drugs such as bevacizumab and ranibizumab to be the most effective treatment.[1] Anti-VEGF therapy in angioid CNV was first reported in 2006.[6] Subsequently, several case reports and case series have confirmed its efficacy and safety over a period ranging from 6 to 24 months.[4,7-14] A recent prospective multicentric study involving 44 patients with AS-associated CNV also confirmed the efficacy of Anti-VEGF therapy in stabilizing CNV over a period of 12 months.[5] However, AS being a chronic disease affecting young individuals, it is important to understand the long-term benefits of anti-VEGF therapy, and so a retrospective analysis of our ten patients (15 eyes) treated with intravitreal bevacizumab (IVB) and with a minimum follow-up of 25 months (range: 25–100 and mean: 57.33 months) was done. To the best of our knowledge, this is the longest follow-up results reported for this rare condition.

Materials and Methods

This is a retrospective chart review of ten patients (15 eyes) treated for CNV secondary to AS in the Retina Services of our hospital from September 2006 to March 2014 and who had completed a minimum follow-up of 25 months. Data collected from the patient's chart included age, gender, details of clinical evaluation, and treatment at baseline and subsequent visits. A total number of injections given, duration of total follow-up (from the initial treatment visit to the last visit), and duration of follow up after the last intervention and any local or systemic adverse effects of treatment were also noted. Ophthalmic evaluation included checking of best-corrected visual acuity (VA) with Snellen's chart, slit lamp biomicroscopy, applanation tonometry, indirect ophthalmoscopy followed by fundus fluorescein angiography (FFA) and optical coherence tomography (OCT). FFA was performed using Zeiss FF450; Zeiss Oberkochen, Germany, and OCT was done using time domain Stratus OCT or spectral domain Cirrus HD-OCT (Carl Zeiss Meditech, USA). Patients were also evaluated by general physician to look for systemic associations of AS. CNV identified at the time of presentation was labelled as primary CNV and its location and activity were evaluated based on the leakage seen on FFA and the morphological changes on OCT such as presence of CNV, subretinal fluid (SRF), and retinal edema. All patients with active CNV and with no systemic morbidities such as uncontrolled hypertension, cardiovascular, or cerebrovascular events in the previous 6 months were administered IVB 1.25 mg in 0.05 ml (Avastin; Genentech, South San Francisco, CA, USA) under aseptic precautions, as an outpatient procedure. Antibiotic eye drops four times a day for 5 days were prescribed after the injection for all patients. The study adhered to the tenets of the Declaration of Helsinki and was approved by the Institutional Ethics Committee. An informed written consent was obtained from all patients.

Patients were followed up at monthly intervals with reinjections on as needed basis till CNV became inactive. At each visit, recording of VA, fundus examination, fundus photography, and OCT was done. FFA was repeated only when a new lesion was suspected or in eyes with poor response to therapy. Improvement or stabilization of VA along with resolution of CNV, retinal edema, and SRF on OCT was considered as a favorable response to therapy. Recurrent CNV was diagnosed if deterioration of vision and/or metamorphopsia was associated with the presence of new hemorrhage or active lesion adjacent to primary CNV or at new foci with the corresponding leakage on FFA and reappearance of SRF or retinal edema on OCT. Additional injections were administered to treat recurrent CNV and monitoring continued at monthly intervals till stabilization was achieved. This was in accordance with the retreatment criteria for neovascular age-related macular degeneration which allows less frequent injections with comparable outcome.[15] Two patients also underwent PDT. This included the first patient in this series who presented with a subfoveal CNV in his left eye (OS) in September 2006, when the standard of care for subfoveal CNV was PDT. IVB was a new option, and its efficacy as monotherapy was not well established. Hence, he was initially treated with a combination of PDT and IVB, but the multiple recurrences in that eye as well as the CNV that developed later in the fellow eye were managed with IVB alone. Similarly, patient 5 initially managed by IVB monotherapy for CNV in the OS, preferred PDT when he was detected later to have bilateral active CNV, to reduce the need for multiple injections in both eyes. Following treatment, OS stabilized with a large subfoveal scar, whereas right eye (OD) developed three more recurrences which were managed by IVB monotherapy.

Primary end points of this study were the percentage of patients with stable or improved VA and with stable or decreased macular thickness at the last visit. Secondary end point was the long-term incidence of ocular and systemic complications in patients with AS who are predisposed to systemic complications. For statistical analysis, Snellen's VAs were converted to logMAR. Any change in VA was defined as improved or worse based on gain or loss of 3 or more lines from baseline VA. If change in vision was within three lines of baseline VA, it was considered as stable. Morphological outcome was analyzed by comparing the mean central retinal thickness (CRT) measured on central macular map on OCT at baseline and at final visit. Data were entered in Excel and analyzed using IBM SPSS software version 19.0. Continuous variables were expressed in mean and standard deviation. Quantitative data were compared

[Downloaded free from http://www.meajo.org on Monday, November 27, 2017, IP: 192.168.30.139]

using Paired "*t*" test, and correlation between baseline and final VA and CRT was done using Pearson correlation. $P < 0.05$ was considered statistically significant.

Results

Fifteen eyes of ten patients treated for AS-associated CNV and with a minimum follow-up of 25 months were analyzed [Table 1]. There were seven males and three females with a mean age of 49.47 ± 4.37 years (range: 46–63 years). Three patients had biopsy-proven PXE, and in others, AS was considered as idiopathic. Follow-up period ranged from 25 to 100 months with a mean of 57.33 ± 21.76 months. Mean follow-up after the last injection was 28.26 ± 23.42 months (range: 0–73). CNV was bilateral in seven patients (70%), of which five had active CNV bilaterally, and two had active CNV in one eye and scarred CNV in the fellow eye. All the three patients with PXE had bilateral CNV, but in two of them, CNV was already scarred in one eye and was not included in the study. All eyes had naïve CNV, of which eight (53.33%) were juxtafoveal and 7 (46.67%) were subfoveal CNV.

A mean number of injections needed to treat primary CNV was 2.26 ± 0.96. Three eyes (20%) stabilized with one injection, seven eyes (46.67%) with two injections, three eyes (20%) with three injections, and two eyes (13.33%) with four injections. Thus, primary CNV resolved with ≤3 injections in 83.67% of eyes. Mean baseline CRT was 283.33 ± 17.21 μm in eyes that responded to one injection compared to 473.50 ± 106.78 μm in eyes which needed four injections. Recurrence was observed in 11 eyes (73.33%) whereas 4 eyes (26.67%) remained inactive throughout follow-up. Most of the recurrences developed adjacent to the primary CNV. Time of detection of the first recurrence ranged from 10 to 26 months. Six eyes had only one recurrence, two eyes had two recurrences, one eye had three recurrences, and two eyes had four recurrences. Number of injections required to obliterate recurrent CNV were 11 injections (in 1 eye), 10 injections (in 1 eye), 5 injections (in 4 eyes), 2 injections (in 4 eyes), and 1injection (in 1 eye) amounting to a total of fifty injections (mean 3.33 ± 3.50). Overall, the mean number of injections administered was 5.60 ± 3.50. There was a statistically significant correlation between the mean number of recurrences to the number of injections given for recurrent CNV ($P = 0.00$) as well as to the total number of injections ($P = 0.00$). All the three eyes treated with PDT had poor outcome, with two of these eyes having the maximum recurrences.

VA improved or stabilized in 73.33% of eyes (11 eyes) and deteriorated in 26.67% of eyes (four eyes). However, the mean logMAR VA worsened from 0.68 ± 0.54 at baseline to 0.71 ± 0.52 at final visit, but the difference was not statistically significant ($P = 0.75$). Mean variation in VA was −0.27 ± 3.63 lines ranging from −6 lines to +9 lines. At baseline, 26.67% (four eyes) had VA 20/40 (logMAR: 0.3) or better which improved to 33.34% (five eyes) at final visit. Similarly, proportion of eyes with VA 20/200 (logMAR: 1.0) or worse also increased from 33.34% at baseline to 40% at final visit. However, no statistically significant conclusions could be derived as the numbers were small. Mean CRT improved from 324.40 ± 88 μm at baseline to 265.53 ± 66.41 μm at the final visit, a difference which approached statistical significance ($P = 0.01$). Following treatment, 14/15 eyes (93.33%) had stable or decreased CRT with inactive CNV. The only exception was the OD of patient 5 (treated with PDT and IVB) which developed multiple recurrences and chronic

*Patients with PXE, †Patients who underwent photodynamic therapy. VA: Best corrected visual acuity, CRT: Central retinal thickness measured in μm, CNV: Choroidal neovascularization, PXE: Pseudoxanthoma elasticum, OD: Right eye, OS: Left eye

[Downloaded free from http://www.meajo.org on Monday, November 27, 2017, IP: 192.168.30.139]

cystoid macular edema (CME) with worsening of CRT from 289 μm to 409 μm. Serial morphological changes in patients with the best and worst outcomes are shown in Figures 1 and 2, respectively. Overall, ten eyes developed macular scar which was associated with CME in three eyes, foveal thinning in two eyes, and vitreomacular traction in one eye. Thus, despite an improvement in the retinal thickness, majority had poor functional outcome due to degenerative macular changes.

The only ocular complication noted during follow-up was increased intraocular pressure in one eye (patient 1, OS) which was controlled with Timolol eye drops. Patient 3, who did not have PXE but a known diabetic, hypertensive, and cardiac patient under our care since 2008, developed minor cerebrovascular accident in April 2012 and also had to undergo coronary artery bypass graft in February 2014. No other ocular or systemic complications were observed during the follow-up.

Discussion

All the published studies regarding IVB in AS-associated CNV and having a minimum follow-up of 23 months are summarized in Table 2. Alagöz *et al*.[16] who have the largest series achieved improvement or stabilization of VA in 65.2% of their eyes, but 61% (14/23 eyes) continued to have active CNV at the last follow-up. Young patients with resistant CNV and those with PXE required more aggressive treatment. However, there are reports with a lesser number of patients that have demonstrated 100% improvement/stabilization both visually and morphologically over a follow-up period ranging from 23 to 28.6 months.[10,17,18] Finger *et al*.,[19] in their analysis of 14 patients with PXE and AS, found visual improvement in those with early disease and emphasizes the need for early initiation of treatment with regular follow-up and prompt reinjection for recurrence. Maintenance therapy with monthly injections is not necessary considering the cardiovascular risk profile of these patients with PXE and also to minimize the risk of RPE atrophy which can be aggravated by repeated anti-VEGF injections. Myung *et al*.[18] treated nine patients with PXE and AS-related CNV and reported statistically significant improvement in the final VA at 6 months in their preliminary study. However, in their extended study of the same cohort of patients followed up for 28.6 months, overall visual outcome was less favorable due to frequent recurrences and scarring. Similar observations were also made by Iacono *et al*.,[20] who followed up 15 patients with nonsubfoveal CNV secondary to AS and found that the efficacy of IVB in halting the CNV deteriorated from 80% at 12 months to 46% at 36 months. Another recent study by Rosina *et al*.[21] evaluating 16 eyes with a mean follow-up of 52 months states that risk of recurrence increased

