolute neutrophil counts in varying categories of absolute CD4 count and HIV viral load showed insignificant associations in both total study population and treatment-naive patients [Tables 2 and 3].

Type of anemia

In the present study, normocytic normochromic blood picture was noted in majority of the patients. Among the types of anemia, anemia of chronic disease blood picture (35.8%) was more prevalent among the study participants. Iron-deficiency and Vitamin B12-deficiency anemia were noted in about 8.6% and 2% of the study participants, respectively. Hemolytic anemia was not observed. Nearly ten patients presented with pancytopenia. Among the individuals on ART, the patients who were on zidovudine-based therapy had normocytic normochromic anemia with macrocytosis.

Bone marrow biopsy

In the current study, bone marrow biopsy was done among five patients. The bone marrow picture in three participants was erythroid hyperplasia with mild dyserythropoiesis, megakaryocytic hyperplasia, and mild increase in plasma cells which were suggestive of HIV infection. In the other two participants, immune thrombocytopenia was observed.

Coinfections

Comparison of occurrence of coinfections in various categories of absolute CD4 count and HIV viral load showed statistically significant differences (P = 0.000). In individuals with high viral load and low CD4 count <200 cells/mm^3, a higher rate of occurrence of coinfections was observed.

Table 1: Comparison of absolute CD4 count and human immunodeficiency virus viral load in groups of patients with varying hemoglobin level

HAART=Highly active antiretroviral therapy; HIV=Human immunodeficiency virus

Among the coinfections, pulmonary tuberculosis was predominant and it was about 25% of the total infections. The other coinfections observed were extrapulmonary tuberculosis (11%), central nervous system toxoplasmosis (4 individuals), oral candidiasis (8%), and esophageal candidiasis (5%). Other coinfections (<5%) noted were *Pneumocystis jiroveci* infection, nocardiosis, and herpes simplex infection. Hepatitis B coinfection was noted in about 2% of the total population.

DISCUSSION

Many studies have been conducted across India on HIV manifestations and various aspects have been addressed. However, the focus on the hematological manifestations was very limited. Most of the available data are from the Western studies and may not be directly applicable to the Indian population. Hence, the present study was an attempt to understand the profile of hematological abnormalities in HIV infection in a South Indian population. The study looked into the hematological manifestations and their correlation with viral markers.

HIV is a retrovirus affecting immunity, impairing the immune function, thereby resulting in opportunistic infections and malignancies. The hallmark of HIV infection is decreasing the activity and number of CD4+ T lymphocytes. Furthermore, it impedes other cell lineages and tissues. Cytopenias have been noted even without highly active antiretroviral therapy (HAART) or opportunistic infections and malignancies, proving that HIV infection is directly associated in causing these hematological derangements.

The present study among HIV-infected individuals from South India showed the prevalence of anemia to be 47%. The incidence and severity of anemia, thrombocytopenia, and neutropenia reflect the underlying immune status, if interpreted cautiously. It will be of great benefit, especially if the patient is on regular follow-up. Cytopenias are the leading cause of morbidity and mortality in HIV patients. Hence, it is necessary to identify and treat for hematological abnormalities to reduce the morbidity and mortality.

Studies done worldwide reveal that the prevalence of anemia in HIV-infected persons has been found to be as high as 63%–95%; they also reveal that anemia is more common than thrombocytopenia or leukopenia. In a US-based study, Mildvan *et al*. noted the prevalence of anemia in 9690 HIV-infected individuals and showed that 39.5% (1721) of patients receiving no ART and 35.5% (7252) of patients receiving HAART were anemic. They found that anemia was more prevalent among men and patients with CD4 <200 cells/mm³.[5] Reasons for anemia were found to be decreased production because of associated infections, ART drugs, low erythropoietin levels, or HIV infection *per se*. Furthermore, red blood cell lysis due to autoimmune hemolytic anemia, disseminated intravascular coagulation or thrombotic microangiopathy, and nutritional deficiencies were causes for anemia.[6] The most common reason for anemia in HIV patients is the anemia of chronic disease. In the Multistate Adult and Adolescent Spectrum of HIV Disease Surveillance Project, Sullivan *et al*. analyzed cytopenia in 32,867 individuals affected by HIV infection. They showed that anemia occurrence increased with the clinical severity of the disease.[7] About 3% of HIV patients developed anemia at 1-year follow-up, compared to 12% among those who had immunologic AIDS that is CD4 count <200/mm³ and 37% among those with clinical AIDS.[8] Among cytopenia, anemia in an HIV-infected individual was significantly correlated with higher mortality.[1] However, on the contrary, decreased risk of death was noted in those who recovered from anemia. Although the levels of serum erythropoietin may be high in these patients, the response to anemia was blunted compared to those with uncomplicated iron-deficiency anemia of comparable severity.[9]

Drug treatment and the subsequent complications were also the common reasons for anemia among HIV patients. Zidovudine is the most common among the ART drug to cause anemia. It inhibits the *in vitro* erythroid colony

[Downloaded free from http://www.ijstd.org on Wednesday, September 16, 2020, IP: 157.46.127.239]

formation. It does it in a dose-dependent manner.[10] Following zidovudine intake, macrocytosis develops within weeks. Macrocytosis in these patients also acts as a useful marker of drug compliance. It was noted that serum Vitamin B12 levels were often low in HIV-infected patients. However, only few patients presented with true Vitamin B12 deficiency. *Mycobacterium avium* complex, *Mycobacterium tuberculosis*, and *Histoplasma capsulatum* caused anemia in AIDS patients by bone marrow infiltration.

In the current study, anemia was more prevalent in individuals with high HIV viral load and low absolute CD4 count. The present finding was concurrent with numerous studies conducted globally.[5,11,12] Low hemoglobin count was observed in both treatment-naive HIV patients and patients on HAART therapy.[11,12] Low hemoglobin levels were also found to correlate significantly with the increased severity of the disease and poor prognosis as in other studies.[1,3,4,13] Normocytic normochromic anemia was the common finding among the blood picture of HIV patients in the present study and was concurrent with the report of Evans and Scadden.[14] The severity of anemia was significantly correlated with high HIV viral load and low absolute CD4 count. The abovementioned findings were consistent with the study done by Volberding *et al*., who reported that more severe levels of anemia are found among HIV-positive patients presenting with low CD4 counts.[15]

Neutropenia was also found in majority of patients with high viral load and low CD4 count.[16] Among leukopenia, neutropenia was more prevalent in HIV patients, ranging from 10% to 30% at later stages of the disease. HIV infection leads to bone marrow suppression causing decreased granulocyte colony-stimulating factor levels, thereby causing low granulocyte–macrophage lineage. This resulted in leukopenia and neutropenia in HIV patients. Bone marrow suppressive drugs or opportunistic infections might also contribute to leukopenia. Moreover, HIV infection *per se* results in lymphopenia at later stages of disease, causing low CD4+ lymphocytes. In HIV patients, lower values of absolute neutrophil counts were due to granulopoiesis inhibition by the HIV virus itself or by bone marrow infiltration by infections. Leukopenia was also attributed to malignancies, adverse drug reactions, autoimmunity, and hypersplenism.

Various studies from developing nations showed a marked decline in mortality in HIV patients following HAART therapy. An Indian study showed a dramatic decline in mortality from 25 to 5 deaths per 100 person years in HIV patients between 1997 and 2003 after starting HAART therapy.[16] Factors such as older age, baseline low CD4 counts, tuberculosis infection at any point of time, and ART-naive status had significant associations with mortality.

Thrombocytopenia was noted during the early stages of the disease and it was not associated with poor prognosis. Thrombocytopenia in HIV infection is due to immune complex-mediated peripheral destruction and antiplatelet antibodies. Interestingly, thrombocytopenia is noted as the first clinical manifestation in otherwise asymptomatic HIV-infected individuals, whereas neutropenia and anemia were mostly noted in the later stages of HIV disease. The possible mechanisms considered for thrombocytopenia are increased destruction of platelets by immune complexes in circulation which nonspecifically get deposited on the platelets. Furthermore, thrombocytopenia can be attributed to the existence of specific antiplatelet antibodies, as well as direct action on megakaryocytic by HIV *per se* causing ineffective platelet production. The incidence of thrombocytopenia among HIV patients was about 40%, and in 10% of HIV patients, it might be the first sign of AIDS. Thrombocytopenia was related to increased morbidity and mortality, by accelerating the deterioration of CD4 counts and leading to progression to AIDS.

Among all the study participants, anemia was more common than thrombocytopenia or neutropenia. In treatment-naive individuals and individuals on ART, thrombocytopenia and neutropenia were more prevalent among high HIV viral load and low CD4 count <200 cells/mm^3. Immune thrombocytopenic purpura remains the most common cause of low platelet count in HIV patients.[17]

Abnormalities in the bone marrow were noted at various stages of the HIV disease and more during the later stages of the disease. HIV infection in the mesenchymal stem cells of bone marrow leads to various bone marrow abnormalities.[2] HIV infection leads to a histiocytic reaction and further resulting in hemophagocytic syndrome and severe pancytopenia. HIV also causes decrease in progenitor cells in the bone marrow.[18] As per Paradela *et al*.'s study, it was reported that bone marrow defects in HIV-infected individuals mainly showed features of increased cell counts, granulomatous changes, and some amount of dysplasias.[19] Studies conducted *in vitro* showed the direct influence of HIV on mesenchymal cells and hematopoietic cell activity.[2]

India has the third largest HIV population with 2 million people affected, more than 60,000 deaths due to AIDS-related illnesses, and only about 43% receiving proper HAART from health sectors. The government spends a huge sum of its health budget over HIV treatment and prevention. Our study can be considered as a pilot study and should be extrapolated to a larger study with case and control group selected within the sample, for instance with low and high absolute CD4 count and HIV viral load.

CONCLUSIONS

Most of the available data on HIV infections and hematological profiles are from the Western studies, which might not be directly applicable to the Indian population. The present study looked into the hematological manifestations and their correlation with viral markers of HIV patients from South India. HIV viral load and absolute CD4 count are the most essential biomarkers to identify the stage of HIV disease and its progression. However, these tests are expensive in both developed and developing countries. The results of the present study suggest that complete blood counts and peripheral smear can be economical alternatives to HIV viral load and absolute CD4 cell counts in staging the disease and assessing the prognosis.

Necessity-concern differential
ASM costs
Newer ASMs
ASM availability
ASM side effects

ABSTRACT

Objectives: Anti-seizure medication (ASM) non-adherence contributes to treatment gap and increases mortality and morbidity associated with epilepsy. Beliefs about medications are considered better predictors of ASM non-adherence than clinico-demographic factors. We aimed to look into ASM non-adherence rates among adults with epilepsy (AWE), identify the contributing barriers and determine whether medication beliefs were more powerful predictors than clinico-demographic factors.

Methods: This was a cross-sectional study of AWE receiving ASMs. Participants (n = 304) were assessed by validated questionnaires, for non-adherence (8-item Morisky Medication Adherence Scale) and perceptions of ASMs (Beliefs about Medicines Questionnaire) along with clinico-demographic details.

Results: Our group with high literacy and low-income had a high non-adherence rate (55 %) despite having positive beliefs (Mean necessity-concern differential [NCD] = 2.86). Among the beliefs, ASM non-adherence was significantly associated with ASM-concern ($t = 4.23$, $p < 0.001$) and NCD ($t = -4.11$, $p < 0.001$). Stepwise multiple linear regression analysis showed that non-adherence was significantly associated with per-capita income ($\beta -0.215$, $p < 0.001$), ASM side effects ($\beta 0.177$, $p = 0.001$), high seizure frequency ($\beta 0.167$, $p = 0.002$), ASM availability ($\beta -0.151$, $p = 0.004$), ASM costs ($\beta -0.134$, $p = 0.013$ and NCD ($\beta -0.184$, $p = 0.001$). NCD accounted for 2.9 % of the variance in non-adherence whereas the other clinico-demographic variables together accounted for 14.6 %.

Conclusion: We describe a paradigm shift in AWE with high non-adherence to ASMs, wherein clinico-demographic variables emerge as better predictors of non-adherence than beliefs. High literacy facilitates the perception of need for ASMs whereas costs and side effects hamper adherence.

1. Introduction

Epilepsy is one of the most common neurological disorders estimated to affect around 70 million people worldwide [1]. Anti-seizure medications (ASM) form the mainstay of treatment and help in achieving good seizure control in 70 % of patients with epilepsy (PWE). Medication non-adherence magnifies the morbidity and causes a threefold increase in mortality [2,3]. Medication adherence is defined as "the extent to which a person's behaviour including taking medication, following a diet, and/or executing lifestyle changes, corresponds with agreed recommendations from a health care provider" [4]. Adherence to long term treatment is around 50 % in developed countries whereas its is much less in the developing nations [4].

The prevalence of epilepsy in India is estimated to be 3.0–11.9 per 1000 populations, which is similar to the developed countries [5]. Treatment gap is a well known obstacle in developing countries, which ranges from 22 % among urban, middle-income people to 90 % in villages in India [6]. Medication non-adherence is one of the main causes of treatment gap which leads to poorer outcomes and increased utilisation and strain of the health care system of a resource poor nation like India.

Hence, identification of barriers followed by implementation of targeted methods to improve adherence is essential to fix the treatment gap and improve outcomes and decrease mortality in our PWE.

Medication adherence is a dynamic process and not a stable patient characteristic [7]. In addition to the various clinical factors, specific and general medication beliefs are known to impact adherence to medications. This is operational as a theoretical necessity-concern framework (NCF) where the perception of need for ASMs is balanced by the concern about their adverse effects [8]. Negative beliefs wherein the patients perceive low necessity and high concern about ASM use are associated with non-adherence. Medication beliefs were found to be more powerful predictors of adherence compared to clinical factors in epilepsy as well as in other chronic illnesses [9,10]. In a metaanalysis of 94 articles, Horne et.al demonstrated the strong association of medication adherence with the NCF in many chronic disorders including epilepsy [11]. This association remained significant irrespective of the sample size, country of research and the type of adherence measure used. Very few studies show contradictory results. Shallcross et al. [12] and Kemp et al. [13] found no correlations between beliefs about medicines and ASM adherence. The sample sizes in these studies were very small and hence not sufficiently powered to draw conclusions. Nakhutina et al. [14] found nonsignificant association between beliefs and adherence with the Morisky scale but significant associations with participant self rating scale. The Morisky scale had low internal reliability in their sample.

Very little data is available from India about the prevalence and causes of non-adherence to ASMs. Hence we conducted this study in our centre located in the South Indian district of TamilNadu. We presumed that the changing socio-economic scenario of increasing literacy rate (>80 % vs the national literacy rate of 74 %) and unemployment rate (7.6 % vs the national rate of 6.1 %) [15] in our state would have a bearing on the predictors of ASM non-adherence. We aimed to (1) determine ASM non-adherence rates among adults with epilepsy (AWE) and identify the demographic and clinical barriers that contribute to ASM non-adherence (2)determine whether medication beliefs influenced non-adherence and if so whether they were more powerful predictors than the demographic and clinical factors.

2. Methodology

2.1. Study site and subjects

This prospective cross-sectional study was conducted at the PSG Comprehensive Epilepsy Care Centre located at Coimbatore, South India. The study was approved by the ethics committee of the hospital. Patients were recruited from the out-patient department of our epilepsy clinic from June 2019 to December 2019. **A**ll the patients are seen by the epilepsy specialist (RSI).The inclusion criteria was as follows (1) diagnosis of epilepsy according to the International League Against Epilepsy (ILAE) [16] and on ASMs (2) age ≥18 years (3) minimum 6 months of ASM therapy; (4) No major cognitive impairment; and (5) can read and write. The exclusion criteria consisted of (1) presence of psychogenic nonepileptic seizures and (2) any surgery for epilepsy. Our sample size was calculated using a single population proportion formula assuming 95 % confidence level, 5 % margin of error and 50 % medication adherence rate.

2.2. Questionnaire

After obtaining written informed consent, information was collected regarding the demographic details, epilepsy and ASM therapy using a questionnaire. The patients then completed few validated self-reported assessments with the assistance of a bilingual research assistant as required.

2.3. Demographic details

Age, sex, urban or rural residence, number of members in the house, marital status and family income details were collected from the participants. An age ≤30 years (median age) was considered young. Family percapita income (PCI) was calculated as total family income divided by the number of members in the house. Occupation was noted as currently employed or not. Educational status was considered as formal if they had completed tenth grade or more and informal if completed less than tenth grade.

2.4. Disease related details

Age at onset, duration and family history of epilepsy along with the presence of generalized tonic clonic seizures (GTCS) over the past six months were noted. Seizure frequency over the past six months was classified using the Engel seizure frequency scoring system [17]. They were divided into 2 groups of low seizure frequency or well-controlled epilepsy with score ≤4 (seizure free or those with auras only or non-disabling nocturnal seizures) and high seizure frequency or poorly controlled epilepsy with score >4. The epilepsy type according to the latest classification by ILAE was noted [16].

2.5. ASM related details

Details regarding ASM consumption were collected. ASMs were divided into old or conventional being marketed before 1980, and new. Thus, carbamazepine, clonazepam, diazepam, phenobarbital, phenytoin, primidone and valproate were defined as old, the remainder as new ASMs. Taking single ASM was considered monotherapy and more than one as polytherapy. Frequency of dosing was categorized into once or twice a day. Any drug intake other than ASMs was noted. Details of side effects and monthly costs of ASMs were collected. Participants were directly queried for adherence as to whether they ever missed ASMs and if so the reasons thereof. Whether they are dependent atleast on few occasions on reminders from family members was noted. The ease of availability of ASMs was obtained.

2.6. Measurement scales

We used the following scales: Morisky Medication Adherence Scale (MMAS) [18] and the Beliefs about Medicines Questionnaire (BMQ) [19]. The BMQ holds two sections: BMQ specific and BMQ general. BMQ specific contains questions regarding beliefs about medicines specific for a disease condition whereas BMQ general involves questions on general beliefs about pharmacotherapy. BMQ Epilepsy specific scale consisting of the ASM-Necessity and ASM-Concern scales and BMQ General scale consisting of the General-harm and General-overuse scales were used. These scales are well validated and used extensively in English language. However translated versions in Indian languages are not available. Two bilingual translators independently translated these scales from English to Tamil and another translator did the reverse translation. The forward and backward translated versions were compared and inconsistencies resolved by consensus. It was tested for content validity in a pilot study. Adequate internal reliability was indicated by post hoc Cronbach's alpha for MMAS (0.76), ASM-Necessity (0.74), ASM-Concern (0.71), General-harm(0.69) and General-overuse(0.72) scales.

2.7. Morisky – 8 item medication adherence questionnaire

An 8-item Morisky medication adherence questionnaire was used to assess patients' adherence to ASMs [18,20]. It consists of 8 questions, with the first seven items having a dichotomous answer(yes/no) indicating adherent or non-adherent behaviour. Scoring was reversed with the "no" answer getting a score of 0 and "yes" answer a score of 1, except for the fifth question which was scored as no = 1 and yes = 0 [21]. For

item 8, a patient can choose an answer on a 5-point Likert scale, expressing how often happens that he/she does not take the medications. The answer "never" was scored as 0 and the rest were taken as 1. MMAS-8 scores can range from 0 to 8 points. Adherence was considered high (score = 0), medium (score = 1) and low (≥2). Patients were dichotomized for further analysis as adherent (high adherence) and non-adherent (medium and low adherence).

2.8. BMQ

The BMQ has been validated in the general population as well as across different patient groups [22,23]. It has high internal consistency, allows assessment of self efficacy and has good test-retest reliability [24–26]. BMQ-epilepsy specific scale comprises of two 5-item factors assessing perceptions about the necessity of ASMs (ASM-Necessity) and concerns about prescribed medication based on beliefs about the danger of dependence and long-term toxicity of ASMs (ASM-Concerns). The BMQ general has two 4-item sections, one looking into the perceptions of patients towards the adverse effects caused by medications in general (General-Harm) and the other focussing on the patient perceptions of physician's approach including overuse of medicines and adequacy of time spent with them(General-Overuse).The response for each question was scored on a five-point Likert type scale (1=strongly agree, 2=agree, 3=uncertain, 4=disagree, and 5=strongly disagree). Scores were reverse coded (score 1 becomes 5 and vice versa) so that higher scores indicate higher and lower scores indicate lower necessity, concern, harm and overuse. Each individual item score was added and the total score calculated for each of the four sections.

2.9. Necessity-Concerns Differential (NCD)

This was calculated by subtracting ASM-Concerns scores from ASM-Necessity scores. The NCD score is an indicator of the personal need for ASMs felt by the patients in relation to their concerns about their side effects. It ranges from -20 to +20, where positive scores indicate that patient perceived benefits outweigh their perception of risk and hence considered as positive belief about ASMs.

2.10. Attitudinal groups

Based on the scoring of necessity and concern, patients were divided into four groups of attitudes towards medications. Patients were dichotomized depending on their score below and above the midpoint of 15. Patients with higher score (≥15) were considered to have high necessity and high concern and those scoring <15, low necessity and low concern. Patients were then categorized into 4 groups with regard to their perception of ASM treatment; Accepting (high necessity & low concern), Indifferent (low necessity and low concern), skeptical (low necessity and high concern) and ambivalent (high necessity and high concern) [27]. For statistical comparison, accepting group was considered to have positive attitude and the remaining three together to have negative attitude.

2.11. Statistical analysis

Statistical package of social sciences (SPSS) version 24 was used to analyze the data. For descriptive statistics, mean and standard deviation were calculated for continuous variables whereas frequency distribution and percentage were used for categorical or ordinal variables. Independent samples t-tests were used to test for differences between adherence and non-adherence groups on perceptions of ASM (ASM Necessity, ASM Concerns, NCD, General Overuse and General Harm). To compare the size of these differences, standardized effect sizes (Cohen's d) were calculated. Stepwise linear regression analysis was used to identify factors associated with treatment non-adherence (dependent variable) by including all demographic and clinical variables and NCD

Table 1
Clinico-demographic details of adults with epilepsy (n = 304).

Age(years)	33.36 ± 15.59 (18–82)[a]	ASMs

(independent variables). This linear regression model was used to assess the relative strength of medication beliefs (NCD scores) vis-à-vis clinical and demographic factors in predicting non-adherence by stepwise entry and removal method. Stepwise linear regression analysis was again used to compare the attitudinal groups wherein negative attitude was used as dependent variable and all clinical and demographic factors and adherence were used as independent variable. Statistical significance was set at $P < 0.05$.

3. Results

Our study included 304 patients. The demographic, disease and ASM related variables are depicted in Table 1.

3.1. Demographic variables

The mean age of the study population was 33.3 years and consisted of 185(60.9 %) males and 119(39.1 %) females. Majority were young (56.9 %) and unemployed (54.6 %). Around 195(64.1 %) of them were staying in urban areas and had formal education whereas 143(47 %) were married. The mean per-capita income of the study group was 7758 INR. The PCI was significantly more in the adherent group than the nonadherent group (7228.77 INR vs 5525.88 INR p = 0.004).

3.2. Disease related variables

The mean age of onset of epilepsy was 20.1 years and the mean duration 13.97 years. Seizure frequency was high in 125(41.1 %) and low in 179(58.9 %) patients. Around 247(81.3 %) had focal epilepsy and 49(16.1 %) generalized epilepsy syndromes whereas 112 (36.8 %) had atleast one GTCS over the past six months.

3.3. ASM related variables

Around half of our population was on monotherapy. Eighty six of them (28.3 %) were on once daily dosing and the remaining on twice daily dosing. The average cost of ASMs was around 1042.84 INR per month. The average ASM costs were the same in the adherent and non-adherent groups. (1105.53INR vs 992.75INR p = 0.33). Only 132 AWE (43.4 %) perceived non-adherence. Forgetfulness and non-availability were the most common reasons of nonadherence. For 211(69.4 %) patients, ASMs were freely available whereas the remaining 93(30.6 %) had difficulty in the local availability of ASMs. Overall 91(29.9 %) patients reported side effects which were predominantly drowsiness and weight gain. Newer ASMs were used exclusively in 245(80.6 %) patients. Oxcarbazepine, clobazam and levetiracetam were the most frequently used newer ASMs.

3.4. Belief variables

Descriptive statistics about the belief variables is given in Table 2. The overall belief about medications is positive with 70 % showing high necessity beliefs and positive NCD scores and 55 % showing low concern beliefs. Similarly 47 % showed low overuse beliefs and 76.7 % had low harm beliefs.

3.5. ASM economics

This is displayed in Table 3. The average PCI of our study group was 73.6 % of the national PCI (10,534 INR). Corresponding values for the adherent and non-adherent groups were 90 % and 60.5 % respectively. Average monthly cost of ASMs for the group was equivalent to 4 days of their PCI or 5.8 days of wages of the lowest paid labour in India in 2019 (178 INR). Corresponding values for the adherent and non-adherent groups were 3.5 days PCI / 6.2 days of daily wages and 4.7 days PCI / 5.6 days of daily wages respectively. An additional cost of 1–4 days of PCI or daily wages is incurred for the monthly purchase of originator brands of newer ASMs when compared to the commonly available generic brands. For the older ASMs, the difference in costs between the originator and generic brands is very negligible.

Table 3
ASM economics of our study group.

	Income (%)[a]	Expenditure[b]
Overall (n = 304)	73.6	(4, 5.8)
Adherent group (n = 135)	90	(3.5, 6.2)
Non-adherent group (n = 169)	60.5	(4.7, 5.6)
Cost of ASMs		
Antiseizure medication (DDD)	**Generic[b]**	**Brand[b]**
Oxcarbazepine (1200 mg)	(1.8, 2.6)	(4.6, 6.7)
Clobazam (20 mg)	(0.6, 0.87)	(1.5, 2.2)
Levetiracetam (1500 mg)	(1.9, 2.8)	(4.6, 6.7)
Divalproate (1000 mg)	(1.2, 1.8)	(1.4, 2)
Phenytoin (300 mg)	(0.15, 0.22)	(0.46, 0.67)
Carbamazepine (1000 mg)	(0.7, 1)	(0.83, 1.26)
Phenobarbitone (100 mg)	(0.12, 0.16)	(0.51, 0.75)

DDD = Defined daily dose.
[a] Per capita income (PCI) as a proportion of the national PCI.
[b] Mean number of day's income required for one month of ASM treatment as a proportion of (PCI of the study group, minimum daily wages in India [2019]).

Table 2
Beliefs about medications in the study group and in both adherence groups.

Variable	Mean(SD)	Median (range)	People above the midpoint[d]	Adherent (n = 135) Mean(SD))	Non-adherent (n = 169) Mean(SD))	Cohen's d (95 %CI)	t (304)	p-value
ASM necessity[a]	17.26 (4.69)	18 (5–25)	213 (70)	17.77 (4.94)	16.86 (4.46)	0.19 (-0.03, 0.42)	1.68	NS
ASM concern[a]	14.41 (4.76)	14 (5–25)	137 (45)	13.15 (4.85)	15.41 (4.45)	−0.48 (-0.71, -0.25)	−4.23	<0.001
ASM NCD[b]	2.86 (6.86)	3 (-17 to 19)	211 (69.4)	4.62 (6.76)	1.44 (6.62)	0.47 (0.24, 0.7)	4.11	<0.001
General overuse[c]	18.74 (3.02)	19(4–18)	161 (53)	12.72 (3.19)	12.75 (2.89)	−0.01 (-0.23, 0.21)	−0.09	NS
General harm[c]	16.22 (3.22)	16(4–20)	71 (23.3)	10.12 (3.6)	10.3 (2.89)	−0.05 (-0.28, 0.17)	−0.49	NS

[d]N(%) Midpoint is 15 in case of necessity and concern, 0 in case of NCD and 12 for overuse and harm. NS = non significant, M (SD) = Mean (standard deviation).
[a] Scale from 5 to 25 where high scores indicate high necessity and high concern towards anti-seizure medication use.
[b] Scale from –20 to 20 where positive scores indicate that patient perceived benefits outweigh risks.
[c] Scale from 4 to 20 where low scores indicate positive attitude towards medicines.

Table 4
Stepwise multiple linear regression model for reported non-adherence to ASMs.

Predictors	β	p	Adjusted R^2 (%variance)
Per capita income	−0.215	<0.001	0.046 (4.6)
ASM side effects	0.177	0.001	0.084 (3.8)
Seizure frequency	0.167	0.002	0.108 (2.4)
ASM availability	−0.151	0.004	0.131 (2.3)
Cost of ASMs	−0.134	0.013	0.146 (1.5)
NCD	−0.184	0.001	0.175 (2.9)

3.6. Adherence to ASMs

MMAS scores were dichotomized into an adherent group (n = 135, 44.4 %) and a nonadherent group (n = 169, 55.6 %).

a) Differences in the adherence groups on perception of ASMs:
This is displayed in Table 2. The necessity, overuse and harm scores were distributed equally between the two groups of adherence. ASM-concern scores and NCD were significantly high in the non-adherent and adherent groups respectively ($p < 0.0001$). Both the factors accounted equally for the largest differences between the adherence groups when effect sizes were compared using Cohen's d.
b) Multivariate analysis for non-adherence:
Stepwise entry and removal of the clinical, demographic, and belief variables resulted in a linear regression model explaining 17.5 % of the variance in reported non-adherence to medication (Table 4). Higher non-adherence rates were associated with PCI (β -0.215, $p < 0.001$), ASM side effects (β 0.177, $p = 0.001$), high seizure frequency (β 0.167, $p = 0.002$), ASM availability (β -0.151, $p = 0.004$), ASM costs (β -0.134, $p = 0.013$ and patients' beliefs represented by NCD (β -0.184, $p = 0.001$). NCD accounted for 2.9 % of the variance in non-adherence whereas the other clinico-demographic variables together accounted for 14.6 % of the variance.

3.7. Attitudinal outcome

This is depicted in Fig. 1. Majority of our patients were either "Accepting" of their ASMs and having positive attitude (n = 114; 37.5 %) or were "Ambivalent" (n = 108; 35.5 %). Very few were "Skeptical" (n = 43; 14.1 %) or "Indifferent" (n = 39; 12.8 %). The non-adherence rate in the various groups was as follows: Accepting (57/114; 50 %), Ambivalent (63/108; 58.3 %), Skeptical (31/43; 72 %) and Indifferent (18/39; 46.1 %). The respective contributions to the overall non-adherence (n = 169) of the four attitudinal groups were 33.7 %, 37.2 %, 18.3 % and 10.6 % respectively. Multiple linear regression analysis with negative attitude as the dependent variable and the various clinico-demographic factors and adherence as independent variables showed 3 predictors of negative attitude; education (β 0.173, $p < 0.001$), positive family history(β 0.156, $p = 0.002$), and ASM side effects(β 0.134, $p = 0.005$).