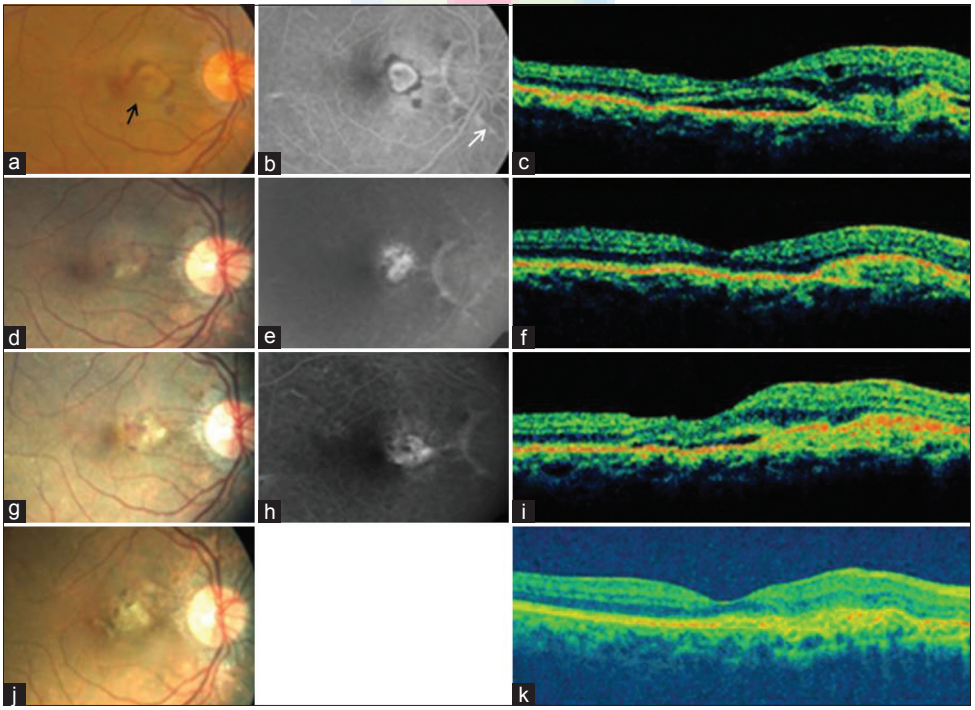

Figure 1: Images of patient 2 who had successful outcome following intravitreal bevacizumab for choroidal neovascularization in the right eye. At presentation, color photograph (CF) (a) and fundus fluorescein angiography (b) showed angioid streak (white arrow) and Juxtafoveal choroidal neovascularization with hemorrhage (black arrow). Optical coherence tomography (c) showed choroidal neovascularization with subretinal fluid, which resolved after treatment as seen on CF (d), fundus fluorescein angiography (e), and optical coherence tomography (f). 10 months later, recurrent choroidal neovascularization was detected based on fresh hemorrhage on CF (g), mottled hyper fluorescence on fundus fluorescein angiography (h), and subretinal fluid on optical coherence tomography (i) and was treated with one more injection. He remained stable at his final visit with a scarred juxtafoveal choroidal neovascularization clinically (j) and on optical coherence tomography (k)

[Downloaded free from http://www.meajo.org on Monday, November 27, 2017, IP: 192.168.30.139]

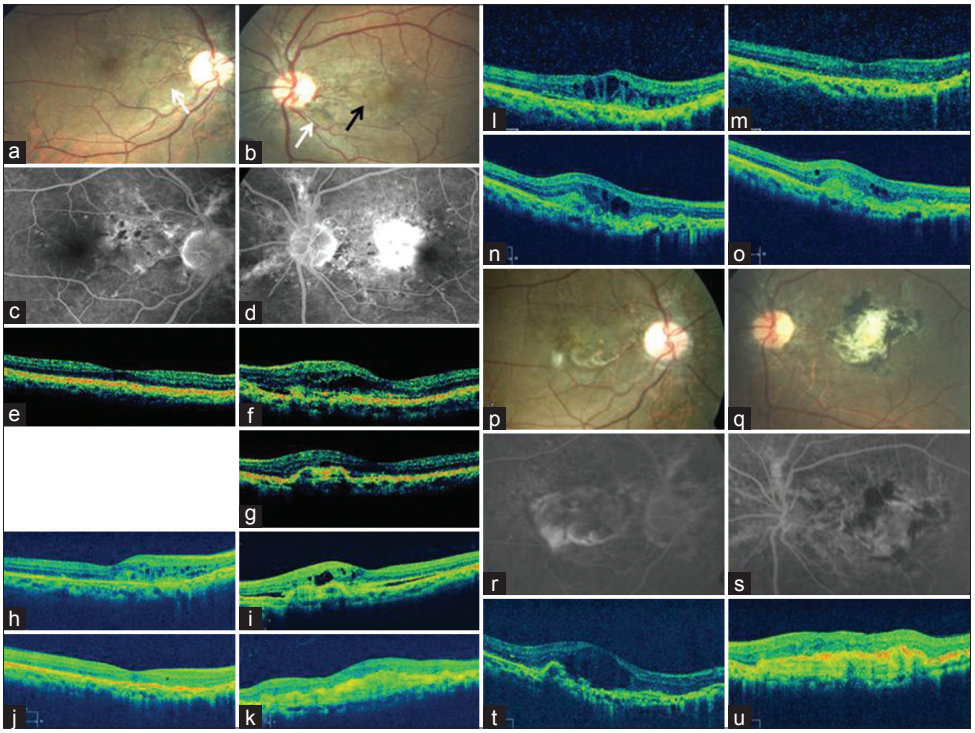

Figure 2: Images of patient five who had the worst outcome. At presentation, color photograph (CF) (a and b), fundus fluorescein angiography (c and d) showed angioid streak (white arrow) in both eyes and choroidal neovascularization (black arrow) in left eye. Optical coherence tomography (e and f) of right eye was normal, left eye had choroidal neovascularization which resolved after treatment (g). 20 months later (h and i), there was new choroidal neovascularization in right eye and reactivation in left eye which stabilized with treatment (j and k). Multiple recurrences in right eye caused chronic edema and scarring as observed in the pre (l and n) and post (m and o) injection scans. CF (p and q), fundus fluorescein angiography (r and s) and optical coherence tomography (t and u) at his final visit showed partially scarred choroidal neovascularization with active inferotemporal edge in right eye and fibrotic scar in left eye

during the first 50 weeks and remains stable afterward. More injections were needed in eyes with increased CNV reactivation, and the final VA is related to the initial VA and not to the number of injections, previous treatments, or baseline CNV size. In a comprehensive review of treatment of AS-related CNV, Gliem *et al*.[1] also support that potential benefit of anti-VEGF therapy correlates best with the structural alterations and functional loss present at baseline. Based on a pooled analysis of 16 studies on the efficacy of bevacizumab or ranibizumab, authors conclude that there is no superiority of one drug over the other and also of fixed versus as needed regimen.

We preferred bevacizumab in our patients due to its affordability and proven efficacy in CNV. In our series with the longest follow-up reported till date (57.33 ± 21.76 months), there was stabilization or improvement in VA in 73.33% and morphological stabilization in 93.33% of patients. These results were achieved with a mean of 5.60 ± 3.50 injections. Our results are comparable to the long-term outcomes with IVB reported by other authors and far superior to the outcome achieved with the treatments in the pre- anti-VEGF era.[1] Recurrent CNV was observed in 73.33% and required more treatment for stabilization (mean of 4.54 injections) than for the primary CNV (mean of 2.26 injections). First recurrence was noted at 10 months and the last recurrence at 87 months in the patient with 100-month follow-up [Figure 3]. Interval between recurrences ranged from 5 months (Patient 5, OD) to 32 months (Patient 1, OS and Patient 2, OD) indicating that reactivation of the CNV can continue to occur at any time and at any location in some eyes in this chronically active disease necessitating long-term monitoring with timely intervention. Here, we differ from Rosina *et al*.,[21] who observed that patients free from disease reactivation showed a smaller recurrence rate. Furthermore, the same authors did not find any difference between those with naïve CNV and those treated with PDT. However, all the three eyes treated with PDT in our study had a recurrence with worse vision at final visit. Abdelkader *et al*. also have reported disappointing results with PDT and recommend anti-VEGF therapy as the treatment of choice at the present time for CNV complicating AS.[5] Since only three patients in our series had PXE, we could not compare the difference in the outcome between those with and without PXE. The reported ocular complications with bevacizumab include lens touch by the needle[12], Bruch's membrane rupture,[22] and arteritic anterior ischemic optic neuropathy.[23] In our series, ocular hypertension was detected in one patient which was well controlled with a single antiglaucoma medication and never developed any progressive glaucomatous optic neuropathy. Besozzi *et al*.[24] have reported acute stoke within 3 days of injection in a patient with PXE and no other systemic illness. Although one patient in our cohort developed two thromboembolic

Table 2: Published data regarding long-term efficacy of intravitreal bevacizumab in choroidal neovascularization secondary to angioid streaks

Author	Number of eyes/patients	Mean age	Follow up (months)	Mean number of injections	Percentage of eyes with improved/ stable VA	Percentage of eyes with stable CNV/ CRT at last visit	Conclusions
Alagöz *et al*.[16]	23/20	45.7	23	5.1	65.2	39	CNV more aggressive in young, more frequent injections in those with PXE
Neri *et al*.[10]	11/11	46.8	23.8	3.5	100	100	IVB is a promising tool for long-term control of CNV
Teixeira *et al*.[17]	5/5		24±5.2	5.8	100	100	More benefit in those with early symptoms
Finger *et al*.[19]	16/14	55	28	6.5±5.7	81.25	56.25	Preserves vision in advanced disease and improves vision in early disease
Myung *et al*.[18]	9/9	53.5	28.6	8.4	100	100	Effective, continued experience needed to establish long-term efficacy and dosing strategy
Iacono *et al*.[20]	15/15	59.2	36	5.2	NR	NR	Monthly monitoring to detect recurrence and prompt treatment
Rosina *et al*.[21]	16/10	56	52	2.5	75	100	Risk of recurrence increased during first 50 weeks. Final VA related to initial VA
Present study	15/10	49.47±4.37	57.33±21.76	5.60±3.50	73.33	93.33	Effective in stabilizing CNV, more effective options needed to reduce risk of recurrence

IVB: Intravitreal bevacizumab, CNV: Choroidal neovascularization, VA: Visual acuity, CRT: Central retinal thickness, NR: Not reported, PXE: Pseudoxanthoma elasticum

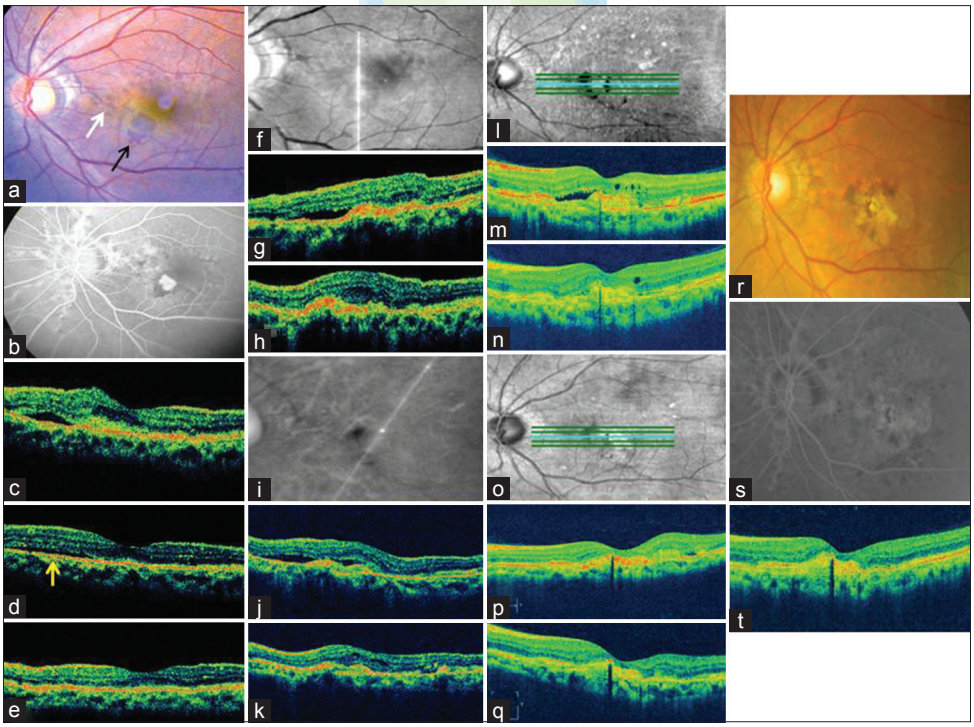

Figure 3: Images of the left eye of patient 1 which had the longest follow-up. At presentation, color photograph (CF) (a) and fundus fluorescein angiography (b) showed angioid streak (white arrow) and juxtafoveal choroidal neovascularization (black arrow). Optical coherence tomography (c) showed choroidal neovascularization with subretinal fluid. Posttreatment Optical coherence tomography (d and e) showed gradual resolution of subretinal fluid (yellow arrow). Serial fundus photographs with optical coherence tomography images pre- and post-treatment of his first recurrence (f-h), second (i-k), third (l-n), and fourth (o-q) demonstrate the progressive macular scarring. He remained stable at his last visit with a scarred choroidal neovascularization clinically (r) and on fundus fluorescein angiography (s). Thinning of neurosensory retina was seen on optical coherence tomography (t)

events, it is difficult to establish a causal relationship with IVB as he had other risk factors such as systemic hypertension and diabetes mellitus. Majority of the authors did not observe any ocular or systemic complications.[3,15,17,19]

[Downloaded free from http://www.meajo.org on Monday, November 27, 2017, IP: 192.168.30.139]

The strength of our study is the long duration of follow-up involving a significant number of eyes which is the longest reported so far, for this relatively rare condition. The limitations include retrospective design and heterogeneous study population. Despite these limitations, our results confirm the long-term efficacy of anti-VEGF therapy to stabilize the CNV and to preserve or even improve vision. It also confirmed the long-term safety of bevacizumab in patients with AS. However, it cannot eliminate the risk of recurrent CNV indicating the need to develop more effective strategies to arrest this visually debilitating condition.

Conclusions

IVB is a safe and effective option in the long-term stabilization of CNV due to AS.

Abstract

Background: Abnormal esophageal motility and low Lower Esophageal Pressure (LES) play an integral role among various etiologies implicated in pathogenesis and severity of Gastro Esophageal Reflux Disease (GERD). Delayed clearance of refluxate leads to prolonged mucosal exposure to gastro duodenal contents which promotes esophagitis and its complications. To find out the association of ineffective esophageal motility (IEM) and low Lower Esophageal Sphincter (LES) pressure with endoscopic esophagitis in patients presenting with symptoms of GERD. Settings and designs: Prospective cross sectional study done in a tertiary medical care center in south India from October 2016 to March 2017.

Methods: This cross sectional study was carried out among patients presenting with symptoms of GERD (heart burn and regurgitation,) at least twice per week for past three months. Based on their endoscopy findings patients with GERD are grouped into two having erosive and nonerosive reflux disease. After general and systemic clinical examination, High resolution Manometry was performed, and data was analyzed using Trace 1.2.3a V software. Statistical methods: Data was analysed using SPSS version 19. Chi square test was used to analyze categorical variables and independent 't' test was used for continuous variables.

Results: A total of 66 patients with GERD symptoms were subjected to esophageal manometry. Out of these 66 patients 42 were males and 22 were females with their mean age 40.82±12.86 years. Among 66 patients presented with GERD symptoms 26.7% were found to have ineffective esophageal motility and only 11.7% had low LES pressure. Ineffective esophageal motility was also found to be more common among older age group individuals with their mean age being 44.64 ±14.154. Among the patients with erosive reflux disease (70.21%), 66.7% had low LES pressure and 75 % had IEM; the association was not statistically significant.

Conclusions: The incidence of Ineffective esophageal motility in patients with GERD is found to be higher than that of low LES pressure. There was no significant association observed between IEM and low LES pressure with endoscopic esophagitis in patients with GERD.

Keywords: Chicago classification, Hypotensive sphincter, High Resolution Manometry, Ineffective peristalsis

Introduction

Globally Gastro Esophageal Reflux Disease (GERD) remains a highly prevalent disease with considerable geographic variation; estimated prevalence rate was found to be 18.1-27.8% in US and 8.8-25.9% in Europe, and less than 10% in Asian countries.[1] GERD causes significant pain and discomfort which compromise

patients' quality of living. It is considered as major risk factor for the occurrence of Barrett's oesophagus and oesophageal adenocarcinoma.[2,3]

Among multiple causes which constitute the pathogenesis of GERD abnormal esophageal motility plays a crucial role and also associated with disease progression and severity.[4] Delayed clearance of the refluxate leads to prolonged mucosal exposure to refluxed gastro duodenal contents which in turn promotes esophagitis and its complications. Prevalence of ineffective esophageal peristalsis was found to be 40-50% among GERD patients.[5]

Moreover, pattern of esophageal motility was found to be different in various sub classes of GERD patients. Abnormal motility pattern and low LES pressure observed in GERD patients are more likely to be related to endoscopic esophagitis. Esophageal High-Resolution Manometry (HRM) an advanced technique which gives a picture of change in intraluminal pressure from upper esophageal sphincter to lower one as well as motor activity of the esophagus while swallowing.[6]

Further studies are warranted to elucidate the role of dysmotility in patients with reflux disease. Hence, we proposed this study to find out the association of ineffective esophageal motility and low basal Lower Esophageal Sphincter (LES) pressure with their endoscopic findings in patients with GERD using High Resolution Manometry, which is the gold standard investigation to diagnose and evaluate esophageal motility disorders using new Chicago classification.

M□□□□□□□

This prospective cross sectional study was conducted among 66 patients of both sexes after obtaining ethical clearance from institutional human ethical committee. Study was conducted during the October 2016-March 2017 for duration of six months. Study participants belonged to the age group ranging from 20-65 years. Patients presented with symptoms of GERD (heart burn or acid regurgitation) at least twice a week for more than 3 months were included in the study after obtaining their informed consent. Patients with achalasia, esophageal or fundic varices, previous gastric or esophageal surgery, esophageal cancer, collagen diseases or previous ingestion of corrosive agents, acute cardiovascular, respiratory, digestive tract or metabolic diseases were excluded from the study.

Patients were asked to discontinue drugs such as nitrates and calcium-channel blockers which affect esophageal motor function 48hours before the manometry. Patients on proton pump inhibitors also were to ask with hold the drug for three weeks. Based on their endoscopic findings patients were categorized into two groups with erosive reflux disease and non-erosive reflux disease. After general and systemic clinical examination manometry was performed 2hours after endoscopy. Manometry was performed with a 16-channel water perfused catheter which has 8 channels placed 1 cm apart at the lower end and the remaining 8 channels were placed 3cm apart (Manufactured by RMH, Victoria, Australia. The data were analyzed using Trace 1.2.3a V software (Geoff Hebbard, Royal Melbourne Hospital, Victoria, Australia).

Manometry procedure

The manometry catheter was introduced by transnasal route. Basal LES pressure was recorded for 1 minute, which is followed by ten 5 ml wet swallows at an interval of 30seconds. 10 wet swallow frames show upper and lower esophageal sphincter relaxation and contraction of esophageal body is represented as isobaric color contour plot. Spatial and temporal analysis of esophageal motor events was made. Tests swallows are characterized based on HRM data using recently evolved Chicago classification.[7] According to Chicago classification it is considered as ineffective esophageal motility, when >50% of swallows are ineffective, that is either failed (DCI* <100 mmHg.cm.sec) or weak (DCI 100-450 mmHg·cm·sec).[8]

*DCI- Distal Contractile Integral- measure of how robust peristalsis is in the smooth muscle of esophagus

Analysis

Data was entered in excel sheet and analyzed using SPSS software version 19. Data was expressed as mean (SD) values for quantitative variables and percentages for continuous variables. Chi square test was used to analyze categorical variables and independent 't' test was used for continuous variables.

□□□□□□□□

A total of 66 patients with GERD symptoms were subjected to endoscopy and esophageal manometry. Out of these 66 patients 42 were males and 22 were females with their mean age 40.82±12.86. Four of the patients had hiatus hernia. Their clinical presentations were heart burn (48.8%), acid regurgitation (30.2%) chest pain (16.3%) and vomiting and nausea (4.7%). Among 66 patients presented with GERD symptoms 26.7% were found to have ineffective esophageal motility and only 11.7% had low LES pressure. 6% of patients with GERD had both low LES pressure and ineffective esophageal motility. Among 18 patients with ineffective esophageal peristalsis 38.8% had failed peristalsis and 61.1% had weak peristalsis. Ineffective esophageal motility was also found to be more common among older age group individuals with their mean age being 44.64±14.154. On upper GI endoscopy 48 patients had erosive reflux disease and 18 patients had non-erosive reflux disease. In the sub group of patients with erosive reflux disease, 66.7% had low LES pressure and 75 % had IEM and the association was not statistically significant (Table 1).

[illegible]	[illegible]		[illegible]
	[illegible]	[illegible]	
Normal lower esophageal sphincter pressure (%)	16 (26.7)	44(73.3)	0.727
Low Lower esophageal sphincter pressure (%)	2(33.3)	4(66.7)	
Normal esophageal motility (%)	13(28.3)	33(71.7)	0.785
Ineffective esophageal motility (%)	5 (25)	15(75)	

[illegible]

Low basal pressure of LES along with low amplitude and ineffective peristaltic waves in the distal esophagus was found to be a more common finding in patients with GERD.[9] In our present study ineffective esophageal motility was found to be higher when compared to low basal LES pressure. Kruse-Anderson et al also had observed increased fewer and low amplitude propagative peristalsis among patients with esophagitis when compared to controls.[10]

Abnormal Esophago Gastric Junction (EGJ), Transient Lower Esophageal Sphincter Relaxations (TLESRs), hypotensive Lower Esophageal Sphincter (LES), anatomic distortion of EGJ and ineffective esophageal peristalsis are found to be the major contributing factors for reflux of gastric contents into the esophagus. We found that ineffective esophageal motility was found to be the more significant abnormality found among GERD patients than low LES pressure as esophageal peristalsis is an important anti reflux mechanism which governs the clearance of refluxed gastric contents. Savarino et al also stated that abnormally low LES pressure, IEM, and hiatus hernia were found to be more prevalent in GERD patients than patients with functional heart burn and healthy controls.[11] Several studies had reported that GERD and its complications are more commonly observed in scleroderma patients, with failed or absent peristalsis which proved the role of esophageal clearance in the development of GERD.[12,13]

It was reported in recent studies that there occurs impairment of esophageal function such as reflux or dysphagia was found to be more prevalent among older individuals which starts from 40 years onwards.[14] In our study we observed increased incidence of ineffective esophageal motility in older patients with GERD. Gutschow et al in his study conducted among patients with reflux symptoms with and without GERD reported that there was significant decrease in peristaltic function in older patients with GERD than in younger patients.[15]

In our study low, LES pressure was found to be reported higher among patients with erosive reflux disease than in patients with Non-erosive reflux disease. Frazzoni et al in a comparative study conducted among GERD patients had observed lower mean LES pressure in patients with erosive and non-erosive reflux disease compared to controls.[16] Both LES pressure and peristaltic abnormality was found to be affected in reflux esophagitis. Somani et al also in this study described that severity of endoscopic esophagitis is inversely related with amplitudes of contraction in the distal esophagus.[17] In our present study ineffective esophageal motility was found to be reported more among patients with erosive reflux disease when compared to non-erosive reflux disease. Daum et al found peristaltic dysfunction in 56% of Non-Erosive Reflux Disease (NERD) and 76% of Erosive Reflux Disease (ERD), they also had observed that esophageal motility disorder was reported higher in GERD patients using HRM than with conventional manometry.[18] In contrast Lemme et al reported that there was no difference observed in the prevalence of IEM among non-erosive (38%) and erosive (38%) GERD patients.[19] Simren et al, also suggested that IEM had little influence on esophageal clearance during upright acid reflux and only severe esophageal motility disturbances, were associated with prolonged esophageal clearance in those with supine reflux.[20]

[illegible]

Ineffective esophageal motility was found to be higher than low basal LES pressure in patients with GERD. There was no significant association observed between IEM and low LES pressure in patients with endoscopic esophagitis. Hypotensive sphincter and Ineffective esophageal motility may be the cause for GERD and may not always associated with esophagitis.