4. Discussion

Our centre receives more refractory cases and this explains why more than 80 % of our patients were suffering from symptomatic focal epilepsy. Our study group is predominantly urban and educated. Majority is unemployed and the average PCI is 73.6 % of the average national PCI. We involve our patients in all decisions including choice of ASMs and counsel them at every visit regarding side effects and drug compliance. Our patients generally express more concern about potential adverse effects than the cost of ASMs and hence newer ASMs were used in more than 80 % of them. The commonly used ones were oxcarbazepine, clobazam and levetiracetam. We use ASMs either once daily or twice daily to facilitate adherence. Since conventional sodium valproate is administered thrice daily, we use only the divalproex or chrono preparations.

We found that non adherence to ASMs is still very common and seen in 55 % of our population of AWE. Our study demonstrated one demographic (PCI) and four clinical (high seizure frequency, presence of side effects, low costs and poor availability of ASMs) predictors of non adherence. The PCI was significantly high in the adherent group than the non-adherent group whereas the ASM costs in both the groups were similar. This would mean that lower ASM costs would improve affordability and hence improve adherence. However regression analysis showed a reversal in the expected relationship between ASM costs and non-adherence. This is explained by a possible correlation between the predictor variables, low R-squared value and a small sample size. The sixth predictor was related to patient perception wherein those with low

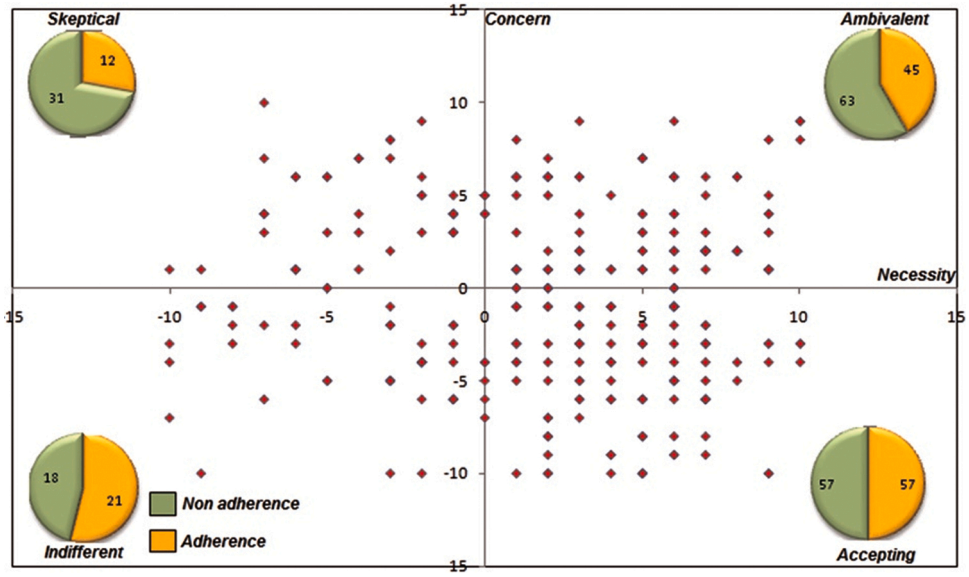

Fig. 1. Scatter diagram showing the four attitudinal groups and their adherence to ASMs. The midpoint (0,0) indicates (15,15) of the necessity and concern scores. Every point score more or less than 15 will have a similar point added or subtracted from 0 so that +10 on the graph represents a score of 25 and -10 represents a score of 5.

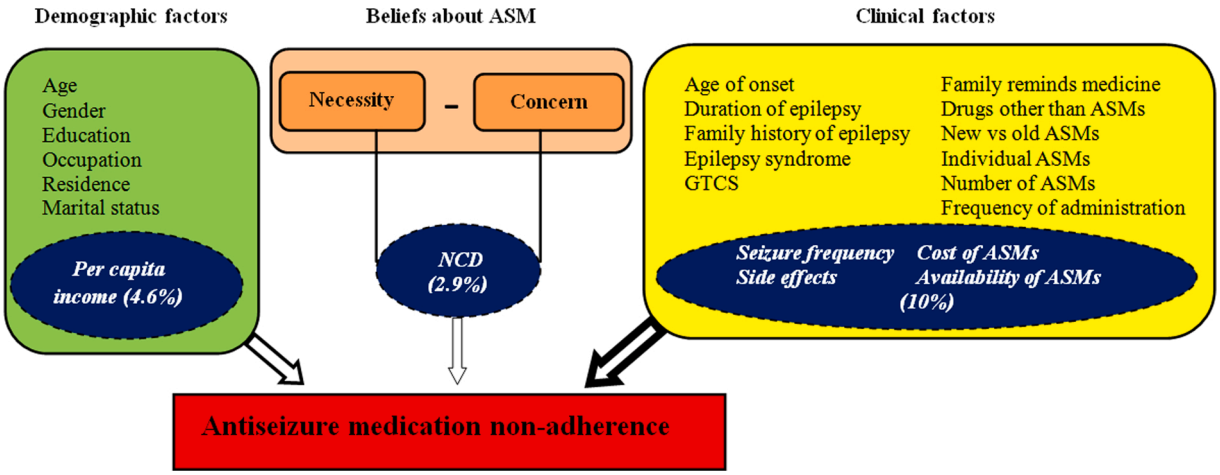

Fig. 2. Schematic diagram showing the various clinico-demographic variables and beliefs. The predictors and their contribution (%) to the variance of non-adherence are shown in dotted oval circles.

NCDs had higher non-adherence.

The two key factors deciding adherence, availability and affordability of ASMs are poor in low- and middle-income countries. Newer ASMs are better available in the private sector compared to the public sector. Data for five conventional ASMs from multiple low- and middle-income countries including India has shown that the average availability of generic ASMs in the public sector was <50 % and 40–70 % in the private sector [28]. Our hospital is in the private sector and patients pay for medicines. Initially they buy ASMs for 2–4 weeks from our pharmacy and subsequently depend on the local pharmacies. Thirty six percent of the study group was from the non-urban or rural setup where there are problems with the availability of ASMs. Many a time, the originator brand ASMs prescribed by us are not available in the rural pharmacies. Some of them use lower-priced generics which may not be quality-assured resulting in breakthrough seizures. Similar problems exist with regard to the ASM costs. The average PCI of our non-adherent group was 30 % less than the adherent group whereas they were spending 1.2 days of PCI more for the monthly purchase of ASMs. For the more commonly used newer ASMs, oxcarbazepine and levetiracetam, an additional 3 days of PCI was needed when compared to their respective generics to meet the monthly requirements. The above data suggest that use of generic medicines in our setup would improve affordability. However we are generally reluctant to switch from brand to generic ASMs for fear of loss of seizure control. Ensuring the supply of quality generic ASMs with good average bioequivalence should improve ASM prescribability for those being treated for the first time.

Around 30 % of our population of AWE reported side effects to ASMs which contributed to non adherence. Drowsiness and weight gain were the most common side effects. The presence of polytherapy in about half of the population has probably contributed towards adverse effects. Studies have shown the negative association of adverse effects of ASMs with adherence [29]. The non-adherence rate in our study goes against the common belief that newer ASMs result in better adherence due to low potential for adverse effects. Recent studies show that despite the increasing use of newer ASMs as the initial therapy, the overall tolerability has not changed [30].

The relationship between seizure outcome and ASM non-adherence is not linear [31]. That non adherence leads to poor seizure control is well known. Early educational and behaviour interventions to improve adherence improve seizure frequency and seizure outcome [32,33]. The paradoxical effect of uncontrolled seizures contributing to non adherence is also well documented in the literature [34–36]. The time since the last seizure has been shown to determine adherence. The presence of seizures within 30 days or 6 months result in more non adherence while absence of seizures for more than a year result in better adherence [36, 37]. The high non-adherence rate would have contributed to high seizure frequency observed in 41 % of our patients. Since our centre deals with more refractory cases, the paradoxical response to uncontrolled seizures of non adherence, arising out of increasing concern is also a possibility. While the relationship between non adherence and poor seizure control could be established by drug level monitoring, the relationship between illness perception and non adherence needs more exploration and understanding.

That the clinico-demographic factors emerged as better predictors accounting for 14.6 % of the explained variation in adherence in contrast to beliefs which accounted for 2.9 % of the variation was not necessarily expected as it was contradictory to the existing observations about medication adherence in epilepsy [10]. Neither was this surprising considering the socioeconomic situation of the state which is reflected in our study group. The overall belief about medications of our group has been positive. A good proportion of those with negative attitude were still adherent, demonstrating that negative attitude doesn't necessarily result in non-adherence. The ASM-related side effects seem to make them develop a negative attitude but being better educated has helped them feel the need for the medications. The human adherence behaviour depends more on the cognitive representation of the beneficial effects of a drug than on the concern regarding its adverse effects [38]. It is possible therefore that high literacy of our group acted as a protective factor against non-adherence by contributing to increased perception of necessity, whereas unemployment with its resultant poverty made the ASM economics more significant contributor to non-adherence.

We acknowledge the following limitations of our study. First, is the use of self-reported adherence scale which is subjected to retrospective and recall bias and usually underestimates non-adherence by 20 % [39]. Direct measures of adherence are impractical in our population. We preferred an ordinal rather than an interval scale of assessment of adherence and gained confidence from our patients by a non-confrontational consultation and ensured the confidentiality of their responses. We also considered both medium and low adherence as non adherent to minimize underestimation of non adherence. Second, is the problem of low adjusted R-squared value. This could be due to the non-inclusion of other potentially important predictors like depression and anxiety, health care related factors and support systems. Any study trying to predict human behaviour is also expected to have low R-squared value. Regardless of the R-squared, the presence of significant

coefficients will help us draw important conclusions about how changes in the predictor value will affect the response value. Third, we recognize that adherence is dynamic and hence best understood by prospectively looking at trajectories rather than by cross-sectional point estimates. Fourth, we did not try to differentiate between unintentional and intentional non-adherence. Intentional non-adherence is more likely to be associated with perceptions of need and concern. Fifth, our findings are not generalizable and could be different in scenarios of low literacy, high dependence on traditional healers and medicines etc.

Despite its limitations, this study demonstrates a high degree of non-adherence and identifies the factors linked to non-adherence to ASMs in our relatively well literate, low income group of adults with chronic epilepsy. The clinico-demographic variables of PCI, ASM related side effects, ASM costs, availability and seizure frequency along with medication beliefs were the predictors identified. Improving the affordability, availability and tolerability of ASMs would facilitate adherence more than interventions to improve beliefs. Making available good quality generic ASMs will be an important step in this direction. Older ASMs may be initiated as monotherapy. Newer ASMs could be limited to those who could afford them, those who develop side effects to older ASMs and also in special situations and to prevent drug interactions. It is imperative to look for side effects during each visit and take corrective steps including proper counselling of patients. We describe a paradigm shift in the relative roles of medication beliefs and clinical factors wherein the latter emerges as better predictor of adherence than beliefs. The closing knowledge gaps due to improving literacy rates and various accesses to epilepsy specific education would mean that our study could herald a changing trend rather than remain an isolated finding. Further studies on adherence to ASMs focussing on various demographic and geographic groups are required to support our observation.

5. Conclusion

The findings of our study are summarized in Fig. 2. We found a high degree of non-adherence to ASMs of 55 % in our study group. We provide novel insights into the predictors of medication adherence from a robust sample of low-income and high literacy. Though medication beliefs predicted non-adherence, the clinico-demographic factors of ASM cost, availability and tolerability proved to be better predictors.

Dental Health Status among College Students and the Treatment Needs

Abhirami K[1], Vallig[1], Karthikeyan MS[2]

[1]Department of Dental Surgery, PSGIMS and R, Coimbatore, India

[2]Department of Community Medicine, PSGIMS and R, Coimbatore, India

ABSTRACT

Aim: The aim of this cross-sectional study was to investigate the oral health status and normative need of college students both from urban –rural population of age group 17-23.

Materials and method: A descriptive cross-sectional study was done among 3312 college students belonging to urban –rural population of age group 17-23 in Coimbatore district, Tamil Nadu using purposive sampling method. Data entered in Microsoft excel sheet and analyzed using statistical package for social science (SPSS) version 24. Chi-square test was used for computing statistical significance

Result: Overall dental caries prevalence accounted to 70% (rural-72.12% urban-68.43%) with a mean DT of (1.14) in the rural population than urban population (1.09) and majority of the student's required one surface restoration. Periodontal status of the students as measured by community periodontal index (CPI) showed that majority of the student participant (32.66%) had calculus necessitating the need for oral prophylaxis, with the mean CPI index of (1.13) rural than (0.94) Urban.

Conclusion: In this study the dental caries prevalence and the periodontal problem was more in the rural population than the urban population with the one surface restoration and oral prophylaxis as the predominant treatment need.

Key words: College students, Oral health, Urban, Rural, Dental caries, Periodontal disease

INTRODUCTION

Oral diseases are the most common of the chronic diseases and are important in public health problems because of their prevalence, their impact on individuals, society, and the expense of their treatment [1]. On September 6, 2016, a new definition of oral health was approved by the FDI (World Dental Federation General Assembly) [2]. The new definition acknowledges the multifaceted nature and attributes of oral health. In developing countries were the resources are sparse it is of utmost importance to plan primordial preventive strategies rather than treating oral diseases and data regarding the prevalence of oral diseases gives us comprehensive picture to identify the target group and impart preventive modalities and there is a paucity of such data of this age group (17-23) in Coimbatore, Tamil Nadu, India.

College life is a crucial period of transition with personal responsibility. Students in this period can be targeted for preventing dental diseases and building future oral health [3] voluminous literature pertaining to oral health status of school children [4,5] is available, but data pertaining to young adults, especially to college students are sparse. Thus, analysing epidemiological data of age groups not customarily studied [world health organisation (WHO) index age groups] give the exact picture of the current oral health status and normative needs of the population. The aim of this study was to accesses the oral health status among and the normative needs among college students in Coimbatore in Tamil Nadu.

MATERIALS AND METHOD

Study Design: Descriptive cross-sectional

study. A health screening camp of dental, ophthalmology and general medicine was conducted for students in a private college in Coimbatore from 22-1-2018 to 22-2-2018 and about 3500 students were screened by a team of doctors from PSGUHTC. Two examiners were involved in this research study, examiner A and examiner B. The study was carried out for a period of 28 days approximately examining 125 students per day. Demographic data including name, age, gender, and permanent address of the candidate were recorded. The Inclusion criteria were subjects with permanent dentition, with no remaining deciduous dentition, subjects with age group of 17-23, Students present during the period of oral examination. The students taken for the study were 3312. The study protocol was submitted to the institutional ethical committee [PSGIMSR] and clearance was obtained Project proposal number-18/223 August 10th 2018.

Oral examination was performed by two trained and calibrated examiners. Before the survey, both the examiners and recording clerks were participated in a training and clinical calibration program in the department. Following this training, 10% of the students were examined by each of the two investigators to assess inter-examiner reliability and Kappa Values of 0. 87 and 0.88 were found, respectively. The interview and examination of a single study subject took 3 to 4 minutes. The study was done using probability sampling method and the sample size of calculated reference to Punitha et al. [6] using prevalence of caries as 36.7%. Sample size was calculated using formula $n=4 \times pq/d^2$ and found to be n=372.

Method of registration

Oral examination was done using the WHO Basic Oral Health Assessment [7] form with plane mouth mirror and WHO periodontal probe. Clinical examination was conducted using natural light with the participant sitting on a chair with a head rest. The examination was performed in a classroom. The examination area was arranged in such a way to allow one person at a time apart from the examiner and the recorder. The recorder was made to stand close to the examiner so that the instructions and the code could be easily heard, and the examiner could see that the findings were being recorded correctly. The data were coded and analyzed using the SPSS version 24 software the level of statistical significance was kept at $p<0.05$. The descriptive statistics were calculated. Chi-square test was used.

RESULT

A total of 3312 (urban-1888; 57%, rural -1424; 43%) participated in this study. The average DMFT among the target group was 1.92 with urban having DMFT score of 1.95 rural with 1.80 (Table 1).

In this study the highest score as measured by CPI showed that a total of 21.13% of the student had a bleeding as their highest score, 32.66% had calculus indicating the need for oral hygiene instruction and oral prophylaxis and 5.07% had a pocket of 4-5mm necessitating surgical interventions (Table 2). The community–wise distribution according to the highest score as measured by CPI showed that35.74% rural and 30.34% urban had calculus as the highest score.

Mean number of sextants with bleeding was higher in urban (0.21), whereas the mean number of sextants with calculus and shallow pocket was more in rural (0.35) compared to urban (0.30) (Table 3).

Association of CPI Index with community (urban/rural) shows that rural population has increased periodontal diseases than urban, and it is statistically significant $p < .000$ with 95% CI (0.255-0.121) (Table 4).

Loss of attachment according to the highest score showed that loss of attachment of 0-3mm was seen in 94.41%, 4-5mm in 3.38%, 6-8mm in 1.20% of the population (Table 5).

Mean number of sextants with score 1 was more in rural than urban (0.04; 0.02) (Table 6).

Association of Loss of attachment with community (urban/rural) shows that rural population has increased Loss of attachment than urban and it is statistically significant $p < .003$ with 95% CI (0.048-0.010) (Table 7).

Among the study participant 0.3% had prosthesis in the upper arch and 0.1% in the lower arch, out of which 0.3% had bridge denture and 0.1% had both bridge and partial denture.

DISCUSSION

Oral health is an essential component of general health and overall well-being of an individual. Oral cavity and its surrounding structures that are free of any diseases are indicative of good oral health. This not only makes a person look and feel good, it is equally relevant in maintaining oral function [8-10]. Oral disease is one of the most common public health issues worldwide with significant socio-economic impacts, and yet it is frequently neglected in public health policy [11].

Schools and colleges play an immense role in the growth of young minds not only for learning new information but also by having long-lasting effects [12]. In India despite improvements in infrastructure and dental manpower, oral health care remains to be neglected entity as it is not considered to be life threatening [13].

As there is no national level oral health policy and fee for services is still the most common mode of payment for dental service preventive strategies hold priority as the most economical way for improving oral health of the community. To advocate preventive measures, it is essential to assess the complete presence of disease burden in the community.

This cross-sectional study aims at finding the percentage and prevalence of dental caries, periodontal diseases in students of age group 17-23 from urban and rural population in a college in Coimbatore district, Tamil Nadu State, India.

Overall caries percentage in the study conducted by DharV et al. [14], Saravanan S et al. [15], Niyanta Joshi et al. [16], Farooqi FA et al. [17], Kumar S et al. [18] was found similar to the present study around 70%

The mean DMFT of the study conducted by theFarooqi et al. [17], Kumar et al. [18] is like the present study (1.94 ± 2.0) and (1.94).

The study conducted by Mohammed A.AL-Rafee et al. [19], Sriailapanan P, et al. [20], Soroye et al. [21], Sanadhya et al. [22], Akinyamoju et al. [23], showed rural population had more caries prevalence which is supporting to the present study.

The study conducted by Maserejian NN et al. [24], Patro et al. [25], David J et al [26] showed Urban population to have more Dental caries prevalence contradicting to the present study.

The study conducted by Kalsbeek H et al. [27] (24%) (Score-1), Hannan et al [28] (33.5%) (score-2) periodontal index was like the present study.

The study conducted by Arvidson et al. [29], Baiju et al. [30], Vadiakas et al. [31] concluded that rural population had more periodontal diseases than urban population like the present study.

The study conducted by Popoola et al. [32], Sane [33] had mean plaque index (1.12 ± 0.41) which was like the present study (1.13 ± 0.997). The study conducted by Zhang S et al. [34] showed that only 7% of the population had normal periodontium which was contradicting to the present study. The limitations of this study are inherent to cross-sectional studies, which do not allow establishing a relationship of cause and effect, and it only addresses the prevalence and severity of the disease without looking at sociodemographic variables such as parental education, economic status or family size. Furthermore, the current paper only reports the dental caries and the periodontal status and does not examine the oral hygiene practice or other individual reasons for the above dental morbidity.

CONCLUSIONS

The caries prevalence and the periodontal diseases severity were higher in students from rural areas than the students from the urban area. The DMFT index was higher in students from urban area than the students from rural area; this is because the FT value was higher in the urban area indicating the awareness and availability of dental care.Dental health care needs are high in rural areas than in urban areas.

RECOMMENDATION

It is recommended that continuous scientific monitoring, design, and effective implementation of preventive and restorative programs to be carried out by dental surgeons and included in national wide program like RBSK (RASHTRIYA BAL SWASTHYA KARYAKRAM).

ABSTRACT

Introduction; Depression is an illness that may affect and be affected by diabetes mellitus. The clinical guidelines for older adults with diabetes mellitus have recognized this by recommending screening for and management of depression in diabetic elderly people. The aim of this study was to find out the prevalence of depression using PHQ -9 questionnaire among elderly diabetics in peripheral primary health care centres attached to a Private medical college. **Objectives:** 1. To find out the prevalence of depression among elderly diabetics 2. To find out the factors associated with depression among elderly diabetics **Methodology:** This cross sectional study was conducted among known diabetics above 60 yrs of age attending the NCD clinic of Peripheral health centres at Peelamedu, Vedapatti, Neelambur during December 2017 – April 2018. The socio demographic factors and morbidity factors such as fasting blood sugar, duration of diabetes, history of hypertension, past history of diabetes related complications, hours of sleep were included to find out the association with levels of depression. **Results:** Among the study population, 40.4 % were having the signs of depression in which the majority have only minimal symptoms of depression. The factors such as Female Gender, Fasting blood sugar >126 mg/dl and hours of sleep < 7 hours found to be statistically significant association with depression. **Conclusion:** The prevalence of depression using PHQ 9 is 40.4% and the factors such as female gender, fasting blood sugar more than 127 mg/dl and sleep at night less than 7 hours were found to have statistically significant association with depression.

Key word: Depression, PHQ-9, Screening, Prevalence, Diabetes, Elderly.

INTRODUCTION

Depression is an illness that may affect and be affected by diabetes mellitus. Depression is an independent risk factor for the onset of type 2 diabetes mellitus. It negatively affects the course of diabetes and is associated with increased risk of complications, hyperglycemia, and mortality. Depression may exert its negative effect through hormonal, neuronal, or immune system changes that directly affect the body's ability to produce or use insulin. or, the effect of depression may be indirect, by resulting in poor self-care behaviours, such as overeating, drinking alcohol, not exercising, skipping medications, or failing to keep medical appointments. Thus, identifying and treating depression in diabetes is strongly recommended.[1]

Evidence suggests that depression may relate to poorer glycaemic control.[2] and that poorer control predicts a poorer course of depression in adult samples.[3]There is some evidence that depression does not prospectively predict worsening of blood glucose control in the elderly, but more research needs to be done to understand this relationship in this group.

In interactions with the health care system, the presence of depression may influence decisions made by health care providers concerning medical outcomes (e.g., blood glucose and blood pressure). For example, providers may set goals that are easier to achieve, yet are less stringent, when they believe that depression will interfere with a patient's ability to adhere to a stricter regimen. Depression can also have an effect on patients' own goals and preferences for treatment, because depressed patients may feel too hopeless or helpless to embark on the lifestyle changes that are most beneficial for diabetes self-care.

Thus, in many different ways, diabetes may become more difficult to manage for elderly people who are also depressed, and depression may become more difficult to resolve in those who have diabetes, resulting in higher health care utilization and medical costs for those with this comorbidity.[4] The clinical guidelines for older adults with diabetes mellitus have recognized this by recommending screening for and management of depression in diabetic elderly people.

Tools such as the short form of the Geriatric Depression Scale, the Patient Health Questionnaire-9, and the newly

developed Depression and Suicide Screen are useful. [5] The present study used PHQ – 9 questionnaire to arrive at a provisional diagnosis of depression as patients with minimal symptoms (score 5-9), minor depression (score 10-14), moderate Major depression (score 15-19), severe major depression (score >20).

The objectives of this study were to find out the prevalence of depression using PHQ -9 questionnaire among elderly diabetics in peripheral primary health care centres attached to a Private medical college and to find out the factors associated with depression.

METHODOLOGY

Department of community medicine of PSG Institute of Medical sciences and Research has one Urban (Peelamedu) and Two Rural health training centres (Vedapati and Neelambur) to deliver primary health care to people. These centres have a basic laboratory services to manage Non communicable diseases (NCD). All these three centres run NCD clinic on a particular day of the week and maintain NCD register. This cross sectional study was conducted among known diabetics above 60 years of age attending the NCD clinic of Peripheral health centres at Peelamedu, Vedapatti, Neelambur during December 2017 – April 2018. By purposive sampling, 104 elderly diabetics those came for review during the study period at NCD clinic were selected. All registered diabetics above 60 years of age attending the NCD clinic included and those who were on treatment for pre-existing major and minor mental illness excluded.

After obtaining approval from Institutional Human Ethics Committee, informed consent obtained from the patients at NCD clinics of peripheral health centres. Study Questionnaire with PHQ-9 administered to the patients till the sample size of 100 reached. Questionnaire contains the following items i.e. Socio demographic variables, fasting blood sugar, presence of hypertension, complications related to diabetes and hours of sleep at past night to find out the association of above factors on depression among the study population.

Those patients found to be having depression will be followed up based on degree of depression at the peripheral health centres. Proportions, test of statistical significance (Chi square) and odds ratio with 95% confidence interval (CI) using SPSS version 24 were calculated.

RESULTS

Table 1: Distribution of study population at Peripheral Health Centres

Peripheral Health centres	Study population	Percent (%)
UHTC (Peelamedu)	46	44.2
VHTC (Vedapatti)	29	27.9
NHTC (Neelambur)	29	27.9
Total	104	100

The present study intended to find out the prevalence of depression among elderly diabetics and the factors associated with depression. There were 104 elderly

Table2: Prevalence of depression among the study population

Depression	Study population	Percent (%)

* Statistically significant (p< 0.05)

diabetics (Table. 1) included in the study. Among the study population, 40.4 % were having the signs of depression (Table.2), of which 24% have only minimal symptoms of depression (Table.3).

The socio demographic factors i.e. age, gender, education, income per capita per month and morbidity factors such as fasting blood sugar, duration of diabetes, history of hypertension, past history of diabetes related complications, hours of sleep and PHQ -9 score are shown in Table.4.

Each of the above variables were categorized into two to find out the statistically significant (p< 0.05) association with depression among the study population using chi square test (Table. 5) in SPSS version 24. The factors such as Female Gender, fasting blood sugar >126 mg/dl and hours of sleep < 7 hours found to be statistically significant association with depression in the present study.

DISCUSSION

In the present study the prevalence of depression among elderly with diabetes mellitus was found to be 40.4%. The study conducted by SA Black et al showed that 31.1% of the older diabetic individuals reported high levels of depressive symptoms. [6] Prevalent major depressive episodes were present in 15.4% of the subjects with diabetes, which was significantly higher than in nondiabetic subjects in a study conducted among community-dwelling elderly persons with diabetes mellitus by P. de Jonge et. al. [7] In a study conducted by Manjiri D Pawaskar et al. among Medicare enrolled elderly population with type 2 diabetes mellitus, 17% had depressive symptoms. [8] In a study conducted by Kee-Lee Chou et al, on Prevalence of depression among elderly Chinese with diabetes, 26% of elderly diabetics reported elevated levels of depressive symptoms. [9] Elderly female diabetics are more among depressed (OR 3.2, 95%CI: 1.40-7.48) than men in this study which is statistically significant. Finkelstein EA et al reported diagnosed annual prevalence rates of major depression more among elderly female diabetics. In our study there is no significant association between the subjects with duration of diabetes less than 10 years and more than 10 years whereas in a study done by Yu-Ling Bai et al. a significant difference was found for depression scores between subjects with diabetes for <1 year and those with diabetes for >10 years.[10] Elderly with high Fasting blood sugar >127 mg/dl have higher risk of depression (OR 2.5, 95%CI: 0.99-6.33) than those with Fasting blood sugar <126 mg/dl in the present study. PJ Lustman et al reported in the meta analytic review of 24 studies that Depression is associated with hyperglycemia in patients with type 1 or type 2 diabetes3. However, association of depression with hyperglycemia in elderly diabetics is not documented. Elderly diabetics who slept more than 8 hours at night had lesser risk of depression (OR 0.279, 95%CI: 0.08-0.89) than those who slept less than 7 hours at night in this study. The factors such as age, education,

income, marital status, past history of diabetes related complications and hypertension were not found to be significant in this study. This study has few limitations like very small sample size, FBS is taken as an indicator for glycemic control instead of Hb A1C and PHQ 9 administered by different doctors at three health centres.

Conclusion:

This cross sectional study among elderly diabetics in primary health centre setting of a private medical college revealed that prevalence of depression using PHQ 9 is 40.4% and the factors such as female gender, fasting blood sugar more than 127 mg/dl and sleep at night less than 7 hours were found to have statistically significant association with depression.

Background: Safety of pentavalent (DTwP-HBV-Hib) vaccine has been a public concern in India and other countries. This study attempted to document the association of serious adverse events following immunization (AEFI, including hospitalizations and deaths of all causes) with the 3 doses of pentavalent and oral poliovirus (OPV) vaccines.

Methods: A cohort of 30,688 infants in 2 south Indian districts were enrolled and followed-up between October 2014 and May 2016, following their first vaccination with DTwP-HBV-Hib and OPV at public health facilities. During weekly follow-ups, by telephone or home visits, the serious AEFIs (hospitalizations and deaths) occurring any time after each vaccination until 4 weeks after third dose were documented. The incidence risk ratios (IRRs) of serious AEFIs in the first (days 0–6) and fourth weeks (days 21–27) after the vaccine doses were compared using the poisson regression analysis.

Results: Of the 30,688 infants enrolled, 30,208 received their third doses of vaccines. During the 4-week periods following each vaccination, there were 365 hospitalizations and 17 deaths. Adjusted incidence risk ratio of 3 doses combined for post-vaccination serious AEFIs during the first week compared with fourth week was 0.8 [95% confidence interval: 0.6–1.0].