Abstract

Background: Childhood obesity is a fast emerging problem in developing countries such as India because of lifestyle changes and economic transition.[1] Childhood overweight and obesity are major risk factors for many chronic diseases such as diabetes, hypertension, cardiovascular diseases, and cancer.[1–4] Effective preventive measures will prevent the risk of developing chronic diseases in adult life.

Objective: To study the prevalence of overweight and obesity among school children in a rural school in Coimbatore using the WHO standard reference for age 5–19 years.

Materials and Methods: A cross-sectional study was conducted along with annual school health check up for the children studying in a rural matriculation school located in Neelambur village, Coimbatore district. A total of 890 school children in the age group 5–15 years enrolled in the study were examined for height and weight, and BMI was calculated. The WHO standard reference for age 5–19 years was used to define overweight (>2SD) and obesity (>3SD).

Result: In our study, prevalence of overweight was 8.32% and prevalence of obesity was 4.72%. Among boys, prevalence of overweight and obesity was 8.43% and 6.43%, respectively. Among girls, prevalence of overweight and obesity was 8.20% and 2.96%, respectively. There is no statistical significant difference in the prevalence of overweight/obesity among boys and girls.

Conclusion: A high proportion of Rural School children in our study are having weight more than their normal weight, indicating the need for public awareness and preventive measures on childhood obesity. Intervention in the form of health education should be initiated at all levels of society to stop the progression of the problem.

KEYWORDS: Overweight, childhood obesity, body mass index, school children

Introduction

India is going through an economic and nutritional transition rapidly. In India under nutrition among children is common. Childhood obesity is also increasing in India due to increased purchasing power, decreasing physical activity, change in dietary habits, more comfortable and luxurious living.[1,2] Childhood obesity and overweight are associated with several risk factors for many chronic diseases such as diabetes mellitus, hypertension, cardiovascular diseases, and cancer.[3]

Estimating early childhood overweight and obesity during schooling helps in preventing disease progression into adulthood. Approximately 50%–80% obese children will continue as obese adults.[3] Studies on prevalence of obesity and overweight in Indian cities such as Delhi, Pune, and Chennai showed higher prevalence of obesity and overweight.[4–6] Different studies used different criteria to define childhood obesity and overweight such as International Obesity Task Force classification (IOTF), NCHS classification, Agarwal classification, and WHO classification.[7–10] So the

prevalence of overweight and obesity varies with each standard classification. Only few studies have been conducted using the WHO growth references.[25] The WHO defines childhood (5–19 years) overweight as >+2SD (equivalent to BMI 25 kg/m2 at 19 years) and obesity as >+3SD (equivalent to BMI 30 kg/m2).[25] This study was conducted to find out the prevalence of obesity and overweight among school children aged 5–15 years in a rural school in Coimbatore using the WHO growth references.[25]

Materials and Methods

This cross–sectional study was conducted along with annual school health check up for the children studying in a matriculation school located in Neelambur village, Coimbatore district. The study protocol was approved by Ethics committee of PSG Institute of Medical Science and Research, Coimbatore. The study was carried out after obtaining prior consent from school authorities, parents, and assent from children. A total of 890 school children in the age group 5–15 years were enrolled in the study.

Their age was verified from school registration records and rounded off to completed years. All anthropometric measurements were taken by medical professionals. Weighing scale and stadiometer were calibrated and validated by Department of Biometrics prior to the study. Height and weight were measured based on the WHO standards with sensitivity of 0.5 cm and 0.1 kg. Zero error was set after every 10 measurements. The children were made to stand straight with heels, buttocks, and back touching the vertical limb of the instrument and stretching upward to the fullest extent with arms hanging on the side. The head was aligned so that the lower rim of the orbit and the auditory canal were in horizontal plane (Frankfurt plane). Weight was measured without any footwear and with minimal clothing (school uniform) using Krup's weighing scale.

BMI was calculated and cut-off values for children as proposed by the WHO growth reference were used for defining overweight and obesity. The WHO defines childhood (5–19 years) overweight as >+2SD (equivalent to BMI 25 kg/m^2 at 19 years) and obesity as >+3SD (equivalent to BMI 30 kg/m^2).[25]

Statistical Analysis

Data entry and analysis was carried out using Statistical Package for Social Sciences (SPSS) version 19. All the entries were double checked and verified randomly. Prevalence of obesity and overweight was shown in percentage. χ^2-Test was carried out to find association of obesity and overweight among boys and girls.

Result

In the study, 890 school children were examined of which 451 (50.7%) were boys and 439 (49.3%) were girls [Tables 1 and 2]. In our study, the overall prevalence of overweight/obesity was found to be 13.03%. There is no statistically significant association between prevalence of overweight/obesity among boys and girls within this study [Table 3].

Discussion

In our study the prevalence of overweight and obesity among children in a private rural school was 8.32% and 4.72%, respectively. Prevalence of obesity was greater in boys when compared to girls (6.43% vs. 2.96%). Prevalence of overweight was almost equal in both sexes. There is no statistically significant association between prevalence of overweight/obesity among boys and girls within this study.

The prevalence in our study was higher compared to a study carried out in rural school in Udupi, Karnataka among school children aged 6–15 years using the WHO percentile criterion which showed prevalence of overweight and obesity as 1.5% and 1.3%,[9] respectively and also a study in Puducherry conducted among urban and rural school children using 85th percentile as overweight and 95th percentile as obesity which showed a prevalence of overweight as 4.98% and obesity as 2.24%,[6] respectively. But the prevalence is lower in our study when compared to a study in Pune using International cut-off points which showed prevalence of overweight as 19.9% conducted among affluent school boys[11] and also a study carried out in urban school children in Delhi using International cut-off points which showed a prevalence of overweight as 11.1% and obesity as 14.2%, respectively. [10] A study carried out in Karnataka using the WHO percentile criterion showed a prevalence of obesity in boys with 2.8% and in girls with 2.6%.[9] A study in Punjab using 85th percentile as overweight and 95th percentile as obesity showed prevalence of obesity and overweight was higher in boys when compared to girls (12.4% vs. 9.9%, 15.7% vs. 12.9%).[13] Our study that was conducted among private rural school children in Coimbatore showed a higher prevalence of overweight and obesity similar to urban school children in other studies. This might be because of lifestyle transition and economic improvement in rural area.

Difference in prevalence of overweight/obesity with other studies might be due to different standards used for estimation in other studies. In this study, the prevalence of overweight and obesity was analyzed using standard WHO growth references[25] among 890 school children age group 6–15 years. Not determining the risk factors for higher prevalence of overweight/obesity was a limitation to this study.

Complications of obesity during adult life worsen if obesity starts in childhood. Early prevention of childhood obesity is easier. It is recommended that high fat and junk foods should be avoided by children. Sedentary lifestyle should be discouraged and increased physical activity should be encouraged. Health education should be given to parents, children, and teachers regarding dietary habits and sedentary lifestyle.

Table 1: Age-wise distribution of overweight and obesity among boys

Age	Total	Normal weight *N* (%)	Underweight *N* (%)	Overweight *N* (%)	Obesity *N* (%)

Table 3: Prevalence of overweight and obesity by sex

	Overweight/obesity			χ2-value	*P*-value
	Present	Absent	Total		
Boys	66(14.63%)	385(85.37%)	451	2.07	0.150
Girls	50(11.39%)	389(88.61%)	439		

Conclusion

The results of the study shows that the prevalence of overweight and obesity among school children is becoming high in rural area which is an alarming signal and calls for an immediate action. Effective implementation of lifestyle modifications behaviors such as healthy diet intake, avoidance of high calorie foods, and promoting physical activity in early school life help in preventing future complications as a part of primordial preventive strategies.[1–4]

Key words:
Body mass index.

ABSTRACT

Objectives: To study the role of Body Mass Index as an independent risk factor and prognostic factor in breast cancer.

Methods: A hospital based epidemiological study was conducted in a tertiary care hospital in India involving 50 patients with a diagnosis of breast cancer who visited the Medical Oncology outpatient department for a period of 3 months. 50 age matched controls who had no detectable breast cancers were selected as controls. Their body mass index was calculated. Data including stage of breast cancer, lymph node status and presence of metastasis, histological type, grade of the tumour and hormone receptor status. (ER, PR and Her 2 neu) were tabulated. Additional information regarding menstrual, menopausal status, co-morbidities like Diabetes mellitus, hypertension and epilepsy was also gathered.

Results: The mean age of patients was 53.8 years and that of controls was 49.08 years. 56 % of cases and 44% of controls were post menopausal. 20 patients and 10 controls were diabetic; 14 patients and 9 controls were hypertensive and 2 patients and 2 controls had hypothyroidism. The odds ratio which quantifies the risk of association of breast cancer and obesity is 0.339 in premenopausal women and 0.045 in post menopausal women. The number of triple negative breast cancers was more in I and II classes of body mass index. Obesity grade 2 and 3 were also associated with advanced disease, including larger tumor size, positive lymph nodes, regional and/or distant stage and deaths after breast cancer.

Conclusion: There is a statistically significant association between obesity and breast cancer in post menopausal women but the same is not applicable in pre menopausal women.

INTRODUCTION

Obesity is increasingly becoming a major public health problem in developing countries. It is defined as an accumulation of adipose tissue that is of sufficient magnitude to impair health. Excess weight is best assessed by body mass index or BMI, which is a surrogate marker for underlying obesity. The normal BMI range is 18.5 to 25 kg/m^2 (Torre *et al*., 2015). According to World Health Organization (WHO) people can be divided into the following categories based on BMI. Approximately 7% of cancers in women are associated with obesity (van den Brandt *et al*., 2000). In women, a BMI greater than 25kg/m^2 correlated strongly with an increased incidence of carcinomas of esophagus, endometrium, gall bladder, breast and kidneys. A proposed hypothesis for such an association is explained by the presence of hyperinsulinemia and peripheral insulin resistance in obese individuals (Roberts *et al*., 2010). Insulin at high concentrations has multiple effects on cell growth.

i. Activation of phosphatidyl inositol 3 kinase, β catenin and RAS
ii. Hyperinsulinemia causes increase in insulin like growth factor 1, which is a mitogenic and anti apoptotic agent, which activates many of the cell growth pathways.
iii. Obesity increases the synthesis of estrogen from androgen precursors through an effect on adipose tissue aromatases.
iv. Insulin increases androgen synthesis in ovaries and enhances estrogen availability in obese persons by inhibiting production of sex hormone binding globulin in liver.