Conclusions: There was no increased risk of a serious AEFIs during the first week after any of the 3 doses of pentavalent and OPV vaccination compared with the fourth week. In the absence of any temporal clustering, mortality and hospitalization rates observed in vaccinated infants probably reflects the natural occurrence of such events.

Key Words: pentavalent vaccine, oral polio vaccine, vaccine safety, serious adverse events, hospitalization, death

(*Pediatr Infect Dis J* 2020;39:389–396)

Vaccination has been one of the major success stories in global health, leading to the eradication of deadly diseases like smallpox and possibly the virtual disappearance of some diseases from several regions.[1] Over the last 25 years, effective vaccination programs have resulted in a >90% decrease in the global disease burdens for diphtheria, pertussis, and tetanus, including India.[2–4] However, in spite of the extensive evidence of their benefits, concerns and controversies about the value and safety of vaccines continue to impact adversely their acceptance in diverse contexts. Public concerns over reports linking autism with measles, mumps, and rubella vaccine in the United Kingdom had negative impact on vaccine coverage causing several disease outbreaks,[5] which spread to other countries, such as the United States, France, Italy, and the Netherlands.[6–9] This misinformation has spread globally. The rumor mongering through social media considerably affected vaccine coverage during the MR campaigns in south India.[10] The growing global challenge of vaccine hesitancy relates largely to vaccine safety concerns, leading to public confidence erosion, which in turn dampens the vaccine coverage.[11] The Global Advisory Committee on Vaccine Safety emphasized the need for thorough investigation and causality assessment of serious adverse events following immunization (AEFI) as a quality assurance mechanism for immunization programs.[12]

The decreased disease burdens in the developed countries have largely been due to the successful implementation of immunization programs using multivalent combination vaccines. The vaccines against diphtheria, tetanus, and pertussis combined (DTwP) are in use for several decades under universal immunization program. Recently the HBV and *Haemophilus influenza* type b (Hib) have been added to DTwP, known as the pentavalent (DTwP-HBV-Hib) vaccine. Over the past 15 years Global Alliance for Vaccines and Immunizations has supported the introduction of pentavalent vaccine in developing countries for protection against invasive Hib disease in universal immunization program.[13] However, there were temporary interruptions and introduction delays in Sri Lanka,

Bhutan, Vietnam[14] and Pakistan[15] during 2011–2016 due to reports of hospitalizations and deaths following vaccination after national launch of the pentavalent vaccine. Temporal association of vaccinations and sudden infant death syndrome (SIDS) has been the subject of extensive speculation, despite several studies having refuted any causal association,[16–18] particularly after the diphtheria-pertussis-tetanus immunization.[19]

In India, the reports of 32 infant deaths following the pentavalent vaccination as part of the national AEFI surveillance between 2011 and 2013 raised concerns, although no causal association could be identified.[20] Some professionals and civil society groups, however, appealed before the Supreme Court of India to ban the pentavalent vaccine.[21,22] Although the safety of pentavalent vaccine has been documented in the pre-licensure studies,[23,24] these studies were too small to identify rare adverse events. Thus, it was deemed necessary to carry out further investigations on this issue. This study was designed in consultation with all key stakeholders including the Ministry of Health and Family Welfare, Government of India and WHO (advised by Global Advisory Committee on Vaccine Safety), to assess the risk of serious AEFIs (hospitalizations and deaths) following pentavalent vaccination in an infant cohort from 2 Indian states, where pentavalent vaccine was first introduced.

MATERIALS AND METHODS

The pentavalent vaccine (manufactured by Serum Institute of India Ltd., Pune, India) was first introduced in the states of Kerala and Tamil Nadu in December 2011 with a 6, 10 and 14 weeks schedule for 3 primary doses. Both states have efficient health systems with high vaccination coverage[25] and low infant-mortality rates (IMR): 12 and 21 per 1000 live births in 2013 in Kerala and Tamil Nadu, respectively, compared with an overall IMR of 40 across India.[26] This study was conducted in 2 districts, Kollam (Kerala State) and Coimbatore (Tamil Nadu State).

Study Design

This prospective self-controlled cohort study enrolled infants who received their first dose of pentavalent and oral poliovirus (OPV) vaccine from the public health system between October 2014 and November 2015 in Kollam district, and between May 2015 and February 2016 in Coimbatore district.

Recruitment and Data Collection

Infants who received their first dose of pentavalent and OPV vaccines at all public health facilities in the 2 districts (District, Special and Taluk Hospitals, Community Health Centers, Primary Health Centers, Sub-centers) and out-reach points of rural and urban areas were traced based on the contact details recorded in the immunization registers. Home visits were made to confirm eligibility (received first dose of vaccine, expected to stay in the district for the 6 months follow-up period and contactable by telephone/mobile) and to enroll infants after obtaining informed written consent. Data on maternal care, infant gender, date of birth, birth weight, pregnancy-related and neonatal illnesses were collected at enrollment. The parent(s) were contacted weekly by telephone or home visit to document the health of the infant including any illness, hospitalization or death. The follow-up contact was continued even if the second and third vaccine doses were delayed due to any reason. Study staff confirmed receipt of the second and third vaccine doses from the vaccination card and the health facility register. If infants received their second and third vaccine doses at private facilities, a copy of the vaccination card was collected as proof of date of exposure. For each dose, the vaccine batch number, date and place of administration was documented. Recruited infants were followed up to 4 weeks after the third dose of the vaccines or death, whichever was earlier. Data were collected on tablets using a customized program developed with open source platforms (Android, PHP and MySQL version 5.1) and data including other materials uploaded, synchronized in the server and stored/deposited in a central data repository. An independent International Advisory Group (IAG) with vaccine safety experts and Brighton Collaboration representation supervised the study implementation including field visits. The IAG reanalyzed the data for validation.

Outcomes

This study captured the serious AEFIs which included both hospitalizations and deaths due to any cause during the follow-up period. The details about the events such as clinical features, diagnosis, treatment, period and place of hospitalization were captured. For hospitalizations, the study team visited the hospital for confirmation and followed till outcome to document the information. Hospitalization episodes of at least 24-hours as inpatient were further categorized as "appropriate," "inappropriate" and "indeterminate" using the Pediatric Appropriateness Evaluation Protocol–India criteria. The PAEP-India tool for child and newborn were adapted from the available tools and validated in hospitalized patients from multiple hospitals in India.[27] Each case was assessed by 2 independent pediatricians using the PAEP-India tool for child and categorized the case based on checklist criteria. A third pediatrician was consulted in cases of mismatch between the 2 reviewers. For deaths, the study confirmed the event by home visit, followed by verbal autopsy by senior investigator 4 weeks later. Causes of death were determined independently by 3 pediatricians trained in review of verbal autopsies and also referred to available hospital records.

Data Analysis

The 4 weeks following every dose of vaccination were considered to be the observation period with weekly intervals post-vaccination as separate risk periods (Figure, Supplemental Digital Content 1, http://links.lww.com/INF/D758). As almost all the serious AEFI (deaths and hospitalizations) reported in the passive national AEFI surveillance program occurred during the first week after any vaccine dose, the first week was considered as the high-risk period and the fourth week as the comparison period. It was hypothesized that, the risks of serious AEFI due to any cause, during the first and fourth weeks post-vaccination remain similar for each dose of the vaccines.

Person-time of observation was calculated based on the time from vaccine administration and the date of occurrence of an event, the date of administration of the next vaccine dose (if <28 days), the last contact date (if lost to follow-up), date of death or the first 28 days after vaccination when the next dose was delayed, according to the recommended schedule, whichever came first. Follow-up was defined by weekly risk windows after each vaccine dose split into first (0–6 days), second (7–13 days), third (14–20 days) and fourth (21–27 days) weeks. If a subsequent dose was given before the end of the fourth week, the follow-up time was censored and follow-up period was assigned to the subsequent dose. If the next dose was delayed, the person-time beyond 27 days after each dose were excluded from the analysis. Poisson regression analysis was used to estimate the incidence rates (IRs) and incidence rate ratios (IRRs) for serious AEFIs (hospitalization and all-cause deaths) during the 4-consecutive weekly risk periods after each dose separately and for all 3-doses combined. IRs were calculated by dividing the number of events by the corresponding person-time denominator and IRRs were calculated by dividing the IR in the risk period of interest by the IR in the fourth week. In a multivariate model, the IRR

© 2020 The Author(s). Published by Wolters Kluwer Health, Inc.

was adjusted for age at start of risk period (continuous, in days) and seasonality (quarterly; January–March, April–June, July–September, and October–December). To assess the potential of healthy vaccinee bias, we performed a sensitivity analysis to compare the risks in the first week after vaccination following the second and third doses with the risks in the fourth weeks of the preceding doses. All statistical analyses were performed using Stata version 15.0 (StataCorp LLC, TX). In addition, all deaths documented were reviewed by the national AEFI committee for causality assessment according to WHO published methodology.[20]

Sample Size

Considering the IMR in the study states to be 12–21 per 1000 live births and a neonatal mortality rate (0–28 days) of 6–15 per 1000 live births,[26] the post-neonatal mortality (29–365 days) was expected to be 6 per 1000 live births. This translated to ~0.125 infant deaths per 1000 live births per week. As there was no information about the hospitalization:death ratio in this age group from India, we assumed that for every infant death there would be ~4 hospitalizations. The required sample size was 27,422 infants to detect an IRR for hospitalizations and or deaths of 1.8 in the analyses pooling the different doses, assuming a 5% significance level ($\alpha = 0.05$) and 80% power ($\beta = 0.2$).[28] With the available sample (30,688), the observed results show that between the risk periods, we are able to detect a risk-ratio of 2.5 and 1.5 (at a 5% significance level and 80% power) of serious AEFIs (hospitalization and deaths), for individual doses and all 3-doses combined, respectively.

Ethical Approvals

The study protocol and related documents were approved by ethics committees of participating institutes. The infants were recruited after obtaining informed written consent from parents or legally authorized representatives. The study protocol and related documents were approved by Institute Ethics committees at The INCLEN Trust International (INCLEN) (vide IIEC-021 dated October 14, 2013), Government Medical College, Thiruvananthapuram (vide 01/01/2014 dated January 17, 2014), PSG Institute of Medical Sciences and Research, Coimbatore (vide 13/351 dated March 5, 2014) and World Health organization, Geneva (vide RPC625 dated January 22, 2014).

RESULTS

During the study period, 34,914 infants received their first dose of pentavalent and OPV vaccines at the public health facilities. Of these, 1377 (3.9%) infants could not be traced, 2818 (8.1%) were not eligible (1287 were not staying in the district for 6 months, and 1531 were from other districts) and consent was refused for 31 (0.1%) infants. Of the 30,688 infants recruited, 30,208 (98.4%) received their third vaccine dose and 29,728 (96.9%) completed the scheduled follow-up (Fig. 1). Of 479,523 scheduled weekly follow-up contacts (including the contacts during the intervals between the different vaccine doses till completion of 4 weeks after third dose), 89.9% were completed with averages of 4.4 (dose 1), 4.8 (dose 2) and 4.9 (dose 3) contacts for the vaccine doses (data not shown).

Baseline characteristics of the cohort are summarized in Table 1. No age or sex differences were observed across the districts. The Kollam population had a higher proportion of low and median socio-economic status and joint or extended families. Median ages of infants were 48, 83 and 118 days at the times of the first, second and third vaccine doses, respectively. A total of 622 hospitalizations and 32 deaths were documented during the follow-up period.

Within the 4 weeks after the 3 vaccine doses (per protocol study risk periods), a total of 365 hospitalizations (120, 137 and 108 after doses 1, 2 and 3, respectively) were documented. Of these 365 hospitalizations, 288 were classified as appropriate (96, 106 and 86 after doses 1, 2 and 3, respectively). A total of 257 hospitalizations (92, 136 and 29 after doses 1, 2 and 3, respectively) occurred after fourth weeks of the first and second doses of vaccination (Fig. 1). Pneumonia/acute respiratory infection (70.1%) was the leading cause followed by diarrhea (6.4%), fever (4.3%) and urinary tract diseases (3.1%) during the 4 week and post-4 week periods after the vaccine doses (Table, Supplemental Digital Content 2, http://links.lww.com/INF/D759).

Of the 32 total deaths observed, 17 deaths (8,7 and 2 after doses 1, 2 and 3, respectively) occurred within 4 weeks after 3 vaccine doses, while 15 deaths (11, 3 and 1 after doses 1, 2 and 3, respectively) occurred during post-4 weeks period, (Fig. 1). The leading causes of death included infections (31.3%), congenital malformations (28.1%), congenital heart diseases with infections (15.6%), SIDS (15.6%) and other causes (9.4%) (Table, Supplemental Digital Content 2, http://links.lww.com/INF/D759). Almost all congenital malformations were diagnosed prior to death. The SIDS was made based on Brighton Collaboration Criteria.[29] Causality assessment by the National AEFI committee classified all deaths as coincidental. Differentials in causes of hospitalization and death during the first 4-weeks (0–27 days) and post-4 weeks (28+ days) after vaccination were small (Table, Supplemental Digital Content 2, http://links.lww.com/INF/D759). Figures 2 and 3 show the IRs of serious AEFIs (hospitalization and deaths) by age and seasonality. Higher serious AEFI (hospitalization and deaths) rates were observed during 91 and 146 days of age (Fig. 2); between October and December, with a peak in December due to higher prevalence of respiratory illnesses (Fig. 3).

Serious AEFIs (Hospitalization and Deaths) Within 4 Risk-periods

The occurrence of serious AEFIs (hospitalization and deaths) across the risk-periods for the 3 doses are summarized in Table 2. Within the 4 weeks after the 3 vaccine doses, a total of 375 serious AEFIs (365 hospitalizations, 17 deaths and 7 hospitalization and deaths) occurred (125, 140 and 110 after doses 1, 2 and 3, respectively) (Fig. 1). For all-3 doses combined, the adjusted IRRs of serious AEFIs within the first week compared with the fourth week were 0.8 [95% confidence interval, (CI): 0.6–1.0]. Compared with the fourth week, the adjusted IRRs of serious AEFIs for the first week after first, second and third doses were 1.2 (95% CI: 0.8–1.9), 0.9 (95% CI: 0.6–1.5) and 0.5 (95% CI: 0.3–0.9), respectively. IRRs for serious AEFIs were not significantly higher in any of the other risk periods (second or third weeks) either for the 3 doses separately or for all doses pooled. Analyses of hospitalizations according to appropriateness did not show any increased risk in any week compared with the fourth week after any dose (Tables, Supplemental Digital Content 3, http://links.lww.com/INF/D760, and Supplemental Digital Content 4, http://links.lww.com/INF/D761). The sensitivity analysis comparing the rates of serious AEFI in the first week after the second or third doses with the fourth week after the first or second doses did not show any differences, suggesting the absence of a healthy vaccinee effect (Table 2).

DISCUSSION

This is the first large study to examine the association between administration of routine infant pentavalent and OPV vaccines and serious AEFIs (all-cause hospitalizations and/or deaths) in India, using a self-controlled prospective cohort design. We have shown that the unadjusted and adjusted risks of hospitalizations

*Total includes a small number of cases information missing for type of family, standard of living index (2 each in Kollam); Age of mother (20 in Kollam and 12 in Coimbatore); education of mother (14 in Kollam and 6 in Coimbatore); education of father (36 in Kollam and 16 in Coimbatore) and birth order (53 in Kollam and 40 in Coimbatore, respectively). Standard of living index (a proxy to household socio-economic status), constructed based on household assets and durable goods.

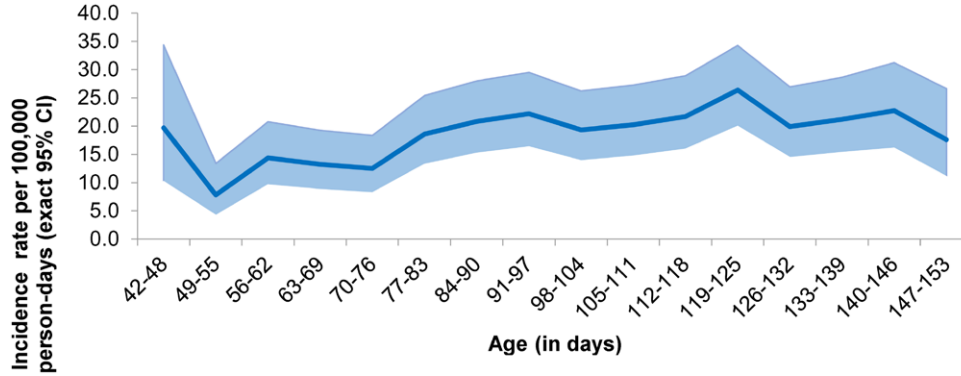

FIGURE 2. Serious AEFI (hospitalization and all-cause deaths) incidence rates (per 100,000 person-days with exact 95% CI as shaded area) by age (independent of vaccination windows). Incidence per 100,000 person-days (with exact 95% CI as shaded area); Week defined as 6-days period, starting on day-0; Person-time starts from age at first dose of vaccination and duration until the first and last day of the age period or until the Serious AEFI (hospitalization/death) events (succeeding vaccinations not considered). The hospitalization incidence presented in the figure is between 42 and 153 days of age, where 98.6% [(3,402,860/3,451,027)*100] of follow-up calls/visits were made. full color online

and deaths after any of the 3 scheduled doses of routine vaccines were similar during the first and fourth weeks post-vaccination, for either each dose separately, or all doses combined. Due to low death rates,we could not perform analyses for each individual dose but the combined analysis and analyzing the first dose only did not indicate any death clusters following vaccination.

In a highly immunized population, self-controlled study designs with defined risk windows for outcome assessment are best suited to assess possible effects during a specific time period as they are not susceptible to control selection.[30] Activation of the immune response to different vaccines occurs at different time points according to the nature of the antigen.[18,31–34] Hence, in the current study, we considered the first week after vaccination to represent the period of highest risk and the fourth week to be the comparison period. The findings of our study refute the concern of an association between serious adverse events and the pentavalent vaccine.

*Risk period corresponds to date of hospitalization (considered as at least 24-hours stay in the hospital) or all-cause death after administration of vaccination (in days); The day of vaccination defined as day-0.

†Adjusted for seasonality (January–March, April–June, July–September, October–December); age at start of risk period (in days), using Poisson regression model.

‡Twenty-one to 27 days as reference category; IR: Number of events per 100,000 person-days of follow-time, calculated as the ratio of the hospitalizations of the person-time at risk.

The main strength of the study is the representativeness of the study cohort with respect to the population in the study area due to the high rates of participation and completion of follow-up. The socioeconomic status of the population enrolled in the study was highly representative of the overall population in the 2 districts. Use of electronic data collection enabled timely follow-up and accurate data capture with real-time monitoring. Documentation of hospitalization from both participants and hospitals allowed confirmation of causes of hospitalizations and deaths. In addition, the availability of source documents and vaccination records ensured accurate confirmation of vaccine exposure.

The main limitation was possible selection bias, as infants received first vaccine dose in the private system were not represented in the study. However, according to recent National Family Health Survey (NFHS-4, 2015–2016) data, 78% and 86% of children 12–23 months of age in Kerala and Tamil Nadu, received their vaccines from a public health facility.[25] We could not trace 3.9% infants due to inaccurate address information and 8.1% could not

© 2020 The Author(s). Published by Wolters Kluwer Health, Inc.

be included due to moving out or residing outside of the 2 districts. To control for confounding by contraindication to vaccination, pre-vaccination time intervals were not included in the control periods in the main analysis. Sensitivity analyses performed to assess the potential of a healthy vaccinee bias did not suggest presence of this. The study was also limited in detecting small changes for deaths, despite the large sample size.

The study found that 128 serious adverse events (120 hospitalizations and 8 deaths) occurred among 30,000 infants during the 4 weeks after receiving their first dose of pentavalent vaccine. Calculating based on Black et al[35] and projected on a 26 million annual Indian birth cohort, it is estimated that with national coverage of 100% at a minimum 26,500 infants per year will suffer a serious health event within 1 week of receiving their first dose of pentavalent vaccine, or there will be at least 21,200 events with the current 3-dose coverage of ~80% for pentavalent vaccine. These events reflect prevailing morbidities and mortality that would have occurred regardless of vaccination as documented in 2 Indian districts with low infant mortality. Investigating these events to ensure that the vaccine product or its administration are safe remains a fundamental function of the vaccine pharmacovigilance system. This highlights the importance of continued monitoring of common serious health problems in the infant population to measure the health burden and provide new epidemiologic information on the true causes of morbidity and mortality in this group.

The study did not find any increased risk of serious AEFIs (all-cause hospitalizations or deaths) in the first week following pentavalent (and OPV) vaccination and the occurrence of these AEFIs were just coincidental. That is, in the absence of temporal clustering, mortality and hospitalization rates observed in vaccinated children reflect the natural occurrence of such events in that age range in this part of India. The study findings should help to address the vaccine safety concerns and controversies around the pentavalent vaccine in India and other low- and middle-income countries, and so boost public confidence in the program. Suspicion about a possible relationship between the vaccination and serious AEFIs among parents, communities and the health providers may not only threaten the success of immunization programs but also potentially hinder introduction of newer vaccines.

CONCLUSIONS

Close monitoring of over 30,000 infants during and after receiving their first 3 doses of DTwP-HBV-Hib and OPV did not identify any relationship between the vaccinations and the occurrence of serious AEFIs (hospitalization and/or death). The study did document the huge number of serious coincidental events that can be expected even when vaccines are properly administered. In view of the recent inclusion of several new vaccines into the immunization program in India, the findings of this study will be very useful in addressing vaccine hesitancy and safety concerns to increase public acceptance and coverage.

ACKNOWLEDGEMENTS

We express our gratitude to the district health officials and health functionaries at the public health facilities in the 2 districts for their constant support. We are highly appreciative of the parents and families of all infants for consenting to participate in this study and for their cooperation during follow-up. We thank the GAVI, the Vaccine Alliance through World Health Organization (WHO) and the patronage from Ministry of Health and Family Welfare, Government of India, New Delhi, India and the Departments of Health and Family Welfare, Government of Kerala and Tamil Nadu States for funding to conduct the study. We also acknowledge the guidance and continued support provided by the technical experts and representatives from WHO, Technical Advisory Group (TAG) members, International Advisory Group (IAG) members, officials from the Ministry of Health and Family Welfare at National and State levels. We appreciate the support from Tom Cattaert and Germano Ferreira, P95 Pharmacovigilance and Epidemiology, Heverlee, Belgium, for the validation of results, and Keith Veitch (keithveitch communication) for editorial guidance.

ABSTRACT

Introduction: Occupational hazards exist in every industry. Along with engineering and administrative measures, usage of personal protective equipments (PPE) by the workers is equally important in protecting the workers. However a high level of non-compliance to PPE usage among the workers is commonly noted. South India has several foundries, giving employment to many workers. The objectives of the study were to find out the level of PPE usage among the foundry workers, before and after an interventional program and to assess the relative effectiveness of different strategies of the program in bringing out the improved PPE compliance among them. **Materials and methods**: After obtaining ethical clearance, the study was conducted among 78 permanent workers of a foundry in Coimbatore. First the demographic details of the subjects and their level of usage of PPE were recorded, in the pre-test. Then a comprehensive three faceted interventional program, consisting of strategies such as health education to the workers, peer motivation by co-workers, and posters in the working environment, was implemented simultaneously among all subjects. After three months of implementation of the program, the post-test was conducted and the data were analyzed to measure the effectiveness of the intervention. **Results**: After the interventional program, the workers showed significant improvement in PPE usage ($p<0.001$) from the 'pre-test' level. Regarding their perception about which of the three strategies relatively contributed to bring out the improvement, most of the workers rated the strategy of peer motivation as 'high' effectiveness, health education- 'average' effectiveness and posters in working environment- 'low' effectiveness. **Conclusion**: Interventional program using multiple strategies in an integrated manner has synergistically enhanced the behaviour change among the workers.

Key Words: Foundry, Personal protective equipment, Intervention.

INTRODUCTION

Foundry[1] is an industry which produces metal castings that are made by pouring molten metal into precise moulds. After the metal has cooled, the casting is removed from the mould and the process of 'fettling' involves cleaning and finishing procedures. Occupational hazards[2] exist in every industry and the hazards in the foundry are heat, electricity, machinery, vibration, noise, dust & fumes, heavy objects, pointed objects, chemicals like formaldehyde and amines etc. Along with engineering and administrative measures, usage of personal protective equipments (PPE) by the workers is equally important in protecting the workers. Various PPE are expected to be used in foundry, such as helmet, goggles, ear plugs, mask, face-shield, gloves, boots, etc.

However, a high level of non-compliance for PPE usage among the workers is commonly noted possibly because of ignorance about benefits, or it may cause discomfort. Research studies[3-6] conducted on non-compliance to PPE usage among industrial workers, found that it is a global problem. A study published by Foundry Management & Technology, USA[3] recorded high level of non-compliance to PPE usage. An Egyptian study[4] among industrial workers found similar findings. A cross-sectional study from Nepal[5] detected that only 47.7% of workers use at least one kind of PPE during work. A study conducted among factory workers in India[6] noted that most workers were aware of the benefits of PPE, but only some workers were using PPE regularly.

Similarly various other studies have been done on the effectiveness of interventional program in bringing out improvement in PPE usage among industrial workers. A study in USA[7] demonstrated statistically significant difference in the use of PPE before and after an interventional training program. Similarly a Nigerian study[8] found significant increase in the usage of PPE, after the intervention. Another multi-faceted interventional study done among foundry workers in Italy[9] showed significant decrease in occupational injuries, after intervention.

Regarding the motivation of workers, Malawi study[10] noted that the workers viewed their high-ability coworkers as a source of motivation. According to WHO[11], one of the components essential to community based program and prevention strategies, is that it should

be an integrated program. Each element of the program should support the other elements and the program should be integrated into the settings where people work (e.g. work-sites) or live their lives.

Since behavior change is difficult to sustain unless a good supporting environment is created, we designed an intervention among foundry workers which went beyond just conducting an awareness program. Our design was guided by the Ecological Approach[11] to Behaviour Change. This approach addresses the multiple determinants that influence health and health behavior through synergy of multi-pronged interventions. Accordingly a comprehensive interventional program which had three strategies integrated together was adopted, to bring out a synergy of effect. The first strategy was health education to the workers (guided by Health Belief Model[11] for behavior change) to create the immediate awareness about the hazards that accrue due to non-usage of PPE. The second one was peer motivation by co-workers and role-models (guided by Social Cognitive Theory[11]) that will help to translate awareness into practice and to use the peer pressure to ensure compliance with PPE usage. The third strategy was posters in the working environment as constant reminders of the statuary nature of the need to use PPE at the workplace and benefits of usage from the health point of view.

The Objectives of the study were to find out the level of PPE usage among the foundry workers, before and after an interventional program and to assess the relative effectiveness of different strategies of the program in bringing out the improved PPE compliance among them.

MATERIAL AND METHODS

The study was conducted in a foundry at Coimbatore, after obtaining the permission from the relevant foundry authorities and ethical clearance from Institutional Human Ethics Committee. There were two categories of workers, permanent and temporary, in the various sections of production/ manufacturing division of the foundry. It was decided to conduct the study among the permanent workers only, because the temporary workers used to get salary in the week-end and they might go elsewhere in the next week. There were 81 permanent workers in the production division. Those workers, who were missed during a visit, were contacted during the second or third visits. Two workers could not be contacted even after three visits and one worker was not willing to participate in the study. So those 3 workers were excluded and the remaining 78 workers were included in the study.

An interview questionnaire was prepared, translated to local (Tamil) language, and back translated. A pilot study was done among the temporary workers, which helped to refine the interview questionnaire. The finalized questionnaire was then used for the study.

Pre-test: After getting informed written consent, the subjects were interviewed. For each subject, the general personal information and frequency of usage of PPE were recorded.

Interventional program: After the pre-test, all of the following three strategies of the program were started and implemented simultaneously among the subjects.

Strategy 1: 'Health education' sessions were conducted for the workers in batches, each batch consisting about 12-15 workers. Thus six sessions were conducted. Power point presentation was used for health education. During the session, it was explained how the different equipments safe-guard the workers from different hazards. 'Question and answer' method was also used which encouraged the workers to involve and pay attention. Thus every subject received health education once.

Strategy 2: 'Peer-motivaton by co-workers' was performed as follows: Some of the workers volunteered to become 'role-models'. These role-models wore PPE throughout the eight hours of work. Apart from that, for the next three months, they talked with other workers once every week, and motivated them for PPE usage. If any worker was found to be resistant to adopt PPE, the role-models talked with them more often and motivated them.

Strategy 3: 'Posters' illustrating the usage of PPE were prepared, laminated and put-up in various prominent places of the working environment. Whenever the workers would see the posters, the posters would remind them to wear PPE.

Post-test: At the end of three months, each subject was interviewed again. Along with the previous questionnaire, some more questions were added to assess the level of effectiveness of each strategy in bringing out the improvement in PPE usage.

Analysis of data: First the data were entered into Microsoft excel sheets and then transferred through SPSS package (Version 19) for analysis. For descriptive analyses, the categorical variables were analyzed by using percentages and the continuous variables were analyzed by calculating mean ± Standard Deviation. Chi-square test was used to ascertain the association between the independent and dependent variables. A 'p' value of <0.05 was regarded as statistically significant.

RESULTS

The interventional study was conducted among 78 permanent workers of a foundry.

Demography of the study subjects: Table-1 shows the general demography of the study subjects.

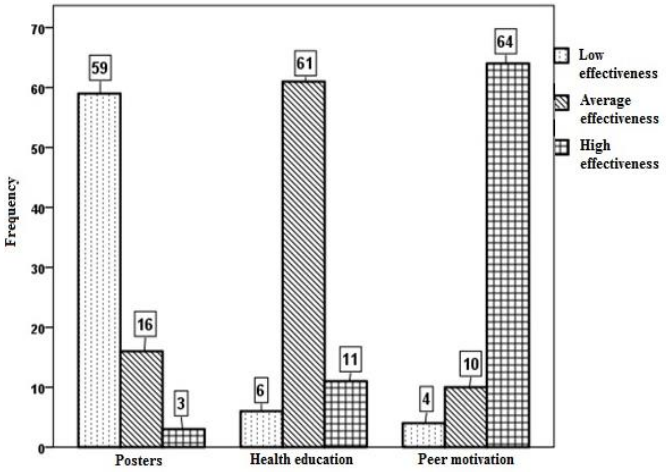
Table 1: General demography of the study subjects.

Demographic details	Group	Frequency (N = 78)	Mean ± SD
Gender	Men	78 (100%)	–
Literacy status	Literate	78 (100%)	–
Training on PPE usage.	All subjects got training.	78 (100%)	–
Age (in years)	< 40 years	1 (1.3 %)	48.38
	40 – 49 years	46 (59.0%)	± 5.49
	50 – 57 years	31 (39.7%)	
	Total	78 (100%)	
Work experience (in years)	5 – 9 years	2 (2.6 %)	25.77
	10 & more years	76 (97.4%)	± 7.44
	Total	78 (100%)	

All workers were men. All were literate. All were of middle age (Range: 38 – 57 years. Mean ± SD = 48.38 ± 5.49). All workers had work experience of more than 5 years (Range: 7 – 40 years; Mean ± SD = 25.77±7.44). All subjects got trained in the usage of PPE, at the time of joining the foundry. However the training was not repeated.

Table 2: Usage of PPE by the subjects during the work time.

	Frequency level of usage of PPE during the work time					
	Very low	Below average	Average	Above average	Very high	**Total**
Pre-test	7 (9.0)	16 (20.5)	38 (48.7)	11 (14.1)	6 (7.7)	**78 (100)**
Post-test	0	6 (7.7)	17 (21.8)	26 (33.3)	29 (37.2)	**78 (100)**



Figures in parentheses are percentage values.

Table 3: Effectiveness of intervention on the workers' usage of PPE during the work time

	Frequency of usage of PPE during the work time (n=78)			X^2	'p'
	Low	Average	High	**value**	**Value**
Pre-test	23 (29.5)	38 (48.7)	17 (21.8)	38.04	**<0.001***
Post-test	6 (7.7)	17 (21.8)	55 (70.5)		

Figures in parentheses are percentage values; 'p' <0.05 is statistically significant*

Figure 1: Perception of workers on the effectiveness of each strategy in bringing out the improvement in PPE usage.

Usage of PPE during the work time, before and after intervention:

During the pre-test, each subject was enquired about his own practice and frequency of usage of PPE during the work time. For this purpose, each subject was asked to select any one of the following five responses viz., very low, below average, average, above average and very high. The response of each subject was recorded. Again during the post-test, the responses for this question were noted. Table-2 reveals the usage of PPE by the subjects during the work time.

In the post-test, all of the 78 (100%) workers reported improvement in the frequency level of usage of PPE. During the pre-test, 7 workers reported that their usage of PPE during the work time as 'very low'. During the post-test, 6 of them reported that their usage of PPE as 'below average' and the remaining one worker reported as 'average'. Similarly the improvement was noted in all categories. Even the six workers who reported in the pre-test 'very high' usage of PPE, reported in the post-test 'still higher level of usage'. However they were included in the same category of 'very high'.

To measure the effectiveness of the intervention, the above table-2 was condensed as follows: The middle category 'Average' was kept as it was. The first two categories were combined together to form one category and named as 'low'. The last two categories were combined together and named as 'high'. Table-3 illustrates the effectiveness of intervention in bringing out PPE compliance by the workers, during the work time.

In the pre-test, 21.8% of subjects reported 'high' level of usage of PPE and 29.5% reported 'low' level of usage. In the post test, 70.5% of workers reported 'high' level of usage of PPE and only 7.7% of workers reported 'low' level of usage. This improvement in PPE usage was statistically significant (Chi square test; $p<0.001$), with substantial improvement in the effect size (70.5 minus 21.8 = 48.7). This shows that a comprehensive approach is very effective in bringing out the change in behavior.

Evaluation of the workers' perception on effectiveness of each strategy:

The subjects informed at the time of post-test, that all three strategies complemented each other in bringing out the improvement in PPE usage, thus validating the synergy of effect described by the Ecological approach to behavior change.

However the subjects were compelled to evaluate their perception of the relative role of each strategy's 'level of effectiveness' in contributing to PPE compliance. For this, they were asked to select any one of the following responses, viz., 'low' 'average', or 'high'. Their responses are shown in Figure 1.

Regarding the role of posters in the working environment, 59 workers (75.6%) felt that it had 'low' level of effectiveness in bringing out the improvement in PPE usage. On the role of health education, 61 workers (78.2%) felt that it had 'average' effectiveness. However, 64 workers (82.1%) felt that the strategy of peer-motivation by co-workers had 'high' level of effectiveness.

DISCUSSION

The present study found that the intervention program of three strategies integrated together resulted in significant improvement in PPE usage among the workers. This is in line with the Ecological Approach to Behaviour Change which posits the need to address the multiple determinants that influence health and health behavior and so there is synergy of effect in multi-pronged interventions since they address multiple determinants of health behavior.

We wanted to know the workers' perception of the relative role played by each strategy, so that we can address any misconception that required remedial action. Our study findings revealed that the workers rightly recognized the strategy of peer-motivation as having

'high' level of effectiveness. This is in line with Social Cognitive Theory which posits that people not only learn through their experiences but also by observing the action of others and the results of that action. In the present study, the 'role-model volunteers' who were fellow workers, had overcome the commonly perceived inconvenience and discomfort in PPE usage and showed by example that it is possible to practice the good behavior in their work environment. Peer-pressure then forced the other workers to fall in line, to avoid being socially rejected as deviant from the expected norm in behavior. That health education had 'average' effectiveness and posters in working environment had 'low' effectiveness goes to show that such interventions they had experienced in the past without leading to increased usage of PPE.

Other interventional studies conducted in various countries had also recorded similar improvement in PPE usage among the workers. A study on the effect of a training program among laborers in USA[7] found significant changes in the usage of PPE. It was a participatory, peer-facilitated training program. Most workers (66%) shared the information of the program with their co-workers and friends. A study in Nigeria[8] also found significant increase in the usage of PPE after intervention. In Italy[9], a multi-faceted intervention study **was done among the workers in two foundries.** The decrease in occupational injuries was significant ($P < 0.01$). Another interventional study in Nigeria[12] revealed that the usage of PPE among the workers in the interventional group were significantly higher than the control group. A study conducted in Behara[13]concluded that the intervention was effective and the results had noticeable improvement in the workers' compliance with PPE usage. An interventional program among factory workers in Iran[14] was found to be very effective in improving the usage of PPE. An interventional study in Hamedan[15] revealed that integration of motivational interviewing principles into the safety program had improved the safe behaviors of the workers in the motivational group and resulted in significant change in PPE usage among them. Another study in Iran[16] observed that the intervention program using peers was effective in promoting safe practices of the workers.

Conclusion:

Most workers perceived that the strategy of peer-motivation had 'high' level of effectiveness, health education had 'average' effectiveness, and posters in the working environment had 'low' effectiveness. However, when the intervention program consisting of three strategies integrated together, it synergistically resulted in significant improvement in PPE usage among the foundry workers because each strategy addresses a different factor that facilitates behavior change.

Limitations:We did not do a repeat study after 3 months to see whether the benefit in terms of increased PPE usage was sustained.

Recommendations: 1. Training program on the usage of PPE and health education should be conducted periodically for the workers, to ensure reinforcement of messages as well as to remove barriers to behavior change.

2. The administration should enforce that the workers should wear PPE during the work time, through promoting the peer workers as role-models and putting up posters at prominent places of the work place, where the work exposure to hazards due to non-usage of PPE take place.

Acknowledgment: We thank the foundry management and the workers for their cooperation.

ABSTRACT

Background: Nutritional assessment in children is very important to prevent nutritional disorders and to decrease the morbidity and mortality. The present study was undertaken to assess the prevalence and determinants of malnutrition among children aged 0-5 years in a tribal community of Coimbatore district. Anaikatty and Palamalai tribal areas of Perianaikenpalayam block (population=347062) was selected for our study.
Methods: A total of 206 children aged 0-5 years were included in the study after implementing the exclusion criteria.
Results: Overall prevalence of malnutrition found to be 51%. These 51% (105) malnourished children consisted of 41.3% underweight, of which 11.2% were severely underweight. Prevalence of stunting was 32.5%, of which 6.3% were severely stunted. About 21.8% children were wasted and 6.8% were severely wasted among them. Socio-demographic factors like total number of family members exceeding four, mother's educational status, father's educational status, mother's occupational status, socio-economic status, alcohol usage by any family member, and mother's nutritional status were found to be significantly associated with malnutrition on univariate analysis.
Conclusions: The problems of low standard of living, hunger, starvation, malnutrition, agricultural illiteracy, poor antenatal care, disease, poor sanitary and housing facilities, etc. has to be improved totally by implementation of policy that already exists.

Keywords: Nutrition, Prevalence, Determinants, Under five aged children

INTRODUCTION

Malnutrition among children in India is a well known public health problem due to inadequate nutrition. According to WHO, malnutrition is defined as a "pathological state resulting from a relative or absolute deficiency or excess of one or more essential nutrients".[1] Malnutrition is the biggest contributor to child mortality where 70%, 26% and 4% of malnourished children live in Asian, Africa and Latin America respectively.[2] The nutritional status of under-five children is causing great concern among social scientists and planners nowadays because child is the principal victim of interaction of nutritional, social, economical and also health related factors that lead to malnutrition. On an average, a child dies every 5 seconds as a direct or indirect result of malnutrition –700 every hour –16,000 each day –6 million every year.[3] Assessment of growth not only serves as a method of evaluating the health and nutritional status of children, but also it provides an alternative method of assessment of the quality of life of the entire community.[4] Death due to common childhood illness is more common in a malnourished child when compared with an adequately nourished child.[5] Under-five children are the most at risk segment in any

population and their nutritional status is a sensitive indicator of their health status and nutrition.[6] Malnourished children are more likely to become malnourished adults and they face increased risks of morbidity and mortality.[7,8] It is essential to pay more attention to correlate between children's nutritional status and their capability to attain the required physical growth and mental development.[9] In South India, only few tribal based studies to determine the prevalence of malnutrition among under-five children has been carried out, with paucity of data regarding prevalence of malnutrition obtained as community based study in tribal areas of Tamilnadu. Hence this community based study was undertaken to assess the prevalence of malnutrition and its association with selected known risk factors among children aged 0-5 years in the tribal hamlets of Periyanaickenpalayam of Coimbatore.

METHODS

Study design

Cross sectional study

Study population

The study included 206 children aged 0-5 years, from 25 tribal hamlets in Anaikatty and Palamalai tribal areas of Perianaikenpalayam block of Coimbatore district, Tamil Nadu. Mothers of all these children were interviewed and anthropometric measurements were taken for the children and their mothers who were included for analysis.

Sample size determination

With an estimated prevalence of 55% from earlier studies[10] and 20% allowable error, sample size was calculated using the formula,

$$n = \frac{(1.96^2)pq}{d^2}$$

$$= \frac{3.84\ x\ 55\ x\ 45}{11\ x\ 11}$$

n=82

Where, n=Number of samples required; p=Prevalence; q=100–p; d=allowable error.

Non response rate = 20%

Sample size = $\frac{82 \times 100}{80}$ = 103

Study period

Home-visits were carried out from December 2013 to August 2014.

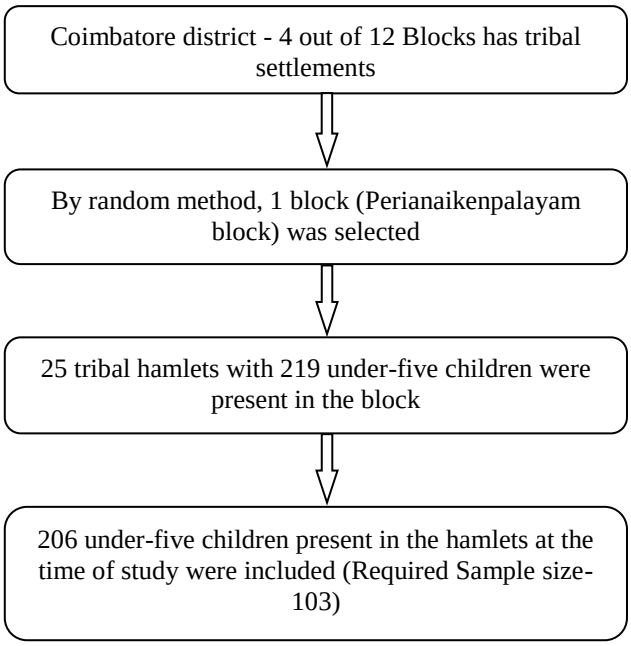

Figure 1: Study protocol.

Inclusion criteria

All the children of age 0-59 months who were permanent residents in the 25 tribal hamlets of Periyanaickenpalayam block.

Exclusion criteria

Under-five children who were not present at home even after three consecutive visits.

Data collection tools

Physical instruments and well-structured questionnaire were used for data collection.

Physical instrument

The physical instrument used in the study included a weighing scale, a Salter scale, retractable metal measuring tape and an infantometer. All the instruments were calibrated by the Department of Biometrics, PSGIMS&R validated through Best Standard Technologies Private Ltd Chennai (Certificate No: BSM-012501-12) prior to the study.

Questionnaire

A Pre-tested semi structured questionnaire was presented in the Department for critical review, following which necessary changes were made in the questionnaire, it was translated into Tamil and back translated to eliminate loss of meaning. Data was collected using this pre-tested semi structured questionnaire by interview technique. The parents of children of age group 0-59 months were

informed about the study and each question was explained to gather the data about socio-demographic factors, environmental factors, birth history and feeding practices, recent illness, availability of health facilities and their utilization. Simultaneously height and weight of the child and mother were measured.

Steps in data collection

After getting approval from the institutional ethics committee, the study was started.

Pilot study

Pilot study was carried out in a rural area, Neelambur, Coimbatore, which is located outside the field practice area of the Rural Health Training Center of the Community Medicine department, PSG IMSR to identify problems in eliciting the data using the prevalidated instruments.

Data collection for study

Consent for the participation in the study was obtained from mother using questionnaire.

Anthropometric measurements

Weight and height of all 206 children and their mothers who participated in the study were measured based on WHO recommended procedure.[11]

Measurement of weight

The weight of the children were measured using the conventional standard weighing scale and Salter spring balance for children aged less than two years. These scales were calibrated before commencement of data collection. These scales are widely used in epidemiological studies. With light clothing and without any footwear, children were asked to stand on the platform of weighing scale with body weight evenly distributed between both feet and weight was measured to nearest 0.5 kg. Zero error was set after each measurement.[11]

Measurement of height

Height was measured using a retractable metal measuring tape. Children whose height has to be measured stood on the floor in an erect position without any foot wear with his / her back against the wall. He / she was asked to put their feet together and move back till their heels touched the bottom of the wall and stretch upwards to the fullest extent with their arms hanging on the side. The head was held in such a way that lower rim of the orbit and auditory canal were in horizontal plane. The height appears in the read off area and measured to nearest 0.5 cm. The supine length was measured in children <than 2 years of age using an infantometer. The child was placed on board with head positioned firmly against the fixed head board, the knees extended by firm pressure and the feet fixed at right angles to the lower legs. Then the up right foot piece was moved to obtain firm contact with the heels and the length was measured to the nearest 0.5 cms.[11]

Assessment of nutritional status using anthropometry method

The 2006 WHO Growth Standards for Preschool Children were used for the determination of nutritional status of preschool children. Standard deviation of scores (Z-scores) for weight-for-age, height-for-age and weight-for-height were calculated. The Z-score (SD score) is calculated as follows. The *Z*-score is defined as the deviation of the value observed for an individual from the median of the reference population, divided by the standard deviation (SD) of the reference population.

Z score = (individual value-median value of reference population)/ SD value of reference population.

For each of the anthropometric indicators of malnutrition a cutoff point of-2 standard deviations (-2 SD) below the median of that of the WHO reference population was used. Deviation of Z-scores less than – 3SD put children in the severe under nutrition category.

24-hour food recall method

It is a retrospective assessment method in which the respondent is prompted to recall and describe all foods and beverages consumed in the preceding 24 hours or the preceding day. Portion size estimating aides were carried to assist the respondent to recall amounts consumed. Total Energy and Proteins in terms of calories and grams consumed was calculated for 24 h period. Percentage of Energy and Proteins consumed in comparison to recommended daily allowance (RDA) by NIN was calculated and the results were analyzed.[12]

Statistical analysis

Body Mass Index (BMI) was computed for all mothers using the following formula:

$$BMI\ (Kg/m^2) = Weight\ (Kg) / Height\ (m^2)$$

The WHO AnthroII. PC software of WHO was used for analyzing the nutritional status of children.

The variables which were found to have statistically significant association ($p<0.05$) with Malnutrition upon univariate analysis were then subjected to multivariate logistic regression analysis. Wald statistics was then used to test the significance of the odds ratio. $P<0.05$ was considered as statistically significant. Data was entered in Microsoft excel and analyzed using SPSS 19.0 version.

RESULTS

Of the 206 children studied, 106 were boys and 100 were girls. The mean (SD) height of the boys was 89.7 cm (12.29) and mean (SD) weight of the boys was 12.2 kg (3.32). Similarly for girls, the mean (SD) height was 89.6 cm (12.72) and mean (SD) weight is 12.2 kg (3.44). The mean (SD) BMI of the mothers was 20.2 (2.69).

Prevalence of malnutrition

The child is considered as "Malnourished" if he/she is underweight or wasted or stunted. The overall prevalence of malnutrition was found to be 51% and 49% of the children was found to be "Normal" anthropometrically. Of these 105 malnourished children, 41.3% were underweight, 32.5% were stunted and 21.8% had wasting.

Low weight-for-age is termed underweight. This is a composite measure of malnutrition. There is no statistically significant gender difference in the prevalence of underweight in any of the age-groups. (p=0.33) (Table 2).

Low weight-for-height is termed wasting. Wasting reflects a state of acute (short-term) under nutrition. There is no statistically significant gender difference in prevalence of wasting among different age-groups (p=0.75). Prevalence of wasting increases as the age of the children increases.

Low height-for age is termed stunting. Stunting is indicative of chronic (long-term) under nutrition. There is no statistically significant gender difference in the prevalence of stunting among different age-groups (p=0.07). Higher prevalence of malnutrition was observed among the lower socio-economic classes (p<0.001).

The study revealed, 81% of malnourished children are consuming <50% of the RDA of energy. Forty two% of normal children according to anthropometry are consuming <50% 0f the RDA of energy. No child in the malnourished category is consuming >90% of recommended allowance and only 3 children are consuming >70% of the RDA of energy.

Table 2: Age sex distribution of underweight children.

Age group (months)	Male			Female			Total		
	Total	**Moderate (%)**	**Severe (%)**	**Total**	**Moderate (%)**	**Severe (%)**	**Total**	**Moderate (%)**	**Severe (%)**
0-12	9	4 (44.4)	1 (11.1)	10	4 (40)	2 (20)	19	8 (42.1)	3 (15.8)
13-24	16	5 (31.3)	3 (18.8)	16	5 (31.3)	3 (18.8)	32	10 (31.3)	6 (18.8)
25-36	26	10 (30.3)	4 (15.4)	19	7 (36.8)	1 (5.3)	45	17 (37.8)	5 (11.1)
37-48	26	6 (230.1)	2 (7.7)	28	7 (25)	2 (7.1)	54	13 (24.1)	4 (7.4)
49-60	29	8 (27.6)	3 (10.3)	27	6 (22.2)	2 (7.4)	56	14 (25)	5 (8.9)
Total	106	33 (31.1)	13 (12.3)	100	29 (29)	10 (10)	206	62 (30.1)	23 (11.2)

Statistically significant gender difference in the prevalence of underweight is $p \leq 0.33$)

Univariate analysis was done to explore the association of malnutrition with socio-demographic characteristics of the child. The risk factors that were significantly associated with malnutrition were: Parents being illiterate, mother not working outside, total family members >4, child belonging to Class IV and Class V SES according to modified Prasad's classification, The children mainly taken care by any other family member other than mother is also not a significant risk factor for malnutrition (Table 3).

Table 4: Household characteristics associated with malnutrition among under-five children.

Factors	Category	Total	Malnourished		Unadjusted odds ratio	95% CI*	P value
			N	%			
Type of house	Pucca	53 (25.7)	18	34	1	1.20–4.95	<0.01
	Semi pucca	144 (69.9)	80	55.6	2.43		
	Kutcha	9 (4.4)	7	77.8	6.81	1.11–53.41	
Water source	Piped water	196 (95.1)	96	49	1	1.18–101.29	<0.05
	Well water	10 (4.9)	9	90	9.38		
Toilet	Private/public	36 (17.5)	5	13.9	1	3.28–23.90	<0.001
	Open air	170 (82.5)	100	58.8	8.85		

The association of semi-pucca house and kutcha house as risk factors relating the house-hold environment with malnutrition found to be significant compared with pucca house. Source of drinking water other than piped water supply and the practice of open air defecation were also found to be significant risk factors for malnutrition (Table 4).

Mother's age less than 20 years during this child birth, deliveries other than institutional deliveries, preterm delivery of this child, and low birth weight were found to be significant risk factors for malnutrition. Birth order of the child was not a significant risk factor (Table 5).

Correct feeding practices of infant and young child are very essential to the nutritional status of any child. Initiation of breastfeeding more than an hour, breastfeeding the child exclusively for a period less than 6 months, breastfeeding the child for a period less than 1 year, not giving any milk supplements to children above 6 months, consumption of <50% of the RDA of calories and proteins are significant risk factors for malnutrition. More than 90% of the children were fed with colostrum after birth. Avoiding colostrum does not turn out to be a risk factor for malnutrition in our study (Table 6).

It is evident from Table 7 that under-five children who suffered from any illness in the past month and those children who were not treated for those illnesses were more prone for malnutrition.

Table 5: Birth history associated with malnutrition among under-five children.

Table 8 shows the health service availability, its utilization and the association of these factors with malnutrition among the tribal children. Availability of health facility within a radius of 3 km is not associated with malnutrition and so show that it is protective against getting malnourished.

Children who are not immunized appropriate for age are at significant risk of malnutrition. It is interesting to see that children who are not attending the ICDS centers are having better nutritional status according to anthropometric measurements.

Table 9 explored the factors identified from univariate analysis and confirmed those truly associated with malnutrition through multivariate logistic regression analysis. This reveals that:

1. The risk of malnutrition is 10.3 times higher in under-five children of illiterate fathers when compared to literate fathers, but there is no association with the educational status of mother.
2. Occupational status of mothers show significant association with malnutrition of under-five children, where the factor that mothers employed for salary is 65% protective against malnutrition when compared to home-makers.
3. Socio-economic status is significantly associated with malnutrition after logistic regression. Under-five children belonging to Class IV and Class V families according to Modified Prasad's classification have 6.42 times more risk of malnutrition when compared to Class I, Class II and class III families.
4. Low birth weight babies have 3.41 times more risk of suffering from malnutrition when compared to babies who are born normal or overweight.
5. Earlier initiation of breastfeeding, less than an hour after birth is protective for malnutrition in under-five children. Babies who are initiated with breastfeeding after the first hour after birth are 2.9 times more prone for malnutrition.
6. Consumption of calories less than 50% of the RDA proved to be a significant risk factor from the above analysis and protein consumption did not show any statistical association. Children who consume < 50% of recommended calories are nearly 6 times at risk of malnutrition.

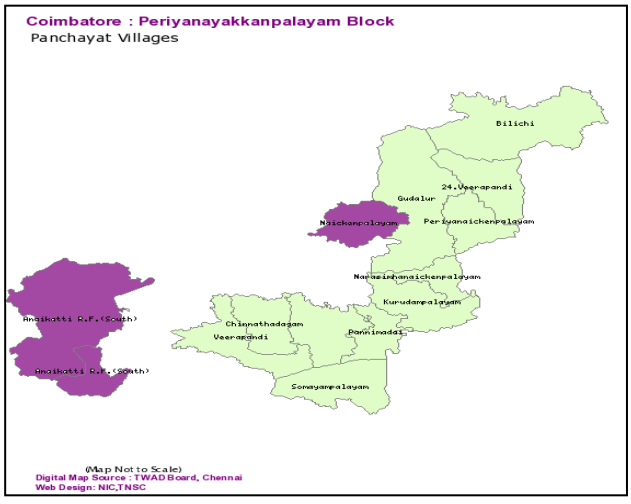

Figure 2: Map showing the tribal areas in Periyanaickenpalayam block.

DISCUSSION

The study is to assess prevalence of malnutrition among 206 under-five children in 25 tribal hamlets of Periyanaickenpalayam block, Coimbatore and to ascertain the determinants of malnutrition among them.

The possible risk factors selected in our study associated with malnutrition are age, sex, number of family members, mother's education, father's education, mother's occupational status, father's occupational status, socio-economic status, alcohol usage by family members, mother's nutritional status, mother's age at pregnancy, place of delivery of the child, term of delivery of the child, birth order of the child, birth weight of the child, time of initiation of breast-feeding, exclusive breast-feeding, total breast-feeding, energy and protein consumption of the child, Immunization status, ICDS utilization by the child, distance of health facility, recent illness, treatment for the illness, type of house, source of drinking water and toilet usage.

Data was collected using Pre tested semi structured Questionnaire by interview technique. The mothers of children of age group 0-59 months were informed about the study and each question was explained to gather the data and simultaneously height and weight of the child and mother were measured. Anthropometric measurements of the children and mothers like height and weight were measured using standardized calibrated instruments as per WHO recommendations.[13]

Prevalence of malnutrition

The study revealed overall prevalence of malnutrition was 51% and 49% of the children studied were "Normal" anthropometrically according to WHO classification. These 105 malnourished children consisted of 41.3% underweight, of which 11.2% are severely underweight. Prevalence of stunting is 32.5%, of which 6.3% are severely stunted. About 21.8% children are wasted and 6.8% are severely wasted among them.

The overall prevalence of underweight, Stunting and Wasting are 55%, 54% and 28% respectively among under-five children of tribal population in India according to NFHS-3 data.[10] Our study showed a lower prevalence of all three indicators of malnutrition when compared with nationwide statistics.

In a study conducted among tribal under-five children in 9 states of India in 2007-08 among a total of 14,587 children by NIN, Hyderabad it was found that the overall prevalence of underweight was about 49%, of which 19% were severely underweight.[14] The extent of overall stunting was about 51%, and of them, about 24% were severely stunted. About 22% of children had wasting, of which 7% had severe wasting. Only the degree of wasting is comparable to our study in this context, which may be due to acute causes of malnutrition.

Meshram et al, in a study conducted among 1751 tribal children of Maharashtra also showed a higher prevalence of underweight, stunting and wasting as 64%, 61% and 29%, respectively.[15]

Rao et al in a study conducted for Regional Medical Research Center for Tribals (ICMR study), Jabalpur, India revealed that 61.6% of preschool children were underweight, 51.6% were stunted and 32.9% were wasted.[16] The study also revealed that severe degree (below -3 SD) of underweight, stunting and wasting in 27.8%, 30.3% and 6.5% children respectively.

According to Bisai et al, in a study conducted among pre-school children of Lodha tribal community of West Bengal, the Overall prevalence of underweight, stunting and wasting was 33.9%, 26.1% and 19.4%, respectively.[17] Of these, 9.1%, 9.7% and 3.6% children were found to be severely underweight, stunted and wasted. These findings show a slightly lower prevalence when compared to our study.

Risk factors for malnutrition

Age of the child and malnutrition

No statistically significant association between different age groups of the under-five children and malnutrition. The findings are in variance to Meshram et al who has reported that there is increased risk of malnutrition in older children when compared with infants, whereas the results of Bisai et al is contradictory showing more risk of malnutrition in early childhood (1-3 years) when compared to older children (3-6 years).[14,17]

Sex of the child and malnutrition

There is no statistically significant difference in prevalence of malnutrition among both the sexes in our study. Meshram et al has concluded that male under-five children are more prone for underweight, stunting and wasting when compared to girl children.[14] He had also reported an increased risk of malnutrition in boys when compared with girls, in a study conducted in Maharashtra.[15]

Number of family members and malnutrition

If the total number of family members exceeds 4 members, it acts as a risk factor for malnutrition in univariate analysis, not so in regression analysis. Meshram et al in India and Mekonnen et al in Ethiopia, the odds for malnutrition is increased in large families (>4 members) when compared to small families (≤4 members).[14,18] Also there is no association between the main care-taker of the child whether it is the child's mother or others in our study, and this finding correlates with the findings of Seetharaman, in a study done among slum under-five children in a part of South India.

Mother's education and malnutrition

The unadjusted odd's ratio for malnutrition and mother's educational status shows that there is significant risk if the child's mother is an illiterate in our study. Nationwide shows that maternal education has a strong inverse relationship with all three measures of nutritional status according to NFHS-3, also Meshram et al al has reported increased risk of malnutrition in children of illiterate mothers.[10,14]

Father's education and malnutrition

Illiteracy state of fathers came as very significant risk for malnutrition in under-five children in our study. The adjusted odds of malnutrition were 10.3 times more for children living with illiterate fathers. The results of our study was consistent with study done by Meshram et al in India and Islam et al in Bangladesh.[14,19]

Mother's occupational status and malnutrition

The factor that mother's working for salary came as a protective factor for malnutrition when compared to home-makers on logistic regression from our study. In our study all the fathers were waged workers and we could not elicit the association of malnutrition with father's occupational status.

Socio-economic status and malnutrition

Children of families belonging to lower SES were at increased risk of malnutrition when compared to children of higher SES. The results were similar to studies done by Harishankar et al and Reddy et al in Uttar Pradesh.[20,21]

Alcohol consumption by any family member and malnutrition

The association of any member being an alcoholic in the family is not a significant risk factor according to the study. But a study done in Nairobi, Kenya involving 170 households has reported that a high percentage (38.1%) of children from alcohol consuming households were underweight, compared to children from non-alcohol consuming households (14.3%).

Mother's nutritional status and malnutrition

Rayhan et al in Bangladesh shows that there is an increased risk of undernutrition in children of mothers belonging to underweight category by BMI classification.[22] In contradiction to their findings our study shows that there is no significant association between mother's nutritional status and children's undernourishment by logistic regression.

Household characteristics and malnutrition

The association of type of the house, source of drinking water supply and usage of toilet factors with malnutrition of under-five children, revealed that Inferior type of the house (semi-pucca/kutcha vs pucca), poor source of water supply (such as dug well water, unprotected well, surface water, unprotected spring, river or dam or lake or ponds or canal, rain water, etc), non-availability and non-usage of available toilet posed as a risk factor for malnutrition

in univariate analysis but it did not turn out to be a risk factor after regression analysis.