BMI	Classification
< 18.5	underweight
18.5–24.9	normal weight
25.0–29.9	overweight
30.0–34.9	class I obesity
35.0–39.9	class II obesity
≥ 40.0	class III obesity

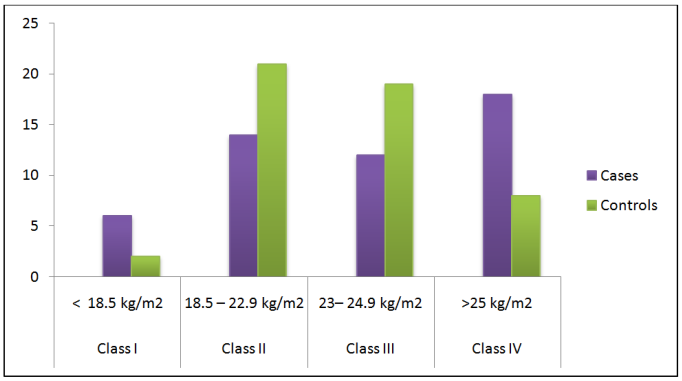
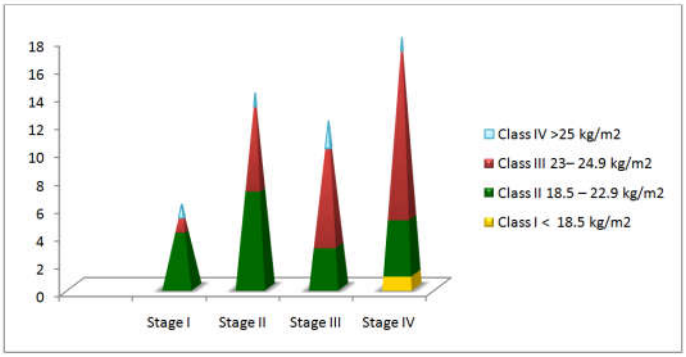
Obese women under the age of 40 have a decreased risk as a result of anovulatory cycles and lower progesterone levels. In contrast, post menopausal obese women have an increased risk, which is attributed to the synthesis of estrogen in fat deposits (Schmidt *et al*., 2015).

MATERIALS AND METHODS



A case control study was carried out at our tertiary care hospital. This was a single institution study drawn from patients who attended the medical oncology outpatient department over a period of three months. The women accompanying the patients and a few voluntary women who had no detectable breast cancers were selected as controls. The study protocol was approved by the Institutional Human Ethics Committee. Informed consent was obtained from every patient and control and the patients were asked to enter the details provided in a questionnaire. Results of their heights and weights were entered. As a relative indicator of body weight, Body Mass Index was calculated as weight in kilograms divided by square of height in meters. The patients and controls were categorized into 4 classes based on BMI.

Class I – BMI < 18.5 kg/m^2
Class II – BMI 18.5 – 22.9 kg/m^2
Class III – BMI 23 – 24.9 kg/m^2
Class IV – BMI > 25 kg/m^2



Data including stage of breast cancer, lymph node status and presence of metastasis was obtained from the case records of the patient. The histopathology reports were analyzed for recording the histological type, grade of the tumour and hormone receptor status (ER, PR and Her 2 neu).

Additional information regarding menstrual, menopausal status, co-morbidities like Diabetes mellitus, hypertension and epilepsy was also gathered. The results were tabulated and analyzed using SPSS (Statistical Package for the Social Sciences). The relationship between body mass index and risk of breast cancer was evaluated using odds ratio and the p value was calculated.

RESULTS AND OBSERVATION

50 women diagnosed with breast cancer during a period of 3 months were taken as cases and 50 women without a history of breast cancer were taken as controls. The mean age of patients was 53.8 years and that of controls was 49.08 years. 56 % of cases and 44% of controls were post menopausal. 20 patients and 10 controls were diabetic; 14 patients and 9 controls were hypertensive and 2 patients and 2 controls had hypothyroidism.

Body mass index in post menopausal women – Cross tabulation

Group	BMI ≤ 24.9 kg/m^2	BMI > 25.0 kg/m^2	P value	Confidence interval	Odds ratio
Cases	17 (60.7%)	11 (39.3%)			
Controls	19 (86.4%)	3 (13.6%)	0.045	0.058-1.024	.045

Histogram showing estrogen receptor expression in various classes of BMI

The odds ratio which quantifies the risk of association of breast cancer and obesity is .339 in premenopausal women and .045 in post menopausal women.

DISCUSSION

Overweight and obesity are current escalating public health issues. The prevalence of obesity in females has accelerated over the past decade in many developing countries. Obesity is an established risk factor for cancer and cancer related deaths, including that of breast cancers. Several studies show that a significantly stronger association is obvious between increased body mass index (BMI) and higher breast cancer incidence. Increased levels of estrogens due to excessive aromatization activity of the adipose tissue, over expression of pro-inflammatory cytokines, insulin resistance and hyper activation of insulin-like growth factors (IGFs) pathways, adipocyte-derived adipokines, hypercholesterolemia and excessive oxidative stress contribute to the development of breast cancer in obese women. Lopez *et al*. (2017) conducted a cross-sectional study of 849 women diagnosed with breast cancer in Columbian patients. Participant's body weight, height, and body mass index were collected at the time of diagnosis. Patients were classified following the Center for Disease control's (CDC) criteria: underweight (BMI $<$ 18.5 kg/m2), normal (18.5 $\leq$ BMI $<$ 25 kg/m2), overweight (25 $\leq$ BMI $<$ 30 kg/m2), and obese (BMI $\geq$ 30 kg/m2). Their data revealed that an association between BMI and menopausal status was not statistically significant in the study population. In the current study, the odds ratio of association was .339 with a p value of 0.23 in premenopausal women, which is not significant. However, the odds ratio in post menopausal women was .045 with a p value of .045 which is significant. Obese breast cancer patients are often associated with advanced stage disease, larger tumors, and axillary lymph node-positive status, partly due to delayed diagnoses and technical difficulties in palpation of the tumors. In a study conducted by Turkos *et al*. (2013), obese patients compared with normal-weight women were older at diagnosis and more often had high grade tumor with lymphovascular invasion. According to the molecular subtypes, overall survival and disease free survival were significantly shorter in obese patients with triple negative breast cancer. Obesity and lymphovascular invasion were found to be independent prognostic factors for TNBC mortality. In our study also we found that more number of obese breast cancer patients presented with stage III or IV disease, although the association was not statistically significant.

The study done by Sahin *et al*. (2017) BMI was an independent factor in patients with BC, with an association indicating a decreased incidence for luminal-like subtype and increased incidence for triple-negative subtype among premenopausal patients. However, this significance was not found in postmenopausal patients. Accordingly, a plausible etiological heterogeneity in BC might play a role among immunohistochemical subtypes in every life stage of women. Makama *et al*. (2017) published an association study of established breast cancer reproductive and lifestyle risk factors with tumour subtype defined by the prognostic 70-gene expression signature. Using prognostic gene expression profiles, they found that specific reproductive factors like higher parity was associated with low-risk (good prognosis) tumours. Also, longer duration of breastfeeding was associated with high-risk (poor prognosis) tumours. Neuhouser *et al*. (2015) performed a randomized control study and detected that A BMI of 25.0 or higher was strongly associated with risk for estrogen receptor-positive and progesterone receptor-positive breast cancers but was not associated with estrogen receptor-negative cancers. In our study we found that there was no significant difference in the distribution of estrogen receptor positive tumours and Her 2 neu positive tumours in obese and non obese patients. However, the number of triple negative breast cancers was more in I and II classes of body mass index. Obesity grade 2 and 3 were also associated with advanced disease, including larger tumor size, positive lymph nodes, regional and/or distant stage and deaths after breast cancer. An article by Schmitz *et al*. (2013) proposes that obesity and related co morbid conditions pose an increased risk for common adverse treatment effects, including breast cancer–related lymphedema, fatigue, poor health–related quality of life, and worse functional health. But we did not notice any significant difference in the post treatment morbidity among obese and non obese individuals.

Limitations of our study

The sample size of our study is limited to derive a statistically significant association of obesity and malignancy. The follow up was for a period of 6 months to one year and so the response of obese and non obese patients to the various treatment strategies could not be compared.

Conclusion

There is a valid association between obesity and breast cancer in post menopausal women but the same is not applicable in pre menopausal women. There is no significant difference in the size, histological type and immunohistochemical profile of breast cancers in obese and non obese patients, although the incidence of triple negative cancers was high in class I and class II BMI individuals. However obese patients presented with more advanced stages, possibly due to delay in detection.

Peer Educators as Change Leaders – Effectiveness of Peer Education Process in Creating Awareness on Reproductive Health among Women Workers in Textile Industry

Suvetha Kannappan, Karthikeyan Shanmugam[1]

Department of Community Medicine, PSG Institute of Medical Sciences and Research, Coimbatore, Tamil Nadu, [1]Department of Community Medicine, Government Medical College, Palakkad, Kerala, India

Abstract

Context: India is one of the leading manufacturers of garments with roughly 80% of the workforce dominated by female migrant workers. Lack of education and access to resources in these women contribute to unsafe sexual behaviors, sometimes leading to unwanted pregnancies or sexually transmitted infections (STIs). Awareness raising, and peer education in particular, is extremely effective in addressing reproductive health issues. **Aims:** This study aims to study the effectiveness of peer health education in improving the awareness on reproductive health among women workers in textile industries. **Settings and Design:** A health educational interventional study for women in garment and spinning mills using peer education process carried out over a period of 18 months. **Subjects and Methods:** The process includes orientation to factory management, health needs' assessment, identifying health topics, peer educators' selection, peer educator trainings followed by outreach sessions, and impact measurement. The impact of peer education on reproductive health has been assessed among 597 participants from 9 factories. **Statistical Analysis Used:** Data were entered in SPSS version 24 and analyzed. Results were expressed as percentages. Chi square test was used where appropriate to find association between categorical variables. **Results:** The mean age of the workers in both the groups is 25.4 (±9.6) years and 25.1 (±8.3) years. In both the groups, most of the workers were single and more than half of them reside within the factory premises. Significant change in menstrual hygiene practices, knowledge in family planning methods, STIs, and cervical cancer has been observed following peer health education. **Conclusions:** A well-designed health educational interventional program using peer educators could be a successful approach to create awareness on sensitive topics.

Keywords: Peer health education, reproductive health, textile industry, women workers

Introduction

India has made a name for itself as a garment manufacturing center of global renown. The textiles and garments industry contributes 16.63% of India's export earnings. However, India's niche in the global garments market has been carved out at the cost of lakhs of workers in this industry's predominantly female and migrant labor force. Roughly 80% of garment workers are women between the ages of 21 and 25. Most are semi-skilled migrant workers and the sole earning members in their families.