A study done by Yadav et al concluded that severe and moderate levels of malnutrition was much higher among those with poor housing conditions even with the same level of dietary intake, whereas in spite of lower dietary intake. Birth order of the child and malnutrition.[23]

No significant association between birth order and malnutrition was observed in our study. According to NFHS-3 data, children of higher birth orders are much more likely to be underweight than children of lower birth orders.[10]

Birth weight of the child and malnutrition

The association of Low Birth Weight with malnutrition is very much significant in our study with an adjusted odd's ratio of 3.41. Our findings are concordant with NFHS-3 which reveals that children with a history of low birth weight (<2.5 kg) are much more likely to be malnourished than other children (≥2.5 kg).[10]

Mother's age at child birth and malnutrition

Mother's age ≤20 during child delivery is not a significant risk factor for malnutrition taking into account of adjusted odd's ratio in our study, but Sonowal, in a study conducted in Maharashtra has reported that prevalence of malnourishment in children delivered by mothers before 20 yrs is high (>12%) when compared to children delivered after 20 years (<8%).[14]

Place of child birth and malnutrition

Home deliveries, when compared to institutional deliveries are reported as a significant risk factor for malnutrition by Biswas et al in a community based study done in West Bengal.[25] Home delivery children had 13 times greater risk to be underweight, 5 times greater risk to be stunted and 6 times greater risk to be wasted than their Institutional delivery counterparts. In our study this factor does not turn out to be a risk factor.

Term of delivery of the child and malnutrition

Under-five children from preterm delivery are not at risk of malnutrition when compared to children from normal or postterm delivery after logistic regression in our study. These results are contradictory to study done by Moster et al in Norway, who has reported that risk of poor physical and social growth is high in preterm children.[26]

Infant and young child feeding practices and malnutrition

Exclusive breast-feeding duration less than 6 months in children aged more than 6 months, total breast feeding duration less than 12 months in children aged more than 12 months, not giving other milk or milk substituent in children >6 months and consumption of <50% of the recommended amount of calories and protein were significant risk factors for malnutrition according to our study.

Hien et al found that duration of exclusive breast feeding <6 months is a significant risk factor to underweight (OR=4.41) and stunting (OR=3.58) and time of initiation of breast feeds was significantly related to underweight (OR=2.54).[27] His results are in consistency with our study. Results regarding total breast feeding duration by Majlesi et al in their study in rural Khorambad Province were also consistent with our study.[28] 10.5% of children breast fed for ≤1 year were underweight whereas only 4.5% of the children breast fed for 1-2 years were underweight as reported by them.

Precedent illness in the child and malnutrition

Suffering from any illness in the past fortnight and not treating the illness, both were significantly associated with under nutrition in our study. Meshram et al from Maharashtra, India reported that children who had suffered any illness in the past fortnight is at more risk for under nutrition.[15]

Immunization status and malnutrition

The factors that the child is not appropriately immunized for age and malnutrition are not significantly associated if we take into account of adjusted odd's ratio in our analysis. Studies done by Devi et al in Andhra Pradesh, India and Mekonnen et al of Fogera District, Northwest Ethiopia has shown that under-five children who are appropriately immunized for age were protected against under nutrition.[18,29]

ICDS attendance and malnutrition

Statistically significant association between of ICDS utilization and malnutrition was obsreved our study, and non- utilization of ICDS services is found to be a protective factor for malnutrition.

Alim et al in a study conducted in Aligarh, Uttar Pradesh, has reported that out of 23.6% children who did not receive supplementary nutrition from ICDS, majority 14.3% of the total children were underweight.[30] On the other hand, out of 76.4% children, who received supplementary nutrition from ICDS majority 62.7% of children were having normal weight for age and these results are in variance to our study.

CONCLUSION

The basic problem of the tribal people is poverty. The problems of low standard of living, hunger, starvation, malnutrition, agricultural illiteracy, poor antenatal care, disease, poor sanitary and housing facilities, etc has to be

improved totally by implementation of policy that already exists.

Review Article

A Review of Research Projects done by Under-Graduate Medical Students over a Period of Fifteen Years in a Medical College in Coimbatore

Senthil Kumar SK[1], Thanigai Nayaki KP[2], Sivamani M[3]

Abstract

Background: As per Medical Council of India guidelines, Under-graduate medical students must involve in planning, implementation and evaluation of a health education program. Problem Solving for Better Health (PSBH) is an excellent opportunity provided to fulfill this objective. PSBH participants are encouraged to generate new ideas and methods to more effectively utilize the resources that are currently available to them to help solve specific health problems in their areas. Many of the PSBH projects are Health Education Intervention projects and Behavior change is the core idea of Health Education. We intend to assess the projects documenting behavior change following Health Education Intervention.

Methods: Abstract, Objectives, Methodology, Results, Discussion and Questionnaires of the submitted Health Education Intervention projects were reviewed for data on the Knowledge, Attitude, Practice, and Change in Behavior of participants before and after Health Education Intervention. Data entered in Epi-Info 6.0 and percentage projects showing Knowledge, Attitude and Behavioral change were assessed.

Results: Out of the 243 PSBH projects 177(72.83%) were Health Education Intervention projects. Behavioral assessment before intervention was done in 152(85.87%) studies. 88(49.71%) studies have documented the changes in behavior after intervention and only 38 out of these 88 studies have documented the statistical significance for the change in behavior. 2(0.01%) of the studies have used Health Education Models other than Knowledge Attitude Practice (KAP) Model. Convenient sampling is done in all the studies.

Conclusion: Nearly half of the PSBH projects on Health Education Intervention have documented the change in behavior. The use of appropriate Health Education Models, standard sampling methods, proper statistical analysis and documenting change in Behavior will add value for their study.

Keywords: Problem Solving for Better Health (PSBH), Health Education, Behavioral change

Introduction

According to Medical Council of India (MCI) guidelines, under-graduate medical students must involve in planning, implementation and evaluation of a health education programme during their medical course. Health education program can enable students of the health professions to promote better health behavior among the underserved,

since such a program provides them with an opportunity to meet and work with people from a different culture in a comfortable setting.

Problem Solving for Better Health (PSBH) is an excellent opportunity provided to fulfill this objective. PSBH as a concept was developed by the Dreyfus Health Foundation (DHF), New York. The mission of the PSBH program is to assist in developing small scale, problem solving projects that will directly benefit many people. PSBH participants are encouraged to generate new ideas and methods to more effectively utilize the resources that are currently available to them to help solve specific health problems in their areas.[1] The goals of the program are to stimulate a series of better-health projects based on individual responsibility and action and to create a collaborative network of small, self-sustaining, and lasting health projects.[1] The satisfaction of having completed a research project and seeing it in print is enough motivation for a young student researcher to want to repeat the feat.[2] The steps in PSBH projects involve Identify a Problem, Refining the Problem, Decide on a Solution, Framing a Question, Develop an Action Plan – The Study Protocol, Ethical clearance, Take Action, Write the Report and Share the Experience. The PSG Institute of Medical Sciences & Research, Coimbatore was among the first to join this movement as far back as in 1997. This study is a review of the Health Education Intervention projects done under PSBH in the last fifteen years.

Health Education is a process aimed at encouraging people to want to be healthy, to know how to stay healthy, to do what they can individually and collectively to maintain health, and to seek help when needed.[3] Behavior change is the core idea of Health Education.[4] This study is intended to measure the number of projects demonstrating and documenting behavior change and whether it is statistically significant.

It is important to improve the methodological quality of health education research. This can be done by using controlled, preferably randomized, designs, ensuring adequate sample sizes, examining only objective changes in behavior or, better yet, changes in morbidity or mortality.[5] The limited use of theoretical frameworks, poor statistical analyses, the use of convenient samples and the short post intervention follow-up periods diminish the contribution to research and the formation of strategies to improve the health of communities.[6]

A health behavior theory can be used as a guide to help explain the processes for changing health behavior and the influences of the many forces that affect it, including social and physical environments.[5] Theories and models are among health educator's most useful tools as they tackle the challenges of needs assessment, program planning, program implementation, program evaluation, coordination of services, acting as a resource of health information, and communicating needs, concerns, and resources outlined in the Framework.[7]

Effective health promotion operates in a number of dimensions at the same time to create the conditions for change, provide support to change, and to maintain healthy behaviors.[8] Reviews of the effectiveness of interventions require three components for calculation of effectiveness for reducing health inequalities:

- A valid measure of health status (or change in health status);
- A measure of socio-economic position (or disadvantage); and
- A statistical method for summarizing the magnitude of health differences between people in different groups.[9]

This study intends to measure the effectiveness of interventions in terms of behavioral change and the magnitude of behavioral change in terms of statistical significance. Our objective is to review the Problem Solving for Better Health (PSBH) projects submitted by undergraduate medical students from the year 1998 till 2012 at PSG Institute of Medical Sciences and Research on changes in behavior documented among participants following Health Education Intervention.

Methodology

Our study is a cross-sectional study based on secondary data, conducted over a period of one month. All PSBH projects on Health Education Intervention done by undergraduate students during the period of 1998 – 2012 (210 projects) were included in the study. PSBH projects not involving pre-test and post-test of the Health Education Intervention were excluded.

Collection of data on documented changes of behavior was done. Data of projects measuring Behavior change was analyzed. Statistical significance shown for the Behavior change was also analyzed. A thorough scrutiny of Abstract, Introduction and Justification of the study, Methodology involving Ethical clearance, Sample size calculation, Sampling method, Validated Questionnaire, the change they have recorded in behavior of study participants, results and its statistical significance was done using check list. The discussion and conclusion part were studied for their comments on recommendations and limitations. Data entered in Epi-Info 6.0 and statistical analysis done.

Results and Discussion

Out of the 243 PSBH projects 177(72.83%) were Health Education Intervention projects.

ISSN: 2454-325X

Table 1.Assessment of Behavioral changes documented in the projects (N=177)

S.No	Variables	n (%)
1	Behavioral assessment before intervention	152(85.87)
2	Change in Behavior documented after intervention	88(49.71)
3	Statistical significance documented for Behavioral change	38(21.47)
4	Health Education Models used	2(0.01)

Behavioral assessment before intervention was done in 152(85.87%) studies. 88(49.71%) studies have documented the changes in behavior after intervention and only 38 out of these 88 studies have documented the statistical significance for the change in behavior. 2(0.01%) of the studies have used Health Education Models other than Knowledge Attitude Practice (KAP) Model. Convenient sampling is done in all the studies.

Table 2.Assessment of Knowledge (K) and Attitude (A) and the Changes documented (N=177)

S.No	Variable	Assessment of K and A before intervention	Change Documented after Intervention for K and A
1	Knowledge(K)	174	159(90%)
2	Attitude(A)	54	37(21%)

Change in Knowledge is documented in most of the projects within the specified project period compared to change in Behavior (mostly attempted in nutrition related projects). Studies involving Nutritional disorder related interventions like Anemia, Obesity, PEM, Vitamin A deficiency and Iodized salt usage have observed and documented significant behavior change.

Studies involving Substance abuse related interventions like Alcohol and Tobacco usage have shown behavior change to a smaller extent

Knowledge change alone will not bring the desired behavioral change in many situations (e.g., smoking, alcoholism) as it needs periodic reinforcing visits and supportive counseling. Most projects on Smoking and Alcoholism were Awareness creation projects directed towards Primordial prevention in schools.

It is possible to bring about change in Behavior within the constraints of time and resources as evidenced by half (50%) of educational interventions being able to demonstrate and document change in behavior indicating the effectiveness of the Health education program. Time constraint of availability of only one semester to complete the PSBH projects influenced the fact that mostly nutritional interventions could demonstrate improved health as an indicator of effectiveness of the health education intervention. Studies mostly used non validated questionnaires. Use of Validated Questionnaires like Global youth tobacco survey in smoking (GYTS) will add value to the project. Many studies measured change in behavior based on self-report / survey. Efforts to assess the behavioral change through observation could be made wherever possible. Appropriate Health Education Models may be used in various contexts.

Our study did not examine the reasons for failure in behavior change or reasons why projects did not attempt measuring behavior change.

Conclusion

Nearly half of the PSBH projects on Health Education Intervention have documented the change in behavior. The use of appropriate Health Education Models, standard sampling methods, proper statistical analysis and documenting change in Behavior will add value for their study.

A Prospective Cohort Study on the Safety of Infant Pentavalent (DTwP-HBV-Hib) and Oral Polio Vaccines in Two South Indian Districts

Narendra Kumar Arora, MD, MMSc, Manoja Kumar Das, MD*, Ramesh Poluru, PhD*, Neeraj Kumar Kashyap, BIT*, Thomas Mathew, MD†, John Mathai, MD‡, Mahesh Kumar Aggarwal, MD§, Pradeep Haldar, MD§, Thomas Verstraeten, MD¶, Patrick L. F. Zuber, MD,‖ and the INCLEN Vaccine Safety Study Group***

Downloaded from https://journals.lww.com/pidj by BhDMf5ePHKav1zEoum1tQfN4a+kJLhEZgbsIHo4XMi0hCywCX1AWnYQp/IlQrHD3i3eAOwX5PbTbYmFBuQ8ZexGG8dZY9KxlZfeZ7JyEY0w= on 04/18/2020

Background: Safety of pentavalent (DTwP-HBV-Hib) vaccine has been a public concern in India and other countries. This study attempted to document the association of serious adverse events following immunization (AEFI, including hospitalizations and deaths of all causes) with the 3 doses of pentavalent and oral poliovirus (OPV) vaccines.

Methods: A cohort of 30,688 infants in 2 south Indian districts were enrolled and followed-up between October 2014 and May 2016, following their first vaccination with DTwP-HBV-Hib and OPV at public health facilities. During weekly follow-ups, by telephone or home visits, the serious AEFIs (hospitalizations and deaths) occurring any time after each vaccination until 4 weeks after third dose were documented. The incidence risk ratios (IRRs) of serious AEFIs in the first (days 0–6) and fourth weeks (days 21–27) after the vaccine doses were compared using the poisson regression analysis.

Results: Of the 30,688 infants enrolled, 30,208 received their third doses of vaccines. During the 4-week periods following each vaccination, there were 365 hospitalizations and 17 deaths. Adjusted incidence risk ratio of 3 doses combined for post-vaccination serious AEFIs during the first week compared with fourth week was 0.8 [95% confidence interval: 0.6–1.0].

Conclusions: There was no increased risk of a serious AEFIs during the first week after any of the 3 doses of pentavalent and OPV vaccination compared with the fourth week. In the absence of any temporal clustering, mortality and hospitalization rates observed in vaccinated infants probably reflects the natural occurrence of such events.

Key Words: pentavalent vaccine, oral polio vaccine, vaccine safety, serious adverse events, hospitalization, death

(*Pediatr Infect Dis J* 2020;39:389–396)

Vaccination has been one of the major success stories in global health, leading to the eradication of deadly diseases like smallpox and possibly the virtual disappearance of some diseases from several regions.[1] Over the last 25 years, effective vaccination programs have resulted in a >90% decrease in the global disease burdens for diphtheria, pertussis, and tetanus, including India.[2–4] However, in spite of the extensive evidence of their benefits, concerns and controversies about the value and safety of vaccines continue to impact adversely their acceptance in diverse contexts. Public concerns over reports linking autism with measles, mumps, and rubella vaccine in the United Kingdom had negative impact on vaccine coverage causing several disease outbreaks,[5] which spread to other countries, such as the United States, France, Italy, and the Netherlands.[6–9] This misinformation has spread globally. The rumor mongering through social media considerably affected vaccine coverage during the MR campaigns in south India.[10] The growing global challenge of vaccine hesitancy relates largely to vaccine safety concerns, leading to public confidence erosion, which in turn dampens the vaccine coverage.[11] The Global Advisory Committee on Vaccine Safety emphasized the need for thorough investigation and causality assessment of serious adverse events following immunization (AEFI) as a quality assurance mechanism for immunization programs.[12]

The decreased disease burdens in the developed countries have largely been due to the successful implementation of immunization programs using multivalent combination vaccines. The vaccines against diphtheria, tetanus, and pertussis combined (DTwP) are in use for several decades under universal immunization program. Recently the HBV and *Haemophilus influenza* type b (Hib) have been added to DTwP, known as the pentavalent (DTwP-HBV-Hib) vaccine. Over the past 15 years Global Alliance for Vaccines and Immunizations has supported the introduction of pentavalent vaccine in developing countries for protection against invasive Hib disease in universal immunization program.[13] However, there were temporary interruptions and introduction delays in Sri Lanka,

Bhutan, Vietnam[14] and Pakistan[15] during 2011–2016 due to reports of hospitalizations and deaths following vaccination after national launch of the pentavalent vaccine. Temporal association of vaccinations and sudden infant death syndrome (SIDS) has been the subject of extensive speculation, despite several studies having refuted any causal association,[16–18] particularly after the diphtheria-pertussis-tetanus immunization.[19]

In India, the reports of 32 infant deaths following the pentavalent vaccination as part of the national AEFI surveillance between 2011 and 2013 raised concerns, although no causal association could be identified.[20] Some professionals and civil society groups, however, appealed before the Supreme Court of India to ban the pentavalent vaccine.[21,22] Although the safety of pentavalent vaccine has been documented in the pre-licensure studies,[23,24] these studies were too small to identify rare adverse events. Thus, it was deemed necessary to carry out further investigations on this issue. This study was designed in consultation with all key stakeholders including the Ministry of Health and Family Welfare, Government of India and WHO (advised by Global Advisory Committee on Vaccine Safety), to assess the risk of serious AEFIs (hospitalizations and deaths) following pentavalent vaccination in an infant cohort from 2 Indian states, where pentavalent vaccine was first introduced.

MATERIALS AND METHODS

The pentavalent vaccine (manufactured by Serum Institute of India Ltd., Pune, India) was first introduced in the states of Kerala and Tamil Nadu in December 2011 with a 6, 10 and 14 weeks schedule for 3 primary doses. Both states have efficient health systems with high vaccination coverage[25] and low infant-mortality rates (IMR): 12 and 21 per 1000 live births in 2013 in Kerala and Tamil Nadu, respectively, compared with an overall IMR of 40 across India.[26] This study was conducted in 2 districts, Kollam (Kerala State) and Coimbatore (Tamil Nadu State).

Study Design

This prospective self-controlled cohort study enrolled infants who received their first dose of pentavalent and oral poliovirus (OPV) vaccine from the public health system between October 2014 and November 2015 in Kollam district, and between May 2015 and February 2016 in Coimbatore district.

Recruitment and Data Collection

Infants who received their first dose of pentavalent and OPV vaccines at all public health facilities in the 2 districts (District, Special and Taluk Hospitals, Community Health Centers, Primary Health Centers, Sub-centers) and out-reach points of rural and urban areas were traced based on the contact details recorded in the immunization registers. Home visits were made to confirm eligibility (received first dose of vaccine, expected to stay in the district for the 6 months follow-up period and contactable by telephone/mobile) and to enroll infants after obtaining informed written consent. Data on maternal care, infant gender, date of birth, birth weight, pregnancy-related and neonatal illnesses were collected at enrollment. The parent(s) were contacted weekly by telephone or home visit to document the health of the infant including any illness, hospitalization or death. The follow-up contact was continued even if the second and third vaccine doses were delayed due to any reason. Study staff confirmed receipt of the second and third vaccine doses from the vaccination card and the health facility register. If infants received their second and third vaccine doses at private facilities, a copy of the vaccination card was collected as proof of date of exposure. For each dose, the vaccine batch number, date and place of administration was documented. Recruited infants were followed up to 4 weeks after the third dose of the vaccines or death, whichever was earlier. Data were collected on tablets using a customized program developed with open source platforms (Android, PHP and MySQL version 5.1) and data including other materials uploaded, synchronized in the server and stored/deposited in a central data repository. An independent International Advisory Group (IAG) with vaccine safety experts and Brighton Collaboration representation supervised the study implementation including field visits. The IAG reanalyzed the data for validation.

Outcomes

This study captured the serious AEFIs which included both hospitalizations and deaths due to any cause during the follow-up period. The details about the events such as clinical features, diagnosis, treatment, period and place of hospitalization were captured. For hospitalizations, the study team visited the hospital for confirmation and followed till outcome to document the information. Hospitalization episodes of at least 24-hours as inpatient were further categorized as "appropriate," "inappropriate" and "indeterminate" using the Pediatric Appropriateness Evaluation Protocol–India criteria. The PAEP-India tool for child and newborn were adapted from the available tools and validated in hospitalized patients from multiple hospitals in India.[27] Each case was assessed by 2 independent pediatricians using the PAEP-India tool for child and categorized the case based on checklist criteria. A third pediatrician was consulted in cases of mismatch between the 2 reviewers. For deaths, the study confirmed the event by home visit, followed by verbal autopsy by senior investigator 4 weeks later. Causes of death were determined independently by 3 pediatricians trained in review of verbal autopsies and also referred to available hospital records.

Data Analysis

The 4 weeks following every dose of vaccination were considered to be the observation period with weekly intervals post-vaccination as separate risk periods (Figure, Supplemental Digital Content 1, http://links.lww.com/INF/D758). As almost all the serious AEFI (deaths and hospitalizations) reported in the passive national AEFI surveillance program occurred during the first week after any vaccine dose, the first week was considered as the high-risk period and the fourth week as the comparison period. It was hypothesized that, the risks of serious AEFI due to any cause, during the first and fourth weeks post-vaccination remain similar for each dose of the vaccines.

Person-time of observation was calculated based on the time from vaccine administration and the date of occurrence of an event, the date of administration of the next vaccine dose (if <28 days), the last contact date (if lost to follow-up), date of death or the first 28 days after vaccination when the next dose was delayed, according to the recommended schedule, whichever came first. Follow-up was defined by weekly risk windows after each vaccine dose split into first (0–6 days), second (7–13 days), third (14–20 days) and fourth (21–27 days) weeks. If a subsequent dose was given before the end of the fourth week, the follow-up time was censored and follow-up period was assigned to the subsequent dose. If the next dose was delayed, the person-time beyond 27 days after each dose were excluded from the analysis. Poisson regression analysis was used to estimate the incidence rates (IRs) and incidence rate ratios (IRRs) for serious AEFIs (hospitalization and all-cause deaths) during the 4-consecutive weekly risk periods after each dose separately and for all 3-doses combined. IRs were calculated by dividing the number of events by the corresponding person-time denominator and IRRs were calculated by dividing the IR in the risk period of interest by the IR in the fourth week. In a multivariate model, the IRR

© 2020 The Author(s). Published by Wolters Kluwer Health, Inc.

was adjusted for age at start of risk period (continuous, in days) and seasonality (quarterly; January–March, April–June, July–September, and October–December). To assess the potential of healthy vaccinee bias, we performed a sensitivity analysis to compare the risks in the first week after vaccination following the second and third doses with the risks in the fourth weeks of the preceding doses. All statistical analyses were performed using Stata version 15.0 (StataCorp LLC, TX). In addition, all deaths documented were reviewed by the national AEFI committee for causality assessment according to WHO published methodology.[20]

Sample Size

Considering the IMR in the study states to be 12–21 per 1000 live births and a neonatal mortality rate (0–28 days) of 6–15 per 1000 live births,[26] the post-neonatal mortality (29–365 days) was expected to be 6 per 1000 live births. This translated to ~0.125 infant deaths per 1000 live births per week. As there was no information about the hospitalization:death ratio in this age group from India, we assumed that for every infant death there would be ~4 hospitalizations. The required sample size was 27,422 infants to detect an IRR for hospitalizations and or deaths of 1.8 in the analyses pooling the different doses, assuming a 5% significance level ($\alpha = 0.05$) and 80% power ($\beta = 0.2$).[28] With the available sample (30,688), the observed results show that between the risk periods, we are able to detect a risk-ratio of 2.5 and 1.5 (at a 5% significance level and 80% power) of serious AEFIs (hospitalization and deaths), for individual doses and all 3-doses combined, respectively.

Ethical Approvals

The study protocol and related documents were approved by ethics committees of participating institutes. The infants were recruited after obtaining informed written consent from parents or legally authorized representatives. The study protocol and related documents were approved by Institute Ethics committees at The INCLEN Trust International (INCLEN) (vide IIEC-021 dated October 14, 2013), Government Medical College, Thiruvananthapuram (vide 01/01/2014 dated January 17, 2014), PSG Institute of Medical Sciences and Research, Coimbatore (vide 13/351 dated March 5, 2014) and World Health organization, Geneva (vide RPC625 dated January 22, 2014).

RESULTS

During the study period, 34,914 infants received their first dose of pentavalent and OPV vaccines at the public health facilities. Of these, 1377 (3.9%) infants could not be traced, 2818 (8.1%) were not eligible (1287 were not staying in the district for 6 months, and 1531 were from other districts) and consent was refused for 31 (0.1%) infants. Of the 30,688 infants recruited, 30,208 (98.4%) received their third vaccine dose and 29,728 (96.9%) completed the scheduled follow-up (Fig. 1). Of 479,523 scheduled weekly follow-up contacts (including the contacts during the intervals between the different vaccine doses till completion of 4 weeks after third dose), 89.9% were completed with averages of 4.4 (dose 1), 4.8 (dose 2) and 4.9 (dose 3) contacts for the vaccine doses (data not shown).

Baseline characteristics of the cohort are summarized in Table 1. No age or sex differences were observed across the districts. The Kollam population had a higher proportion of low and median socio-economic status and joint or extended families. Median ages of infants were 48, 83 and 118 days at the times of the first, second and third vaccine doses, respectively. A total of 622 hospitalizations and 32 deaths were documented during the follow-up period.

Within the 4 weeks after the 3 vaccine doses (per protocol study risk periods), a total of 365 hospitalizations (120, 137 and 108 after doses 1, 2 and 3, respectively) were documented. Of these 365 hospitalizations, 288 were classified as appropriate (96, 106 and 86 after doses 1, 2 and 3, respectively). A total of 257 hospitalizations (92, 136 and 29 after doses 1, 2 and 3, respectively) occurred after fourth weeks of the first and second doses of vaccination (Fig. 1). Pneumonia/acute respiratory infection (70.1%) was the leading cause followed by diarrhea (6.4%), fever (4.3%) and urinary tract diseases (3.1%) during the 4 week and post-4 week periods after the vaccine doses (Table, Supplemental Digital Content 2, http://links.lww.com/INF/D759).

Of the 32 total deaths observed, 17 deaths (8,7 and 2 after doses 1, 2 and 3, respectively) occurred within 4 weeks after 3 vaccine doses, while 15 deaths (11, 3 and 1 after doses 1, 2 and 3, respectively) occurred during post-4 weeks period, (Fig. 1). The leading causes of death included infections (31.3%), congenital malformations (28.1%), congenital heart diseases with infections (15.6%), SIDS (15.6%) and other causes (9.4%) (Table, Supplemental Digital Content 2, http://links.lww.com/INF/D759). Almost all congenital malformations were diagnosed prior to death. The SIDS was made based on Brighton Collaboration Criteria.[29] Causality assessment by the National AEFI committee classified all deaths as coincidental. Differentials in causes of hospitalization and death during the first 4-weeks (0–27 days) and post-4 weeks (28+ days) after vaccination were small (Table, Supplemental Digital Content 2, http://links.lww.com/INF/D759). Figures 2 and 3 show the IRs of serious AEFIs (hospitalization and deaths) by age and seasonality. Higher serious AEFI (hospitalization and deaths) rates were observed during 91 and 146 days of age (Fig. 2); between October and December, with a peak in December due to higher prevalence of respiratory illnesses (Fig. 3).

Serious AEFIs (Hospitalization and Deaths) Within 4 Risk-periods

The occurrence of serious AEFIs (hospitalization and deaths) across the risk-periods for the 3 doses are summarized in Table 2. Within the 4 weeks after the 3 vaccine doses, a total of 375 serious AEFIs (365 hospitalizations, 17 deaths and 7 hospitalization and deaths) occurred (125, 140 and 110 after doses 1, 2 and 3, respectively) (Fig. 1). For all-3 doses combined, the adjusted IRRs of serious AEFIs within the first week compared with the fourth week were 0.8 [95% confidence interval, (CI): 0.6–1.0]. Compared with the fourth week, the adjusted IRRs of serious AEFIs for the first week after first, second and third doses were 1.2 (95% CI: 0.8–1.9), 0.9 (95% CI: 0.6–1.5) and 0.5 (95% CI: 0.3–0.9), respectively. IRRs for serious AEFIs were not significantly higher in any of the other risk periods (second or third weeks) either for the 3 doses separately or for all doses pooled. Analyses of hospitalizations according to appropriateness did not show any increased risk in any week compared with the fourth week after any dose (Tables, Supplemental Digital Content 3, http://links.lww.com/INF/D760, and Supplemental Digital Content 4, http://links.lww.com/INF/D761). The sensitivity analysis comparing the rates of serious AEFI in the first week after the second or third doses with the fourth week after the first or second doses did not show any differences, suggesting the absence of a healthy vaccinee effect (Table 2).

DISCUSSION

This is the first large study to examine the association between administration of routine infant pentavalent and OPV vaccines and serious AEFIs (all-cause hospitalizations and/or deaths) in India, using a self-controlled prospective cohort design. We have shown that the unadjusted and adjusted risks of hospitalizations

*Total includes a small number of cases information missing for type of family, standard of living index (2 each in Kollam); Age of mother (20 in Kollam and 12 in Coimbatore); education of mother (14 in Kollam and 6 in Coimbatore); education of father (36 in Kollam and 16 in Coimbatore) and birth order (53 in Kollam and 40 in Coimbatore, respectively). Standard of living index (a proxy to household socio-economic status), constructed based on household assets and durable goods.

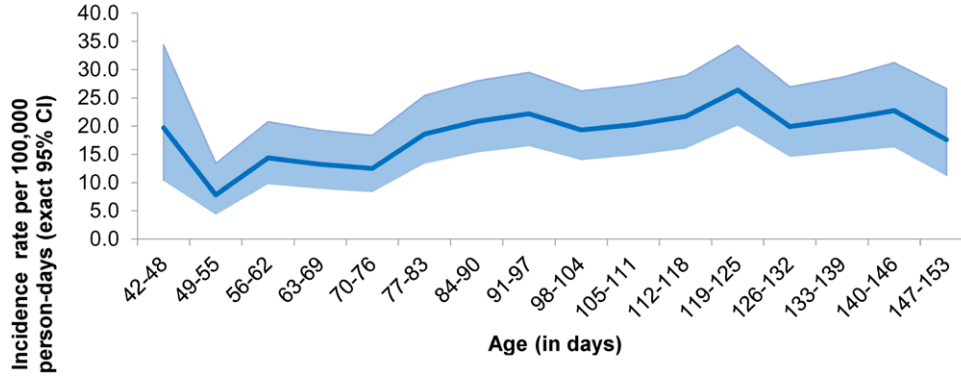

FIGURE 2. Serious AEFI (hospitalization and all-cause deaths) incidence rates (per 100,000 person-days with exact 95% CI as shaded area) by age (independent of vaccination windows). Incidence per 100,000 person-days (with exact 95% CI as shaded area); Week defined as 6-days period, starting on day-0; Person-time starts from age at first dose of vaccination and duration until the first and last day of the age period or until the Serious AEFI (hospitalization/death) events (succeeding vaccinations not considered). The hospitalization incidence presented in the figure is between 42 and 153 days of age, where 98.6% [(3,402,860/3,451,027)*100] of follow-up calls/visits were made. full color online

and deaths after any of the 3 scheduled doses of routine vaccines were similar during the first and fourth weeks post-vaccination, for either each dose separately, or all doses combined. Due to low death rates,we could not perform analyses for each individual dose but the combined analysis and analyzing the first dose only did not indicate any death clusters following vaccination.

In a highly immunized population, self-controlled study designs with defined risk windows for outcome assessment are best suited to assess possible effects during a specific time period as they are not susceptible to control selection.[30] Activation of the immune response to different vaccines occurs at different time points according to the nature of the antigen.[18,31–34] Hence, in the current study, we considered the first week after vaccination to represent the period of highest risk and the fourth week to be the comparison period. The findings of our study refute the concern of an association between serious adverse events and the pentavalent vaccine.

*Risk period corresponds to date of hospitalization (considered as at least 24-hours stay in the hospital) or all-cause death after administration of vaccination (in days); The day of vaccination defined as day-0.

†Adjusted for seasonality (January–March, April–June, July–September, October–December); age at start of risk period (in days), using Poisson regression model.

‡Twenty-one to 27 days as reference category; IR: Number of events per 100,000 person-days of follow-time, calculated as the ratio of the hospitalizations of the person-time at risk.

The main strength of the study is the representativeness of the study cohort with respect to the population in the study area due to the high rates of participation and completion of follow-up. The socioeconomic status of the population enrolled in the study was highly representative of the overall population in the 2 districts. Use of electronic data collection enabled timely follow-up and accurate data capture with real-time monitoring. Documentation of hospitalization from both participants and hospitals allowed confirmation of causes of hospitalizations and deaths. In addition, the availability of source documents and vaccination records ensured accurate confirmation of vaccine exposure.

The main limitation was possible selection bias, as infants received first vaccine dose in the private system were not represented in the study. However, according to recent National Family Health Survey (NFHS-4, 2015–2016) data, 78% and 86% of children 12–23 months of age in Kerala and Tamil Nadu, received their vaccines from a public health facility.[25] We could not trace 3.9% infants due to inaccurate address information and 8.1% could not

© 2020 The Author(s). Published by Wolters Kluwer Health, Inc.

be included due to moving out or residing outside of the 2 districts. To control for confounding by contraindication to vaccination, pre-vaccination time intervals were not included in the control periods in the main analysis. Sensitivity analyses performed to assess the potential of a healthy vaccinee bias did not suggest presence of this. The study was also limited in detecting small changes for deaths, despite the large sample size.

The study found that 128 serious adverse events (120 hospitalizations and 8 deaths) occurred among 30,000 infants during the 4 weeks after receiving their first dose of pentavalent vaccine. Calculating based on Black et al[35] and projected on a 26 million annual Indian birth cohort, it is estimated that with national coverage of 100% at a minimum 26,500 infants per year will suffer a serious health event within 1 week of receiving their first dose of pentavalent vaccine, or there will be at least 21,200 events with the current 3-dose coverage of ~80% for pentavalent vaccine. These events reflect prevailing morbidities and mortality that would have occurred regardless of vaccination as documented in 2 Indian districts with low infant mortality. Investigating these events to ensure that the vaccine product or its administration are safe remains a fundamental function of the vaccine pharmacovigilance system. This highlights the importance of continued monitoring of common serious health problems in the infant population to measure the health burden and provide new epidemiologic information on the true causes of morbidity and mortality in this group.

The study did not find any increased risk of serious AEFIs (all-cause hospitalizations or deaths) in the first week following pentavalent (and OPV) vaccination and the occurrence of these AEFIs were just coincidental. That is, in the absence of temporal clustering, mortality and hospitalization rates observed in vaccinated children reflect the natural occurrence of such events in that age range in this part of India. The study findings should help to address the vaccine safety concerns and controversies around the pentavalent vaccine in India and other low- and middle-income countries, and so boost public confidence in the program. Suspicion about a possible relationship between the vaccination and serious AEFIs among parents, communities and the health providers may not only threaten the success of immunization programs but also potentially hinder introduction of newer vaccines.

CONCLUSIONS

Close monitoring of over 30,000 infants during and after receiving their first 3 doses of DTwP-HBV-Hib and OPV did not identify any relationship between the vaccinations and the occurrence of serious AEFIs (hospitalization and/or death). The study did document the huge number of serious coincidental events that can be expected even when vaccines are properly administered. In view of the recent inclusion of several new vaccines into the immunization program in India, the findings of this study will be very useful in addressing vaccine hesitancy and safety concerns to increase public acceptance and coverage.

ACKNOWLEDGEMENTS

We express our gratitude to the district health officials and health functionaries at the public health facilities in the 2 districts for their constant support. We are highly appreciative of the parents and families of all infants for consenting to participate in this study and for their cooperation during follow-up. We thank the GAVI, the Vaccine Alliance through World Health Organization (WHO) and the patronage from Ministry of Health and Family Welfare, Government of India, New Delhi, India and the Departments of Health and Family Welfare, Government of Kerala and Tamil Nadu States for funding to conduct the study. We also acknowledge the guidance and continued support provided by the technical experts and representatives from WHO, Technical Advisory Group (TAG) members, International Advisory Group (IAG) members, officials from the Ministry of Health and Family Welfare at National and State levels. We appreciate the support from Tom Cattaert and Germano Ferreira, P95 Pharmacovigilance and Epidemiology, Heverlee, Belgium, for the validation of results, and Keith Veitch (keithveitch communication) for editorial guidance.

[illegible]

[illegible] Anaemia is almost universal in haemodialysis patients. Here, we evaluated the utility and clinical implications of the commonly employed tests in assessing iron status in haemodialysis patients.

[illegible] In this prospective observational study, we enrolled 100 prevalent haemodialysis patients, and measured transferrin saturation (TSAT) and serum ferritin at enrolment. Patients were categorized to have normal, deficient, overload, or indeterminate status of iron based on KDOQI guidelines. To study anaemia trend, haemoglobin (Hb) level at time of enrolment, as well as levels 3-months before and 3-months after enrolment, were collected. Patient survival outcomes were also obtained till October 2016.

[illegible] Using serum ferritin and TSAT, iron status was determinable in 48% of the patients ie 20%-normal iron status, 25% - iron deficiency, 3% - iron overload. Fifty-two percent of the patients' iron status was indeterminate by current parameters. In spite of being on standard-of-care treatment in our centre, we observed that mean-Hb level of patients in the indeterminate group showed insignificant increases compared to normal- and deficient-groups. Mean delta-Hb levels over 6-months were 0.80±1.54 g/dl in the indeterminate group, compared to 1.87±1.95 g/dl in the deficient group (P=0.03). In our cohort, 57% had died and 5 lost follow-ups during the study (P=0.30 between groups).

[illegible] Serum ferritin and TSAT accurately categorized the iron status of 48% haemodialysis patients in our study. Divergent serum ferritin and TSAT values, or an iron indeterminate state was prevalent in 52% of our urban dialysis cohort. The indeterminate group had inferior increases in Hb over time with current treatment, showing clinical relevance of this finding. Our data suggests the need for more sensitive indices to accurately assess iron status, and improve anaemia management.

[illegible] ESRD patients, Iron status, Serum ferritin, TSAT

[illegible]

Anaemia is frequently found in chronic kidney disease (CKD) patients and is an almost universal finding in patients with end stage renal disease (ESRD).[1] Additionally, anaemia is associated with increased cardiovascular morbidity and mortality in this patient population.[2]

The pathophysiology of anaemia in CKD is multifactorial.[3] The proximate cause of the anaemia is relative deficiency of erythropoietin, a glycoprotein produced by renal tubular cells. Other factors which may cause or contribute to anaemia includes iron deficiency, vitamin B12 and/or folic acid deficiency, decreased erythrocyte survival, severe hyperparathyroidism, aluminium toxicity and hypothyroidism. The use of erythrocyte stimulating agents (ESA) such as recombinant human erythropoietin (EPO) began two decades ago and has revolutionized the treatment of anaemia in ESRD. This has decreased the need for blood transfusions and consequently the incidence of associated complications.[4]

Despite the widespread use of EPO, over 50% of the patients do not reach target haemoglobin levels.[1,5] Resistance to erythropoietin most commonly is due to iron deficiency but chronic inflammation, infection, and/or hyperparathyroidism also contribute.[6,7] Iron deficiency in ESRD is primarily due to impaired dietary intake and impaired gastrointestinal absorption but blood loss during haemodialysis and increased iron demands from ESA use also contribute.[8] Management of iron deficit is crucial in haemodialysis patients. Adequate treatment of iron deficiency is vital to attain target haemoglobin concentration and avoid excessively high EPO doses, which has been associated with increased risk of malignancy.[9] Furthermore, IV iron and blood transfusions both increase the risk of developing hospital acquired infections.[10,11] Therefore effective treatment of anaemia in haemodialysis patients requires continuous assessment of iron status.

Serum ferritin and transferrin saturation (TSAT) are the commonly used tests for the assessment of iron status in ESRD. However, measurement of these parameters in ESRD patients may be altered by inflammation, infection, or nutritional status.[12] Therefore, we conducted this study to evaluate the utility of the common tests, serum ferritin and TSAT, in assessing iron status in haemodialysis patients. In order to examine the clinical utility of iron status as defined by the current guidelines, we evaluated anaemia in this cohort, as well as patient outcomes.

M□□□□□□□

This study was conducted from August 2011 to March 2012 in a large tertiary care teaching hospital in South India. The study was conducted among the ESRD patients undergoing haemodialysis. All ESRD patients on haemodialysis for at least 3 months were enrolled in the study after the application of the exclusion criteria and after obtaining informed consent. The study was done after obtaining institutional ethical committee clearance. The exclusion criteria were: age less than 18 years old, evidence of acute or chronic infection, trauma within the previous 4 weeks, recent bleeding episodes, blood transfusion within the last one month, malignancy, post-transplant status, liver disease, haemoglobinopathies and other haematological diseases. The diagnostic biochemical tests used to assess the iron status were TSAT and serum ferritin.

Patients were categorized to have normal, deficient, overload, or indeterminate status of iron based on serum ferritin and TSAT values. Based on NKF-DOQI guidelines, iron deficiency is taken as ferritin level less than 200mg/dl and TSAT less than 20%, iron overload as ferritin level more than 500 mg/dl and TSAT more than 50%. The values in between the above ranges (ferritin between 200 and 500 mg/dl; TSAT between 20 and 50 %) are considered as normal iron status, whereas values not conforming to these categories are said to be indeterminate. The combined utility of the above tests in assessing iron status was determined by dividing the number of patients in whom iron status was detected (normal, deficient or overload) by total number of patients and expressed in percentage. The haemoglobin level of all the enrolled patients at time of enrolment was collected. To determine haemoglobin trend within each group, we collected haemoglobin levels 3-months before and 3-months after enrolment from chart review. Patient outcomes (death, alive and lost follow up) were obtained by chart review and telephone-follow up till October 2016.

Statistical analysis

The data were analysed using Statistical Package for Social Science (SPSS) Version 19.0, Graphpad Prism-6 and Microsoft Excel 2010. Non-parametric characteristics between any two groups were compared using Mann-Whitney test, and proportions using Chi-square test. For comparing more than two mean values we have used one-way analysis of variance. P value less than 0.05 was considered as statistically significant.

□□□□□□□□

Demographics of study population

A total of 100 prevalent ESRD patients on haemodialysis were studied. The key demographics of the study cohort are summarized in Table 1. Patients ranged from 18 to 80 years. The mean age of the patients was 48.5 years. Among 100 patients, 63 were male and 37 were female.

Description by iron status

We classified these patients based on their iron status as per the NKF-KDOQI (see methods). Using serum ferritin and TSAT, iron status could be determined in 48% of the patients; 20% had normal iron status, 25% had iron deficiency, 3% had iron overload. The remaining 52% of the patient's iron status was indeterminate (Table 1 and 2). In univariate analysis, patients who were iron indeterminate were nearly indistinguishable from other groups by clinical and epidemiologic variables (as shown

in Table 1). However interestingly, iron indeterminate and overload groups had significantly greater dialysis vintage than the normal/iron-deficient groups.

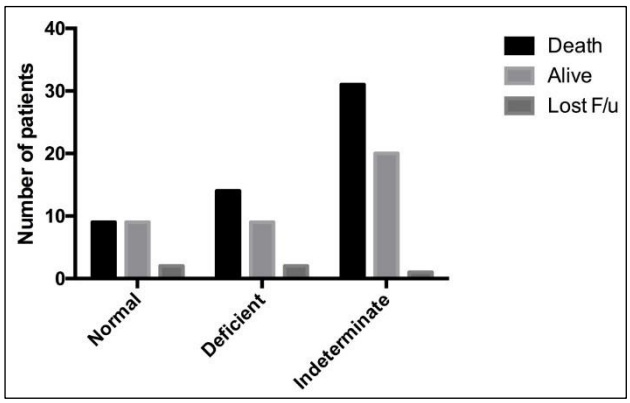
Outcomes by iron status

Anaemia outcomes: To examine the haemoglobin responses and anaemia, trends of patients according to iron status, we tabulated haemoglobin levels of patients in each group by iron status at enrolment at different time points before- and after- study enrolment (Figure 1 and Figure 2).

[illegible]

[illegible]



[illegible]

[illegible]	[illegible]	[illegible]	[illegible]	[illegible]	[illegible]
	[illegible]	[illegible]	[illegible]	[illegible]	[illegible]
Haemoglobin 3months before (g/dL)	n=94 7.56(1.64)	n=19 7.51(1.61)	n=23 7.05 (1.67)	n=3 7.46 (1.15)	n=49 7.82 (1.66)
Haemoglobin 0 month (g/dL)	n=100 7.95(1.74)	n=20 8.14(1.76)	n=25 7.23 (1.60)	n=3 8.26 (2.39)	n=52 8.21 (1.71)
Haemoglobin 3 months after (g/dL)	n=90 8.64 (1.91)	n=19 8.98(1.63)	n=23 8.73 (2.00)	n=3 9.56 (3.13)	n=45 8.39 (1.92)

Table 3 summarizes haemoglobin levels and patients (n) in each group at each of the different time points studied. As the overload group consisted of 3 patients only, we excluded these from subsequent analysis. We interestingly observed that the mean haemoglobin level of patients in the Normal and Deficient groups showed significant increases over a 6-month time period, while those in the indeterminate group had insignificant increases in haemoglobin levels in this period (Figure 1). Mean delta haemoglobin levels over 6 months (3-months before enrolment to 3-months after enrolment) were 0.80±1.54 g/dl in the indeterminate group, compared to 1.87±1.95 g/dl in the deficient group (Mann Whitney P=0.03; Figure 2).

Patient outcomes

Overall during the follow up period, 29 patients continued on dialysis, 5 were at outside dialysis units, 8 patients received kidney transplants (4 of whom expired after transplantation). A total of 57 patients in our cohort had died during the follow up period (till October 2016). Five patients were lost to follow up in this time. There were no significant differences detectable in number of deaths between any of the groups by iron status in the duration of our follow-up, although all 3 patients in the overload group had expired (Table 1 and Figure 3).

[illegible]

Anaemia contributes significantly to the morbidity and mortality in ESRD. ESA and iron supplementation are the most important factors in treatment of anaemia in ESRD patients.[13] Iron deficiency has been identified as a major factor for anaemia in CKD patients, with a 43-90% prevalence in different series.[6,14-16] Hence the periodical monitoring of iron status is crucial in ESRD.

There are two forms of iron deficiency, absolute iron deficiency and functional iron deficiency. Reduction of reticuloendothelial system iron in the bone marrow is referred to as absolute iron deficiency. Absolute iron deficiency may occur from impaired intestinal absorption, blood loss through the dialysis circuit, vascular access surgeries, repeated phlebotomies and increased iron utilization with erythropoietin therapy. In clinical practice, absolute iron deficiency is determined by serum ferritin less than 200ng/ml and TSAT less than 20%.[17] In the non-ESRD population, "functional" iron deficiency is ascribed when iron reserves in the bone marrow are adequate, but iron mobilization is impaired as in states of chronic inflammation.[18]

The current study assesses the utility of combining serum ferritin and TSAT to assess iron status among an Indian haemodialysis population. The evaluation of iron status is straightforward when both serum ferritin and TSAT are either high or low. But when these parameters are divergent, for instance, if the TSAT is low and serum ferritin is high, the accurate interpretation of iron status is difficult. This entity was common in our study where the iron status of only 48% of the patients were clearly determined (20% had normal iron status, 25% had iron deficiency and 3% had iron overload), and was indeterminate in the remaining 52% of patients. Interestingly in our study, the only epidemiologic factor associated significantly with indeterminate status was dialysis vintage. Why patients with indeterminate or overload status appeared to have longer durations of dialysis, is unclear but requires further exploration. Our data suggest that in a significant proportion of haemodialysis patients in a typical urban dialysis unit in India, the conventionally applied parameters were insufficient to accurately categorize iron status. Similar data has emerged from other groups.[19] Further, our data crucially demonstrates that patients with indeterminate status by conventional assessment have significantly inferior increases in haemoglobin levels with current therapy, suggesting the need for development of more specific diagnostic strategies to ascertain iron status in this group, to accurately manage iron status and anaemia.

Most studies have revealed that serum ferritin is very well related with iron stores in the bone marrow is the best surrogate of iron status in healthy individuals.[20-22] However, ferritin is an acute phase reactant increasing in states of chronic inflammation (such as dialysis), malignancy, or systemic disease, and ferritin levels alone may not reflect iron stores available for haematopoiesis. Thirty-six patients had low ferritin (<200) in our study. Only 25 of them had iron deficiency (combined with low-TSAT), whereas ~31% of them were in indeterminate group. Further, 29 patients had high serum ferritin. Only 3 of these had iron overload (combining TSAT), while 4/29 had low TSAT (<20%). Hence, decision to treat these patients with iron supplements based on these parameters would likely be imprecise. Similarly, a transferrin saturation of less than 20% in patients on haemodialysis is considered to be suggestive of iron deficiency whereas other studies have suggested that a transferrin saturation < 20% versus >20% alone may be inaccurate for assessing iron deficiency.[23-28] While most patients with TSAT less than 20% are iron deficient, few patients don't respond to an increase in iron supplements with either increase in haematocrit or maintenance of haematocrit with a decreased ESA requirement. On the other hand, numerous patients with a TSAT greater than 20% have functional iron deficiency respond to increased iron doses with elevations in the haematocrit, or maintenance of their haematocrit at decreased erythropoietin doses.[25-28] In our study, 43 patients had low TSAT (<20%); only 25 of them had iron deficiency (combined with ferritin). We found that 57 patients had TSAT values more than 20%, out of which 11 had low ferritin (<200). TSAT values in these 11 patients may be falsely high because of low total iron binding capacity (TIBC) during inflammation and infection.

The difficulties in the interpretation of iron status using TSAT and serum ferritin in ESRD patients and the consequent hematologic implications we show, warrant the application of other erythrocyte and reticulocyte based indices, such as the percentage of hypochromic red blood cells (Hypo) and the reticulocyte haemoglobin content (CHr). CHr requires a special analyser and is recommended as an alternative iron status indicator as well as an initial measure of the response to iron treatment in haemodialysis population.[29-31] Fishbane et al evaluated the reticulocyte haemoglobin content among 32 haemodialysis population and showed it to have a sensitivity of 100% and specificity of 80%.[29] Mittman et al evaluated reticulocyte haemoglobin content among 364 haemodialysis population receiving EPO and proved it to be an indicator of functional deficiency of iron.[30] Based on these and other data, NKF DOQI recommends a target of CHr greater than 29pg/cell.[32-35] The Hypo is an indicator of the percentage of red blood cells that contain low haemoglobin. Thus, it indicates only the functional iron availability and does not reflect storage iron. A Hypo level of greater than 10% indicates definitive functional iron deficiency. European Best Practice Guidelines stated that Hypo >10% is the most accurate marker for ID.[36] However, there are other studies which suggested lower threshold values for Hypo.[32,37-40] Both these tests are not widely available in India.

Here, we report that the combination of serum ferritin and TSAT accurately categorized the iron status in only 48%

of ESRD patients in our study. When serum ferritin and TSAT values diverged, they become unreliable for accurate interpretation of iron status, signaling an iron indeterminate state that was prevalent in 52% of our urban dialysis cohort. As we show here, this group of iron-indeterminate patients has inferior increases in haemoglobin over time, showing clinical relevance of this finding. Our data suggests that more sensitive indices such as Hypo and/or CHr may need to be employed (along with conventional tests) to accurately assess iron status, and improve management tools. This could lead to more accurate dosing of iron and ESAs, decrease overtreatment of anaemia, and possibly translate to cost savings from medication usage. Future studies on iron markers including both traditional and newer indices are required to improve iron management in ESRD population, especially in Indian population, where iron deficiency is common and similar studies are lacking.

Departments of Cardiac Anesthesiology and [1]Cardiac Surgery, G Kuppuswamy Naidu Memorial Hospital, [2]Department of Community Medicine, PSG Institute of Medical Science and Research, Coimbatore, Tamil Nadu, India

ABSTRACT

Background: Prophylactic milrinone is commonly used to prevent Low Cardiac Output Syndrome (LCOS) after pediatric cardiac surgery. This study compares the use of levosimendan with milrinone when used as the primary inotrope following pediatric cardiac surgery.

Subjects and Methods: Forty infants undergoing corrective surgery for congenital heart disease were recruited during the study and randomized into two groups (group L and group M). During rewarming, a loading dose of levosimendan or milrinone was administered followed by a 24-hour infusion of the chosen inotrope. Echocardiographic variables were measured postoperatively. Statistical analysis was done with SPSS-20 computer package. Association between the variables was found by independent t test. $P < 0.05$ was considered statistically significant.

Results: Mean age and weight of the patient in Group L was 8.55 ± 5.83 months and 6.05 ± 2.09 kgs, while that in group M was 6.85 ± 3.57 months and 5.26 ± 2.11 kgs. 4 patients (20%) treated with levosimendan had LCOS in comparison with 6 (30%) patients in those treated with milrinone. Echocardiographic parameters in both groups L and M were comparable (cardiac index 3.47 ± 0.76 vs 3.72 ± 1.05 L/min/m^2, EF 66.10 ± 7.82% vs 59.34 ± 10.74%, stroke volume index 25.4 ± 6.3 vs 27.74 ± 10.35 mL/m^2). The duration of ventilation, ICU stay and hospital stay were lesser in group L (12.75 ± 9.69, 35.95 ± 12.11, 119.10 ± 46.397 vs 23.60 ± 22.03, 51.20 ± 29.92, 140.20 ± 52.65 hours).

Conclusions: The incidence of LCOS was lesser in those patients treated with levosimendan, when compared with those treated with milrinone. Cardiac index and stroke volume index were comparable between the two groups. Thus, levosimendan provides a non-inferior alternative to milrinone when used as the primary inotrope following pediatric cardiac surgery.

INTRODUCTION

Low cardiac output syndrome (LCOS) is defined as a reduction in cardiac output and is a common occurrence following cardiac surgery in the pediatric population. It was first defined in the pediatric population by Parr and colleagues in 1975 using the dye dilution technique.[1] Early recognition and treatment of LCOS is paramount due to its adverse impact on perioperative morbidity and mortality.

A myriad of strategies exist for managing low cardiac output syndrome such as optimization of preload, inotropes, afterload reducing agents, and positive pressure

ventilation. Multiple regimens combining an inotrope or inodilator along with vasopressor are utilized in various institutes to prevent LCOS. However, most inotropes currently available cause an undesirable increase in heart rate and therefore myocardial oxygen demand. An inotropic regimen which increases myocardial performance without substantially increasing oxygen consumption is therefore desirable. Prophylactic milrinone is most commonly used to prevent LCOS following pediatric cardiac surgery. Other alternatives available include dobutamine and levosimendan.

Levosimendan is an inodilator with calcium sensitizing properties, as a result of which it has a unique catecholamine sparing property. There is probably more controlled clinical data available on levosimendan than any other inotrope in adult cardiac surgery.[2] In the pediatric population, it has been used mainly as a rescue agent, when other inotropic agents are insufficient to maintain stable hemodynamics.[3] However, studies in the pediatric population are limited. In fact, a meta-analysis of studies using levosimendan in pediatric cardiac surgery, published in the Cochrane Database of Systematic Reviews in 2017, included 5 studies and had a total number of only 212 infants and children.[4]

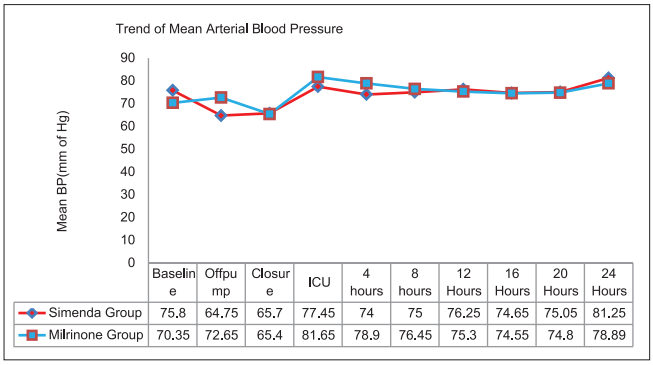
Therefore, it was decided to conduct a randomized prospective study at our institute, in children under 1 year of age undergoing cardiac surgery, to compare the clinical efficacy of levosimendan with milrinone and to study the incidence of LCOS with both these drugs.

SUBJECTS AND METHODS

Study design

This was a single center, randomized study comparing the efficacy of milrinone and levosimendan in preventing LCOS after congenital heart surgery in infants. This study was conducted in the Department of Cardiothoracic and Vascular Surgery at our hospital.

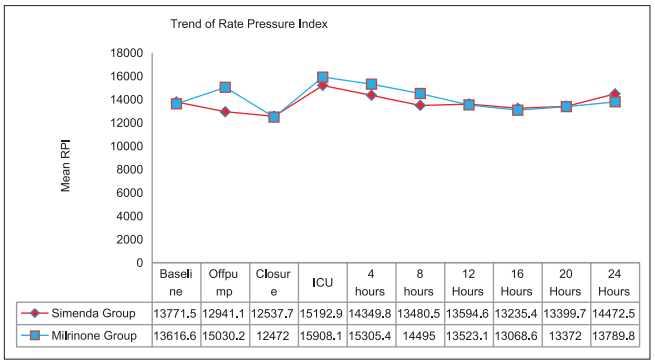
Study population



Approval from the institutional ethical committee was obtained following which written informed consent was obtained from the patients parents. 40 infants undergoing corrective open heart surgery were chosen. Patients were randomly assigned using computer- generated randomization into two groups, Group L (levosimendan) and Group M (milrinone). Some types of congenital heart diseases were not included during the study. The exclusion criteria were:

a. Single ventricle physiology
b. RACHS-I score 5, 6
c. Preoperative LCOS requiring inotropic support
d. Preoperative renal failure, cardiac arrest, thrombocytopenia.

Study method



After standard induction and surgical exposure, CPB was initiated. Del Nido cardioplegia was used in all patients to achieve cardiac standstill. Continuous ultrafiltration was used in all patients to ensure zero-fluid balance at the end of CPB. The initial therapeutic intervention comprised of administration of

Figure 4: Trend of arterial lactate level

loading dose of either inotrope over 10 minutes at the time of rewarming during cardiopulmonary bypass. This was followed by a 24-hour infusion of the chosen inotrope. Children in group M, received milrinone, prepared and marketed as MILRON by United Biotech (P) limited. Children in group L received levosimendan, prepared by Gufic Biosciences Limited and marketed as SIMENDA by Lupin Ltd.

Drug dosages

Patients in group L received a loading dose of 10 μg/kg levosimendan followed by a 24-hour infusion at 0.1 μg/kg/min. On the other hand, patients in group M received a loading dose of 50 μg/kg milrinone followed by a 24-hour infusion at 0.5 μg/kg/min. The dose has been extrapolated from adult literature as standard pediatric dosage has not been described. Adrenaline was used to aid separation from cardio-pulmonary bypass in both the groups and was continued in the ICU, if required.

Parameters measured

Hemodynamic parameters like heart rate, blood pressure, saturation, central venous pressure, and urine output were measured at the time of induction, coming off CPB, chest closure, transfer to the ICU and subsequently every 4 hours through 24 hours. Clinical evidence of LCOS and inotropic requirements were recorded during this period.

LCOS was defined as two or more of the following:[4]

a. Arterial lactates >27 mg/dL (or 3 mmoL/L) on two consecutive readings
b. Increase in blood lactate of at least 18 mg/dL (or 2 mmoL/L) from baseline
c. Central venous oxygen saturation <50% in the absence of intracardiac shunts
d. Decrease in central venous oxygen saturation by at least 20% from baseline
e. Urine output <1 mL/kg/hour for two consecutive hours
f. Cardiac index less than 2.2 L/min/m^2.

Inotropic requirements were measured with the Vasoactive Inotropic Score (VIS) for group M and Levosimendan- Vasoactive Inotropic Score (LVIS)[5] for group L. Arterial blood gases along with central venous oxygen saturation were serially monitored. Echocardiographic measurement of cardiac output, cardiac index, ejection fraction, stroke volume, and stroke volume index was done on arrival in the ICU and 24 hours later. Ejection fraction was measured using Simpsons monoplane method, while the Doppler- VTI method was used to derive the cardiac output. Morbidity, duration of ventilation, ICU stay and duration of hospital stay were also recorded.