These women workers often suffer from anemia, poor hygiene, inadequate pre- and post-natal care, sexual violence, and exposure to infections and illness. Lack of education and access to resources contribute to unsafe sexual behaviors, sometimes leading to unwanted pregnancies or sexually transmitted infections (STIs). They also contribute to high rates of malnutrition, maternal and infant mortality, and the spread of sexually transmitted and other preventable diseases such as HIV/AIDS and tuberculosis.[1]

Facility-based studies done in Chennai[2] and other parts of India[3] have shown that unwanted pregnancies among young

unmarried women are high and emphasize the need for educating them about contraceptives. Data from subnational study conducted in 2006 have shown that around 80% of young women perceive the need for family life education. The same study has shown that peers are the major sources of information regarding contraception.[4]

Awareness raising, and peer education in particular, is extremely effective in addressing reproductive health issues. Women are grateful for such education focusing on personal and family health, with information they have seldom received before. An environment focused on education rather than behavior change empowers the women to make better health choices for themselves.

Peer education typically involves training and supporting members of a given group to affect change among members of the same group. The peer education model initiated by business for social responsibility for improving health of women at factories has proven to be an effective model that encourages women to share their knowledge with other family and community members extending the benefits well beyond the factory floor.[5,6] A study conducted among women workers in garment industries has shown that peer education approach is effective in raising the awareness on STIs. The study also concludes that it is likely that the health education program may help to reduce the burden of healthcare costs to the community in the long run.[7]

This study looks into the effectiveness of peer health education in improving the awareness on reproductive health among women workers in textile industries.

Subjects and Methods

This study is part of an ongoing health education program done by the Department of Community Medicine for women workers in garment and spinning mills located within 100 kilometer radius from our institution. Pooled baseline and endline assessment data of 597 workers from nine industries which include six spinning mills and three garment factories have been analyzed for the study purpose. The study has been approved by the institution's human ethics committee.

Data were entered and analyzed using statistical package for social sciences (SPSS) version 19 (IBM SPSS statistics Company, IBM corporation). Results are presented as percentages. Chi-square test is done for statistical association wherever appropriate.

Salient steps of the health education program

As part of the program, baseline assessment is conducted by survey method using a prevalidated questionnaire among 10% of women workers chosen by simple random sampling. Health education was then conducted by peer education process. Peer educators were selected by the factory representatives(supervisory level) using the following guidelines: workers who have ability to read and write in local language, working in the factory for at least one year and having exhibited leadership skills. As a measure to ensure sustainability, nurse, female human resource (HR) representatives, and volunteers from staff level were also included. Peer educator strength in each factory ranged from 10 to 20 proportionate to the total strength of the women workforce.

Peer education process

Health education in reproductive health issues focused on menstrual hygiene and reproductive tract infections, STIs including HIV and hepatitis B, family planning and cancers. Health education sessions for the peer educators were conducted once in 2 months. Each session was conducted for over 2 h by interactive lecture aided by flip charts and videos supplemented with demonstrations where appropriate. Participatory methods such as body mapping exercise were used to teach anatomy of reproductive system. Energizers were conducted to break monotony and avoid boredom.

Following the session, peer educators conduct outreach sessions during weekends, lunch breaks, etc., for their coworkers in small groups ranging between 10 and 15. These sessions were facilitated by the HR department in coordination with the nurse. Informal discussions also took place in leisure times in the dormitories. A refresher session was conducted after a month following the main session to reemphasize the important points and clarify any doubts the peer educators might have. An endline assessment at the end of the program was done among 10% of randomly chosen workers.

Results

The pooled data of 597 female workers interviewed during baseline (316) and endline (281) assessment were included for analysis. The mean age of the workers in both the groups is 25.4 (±9.6) years and 25.1 (±8.3) years.

Table 1 shows the distribution of the female workers based on certain sociodemographic variables.

Table 1: Distribution of workers based on certain sociodemographic variables

Sociodemographic variables	Baseline (%) (n=316)	Endline (%) (n=281)
Mean age (years)	25.4±9.6	25.1±8.3
Marital status		
Single	69.3	71.8
Married	29.8	26.4
Divorced/widowed/separated	0.9	1.8
Educational status		
None	7.7	6.8
Primary	27.5	30.0
Secondary	53.8	52.5
Postsecondary	11.0	10.7
Residence		
Within the factory premises	52.2	67.3
Home outside factory	47.8	32.7

In both the groups, most of the workers were single and more than half of them reside within the factory premises.

Table 2 shows the comparison of practices during menstruation before and after intervention. A statistically significant ($P < 0.01$) improvement in frequency of changing pads has been observed before and after intervention. The results also reveal a significant ($P < 0.01$) decrease in menstrual problem-related absenteeism.

A significant increase in knowledge on awareness about family planning and its methods has been observed following the intervention [Table 3].

Knowledge regarding both HIV and hepatitis B has improved significantly among the workers, but very few women (17.1%) had awareness about hepatitis B before intervention compared to HIV where the preintervention knowledge was 74.4% [Table 4].

During baseline assessment, it was observed that only 40% women have heard of cervical cancer, and among them, only 24.6% were aware about the symptoms [Table 5]. Following health education, significant increase in knowledge has been observed.

Discussion

The mean age of the female workers in the textile industry is around 25 (±9 years). Similar age profile was observed in studies conducted among women workers in textile industries in Bangladesh and China.[8,9] Around 30% of the workers in our factories have no or limited literacy. This finding is similar to studies done in other parts of India,[10] but low literacy rate in Chinese workers is only around 2%.[9] More than half of the workers in our study population reside the dormitories within the factories. This is in contrast to situation in others places[8] where most workers come from their residence. Women of younger age together with limited literacy and being away from home warrant need for creating awareness and providing enabling environment for reproductive health issues in industries.

Peer education process is a successful method in bringing about awareness, especially in sensitive health issues. Peer educators could be powerful change agents as evidenced by interventional studies in HIV/AIDS using peer educators.[11,12] Our study has also proven that peer education process has led to significant change in knowledge and practice in reproductive health issues. A significant improvement in menstrual hygiene practices (59.7% vs. 84.2%, $P < 0.05$) and decrease in absenteeism (36.6% vs. 27.2%, $P < 0.05$) during menstruation has been observed. There is slight increase in the proportion of workers using sanitary pads, but this difference is not statistically significant. This could be due to a relatively higher proportion of workers already using sanitary pads.

Although 75% of women have heard about family planning methods, the baseline assessment findings showed that only around a quarter of them could mention few contraceptive methods. Peer educators were able to bring a significant improvement in knowledge on the different contraceptive methods (8.2% vs. 55.6%, $P < 0.05$). This is important considering the age profile of the workers and most of them being away from home. Our study has shown that peer education has been effective in bringing about a significant awareness about various contraceptive methods.

Educational intervention on STI focusing on HIV and hepatitis B has brought a significant increase in awareness, especially in hepatitis B (17% vs. 89%, $P < 0.05$). Many of the workplace based health educational interventions focus mainly on HIV[13] even though the awareness on hepatitis B is very low[14] conducted among women in reproductive age. Our study also showed that the preintervention knowledge was only 17%.

Despite being the leading cause of all cancers among women in India, the awareness of cervical cancer and its symptoms was

Table 2: Comparison of certain practices during menstruation before and after intervention

Parameters	Baseline ($n=303$) (%)	Endline ($n=279$) (%)	*P*
Frequency of changing pads more than two times a day	181 (59.7)	235 (84.2)	0.000
Absenteeism during menstruation	111 (36.6)	78 (27.9)	0.026
Use of sanitary pads during menstruation	277 (91.4)	261 (93.5)	0.748

P<0.05 is considered statistically significant

Table 3: Knowledge regarding family planning and its methods

Parameters	Baseline ($n=316$) (%)	Endline ($n=281$) (%)	*P*
Heard of family planning	231 (74.3)	257 (94.5)	0.000
Can mention at least two methods of family planning	26 (8.2)	176 (55.6)	0.000

P<0.05 is considered statistically significant

Table 4: Knowledge regarding HIV and hepatitis B

Parameters	Baseline ($n=316$) (%)	Endline ($n=281$) (%)	*P*
Heard of HIV	235 (74.4)	260 (92.5)	0.000
Heard of Hepatitis B	54 (17.1)	250 (89.0)	0.000

P<0.05 is considered statistically significant

Table 5: Knowledge regarding cervical cancer and its symptoms

	Baseline (%)	Endline (%)	*P*
Heard of cervical cancer	(n=316) 126 (39.9)	(n=281) 247 (87.9%)	0.000
Heard of cervical cancer symptoms	(n=126) 31 (24.6)	(n=247) 193 (78.1)	0.000

P<0.05 is considered statistically significant

less among our study population. Community-based studies in other parts of the country have shown even higher level of lack of awareness.[15] Our study showed a significant improvement in knowledge of cervical cancer (39.9% vs. 87.9%, $P < 0.05$), and its symptoms were brought about following health education (24.6% vs. 78.1%, $P < 0.05$).

Conclusions

A significant increase in knowledge and practice has been brought about in menstrual hygiene, family planning methods, STIs, and cervical cancer. Our study has shown evidence that peer education approach is effective in bringing about significant change in knowledge in reproductive health issues. A well-designed health educational interventional program using peer educators could be a successful approach to create awareness on sensitive topics.

ABSTRACT

Background: Under normal circumstances, a woman's uterus sheds a limited amount of blood during each menstrual period (around 80 ml). Bleeding that occurs erratically or excessive menstrual bleeding is called abnormal uterine bleeding (AUB). The causes of AUB are many and varied. Initial investigations include transvaginal ultrasound and histopathologic assessment of the endometrium. Objective of this study was to evaluation of endometrial thickness with trans-vaginal ultrasound and its correlation with histopathology by dilatation and curettage in abnormal uterine bleeding. To determine the efficacy of transvaginal ultrasound in evaluating the endometrial thickness. To correlate the endometrial thickness by transvaginal ultrasound with endometrial histopathology in women with AUB.
Methods: It is a retrospective observational study. All reproductive and perimenopausal age group women who underwent dilatation and curettage for abnormal uterine bleeding during the period June 2014-June 2016 was taken and analyzed and correlated with their endometrial thickness measured with Transvaginal ultrasound.
Results: Around 478 patients who underwent endometrial sampling over a period of two years were analyzed. Maximum number of patients were in the fourth decade and the overweight category 36.6%. Proliferative endometrium was the most common histopathologic picture (44.76%). Detection of precancerous lesions were-5.87% and endometrial cancer was 1.05%.
Conclusions: An ET of 8 mm and above gave 100% sensitivity and negative predictive value for precancerous and cancerous lesions.

Keywords: Abnormal uterine bleeding, Dilatation and curettage, Endometrial hyperplasia and cancer, Endometrial thickness, Transvaginal ultrasound

NTRODUCTION

Abnormal uterine bleeding is one of the most common gynecological problems in patients approaching the outpatient clinics in the country. These complaints definitely affect the quality of life of the patient. The etiology of AUB varies with the age group of the patient. There is the PALM COEIN classification for AUB by FIGO.[1] There are many diagnostic modalities for evaluating endometrial pathologies in women who have AUB. Transvaginal sonogram (TVS) has permitted the use of higher frequency ultrasound waves at greater proximity of the uterus. It is a relatively cheap and non-invasive diagnostic modality for studying the endometrial pattern and its thickness and at the same time to exclude organic pathology in case of AUB while dilatation and curettage gives us a definitive histopathologic picture. This study attempts to correlate the USG findings and histopathology in patients with AUB. The gold standard

for diagnosing AUB is hysteroscopy and directed biopsy but it is expensive when compared to the simple endometrial sampling. According to the PALM COIEN classification the causes of AUB can be divided into structural and non-structural cause which is given in detail in Table 1.