[Downloaded free from http://www.annals.in on Friday, December 17, 2021, IP: 103.224.34.2]

Primary outcomes measured were the incidence of LCOS, while the secondary outcomes were hemodynamic parameters, inotropic requirements, duration of mechanical ventilation, ICU stay, and hospital stay.

Statistical analysis

Data entry was made in the Microsoft Excel software in codes and analysis was done with SPSS-20 computer package. Categorical variables are expressed as percentages whereas continuous variables are expressed as mean ± standard deviation. The trend of vitals and biochemical parameters of the study participants were followed and their mean ± standard deviation assessed.

RESULTS

Demographic data

Forty patients received one of the two inotropes during the study and were randomized into two groups. There was no statistically significant difference between the two groups as regards the demographic data. The demographic data in both the groups has been represented in the Table 1.

The RACHS-I scoring in both the groups were comparable. Most of the patients (85% in group L, 90% in group M) enrolled were in the RACHS 2 category of patients [Table 2].

Pump-related variables

Pump-related variables in both the groups were also identical [Table 3]. Patients in both the groups had similar pump times and clamp times. None of the patients required low flows during CPB. We followed a zero-balance continuous ultrafiltration technique to ensure nil balance at the end of cardiopulmonary bypass. However, post- CPB, patients treated with levosimendan had a slightly higher fluid requirement compared with those treated with milrinone. This was indicated by the difference in intraoperative fluid balance between both the groups.

(122 + 165.406 mL in group L vs 57.10 + 103.322 mL in group M).

Primary outcomes

We found that 4 patients (20%) had LCOS in the levosimendan group, in comparison to 6 patients (30%) in those treated with milrinone during the first 24 hours post surgery. However, none of the 40 patients had LCOS by echocardiographic criteria on arrival in the ICU and 24 hours thereafter.

Secondary outcomes

Hemodynamic parameters

The mean arterial pressure in both the groups was comparable at all points of time after arrival into the ICU for the first 24 hours [Figure 1]. None of the patients in the two groups had severe hypotension requiring vasopressor therapy during the study. The heart rate of patients in both the groups was comparable during this time frame. None of the patients in either group had any tachyarrhythmia during the first 24 hours post-surgery. The rate-pressure index (RPI) was used to assess the myocardial oxygen demand. It was found that the RPI was comparable between both groups and was lower during the first 24 hours in those patients treated with levosimendan [Figure 2].

Echocardiographic data

Echocardiography demonstrated a consistently good cardiac function in both the groups [Table 4]. The cardiac index in both the groups were similar at arrival in ICU (3.47 ± 0.765 in group L vs 3.72 ± 1.05 in group M) and 24 hours after surgery (3.33 ± 0.65 in group L vs 3.67 ± 1.16). None of the patients in both the groups had LCOS by echocardiographic criteria at the time of measurement. The ejection fraction in patients treated with levosimendan was similar to those treated with milrinone at the time of arrival into the ICU (66.10 ± 7.82% vs 59.34 ± 13.50) and 24 hours thereafter (64.05 ± 5.68 vs 57.69 ± 10.74). The stroke volume index in both the groups was comparable as well (25.40 + 6.30 vs 27.7 + 10.35).

Inotropic requirements

Only 3 patients in group L required adrenaline to maintain adequate cardiac output on arrival into the ICU. This was in contrast to 11 patients requiring adrenaline in group M. Thus, almost 85% of the patients in group L were discharged from the operation theatre on a single inotrope. One patient in both the groups required high inotropic support (more than 0.1 μg/kg/min adrenaline) at the time of arrival into the ICU. Overall inotropic requirements were much lesser in those patients treated with levosimendan compared to milrinone following surgery [Figure 3].

Lactates and mixed venous oxygen saturation

Lactate levels on arterial blood gases were consistently lower in those patients treated with levosimendan in the immediate post surgical period, until 16 hours. Thereafter, there was a slight increase in lactate levels in group L, which coincided with the timing of diuretic administration [Figure 4]. The mixed venous oxygen saturation was comparable in both groups.

Fluid requirements

The intraoperative fluid requirements was higher in group L, compared with group M. Only 2 patients (10%) in group L had a negative fluid balance at the end of surgery, in

[Downloaded free from http://www.annals.in on Friday, December 17, 2021, IP: 103.224.34.2]

comparison to 5 patients (25%) in group M. However, at the end of 24 hours, most patients in both the groups (13 in group L vs 11 in group M) had a negative fluid balance. The fluid overload index at 24 hours was comparable in both groups (-0.66 ± 3.53% in group L vs -0.99 ± 2.85% in group M).

Other secondary outcomes

Patients in group L had a shorter (statistically insignificant) duration of ventilation (12.75 ± 9.68 hours in group L vs 23.60 ± 22.03 hours in group M), as well as hospital stay (119.10 ± 46.397 hours in group L vs 140.20 ± 52.65 hours in group M). The duration of ICU stay was also lesser in those patients treated with levosimendan (35.95 ± 12.11 hours) as compared to those treated with milrinone (51.20 ± 29.92 hours). This difference in ICU stay was statistically significant [Table 5].

DISCUSSION

Levosimendan is an exciting inodilator with a unique non-catecholamine-based mechanism of action. It improves cardiac function, hemodynamic performance and survival in critically ill adult patients, but limited data exists on levosimendan use in the pediatric population.[6] In these patients therefore, its use is off-label, where it is mainly used as a rescue agent.[7,8]

Several smaller trials in the past have suggested a beneficial effect with levosimendan in the perioperative scenario. A meta-analysis published in the Cochrane Database of Systematic Reviews in 2017 evaluated studies in the pediatric population and concluded that the current level of evidence is insufficient to judge whether levosimendan prevents LCOS in pediatric patients.[4] In the wake of several neutral or inconclusive trials of late in the adult population, (CHEETAH, LEVO-CTS, LICORN) this study was designed with the purpose of addressing one quintessential question: How effective is levosimendan, when compared with standard inotropic regimens in preventing LCOS in children? We also aimed to study its hemodynamic repercussions and whether it had any outcome on the duration of ICU and hospital stay.

Unlike most other inotropes available today, levosimendan acts independently of the β-adrenergic receptors and cyclic adenosine monophosphate mechanism. It produces its effects by two mechanisms. First, being a calcium sensitizer, it stabilizes the interaction between calcium and troponin C, thereby improving inotropy without adversely affecting lusitropy.[9] Diastolic relaxation remains unhampered as there is no intracellular accumulation of calcium.[10] Second, it is a potassium-channel opener on vascular smooth muscle, which causes hyperpolarization leading to coronary and peripheral vasodilatation.[11] This renders it with several hemodynamic advantages over other conventional inotropes available today. Thus, amongst the wide spectrum of inotropic agents available today, levosimendan offers a unique alternative to prevent LCOS following cardiac surgery in the pediatric population.

In our study, we found that the incidence of low cardiac output syndrome was lower in patients treated with levosimendan compared with those treated with milrinone. This was in conjunction with multiple studies conducted in the pediatric population in the past.[12,13]

LCOS is a common occurrence following pediatric cardiac surgery with an incidence as high as 25%.[14] No stringent diagnostic criteria exist at present for the diagnosis of LCOS in the pediatric population. The existing criteria rely on hemodynamic measurements, rather than an objective measurement of cardiac output. This is in contrast to the adult population, where a definition based on objective measurement of cardiac index exists.[15] Levosimendan offers a better hemodynamic profile compared to standard inotropic therapy owing to its catecholamine independent mechanism of action.[12] This reliance on hemodynamic parameters for diagnosis of LCOS in children, in conjunction with the better hemodynamic profile offered by levosimendan may account for the low incidence of LCOS in these patients.

The mean arterial pressures in both the groups were comparable, as was the rate pressure index. The rate pressure index can be used as a surrogate marker of myocardial oxygen demand and was found to be lower in those patients treated with levosimendan. Our findings were consistent with those of Momeni *et al*.[12]

Fluid requirement in patients treated with levosimendan was higher in the immediate postoperative period. This maybe explained in part due to the fact that we used a loading dose of levosimendan given over 10 minutes at the time of rewarming during cardiopulmonary bypass. Most studies in the past have avoided using the loading dose of levosimendan or milrinone due to fear of hypotension. Therefore, although almost all patients had a zero fluid balance at coming off CPB, those treated with levosimendan required additional fluids to maintain optimal hemodynamics. This difference was in stark contrast to the patients treated with milrinone, whose reliance on fluid therapy was minimal.

Serum lactate level is considered to be one of the most important biochemical markers of early adverse outcome after congenital cardiac surgery. It is one of the biochemical markers used to support the diagnosis of LCOS. In our study, levosimendan was found to cause a greater reduction in lactate levels between 4-12 hours post surgery, compared with milrinone. Thus, the beneficial effects of levosimendan administration were more pronounced in the typical time frame when LCOS is known to occur. A parallel conclusion was drawn by Ricci *et al*., in his study published in 2012.[16] In our study, the lactate levels in patients treated with levosimendan were consistently lower during the first 16 hours of stay in the ICU. Thereafter, there was a slight increase in lactate levels in these patients, which coincided with the time of diuretic administration (1 mg/kg of furosemide). This may suggest a reliance on optimal preload for levosimendan to maintain adequate cardiac output.[17]

The ejection fraction of patients treated with levosimendan was slightly higher than those treated with milrinone at the time of arrival in ICU. A study published in 2018, found that the inotropic and lusitropic properties of levosimendan and milrinone were comparable at clinically relevant and equipotent infusion rates.[18] This difference in ejection fraction was despite the fact that most of these patients (almost 85%) were on a single inotrope on arrival in the ICU. Thus, levosimendan clearly allowed an early weaning of catecholamines in our patients, ensuring that these patients were on minimal inotropes on arrival in the ICU. This benefit was sustained during the entire length of stay in the ICU. Similar conclusions were drawn in multiple studies published earlier.[8,19] Levosimendan, therefore, reduced the reliance on catecholamine pathways to maintain an optimal cardiac output.[20]

In our study, patients who were supported post cardiac surgery with levosimendan had a shorter duration of ventilation and stay in the ICU. This led to an earlier discharge of these patients from the hospital. None of the patients in both the groups had any sustained arrhythmias or required mechanical circulatory support. There were no in-hospital mortalities in both the groups.

Limitations

Our study had several limitations. Most glaring was the lack of a definitive definition of LCOS and the dependence on clinical parameters for the diagnosis of the same. Also, we excluded patients in the RACHS 5 and 6 category, along with single ventricle physiology. Thus, sicker patients were excluded. The study also does not delve into the different dose ranges of levosimendan to study its effect. The study population, though more or less homogenous, is restricted. Thus, larger, multicenter studies may be warranted.

CONCLUSIONS

We found that the incidence of LCOS was lesser in patients treated with levosimendan, when compared with those treated with milrinone. Also, the hemodynamic profile offered by levosimendan was better, as suggested by the rate-pressure index (RPI). These effects were exerted at a time when the heart most required it and when the incidence of LCOS was highest. However, the cardiac output enhancement by levosimendan was more sensitive to changes in the fluid status of the patient. Also, children treated with levosimendan had a shorter duration of ICU stay and hospital stay. Thus, levosimendan offers a unique, timely, attractive, and equipotent alternative to standard inotropes in use today to prevent LCOS following cardiac surgery in the pediatric population.

Are Body Image Issues Affecting Our Adolescents? A Cross-sectional Study among College Going Adolescent Girls

Subhashini Ganesan, S. L. Ravishankar, Sudha Ramalingam
Department of Community Medicine, PSGIMSR, Coimbatore, Tamil Nadu, India

Abstract

Background: Body image relates to how people think and feel about their own body. In today's society, with the growing sense of ideal body image, adolescents try to lose or gain body weight to attain that perfect body. Body image perception is still naive, and this research will try to understand these unexplored areas, where there is paucity of body image-related studies. **Objectives:** The objective of the study is to find out the proportion of girls dissatisfied about body image, and the association of various factors with body image dissatisfaction and to ascertain the weight control behaviors adopted by adolescent college girls. **Methodology:** A cross-sectional study was done among 1200 college girls in Coimbatore. A semi-structured questionnaire was used to collect data on various factors associated with body image dissatisfaction. Body mass index (BMI) of the participants was calculated. **Results:** Body image dissatisfaction was there among 77.6% of the girls. It was found that factors such as higher BMI, sociocultural pressure to be thin and depression were all significantly associated with body image dissatisfaction. The most commonly followed weight control behaviors were eating small meals and skipping meals. Improving the appearance and body shape were the main reasons for weight control behaviors. **Conclusion:** This study establishes the fact that body image dissatisfaction is no longer a western concept and affects Indian adolescent girls to a great extent. Hence, effective interventions have to be planned to increase awareness on ideal body weight and protect our young generation from pressures of negative body image.

Keywords: Adolescent, body image dissatisfaction, body weight, college girls, weight control

Introduction

Body image relates to how people think and feel about their own body. It relates to a person's perceptions, feelings, and thoughts about his or her body and is usually conceptualized as incorporating body size estimation, evaluation of body attractiveness, and emotions associated with body shape and size.[1]

Adolescents are particularly vulnerable to body dissatisfaction due to the physiological, social, and psychological changes they are going through.[2] For adolescent girls, a range of body and social changes take place during and following puberty that can strongly influence their body image and become more pronounced by late adolescence.[3]

Perception of overweight and dissatisfaction with body size, rather than actual weight appears to be a potent force behind girls' dieting and weight control behaviors. Such behavior is related to negative physical and psychological changes and can lead to life-threatening conditions including eating disorders.[4]

With rapid economic development and affluence, there is a progressive shift toward thinness as the ideal body shape and increasing concerns about body weight leading to dissatisfaction.[5]

Factors contributing to body image problems have been studied, and biopsychosocial model of risk factors was developed by Paxton.[6] This model [Figure 1] suggests that biological factors, such as body size, together with individual psychological characteristics such as low self-esteem, depression, and perfectionism, which refers to individuals desire to attain idealistic goals without failing, social influences, and interpersonal interactions, all contributes to the development of body image.

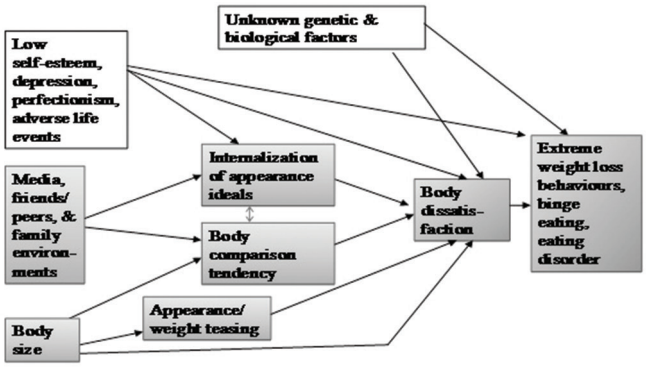

Figure 1: Biopsychosocial model of risk factors for the development of body dissatisfaction by Susan J Paxton

There is a paucity of studies in India and gaps remain in our understanding of the factors responsible for the development of attitudes and behavior related to body weight and appearance among adolescent girls.[7]

Hence, this study aimed to find out the proportion of girls dissatisfied about body image, and the association of various factors with body image dissatisfaction and to ascertain the various weight control behaviors adopted by adolescent college girls.

Methodology

This study was conducted in a college located in an urban area of Coimbatore. With an estimated prevalence of body image dissatisfaction of 33.3% from a study in Mangalore,[8] sample size was calculated to be 978, with the precision of 3.3%, and nonresponse 20%. After approval by the Institutional Human Ethics Committee, 1220 college going adolescent girls in the age group of 18–19 years, were enrolled in the study by convenience sampling. After obtaining informed consent, a semi-structured questionnaire was used to collect the data on body image dissatisfaction and the associated factors namely demographic factors, socioeconomic and media influence, sociocultural pressure, self-esteem, perfectionism, and depression. Furthermore, data regarding weight control measures adopted were collected.

Measuring body image dissatisfaction

Body image dissatisfaction of the adolescents was measured using the Stunkard silhouettes Figure Rating Scale (FRS). It includes drawing of nine silhouettes ranging from very thin (1) to very heavy (9). Students were presented with female versions of the FRS and were asked to identify the figure they currently perceived themselves with, and the figure they would wish to have. Discrepancy scores were calculated based on the difference between the actual and ideal figures chosen. Positive scores indicate a desire to be smaller, while negative scores suggest a desire to be larger. The discrepancies between the current and desired figures were interpreted as an indication of body image dissatisfaction.[9,10] Hence, participants who had discrepancies in the figures chosen were identified as having body image dissatisfaction.

Measuring factors associated with body image dissatisfaction

The factors associated with body image dissatisfaction such as self-esteem, depression, sociocultural pressure, media influence, and perfectionism were measured using previously validated questionnaires and using Likert scale ratings, and score was given.[11-15] Rosenberg Self-Esteem Scale was used to measure Self-esteem with the Likert scales ranging from strongly agree (score 1) to strongly disagree (score 4). Higher scores indicate higher self-esteem.[11] Depression was measured using Center of Epidemiological studies (CES) Depression questionnaire with Likert scale which graded from rarely to mostly with the scoring of 0–3, respectively. Score on the CES-Depression questionnaire range from 0 to 60, with higher scores indicating more severe levels of depressive symptoms.[12]

Socio-cultural pressure was measured with the pressure grading from none (score 1) to a lot of pressure (score 5). The scoring ranges from 10 to 50.[13] Media influence was measured using SATAQ 3 questionnaire with Likert scale grading of completely disagree to completely agree with a scoring of 1–5. The scoring ranges from 14 to 70.[14] Perfectionism was measured using the EDI questionnaire with Likert scale grading from always to never with score from 1 to 6, respectively. The scoring ranges from 6 to 36.[15]

The height and weight of the participants were measured and body mass index (BMI) was calculated. According to the WHO standards in our study, BMI <18.5 kg/m^2 was classified as underweight, a BMI of 18.5–24.9 kg/m^2 was considered normal, overweight is 25–29.9 kg/m^2, and obesity is ≥30 kg/m^2.[16]

The association between the possible risk factors and body image dissatisfaction was assessed by univariate analysis using Chi-square test, *t*-test, and odds ratio was estimated. Those factors found significant by univariate analysis were further subjected to multivariate logistic regression analysis to identify factors that were significantly associated with body image dissatisfaction.

Results

Majority of the study participants (60.6%) were from an urban background. About 67.5% of them belonged to Class I and Class II and 32.5% of them belong to Class III and Class IV socioeconomic status according to modified Prasad classification.[17]

Based on the BMI, about half (53.6%) of them were having normal BMI while 26.7% of them were undernourished, 15.7% were overweight, and 3.9% were obese.

The study showed that 947 (77.6%) girls were dissatisfied with their body image (95% CI: 75.2–79.9). Among the 947 participants who were dissatisfied the mean score of the perceived silhouette figure was 4.0 ± 1.5 (four corresponds to the normal range of BMI), and the mean of the chosen ideal

silhouette was 3.3 ± 0.8 (three corresponds to the lower end of the normal BMI toward the underweight range).

Table 1 shows the distribution of body image dissatisfaction based on the calculated BMI of the participants. It shows that 58.3% of the participants of normal BMI also were dissatisfied with their appearance and wanted to reduce weight. In the underweight category, 23.3% were satisfied, and 7.4% wanted to reduce their weight further showing the tendency of the college students to have a thin appearance. Tables 2 and 3 show the association of body image dissatisfaction with its risk factors by univariate analysis. Higher BMI, higher socioeconomic status, depression, increased sociocultural pressure to be thin, media influence and low self-esteem were found to be significantly associated with body image dissatisfaction.

There was no significant association with the place of residence and perfectionism.

Table 4 shows multivariate logistic regression exploring the association of body image dissatisfaction with those risk factors having statistically significant association with body image dissatisfaction by univariate analysis.

Factors such as higher BMI, higher socioeconomic status, depression, and increased sociocultural pressure to be thin were found to be significantly associated with body image dissatisfaction by multivariate logistic regression analysis.

Among the 1220 students who participated in the current study, 791 (64.8%) of them had undertaken at least one weight control measure in the past 1 year. Of which 157 (19.8%) were satisfied and 634 (80.2%) were dissatisfied with their body image.

Among the multiple options of weight control measures adopted, the most common method was taking small meals (53.2%) followed by skipping meals (42.7%). Extreme measures such as taking laxatives (5.3%) and vomiting after meals (9.7%) were also seen.

Among participants who followed weight control measures, multiple reasons were given by them, of which 61.7% gave improving the appearance and body shape as the main reason for going in for weight control measures and 33.5% said to look better in clothes.

Our study also showed that 67% of participants who were dissatisfied with their body image were adopting one or more weight control measures while in the satisfied group 57.5% have adopted weight control measures. The difference was found to be statistically significant ($P < 0.01$) with an odds ratio of 1.49 (1.13–1.97).

Table 1: Distribution of body image dissatisfaction of study participants based on calculated body mass index (*n*=1220)

BMI status (BMI in kg/m²)	Total number	Frequency of dissatisfaction	
		Increase weight	Reduce weight
Underweight (<18.50)	326 (26.7)	226 (69.3)	24 (7.4)
Normal (18.50-24.99)	654 (53.6)	84 (12.8)	381 (58.3)
Overweight (25.00-29.99)	192 (15.7)	0	185 (96.4)
Obese (≥30.00)	48 (3.9)	0	47 (97.9)
Total	1220 (100)	310 (25.4)	637 (52.2)

BMI: Body mass index

Table 2: Association of body image dissatisfaction with the risk factors (continuous variables) by univariate analysis

Factor	Mean±SD		OR (95% CI)	*P*
	Satisfied	Dissatisfied		
Media influence	37.60±8.96	40.35±8.19	1.04 (1.02-1.05)	<0.001
Depression	15.7±7.38	19.2±9.19	1.05 (1.03-1.06)	<0.001
Sociocultural pressure	15.49±5.57	19.08±7.70	1.08 (1.05-1.10)	<0.001
Perfectionism	19.09±5.53	19.21±6.09	1.00 (0.98-1.02)	0.77
Self esteem	18.65±3.20	17.92±3.30	0.937 (0.90-0.97)	<0.01
BMI	19.92±2.27	21.99±4.40	1.15 (1.111.20)	<0.001

Higher socioeconomic status	1.28	1.06-1.54	<0.001

BMI: Body mass index, AOR: Adjusted odds ratio, CI: Confidence interval

Discussion

Our study showed that body image dissatisfaction was there in 77.6% of the adolescents. This was similar to a study done by Sasi and Maran in Chennai among adolescents above 12 years of age which showed a prevalence of 81%.[18]

Our study also showed that 23% of the underweight people were satisfied with their BMI, and among those who were dissatisfied 7.4% wanted to reduce their weight further. Similarly, 71% of the normal BMI category was dissatisfied

with their appearance of which 58.3% wanted to reduce their weight. This clearly shows the tendency for liking toward thin body shapes.

Socioeconomic status of an individual impacts their body image perceptions and satisfaction/dissatisfaction with the body. Studies have shown that body image dissatisfaction is seen more among higher socioeconomic status.[19] Our study also showed that the proportion of girls having body image dissatisfaction, who belonged to class I socio economic status are slightly higher than other classes and it was statistically significant.

Studies have also shown that urban adolescents have more body image dissatisfaction compared to rural,[20] but our study did not show any significant association.

Our study also showed that increased socio-cultural pressure, depression and higher BMI had significant association with body image dissatisfaction. Literature also shows that these factors are associated with body image dissatisfaction.[21-23]

Our study failed to show any significant association between body image dissatisfaction and media influence, self-esteem, and perfectionism which were also established in other studies.[24-26]

This study also showed that 64.8% of the college students had undertaken at least one weight control measure in the past 1 year. It also showed that girls who were dissatisfied with their appearance tend to do more weight control measures and the most common weight control measures were eating small meals, skipping meals, and avoiding certain foods. It also showed that the majority of students have cited improving the appearance and to look better in clothes as main reasons for going in for weight control measures. This was also found similar to other studies which showed that appearance was a major motivation for dieting practices.[27,28]

Our study was done in a large sample and measured the different factors which were associated with body image dissatisfaction. The study of these factors is crucial for improving our understanding of body image dissatisfaction in adolescent girls which is still naive in our cultural setup.

Limitations

Although the study area was in a college which had both self-financing and government aided divisions which brought together adolescents from different socioeconomic and cultural backgrounds, it was done in only one college - this restriction may limit the generalizability of the findings.

Conclusion

This study establishes the harsh fact that body image perceptions and dissatisfaction is no longer a western concept and affects our adolescent girls to a great extent. There is also a tendency favoring toward thin body figures which is evident in the study.

Recommendations

Effective interventions to improve awareness on ideal body weight, media literacy, and harmful effects of extreme weight control measures have to be planned, and young people both maintain a healthy body weight and are protected from the pressure of negative body image and weight control practices.

Further studies are recommended to establish the cause-effect relationship of the identified factors.

ABSTRACT

Background: Lifestyle diseases like hypertension, atherosclerosis, coronary heart disease (CAD), type –II diabetes mellitus, ischemic stroke are Non -communicable diseases leading to premature sickness, disability and death. To determine the risk factors of lifestyle diseases like hypertension and diabetes mellitus and to impart health education on the risk factors of lifestyle diseases and to determine the impact of health education.
Methods: A educational interventional study was conducted in a randomly selected urban slum in Peelamedu, Coimbatore funded by ICMR STS.100 Men in the age group of 30-50 years were administered questionnaire to determine the risk factors of lifestyle diseases. Health education was given to the respondents regarding risk factors. The same questionnaire was given to the respondents after the health education to determine the impact of health education. Statistical analysis was performed by using SPSS version 20. Prevalence of risk factors was presented in percentage. Paired T test was used to find out the effectiveness of Health Education.
Results: Among the study population, the risk factors for life style diseases in our study are smoking (39%), alcohol intake (27%), lack of physical activity (40%), overweight (36%), obesity (14%). The impact of health education on risk factors of lifestyle disease and it was statistically significant with smoking (p=.000), alcohol (p=.02), physical activity (p=.001) and not significant with BMI (p=.71).
Conclusions: Regular health checks can be done to improve the frequency of preventive care and support for behavior change. Effective implementation of lifestyle modifications behavior like healthy diet intake, avoidance of high caloric foods, promoting physical activity help in preventing future complications as a part of primary preventive strategies at primary care level. The importance of lifestyle modifications should be reinforced.

Keywords: Alcohol, Health education, Lifestyle diseases, Overweight, Physical activity, Smoking

INTRODUCTION

Lifestyle diseases like hypertension, atherosclerosis, Coronary Heart disease (CAD), Type -II Diabetes mellitus, Ischemic stroke are Non -communicable diseases leading to premature sickness, disability and death. Lifestyle diseases now emerge as the most severe health problems in developed and developing countries like India.[1] These diseases take a tremendous toll in premature sickness, disability, death and have a major

economic impact on its victim and health care delivery system. ICMR and WHO have predicted that cardiovascular diseases would be the most important cause of mortality and morbidity in India by the year 2015.[2] India is undergoing a rapid health transition with rising burden of coronary heart disease (CHD).[3] Among adults over 20 years of age, the estimated prevalence of CHD is around 3-4 per cent in rural areas and 8-10 per cent in urban areas, representing a two-fold rise in rural areas and a six-fold rise in urban areas between the years 1960 and 2000.[4]

Several studies conducted in India had shown an increase in the prevalence of many risk factors contributing for chronic diseases and strengthens the needs of interventions to reduce the prevalence of these risk factors.[5] Recent figures released by WHO indicated that approximately 80% of the global deaths due to chronic diseases are occurring in developing countries and only 20% occurs in developed countries. There is thus a widespread scientific and public health consensus that the likelihood of developing chronic diseases linked to the exposure of an individual, community or population to a cluster of behavior risk factors such as tobacco use, unhealthy diets and physical inactivity.[6] At present the health care system do not focus on preventive health services. A highly structured family life, education with appropriate intervention and counseling services can tackle many of these issues. Cardiovascular risk factors can be combated and controlled by adherence to current lifestyle recommendations.[7-9] The INTERHEART study emphasizes the role of behavioral and conventional risk factors in the prediction of CHD risk among Indians.[10] These findings have implication for the health care providers and policy makers in the country due to the fact that all these conventional risk factors are potentially modifiable and are good starting points for prevention. The policy measures by means of legislation and regulatory approaches on food industry or tobacco or physical activity will have large impact on CHD risk factor reduction in the population.[11,12] The development of an effective education program should impact on self-care, lifestyle change and adherence to medication and lead to better control of diabetes, fewer complications and better quality of life. As the prevalence of non communicable disease is increasing, regular interactive awareness programs involving small groups targeting the vulnerable group of the population is the need of the hour.[13,14] Early intervention will be critical to reduce the occurrence of lifestyle diseases and associated complications in the vulnerable population. Hence we took up this study to create awareness on risk factors and measures to combat these diseases among the study subjects.

METHODS

The present study was conducted in a randomly selected urban slum in Peelamedu, Coimbatore among men in the age group of 30-50 years funded by ICMR STS. All Urban slums in Peelamedu, Coimbatore were listed. An Urban slum was selected by simple random method. From the selected urban slum, number of men aged 30-50years was listed from the data already available and among them 100 men who have one of the lifestyle diseases like Diabetes and Hypertension were included in the study was selected by systematic sampling. House to house survey was conducted and 100 men with the above inclusion criteria were selected from the urban slum area and those who have no lifestyle diseases were excluded from the study. After a period of 3 months each participants were made phone calls to ensure their availability for follow-up and everyone responded. The weight and height of the participants were measured by Weighing scale and portable stadiometer which were calibrated and validated by Department of Biometrics prior to the study. Height and weight were measured based on WHO standards with sensitivity of 0.5 cm and 0.1 kg. Zero error was set after every 10 measurements. The participants were made to stand straight with heels, buttocks and back touching the vertical limb of the instrument and stretching upwards to the fullest extent with arms hanging on the side. The head was aligned so that the lower rim of the orbit and the auditory canal were in horizontal plane (Frankfurt plane).Weight was measured without any footwear and with minimal clothing (school uniform) by using Krup's weighing scale. Based on the height and weight BMI were calculated. Ethical clearance was obtained from Institutional Human Ethics Committee.