Table 1: PALM COEIN classification for AUB.[1]

Structural	Non structural
Polyps	Coagulopathy
Adenomyosis	Ovulatory dysfunction
Leiomyomas	Endometrial hyperplasia
Malignancy	Iatrogenic
	Not yet specified

Aims and objectives of this study were

- Evaluation of endometrial thickness with trans-vaginal ultrasound and its correlation with histopathology by dilatation and curettage in abnormal uterine bleeding.
- To determine the efficacy of Transvaginal ultrasound in evaluating the endometrial thickness.
- To correlate the endometrial thickness by Transvaginal ultrasound with endometrial histopathology in women with AUB.

METHODS

Retrospective observational study included all reproductive and perimenopausal age group women who underwent dilatation and curettage for abnormal uterine bleeding during the period June 2014 to June 2016.

Inclusion criteria

- AUB in all reproductive and perimenopausal women
- Only gynecological indications for dilatation and curettage.

Exclusion criteria

- Unmarried women
- Pregnancy and related causes of bleeding
- Postmenopausal bleeding
- Puberty menorrhagia.

From minor and major OT registers, list of all D and Cs which were done during 2014 June to 2016 June was taken. Cases which satisfied the inclusion and exclusion criteria was taken and analyzed

Statistical analysis

Chi square test was used for the statistical analysis.

RESULTS

All the patients with abnormal uterine bleeding, fitting the inclusion criteria, who underwent endometrial sampling was taken for analysis. There were around 478 patients. All of them had a premenstrual ultrasound before the procedure. The age distribution, parity, BMI, presenting complaints, the histopathology and the endometrial thickness by TVS was evaluated. The results are given below:

Of the 478 patients, the youngest patient was 22 years old and the oldest was 55 years, the mean age was 38.5 years. Maximum number of patients were in the 41-50 years age group which was 60.25% and the least in the 20-30 years group and was 4.6% (Table 2).

Table 2: Age distribution of patients with AUB.

Age	No. of cases	%
20-30	22	4.60%
31-40	117	24.48%
41-50	288	60.25%
51-60	51	10.67%
Total	478	100%

Majority of the patients were multiparious i.e. 79.71% and 2.93% was nulliparous as seen in (Table 3).

Table 3: Parity of the patients with AUB.

Parity	No. of cases	%
Nullipara	14	2.93%
Primipara	83	17.36%
Multipara	381	79.71%
Total	478	100%

A total 35.8% of the patients under analysis were of the normal BMI and maximum numbers of patients were overweight-36.6% and the least number of patients were underweighted i.e. 3.3% as given in Table 4.

Table 4: BMI of patients with AUB.

BMI	No. of cases	%
Underweight	16	3.3%
Normal	171	35.8%
Overweight	175	36.6%
Obese	116	24.3%
Total	478	100%

A total 98.3% had heavy menstrual bleeding among the 478 patients and 72.4% had undergone tubal ligation. Among the other USG findings, adenomyotic changes were found in 11.1%, fibroids seen in 18.6%, while simple ovarian cysts were found in 11.7% and PCO in 4.2%.

There were 42 cases of hormone induced changes, 25 menstrul endometium, 17 were inadequate and 2 were TB endometritis which were all entered under others.44.7%

were having proliferative phases (Figure 1), of which 29.7% was disordered proliferative (Figure 2). 30.33% showed secretory changes (Figure 3) endometrial adenocarcinoma (Figure 4) was found in 1.05% of the cases and hyperplasia was seen in 5.86% (Table 5).

Table 5: Histopathology findings in study population.

HPR	No. of cases	Percentage	
Disordered proliferative	142	29.7%	44.76%
Proliferative	72	15.06%	
Secretory	145	30.33%	
Endometrial hyperplasia	28	5.86%	
Endometrial carcinoma	5	1.05%	
Others	86	17.99%	
Total	478	100%	

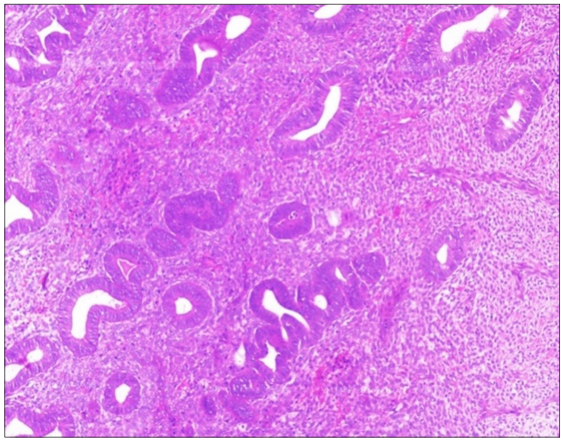

Figure 1: Proliferative endometrium.

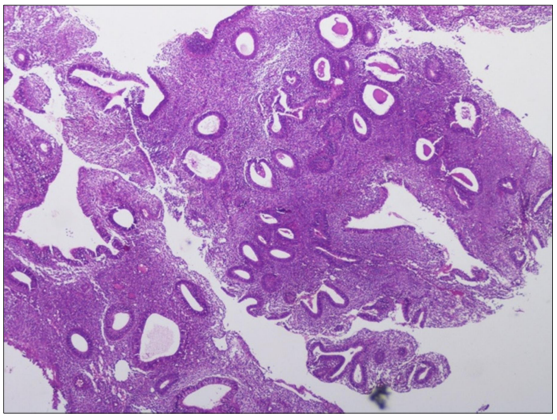

Figure 2: Disordered proliferative.

Among the hyperplasia, 50% was simple hyperplasia without atypia. Atypical hyperplasia (Figure 5) was found in 12 cases. Complex hyperplasia was found in 13 out of the 28 cases of hyperplasia of which complex atypical was 11 cases (Table 6).

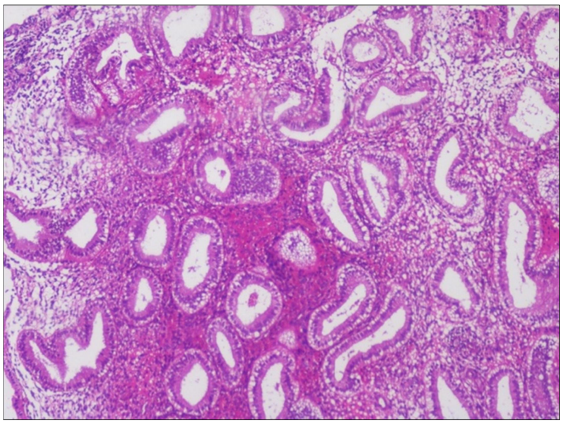

Figure 3: Secretory endometrium.

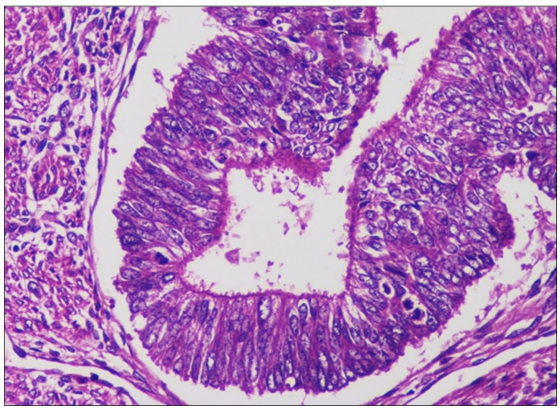

Figure 4: Adenocarcinoma.

Table 6: Cases of endometrial hyperplasia.

Type of hyperplasia	Number	%
Simple hyperplasia without atypia	14	50%
Simple hyperplasia with atypia	1	3.57%
Complex hyperplasia without atypia	2	7.14%
Complex hyperplasia with atypia	11	39.29%
Total	28	100%

Endometrial thickness was 8mm and above up to 15 mm in majority of cases of AUB-54.81%. ET less than 8mm was found only in 19.3% of the study population.ET 15 mm and above was also less which was 25.5% (Table 7). ET less than 4mm in AUB was very less-only 1.67%. One ET was not measured due to diffuse adenomyosis. Out of the 477 patients whose endometrial thickness were measured, all the five cases of endometrial carcinoma was found with an ET ≥15 mm among the 28 cases of endometrial hyperplasia 12 cases of hyperplasia were also found with ET ≥15 mm and the rest 16 cases had ET ≥8-15 (Table 8). Surprisingly all the five cases of carcinoma was endometrioid adenocarcinoma.

It was found in this study that proliferative and secretory endometrium was maximum when the endometrial

thickness was ≥8-15 mm and least with an ET less than 4 mm (Table 9).

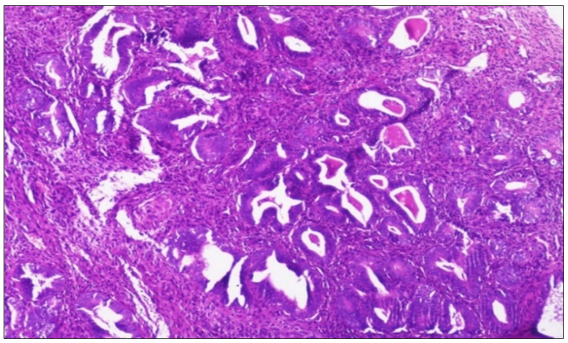

Figure 5: Atypical hyperplasia.

Table 7: Endometrial thicknesses by transvaginal ultrasound.

ET IN mm	Number	%
<4	8	1.67%
4-8	85	17.78%
≥8-15	262	54.81%
≥15	122	25.52%
Not measured	1	0.22%
Total	478	100%

If we take 8 mm as the cut off, we can see that in this study population all the cases of hyperplasia and malignancy had an ET ≥ 8 mm. Out of the 384 cases with ET ≥ 8 mm 28 cases had hyperplasia and five patients had endometrial carcinoma i.e. 8.59% (Table 10).

Table 8: Co-relation of et with endometrial hyperplasia and carcinoma.

ET in mm	Number	Endometrial hyperplasia	%	Endometrioid carcinoma	%
≥15	122	12	9.84%	5	4.46%
≥8-15	262	16	6.11%	0	0%
4-8	85	0	0%	0	0%
<4	8	0	0%	0	0%
Total	477	28	5.87%	5	4.46%

Table 9: Co-relation of et by TVS and histopathology.

ET	Number	Proliferative	Secretory	EH	Carcinoma	Others
<4 mm	8	3	3	0	0	2
4 - <8	85	34	29	0	0	22
≥8-15	262	121	86	16	0	39
≥15	122	56	27	12	5	22
Total	477	214	145	28	5	85

Table 10: Co-relation of endometrial thickness with hyperplasia and malignancy.

ET in mm	Number	Hyperplasia and carcinoma	%
≥8	384	33	8.59%
<8	94	0	0%

Table 11: Co-relation of endometrial thickness with HPR.

ET in mm	Number	Hyperplasia and carcinoma	Not having carcinoma
≥8	384	33 (a)	351 (b)
<8	94	0 (c)	94 (d)

Sensitivity, specificity, the positive and negative predictive value for an ET of ≥8 mm was calculated. 94 patients with ET less than 8 and 351 patients with ET ≥8 mm did not have carcinoma (Table 11).