Pre–tested Questionnaire was administered to find out the level of risk factors of lifestyle diseases. Health education was given simultaneously to the respondents regarding risk factors after administering questions and 1 month after health education was again repeated to the participants. After a period of 3 month impact of health education was analyzed among the same participants.

Statistical analysis was performed by using SPSS version 20. Prevalence of risk factors was presented in percentage. Paired T test was used to find out the impact of health education on risk factors.

RESULTS

The study was conducted to find out the prevalence of risk factors of life style diseases and also to determine the impact of Health education regarding risk factors of life style diseases. A total of 100 Men in the age group of 30-50 years were involved in the study. The findings of the study are as follows:

Table 1 shows 41% were diabetic and 43% hypertensive and 16 % were both. Among them the diabetes (44.1%) is more in the age group 46-50 years, hypertension (59.4%) is more in the age group 36-40years and both diabetes & hypertension (29.4%) is more common in the age group 46-50 years.

Table 2 shows the risk factors of life diseases among the study population. Among Diabetics (n=41) 43.9% were smokers, 66.4% were alcoholic, 31.7% were overweight, 19.5% were obese and 58.5% were not doing any physical activity. Among Hypertensive (n=43) 37.2% were smokers, 23.3% were alcoholic, 44.2% were overweight, 14.0% were obese and 25.6% were not doing any physical activity. Among both Diabetics & Hypertensive (n=16) 31.3% were smokers, 25.5% were alcoholic, 25.0% were overweight and 31.3%were doing any physical activity.

Table 3 shows the Impact of health education on risk factors of lifestyle disease and it was statistically significant with Smoking (p=0.000), Alcohol (p=0.02) and Physical activity (p=.001) and not significant with BMI (p=0.71).

Table 1: Age distribution of the Life style diseases in the study population.

Age in years	Number (%)	Diabetes No (%)	Hypertension No (%)	Diabetes & Hypertension No (%)
30-35	11 (11%)	3 (27.3%)	8 (72.7%)	0
36-40	32 (32%)	13 (40.6%)	19 (59.4%)	0
41-45	23 (23%)	10 (43.5%)	7 (30.4%)	6 (26.1%)
46-50	34 (34%)	15 (44.1%)	9 (26.5%)	10 (29.4%)
Total	100	41	43	16

Table 2: Risk factors of life style diseases.

Life style diseases	Smokers	Alcoholics	BMI		No physical activity
			Overweight	Obese	
Diabetes (n=41)	18 (43.9%)	13 (66.4%)	13 (31.7%)	8 (19.5%)	24 (58.5%)
Hypertension (n=43)	16 (37.2%)	10 (23.3%)	19 (44.2%)	6 (14.0%)	11 (25.6%)
Diabetes & Hypertension (n=16)	5 (31.3%)	4 (25.5%)	4 (25.0%)	0	5 (31.3%)
Total	**39**	**27**	**36**	**14**	**40**

Table 3: Impact of health education on risk factors of life style disease using Paired‘t’ test.

Risk factors		Mean ± SD	P value
Smoking	Pre-test	1.6±**0**.49	0.000
	Post-test	1.73±**0**.44	
Alcohol	Pre-test	1.73±**0**.44	0.02

Physical activity	Pre-test	1.29±**0**.45	0.001
	Post-test	1.40±**0**.49	
BMI	Pre-test	25.75±8.4	0.71
	Post-test	25.6±8.2	

DISCUSSION

The most common life style disease in developing nations like India is Diabetes and Hypertension. The common risk factors for both were obesity, decreased physical activity, stress, hereditary, alcohol, and smoking. Identifying these risk factors will help to reduce the incidence of the lifestyle diseases and effective implementation of lifestyle modifications at primary care level also can reduce the mortality and morbidity rates.[15-17] Hence we conducted a study among 100 people with life style disease like diabetes and hypertension to find out the risk factors and to determine the impact of health education regarding risk factors of life style disease given to the study participants.

In our study around <11.0% of the participants are less than 35years of age and >89% were in the age group 36-50 years. In our study 41% are having diabetes, 43% are having hypertension and 16% are having both diabetes & hypertension.

In our study diabetes (44.1%) is more in the age group 46-50 years, hypertension (59.4%) is more in the age group 36-40years and both diabetes & hypertension (29.4%) is more common in the age group 46-50 years. In

our study we have taken participants with known diabetes and hypertension and so the prevalence is high in our study.

In our study among Diabetics (n=41) 43.9% were smokers, 66.4% were alcoholic, 31.7% were overweight, 19.5% were obese and 58.5% were doing any physical activity. Among Hypertensive (n=43) 37.2% were smokers, 23.3% were alcoholic, 44.2% were overweight, 14.0% were obese and 25.6%were doing any physical activity. Among both Diabetics & Hypertensive (n=16) 31.3% were smokers, 25.5% were alcoholic, 25.0% were overweight, 0% were obese and 31.3%were doing any physical activity. The risk factors for life style diseases in our study are smoking (39%) , alcohol intake (27%), lack of physical activity (40%), overweight (36%),obesity (14%). A study conducted by Prasanna D et al in Karnataka identified the presence of various risk factors among noncommunicable disease are smoking (45.4%), alcohol intake (41.8%), lack of physical activity (38.1%), high BMI (49.34%).[18]

In our study the impact of health education on risk factors of lifestyle disease was statistically significant with Smoking (p=.000), Alcohol (p=.02), Physical activity (p=.001) and not significant with BMI (p=.71). Prabhakaran et al study showed that Change in proportion of risk factors in intervention vs. control sites: tobacco use: 39% to 29% vs. 17% to 20%, median physical activity score: 6 to 11 vs. 8 to 6.[19] The limitation of the study was changes in their behavior after health education was assessed subjectively.

CONCLUSION

The prevalence of risk factors for life style diseases in the study is high. The Impact of health education on risk factors of lifestyle disease was statistically significant. Targeting groups who are at risk will help to reduce the burden arising due to lifestyle disease. Implementation of relevant health promoting activities is advised for people who are at risk. Regular health checks can be done to improve the frequency of preventive care and support for behavior change. Effective implementation of lifestyle modifications behavior like healthy diet intake, avoidance of high caloric foods, promoting physical activity help in preventing future complications as a part of primary preventive strategies at primary care level.

Clinico-mycological and Antifungal Susceptibility Profiles of Candiduria in A Tertiary Care Hospital From South India

DINOOP KOROL PONNAMBATH, SWARAN KUMAR M, APPALARAJU BOPPE, KARTHIKEYAN SHANMUGAM

ABSTRACT

Introduction: *Candida* is one of the common causative agent of Urinary Tract Infections (UTI) worldwide. The most common reported species causing UTI is *Candida albicans*. Incidence of UTI due to non-albicans *Candida* species. is on rise in recent years because of their better adaptability and increased resistance to antifungals. Susceptibility profile reports of various *Candida* species. to newer azoles like voriconazole and beta-glucan inhibitors (e.g., caspofungin) are deficient in India, since the reference broth microdilution method is not widely utilized. In this study, a rapid reliable and easier alternative, VITEK 2 compact system was utilized to determine the antifungal susceptibility profile.

Aim: To analyse the clinical and mycological profile with determination of drug susceptibility pattern of *Candida* isolates from urine samples.

Materials and Methods: This observational study was conducted in PSG Institute of Medical Sciences and Research, during April to September 2015. *Candida* isolated with a colony count of ≥103 CFU/ml of urine from clinically suspected cases of UTI were included in the study. Urine samples (n=3821) from clinically suspected UTI cases (n=3821) were subjected to microscopic examination and semi quantitative estimation of yeast culture obtained by inoculated of calibrated volume of urine onto blood, Mac-conkey and HiCrome UTI agar. Clinical parameters of the cases were obtained for analysis. Speciation of *Candida* was performed using germ tube test, observation of morphology in corn-meal agar and pigment production in HiChrome *Candida* differential agar. Confirmation of the species identification and anti-fungal susceptibility profile were obtained using VITEK-2 compact system.

Results: Total 101 patients were identified with significant candiduria. Community-Acquired Candiduria (CAC) was seen in 11 (10.8%) of the cases. 23 (22.7%) cases of candiduria were associated with pyuria. Concomitant candidemia was observed in 4 (3.9%) cases of candiduria The most common species identified was *Candida* albicans (n=53, 52.4%). The commonest non-albicans *Candida* species causing significant candiduria cases were *C. glabrata* and *C. tropicalis* (n=18, 17.8% each). The antifungal susceptibility testing revealed an overall 94% susceptibility to amphotericin B, 89% susceptibility to flucytosine, 84% & 88% susceptibility to azoles, fluconazole and voriconazole respectively with 90% susceptibility to caspofungin. Significant high linear correlation existed between fluconazole and voriconazole resistance for *C. glabrata*, *C. albicans* and *C.tropicalis*. [Pearson's correlation coefficient, *C. glabrata* [r =1.00 (p<0.001)], *C. albicans* [r=0.91 (p<0.001)] and *C.tropicalis* [r=0.79 (p<0.001)].

Conclusion: *C. albicans* was found to the commonest species in our Tertiary Care Center in contrast to the reporting of non-*albicans Candida* species as the commonest species in most other recent studies. Determination of the antifungal susceptibility profile showed increasing trend of resistance to most antifungal agents, particularly azoles.

Keywords: Antibacterial agents, Antibiotics, Immunosuppression

INTRODUCTION

Candida species. has been reported as one of the common etiological agent of UTI, especially in a hospital setting. Advances in critical care management, immunosuppression and widespread use of antibacterial agents have led to their increased prevalence. Common risk factors associated with candiduria are extremes of age, diabetes mellitus, females in reproductive age group, structural abnormalities of the urinary tract, broad-spectrum antibiotic use, immunosuppression, indwelling catheters, abdominal surgeries, admission in ICU etc., [1]. Identification and susceptibility testing of the yeast helps targeted therapy of the infection and yields epidemiological

data for assessment of the prevalence and resistance pattern. Fungal UTI are mostly asymptomatic, occasionally can present with upper or lower urinary tract symptoms. Despite the lack of symptoms, increased colonization burden may predispose to invasive candidiasis particularly in debilitated individuals. It necessitates differentiation of asymptomatic and symptomatic candiduria since unnecessary treatment, catheter changes, and hospital prolongation can be avoided, since hospital cost burden and patient morbidity increases substantially. The scenario of presence of yeast in microscopic examination or isolation in culture needs to be evaluated with the clinical picture to determine its relevance and the decision on the commencement of antifungal therapy. Semi-quantitative/ quantitative urine culture is performed in evaluation of significant candiduria and a colony count of ≥1000 CFU/ml of urine, obtained in culture media in most situations represents significant candiduria. Significant candiduria occurs as 2 clinical presentations, asymptomatic and symptomatic candiduria. Patients with symptomatic candiduria need to be started on antifungal therapy, whereas asymptomatic candiduria needs to be interpreted with care. The significance of asymptomatic candiduria arises when the patient is severely debilitated/immunosuppressed, or is planned for urological instrumentation/procedures. Asymptomatic candiduria can also represent a picture of sample contamination (inappropriate collection) or colonization (in catheterized patients). In these cases, evaluating a repeat urine sample rules out contamination and colonization when the repeat sample has been collected after removal of indwelling catheter [2]. The most common reported species causing UTI is *Candida albicans* [3]. Incidence of Non-*albicans Candida* species. (e.g.: *C. glabrata*, *C. krusei*, *C. parapsilosis*, *C. tropicalis* etc.,) causing UTI have been increasingly reported due to enhanced adaptation potential and increased resistance to antifungal agents [4]. In the past few years, there has been emergence of drug-resistance in *Candida* species causing clinical infections, leading to high morbidity and mortality in hospitalized patients [5]. Testing for antifungal drug susceptibility in clinically significant *Candida* species isolates guides prompt treatment thereby improving the patient's outcome. Susceptibility profile reports of various *Candida* species. to newer azoles like voriconazole and beta-glucan inhibitors (eg: caspofungin) are deficient in India, since disc diffusion interpretation guidelines are not available for all antifungals and the reference broth microdilution method is not widely practiced. The VITEK 2 antifungal drug susceptibility determination system has emerged as an easier and an expeditious alternative to the reference broth microdilution method (CLSI and EUCAST) [6]. Studies report 95-100% essential agreement between the results of VITEK 2 and the reference methods [7,8]. This study was undertaken to analyse the clinical and mycological profile with determination of drug susceptibility pattern of *Candida* isolates from urine.

MATERIALS AND METHODS

This was an observational study conducted in PSG Institute of Medical Sciences and Research (PSGIMS&R) during the period April 2015 - September 2015 (6 months). The Institute's ethics committee approval was obtained before the conduct of the study. (IHEC approval number: 15/039).

Inclusion criteria: *Candida* being isolated with a colony count of ≥1000 CFU/ml of urine either in pure culture or as one among the 2 isolates obtained from urine samples collected from clinically suspected cases of urinary tract infection (UTI)/ screening prior to urological instrumentation/intervention of all ages and both sex.

Exclusion criteria: If growth of *Candida* with a colony count of <1000 CFU/ml of urine or when >3 types of growth was obtained.

Urine samples were received in sterile screw capped leak-proof container, immediately transported from the collection center to the microbiology laboratory and stored in refrigerator until further investigations were undertaken. Urine wet mount examination was performed to look for the presence of pus cells, epithelial cells, red blood cells, casts, crystals, budding yeast cells with/without pseudohyphae. The urine samples were inoculated onto blood, mac-conkey and chromogenic media (HiCrome UTI agar, HiMedia Laboratories) by a calibrated wire loop standardized to deliver 5µl for semi-quantitative estimation of yeast growth. The inoculated culture plates were incubated aerobically at 37°C for 24-48 hours. *Candida* isolates with colony count of ≥1000 CFU/ml of urine were considered significant and included in the study. Clinical parameters of the cases were obtained in the case study form which included age, sex, details of admission (outpatient/ ward/ICU), presence/absence of any risk factors like extremes of age (elderly and pre-mature neonates), diabetes mellitus, structural abnormalities of the urinary tract, broad-spectrum antibiotic use in preceeding 30 days, immunosuppression (neutropenia, HIV etc.,), indwelling catheters, abdominal surgeries and admission in ICU etc. Significant candiduria was classified as hospital-acquired and community-acquired. CAC was defined as candiduria observed in outpatients with no prior hospitalization or within 48 hours of hospitalization. When the onset of candiduria is >48 hours of hospitalization, it was classified as Hospital-Acquired Candiduria (HAC) [9]. Preliminary speciation of *Candida* was performed using Germ Tube Test (GTT), observation of morphology in corn-meal agar and pigment production in chromogenic medium (HiChrome *Candida* differential agar, HiMedia Laboratories) [10]. Confirmation of the species identification and anti-fungal susceptibility profile were obtained using VITEK-2 compact system (YST ID and AST card, bioMerieux, Marcy-l'Etoile, France) for the following antibiotics: amphotericin B, flucytosine, fluconazole, voriconazole and caspofungin. The VITEK 2 cards were stored at 2-8°C until testing was performed. An inoculum turbidity equivalent to 2.0 McFarland was prepared in sterile saline as per the manufacturer's instructions using the DensiChek instrument, for antifungal susceptibility testing [11]. *Candida albicans* ATCC 10231 was used as the control

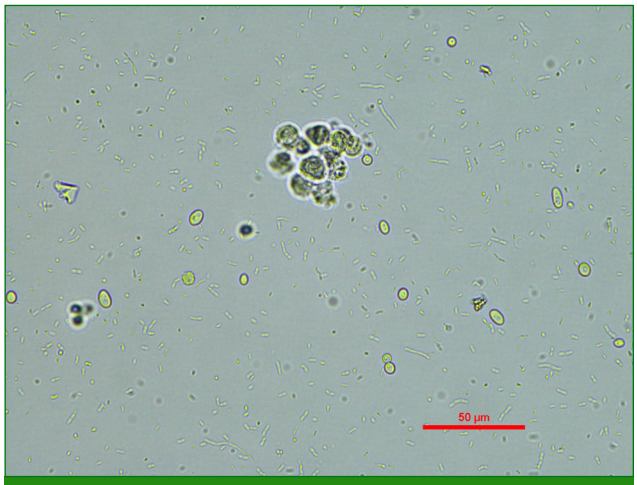
strain for the antifungal susceptibility testing.

STATISTICAL ANALYSIS

The data obtained were analyzed using SPSS software version 19. Fischer' exact/Chi-square test were used for comparative analysis and a p value of ≤0.05 was considered significant. Association/correlation between variables were analysed using Pearson's correlation coefficient (r).

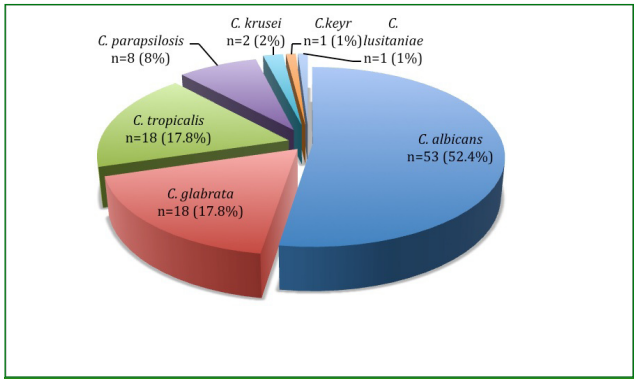
RESULTS

During the study period of April - September 2015 (6 months), 101 patients were identified with significant candiduria. The mean age of the study population was 55.9±16.9 years (Median age-60 years). The age distribution of the study population ranged between 12-89 years and the majority of the candiduria cases (76%) were observed in the 41-80 years age group with a peak observed in the 61-70 years age group [Table/Fig-1]. In the study population, males (n=56, 55.4%) were more commonly affected than females (n=45, 44.6%). Candiduria was observed more commonly in the in-patient wards (n=58, 57.4%), followed by intensive care units (n=32, 31.8%) and outpatient department (n=11, 10.8%).



Age Group (in years)	Number (n)
0-10	0
11-20	4
21-30	9
31-40	9
41-50	10
51-60	22
61-70	30
71-80	15
81-90	2

[Table/Fig-1]: Age distribution of the patients with significant candiduria.



Among the risk factors, the commonest cause was broad-spectrum antibiotic usage (67.3%) followed by indwelling foley's catheterisation (56.4%), diabetes mellitus (16.8%), immunosuppression (13.8%), previous abdominal surgeries (1.9%) and urinary tract structural abnormality (0.9%) [Table/Fig-2]. Among the broad spectrum antibiotics, cephalosporin (68%) and fluroquinolone (32%) were the common antibiotics observed to be used in patients with significant candiduria, in the preceeding 30 days. Pyuria was observed in 23 (22.7%) cases of significant candiduria [Table/Fig-3], while concomitant candidemia was observed in 4 (3.9%) cases. The various species of *Candida* identified in the candiduria cases are depicted in [Table/Fig-4]. The most common species of *Candida* identified was *Candida albicans* (52.4 %). A case of significant candiduria had both *C. albicans* and *Trichosporon* species. The commonest non-*albicans Candida* species causing significant candiduria cases were *C. tropicalis* and *C. glabrata* (18% each).

Risk Factors	Number (n)	Percentage (%)
Diabetes Mellitus	17	16.8
Structural abnormalities of Urinary Tract	1	0.9
Broad Spectrum Antibiotic usage	68	67.3
Immunosuppressive Conditions	14	13.8
Indwelling Foley's Catheter	57	56.4
Underwent Abdominal Surgeries	2	1.9

[Table/Fig-2]: Distribution of risk factors in patients with significant candiduria.

[Table/Fig-3]: Wet mount examination of urine from showing pus cells and budding yeast cells (Magnification – 400X).

[Table/Fig-4]: Frequency of *Candida* species in the study population.

The antifungal susceptibility testing revealed an overall 94% susceptibility to amphotericin B, 89% susceptibility to flucytosine, 84% and 88% susceptibility to azoles, fluconazole and voriconazole respectively with 90% susceptibility to caspofungin. Susceptible-Dose Dependent (SDD) for fluconazole was observed in 5 isolates (9.4%) of *C. albicans*, 2 isolates of *C. glabrata* and *C. tropicalis* (11.1% each). The species-based susceptibility profiles to the antifungal agents tested are provided in [Table/Fig-5]. A significant high linear correlation existed between fluconazole and voriconazole

Candida species	Sensitive									
	Amphotericin B		Flucytosine		Fluconazole		Voriconazole		Caspofungin	
	n	%	n	%	N	%	N	%	N	%
C. albicans	50	94.3	47	88.6	46*	86.7	47	86.7	48	90.5
C. glabrata	17	94	16	88.8	15*	83.3	15	83.8	17	94
C. tropicalis	17	94	16	88.8	15*	83.3	16	88.8	14	77.7
C. parapsilosis	7	87.5	7	87.5	7	87.5	7	87.5	8	100
C. krusei	2	100	2	100	1	50	2	100	2	100
C. kefyr	1	100	1	100	1	100	1	100	1	100
C. lusitaniae	1	100	1	100	1	100	1	100	1	100
All species	95	94	90	89	85	84	89	88	91	90

[Table/Fig-5]: Antifungal susceptibility pattern of the isolated *Candida* species.
* includes susceptible-dose dependent (SDD) isolates

resistance for *C. glabrata* [Pearson correlation coefficient, r =1.00 (p<0.001)], *C. albicans* [r=0.91 (p<0.001)] and *C. tropicalis* [r=0.79 (p<0.001)].

DISCUSSION

Candiduria is a common nosocomial phenomenon and large scale observational surveys reveal *Candida* as the third most common organism isolated from urine in hospitalized patients [12]. During the study period, a total of 101 *Candida* species were isolated from cases of significant candiduria. Candiduria cases proportionally increased with age and were predominantly observed in the 41-80 years age group (76.2%). This observation could be due to the increased prevalence of co-morbid conditions like diabetes mellitus, benign prostatic hypertrophy, immunosuppression, frequent use of broad-spectrum antibiotics and foley's catheter etc. seen in the elderly age group. The median age and age distribution was similar to observational study reports by Nayman Alpat S et al., and Bobade O et al., [13,14].

Males and females were almost equally affected in our study population, whereas most reports from literature show the incidence of candiduria being more common in females [14,15]. Significant candiduria were observed commonly in hospitalized patients (inpatient and ICU settings) probably because of the presence of risk factors like broad spectrum antibiotic use, long term indwelling catheters and also to presence of other debilitating illness like uncontrolled diabetes commonly in the inpatient population than the outpatients. The broad-spectrum antibiotics implicated in cases of significant candiduria cases in our study population were cephalosporins (68%) and fluoroquinolones (32%) use in the preceding 30 days. There are documented reports of use of broad-spectrum antibiotics like cephalosporins attributing to causation of candiduria [16]. CAC was seen in 10.8% of the cases and the risk factors associated were diabetes mellitus, pregnant women and chronic indwelling catheters. Similar risk factors for CAC have been reported by Colodner R et al., [9].

Pyuria is defined as the presence of ≥3 leucocytes/hpf of unspun urine or ≥10 leucocytes per cubic mm of urine or positive dipstick test for leucocyte esterase [17]. In our study, 23 (22.7%) cases of candiduria were associated with pyuria. Pyuria is an important sign of candiduria yet lacks sensitivity and doesn't differentiate colonization from infection (lacks specificity) [18]. Concomitant candidemia was observed in 4 (3.9%) cases of candiduria. Studies report that approximately 1-8% of patients with candiduria particularly ICU admissions may have concomitant candidemia [3,12,19].

The commonest *Candida* species identified in our study was *Candida albicans* (52.4%), while non-*albicans Candida* species attributed to the remaining 47.6% of cases of significant candiduria. Among the non-*albicans Candida* species, *C. glabrata* and *C. tropicalis* were the common species isolated. Earlier multicentric reports on candiduria had similar findings of *Candida albicans* being the commonest species yet recent studies report the emergence of non-*albicans Candida* species as the commonest cause of significant candiduria due to the widespread use of antifungal agents for antifungal prophylaxis and treatment, particularly increasing incidence of *C. glabrata* and *C. krusei* infections which are intrinsically less susceptible to the commonly used azole drug, fluconazole [14,20,21]. Our report suggests relatively lower prevalence of non-*albicans Candida* species, in contrast to reports from other centers in India [22,23].

Analysis of the antifungal susceptibility pattern showed that most isolates were susceptible to amphotericin B. Resistance to the polyene drug, amphotericin B was observed in 6 isolates (6%) (3-*C. albicans*, 1-*C. tropicalis*, 1-*C. glabrata* and 1-*C. parapsilosis*). Increasing resistance was observed for azole group of drugs particularly fluconazole in non-*albicans Candida* species (16.7% for both *C. glabrata* and *C. tropicalis*, 50% for *C. krusei*) when compared to *C. albicans* (13.3%). These drugs (fluconazole and voriconazole) belong to triazole group of azoles and exert their action by inhibiting cytochrome P450-dependent enzyme lanosterol 14 alpha-demethylase. Voriconazole have better activity against *Candida* species (16-32 fold potent than fluconazole) due to effective binding to the cytochrome P450 enzyme. Yet, cross-resistance between fluconazole and voriconazole have been increasingly reported

in *Candida* species, particularly *C. glabrata* [24]. Pfaller et al, (2007) had reported the use of fluconazole as a surrogate marker to predict voriconazole susceptibility in resource-poor settings [25]. In our study, high cross-resistance correlation between azoles was observed in *C. albicans*, *C. glabrata* and *C. tropicalis*. One *C. glabrata* isolate was resistant to three classes of drugs (Polyene, azoles and β-glucan inhibitors). This is of high-concern because azoles and β-glucan inhibitors are increasingly recommended for prophylaxis, thereby leading to selection of drug-resistant non-*albicans Candida* strains [26,27]. The echinocandin, caspofungin had excellent activity against most *Candida* isolates, while 5 isolates of *C. albicans* (9.5%) and 4 isolates of *C. tropicalis* (22.3%) were found to be resistant. This observation predicts that echinocandins like caspofungin and micafungin may emerge in the recent future as the drug of choice for prophylaxis and treatment of cases with symptomatic candiduria.

LIMITATION

The limitation of our study was the lack of genomic characterization of the resistant isolates with MIC correlation and follow-up assessment of clinical/microbiological outcome.

CONCLUSION

This study describes the clinical profile and the distribution of various *Candida* species causing significant candiduria, where *C. albicans* was found to the commonest species in our Tertiary Care Center, in contrast to the reporting of non-*albicans Candida* species as the commonest species in most other recent studies. Although, *C. albicans* was the predominant cause of candiduria, increasing trend towards non-*albicans Candida* species causing significant candiduria was observed. Most health care centers in India do not routinely test for antifungal susceptibility for the clinical isolates due to the laborious phenotypic procedures, lack of expertise and lack of availability of updated interpretative guidelines, thereby leading to lack of drug-resistance data for fungal infections. Newer automated technologies like VITEK 2 compact system have emerged as an effective and promising alternative in determination of antifungal susceptibility thereby guiding prompt treatment and early detection of emerging drug resistance. In our study, antifungal susceptibility profile showed increased resistance to fluconazole and associated cross-resistance to voriconazole in commonly isolated *Candida* species., probably due to their increased usage for prophylaxis and treatment. Newer antifungal drugs like caspofungin and micafungin (echinocandins) are emerging as promising agents for prophylaxis and treatment of symptomatic candiduria. In addition, strengthening the hospital antimicrobial stewardship programs would taper this scenario of widespread drug resistance similar to Multi-Drug Resistant (MDR) bacterial isolates.

Declaration: A part of this study has been presented as a poster at the MICROCON 2015 conference organized by Jawaharlal Institute of Postgraduate Medical Education & Research (JIPMER), Puducherry. (Abstract available at http://microcon2015.co.in/abstracts/free_ePosters/Abstracts/abs-1153.html).

Intravitreal Bevacizumab for Choroidal Neovascularization Associated with Angioid Streaks: Long-term Results

T. Lekha[1,2], Hari Narayan Prasad[2], Renuka Nikit Sarwate[2,3], Manasi Patel[4], S. Karthikeyan[5]

Abstract:

PURPOSE: The purpose of the study was to evaluate the long-term efficacy and safety of intravitreal bevacizumab (IVB) in the treatment of choroidal neovascularization (CNV) secondary to angioid streaks (AS).

MATERIALS AND METHODS: Noncomparative, interventional retrospective case series involving ten patients (15 eyes) with a minimum follow-up of 25 months following IVB for AS-associated CNV. Demographic and clinical details at baseline and during follow-up were collected from patient records. Detailed clinical examination was followed by fundus fluorescein angiography and optical coherence tomography to confirm CNV. Both primary and recurrent CNVs were treated with monthly injections of IVB till the lesion stabilized. Primary outcome measures were the percentage of patients with stable or improved visual acuity (VA) and with stable or decreased central retinal thickness (CRT) at the last visit. Secondary outcome measure was the incidence of ocular and systemic complications.

RESULTS: Recurrence was observed in 11 eyes (73.33%) over a mean follow-up of 57.33 months (range: 25–100). A mean number of injections administered was 5.60. VA improved or stabilized in 73.33% and deteriorated in 26.67% of eyes at the final visit. Mean CRT improved from 324.40 μm at baseline to 265.53 μm at final visit, which was statistically significant. Complications observed were ocular hypertension in one patient and thromboembolic event in another patient.

CONCLUSIONS: IVB appears to be a safe and effective option to treat CNV and to preserve vision over a prolonged period. It cannot eliminate the risk of recurrent CNV indicating the need for more effective treatments to arrest this visually debilitating condition.

Introduction

Angioid streaks (ASs) are reddish brown, jagged lines radiating from peripapillary area into the peripheral fundus, predominantly affecting population in the second to fifth decade. Systemic associations include pseudoxanthoma elasticum (PXE), Ehler-Danlos syndrome, Paget's disease, or hemoglobinopathies.[1,2] Choroidal neovascularization (CNV) complicating AS (prevalence: 72%–86%) is an important cause of legal blindness and financial burden in middle-aged individuals affected by this condition.[3] Treatment of CNV has remained a challenge, and different modalities such as laser photocoagulation, transpupillary therapy, photodynamic therapy (PDT), or surgery usually resulted in poor outcomes.[1,4,5]

Vascular endothelial growth factors (VEGFs), a potent mitogen for endothelial cells, have been implicated in the pathogenesis of CNV.[4] A recent review on the treatment of AS-related CNV has shown Anti-VEGF