- Sensitivity = a/a + c =33/33 = 100%
- Specificity= d/b + d = 94/445 = 21.12%
- Positive predictive value = a/a + b = 33/384 = 8.59%
- Negative predictive value = d/c + d = 94/94 = 100%

DISCUSSION

Abnormal uterine bleeding is a very common diagnosis in the op population. According to this study the maximum age groups of the patients were in the perimenopausal age of 41-50 years-around 60.25%. This is similar to the study by Shobitha et al -68.1% in the same age group while it was 38% in a study by Mahapatra M et al where the study group was less.[2,3]

The youngest patient was a 22-year-old primary infertility patient with heavy menstrual bleeding for which diagnostic curettage was done and had an ET of 6 mm and secretory endometrium.

In this study, 79.7% were multiparious while 2.93% were nulli, in almost all the studies this is similar. This is in accordance to the study by Nidhi et al, where 88% were multipara and 1.2% were nulliparous.[4] In a study by Betha K et al 81% were multipara.[5]

BMI was in the overweight category in 36.6% and obese in 24.3% in this study which is similar to the study in Iran by Kazamijalezah et al, where it was 33% and also with the study by Sahai A et al, where 56.2% were in overweight category and obese was 25%.[6,7]

There was heavy menstrual bleeding in 98% of patients.

Of these 478 patients only 39 had diabetes as risk factor and out of 39 one had endometrial carcinoma.

When we analyze the histopathologic findings of the 478 cases 44.5% was proliferative endometrium, of this disordered proliferative endometrium seems to be the commonest, in a study by Elavarasan et al, where disordered proliferative endometrium seems to be the commonest pattern observed i.e. 31.1%.[8] The term disordered proliferative endometrium refers to proliferative phase that does not seems to be appropriate for any one time in the menstrual cycle and mimics simple hyperplasia, but the process is focal rather than diffuse. Histologically there shows mild disorganization of architecture, with focal dilated glands, with normal gland to stromal ratio. In this study 30% was secretory endometrium; endometrial hyperplasia was found in 5.8% and endometrial cancer in 1%.

Transvaginal ultrasound was done to assess the endometrial thickness and it was done in the premenstrual phase, of the 478 cases 54.8% had an ET of ≥8-15, 25.5% had ET more than 15 mm. In a study by Jikki et al, 57% had et ≥8 mm which is similar to this study of 54%.[9]

In the study by Jikki et al, the endometrial hyperplasia was seen in 96.4% cases when ET was more than 8 mm and in this study 100% of the patients with endometrial hyperplasia had ET ≥8 mm.[9] In this study 100% cases of endometrial carcinoma occurred with ET ≥15 and all cases of hyperplasia had ET ≥8 mm.

Simple hyperplasia without atypia was 50% in this study which was comparable to 62% in a study by Tabata et al.[10]

Complex endometrial hyperplasia was 14.8% in a study conducted by Idris et al, while their atypical hyperplasia was only 2% whereas atypical hyperplasia was 42.4% in this study.[11] This may be because of the fact that most of the patients in the study group were in the fourth decade (60%) and in their study was in the third decade (80%).

Of the 384 cases with ET ≥8 mm, 33 had endometrial hyperplasia and carcinoma, and 351 did not have e/o hyperplasia and carcinoma, none of the cases below 8mm had any e/o hyperplasia or carcinoma. Sensitivity and negative predictive value was 100% for an ET of ≥8 mm. This is similar to studies by Chatpavit Getpook an ET of 8 mm showed optimal sensitivity and specificity -83.9% and 58.8% respectively and 90.4% negative predictive value for an abnormal endometrium.[12] They concluded that an ET of 8mm or less is less likely to be associated with malignant pathologies. In this study the negative predictive value was 100% and sensitivity was 100% but the specificity was only 21.1%. According to a study by Ozdemir S et al, there was negative predictive value of 95.6%, sensitivity and specificity of 83.6 and 56.4% respectively for an ET of 8 mm.[13]

Kurman et al, classified hyperplasia in to simple and complex and subcategory as atypical.[14] The 2014 revised WHO classification simply separates endometrial hyperplasia into 2 groups-hyperplasia without atypia and atypical hyperplasia.[15] According to the EIN classification all atypical endometrial hyperplasia is classified as endometrial intraepithelial neoplasia.[15] Progesterone was found to cause regression in 90% cases with hyperplasia.

The RCOG cutoff of ET is less than 7 mm below which there is no endometrial hyperplasia in a prospective study of 56 women with pcos.[11,16] In studies by Gianella et al, 11 mm was taken as the cut off.

The most common presenting symptoms of endometrial hyperplasia is abnormal uterine bleeding. According to studies, the risk of progression of simple hyperplasia to carcinoma is 1% and complex hyperplasia with atypia is 29%.[18]

CONCLUSION

The clinical importance of endometrial hyperplasia is because of its progression to endometrial carcinoma. An ET of 8 mm in this study gives a 100% negative predictive value for hyperplasia and carcinoma and can be taken as a cut off for deciding the patients for dilatation and curettage especially in low risk patients.

Abstract

Introduction: India is the first country to implement National Family Program in 1952. Acceptance of contraceptive methods is influenced by various factors at the individual, family, and community level with their roots in the socioeconomic and cultural milieu of Indian society. This study was carried to find the contraceptive prevalence rate among eligible couples as well as to find the factors influencing it in a rural area of Coimbatore. **Methodology:** The study was carried out using the data extracted from the family health survey conducted by trained field staff for the purpose of furnishing details regarding people residing in the field practice area of Rural Health Training Centre (RHTC), Vedapatti located in Coimbatore district after obtaining Institutional Human Ethical clearance. All eligible couples were included for the study. Contraceptive prevalence is expressed in percentage with 95% Confidence interval. Univariate analysis (Chi-square test) was done to find the association between contraceptive acceptance and independent variables. Strength of association is determined by odds ratio with 95% Confidence Interval (CI). $P < 0.05$ was considered statistically significant. **Results:** Contraceptive Prevalence Rate among eligible couples was found to be 75% (95% CI: 73.6–76.4). Most commonly used method among the study participants was tubectomy (81.6%), followed by condoms (11.4%), intrauterine devices (6.3%), and oral contraceptive pills (0.7%). Higher age of the women, religion, educational status of the women, socioeconomic status, working status of the women, number of living children, age at the time of marriage, and age at the time of first child birth were found to have statistical significant association with higher usage of contraception. **Conclusion:** The contraceptive prevalence rate was found to be higher in this study population and multiple factors were influencing the contraception usage among the eligible couples.

Keywords: Contraceptive prevalence, eligible couples, rural population

Introduction

Population explosion has been the major problem of India since Independence.[1] Considering the consequences, population stabilization has been identified as an essential prerequisite for the economic development of the nation resulting in improved quality of life.[2] India became the first country in the world to formulate National Family Planning Program in 1952, with the objective of "reducing birth rate to the extent necessary to stabilize the population at a level consistent with requirement of national economy."[2,3] As per the projections by United Nations, India will become the most populous country by the year 2045. One of the important components of family planning program management is to assess the potential demand for contraceptive services so as to mitigate the adverse impact of population growth.[4] Family planning can reduce maternal mortality by reducing the number of pregnancies, abortions, and the proportion of births at high risk.[5]

How to cite this article: Osborn JA, Rm S, Karthikeyan S, Ravishankar SL. A study on contraceptive prevalence rate and factors influencing it in a rural area of Coimbatore, South India. J Family Med Prim Care 2021;10:2246-51.

Many empirical studies have shown the acceptance of contraceptive methods is influenced by various factors operating at the individual, family, and community level with their roots in the socioeconomic and cultural milieu of Indian society.[6] The contraceptive prevalence rate is "the percentage of women of reproductive age (15–49 years) who are married or in a union: Who are currently using, or whose sexual partner is currently using, at least one contraceptive method, regardless of the method used".[7,8] Contraceptive prevalence rate serves as a proxy measure of access to reproductive health services and is an indicator of health, population, development, and women's empowerment[7,8] that are essential for meeting many of the Sustainable Development Goals (SDG), especially the child mortality and maternal health related goals.[8]

If the population has ready access to good quality services at affordable cost, it will be possible for them to meet all their needs, achieve the desired family size, and enable the country to achieve population stabilization rapidly.[1,9] Majority of India's population (about 70%) live in the rural communities[9] but majority of the health facilities are concentrated in the urban localities leading to a disparity in access to health care. Contraceptive use is influenced by a wide range of factors including demographic, social, and economic characteristics.

There is paucity of community-based rural studies with regard to contraceptive usage. Identifying the prevalence of contraceptive usage and the local determinants could help to plan strategy and make necessary recommendations that would help improve utilization of family planning services. Hence, this study was carried out to determine the contraceptive prevalence rate among eligible couples as well as to study the association of selected social, economic and demographic factors with contraceptive usage in a rural area of Coimbatore.

Methodology

The study was carried in accordance with the ethical standards of PSGIMSR Institutional Human Ethics Committee and Ethical Principles for Medical Research was followed. The Ethics committee approval was obtained prior to carrying out the study. Date of approval : 18/12/2019. The Institute permission was obtained prior to carrying out the study. In the current study, the data were extracted from the family health survey conducted by trained field staff for the purpose of furnishing details regarding people residing in the field practice area of Rural Health Training Centre (RHTC), Vedapatti, a rural area of Tamil Nadu located in Coimbatore district. The RHTC caters to 14 villages with a population of 25,886.

Sample size was calculated based on NFHS IV report- Contraceptive Prevalence Rate of rural Tamil Nadu was 52.3%.[10] Using the formula, $n = 4\,pq/d^2$ where P is 52, q is 100-52, that is, q = 48 and d is the relative precision (5% of p), the sample size required was estimated to be 1,477. Though the required sample size was only 1,477, all 4,438 eligible couples in the field practice area were included for the current study and their data was analyzed.

Various demographic, social, and economic factors like age of women, number of children, age at marriage, age at first child birth, religion, caste, family type, educational status of husband and wife, working status of women, socioeconomic status classification (based on Modified Prasad classification - Class I – ≥Rs. 6,414; Class II – Rs. 3,207–6,413; Class III – Rs. 1,924–3,206; Class IV – Rs. 962–1,923, and Class V - ≤Rs. 961) were included in the study.

Statistical analysis

Data was entered in Microsoft excel and analyzed in SPSS 20.0 version Univariate analysis (Chi-square test) was used to find out the association between the independent variables and the dependent variable. Odds ratio was calculated with 95% Confidence Interval (CI) to find the strength of association. $P < 0.05$ was considered as statistically significant.

Results

Total number of eligible couples enrolled in the study was 4,438.

The demographic profile of the participants is shown in the Table 1. Majority of the participants (41.3%) were in the age group of 35–49 years, 96.3% of women were Hindus. Majority of married women (70.4%) were living in nuclear families, 64% were

≥18 years	3481	78.4

having two children, 26% of the women in the study population got married before completion of 18 years and 21.6% women delivered a baby before completion of 18 years.

Table 2 shows that most of the eligible couples were educated up to middle school. Female literacy rate was 84.8%, whereas male literacy rate was 87.3%. Higher proportion (37.4%) belonged to Class IV socioeconomic class and 31.4% women were employed with salary.

Out of 4,438 eligible couples studied, 3,328 were current users of contraception at the time of the survey. Hence, the Contraceptive Prevalence Rate was 75% (95% CI: 73.6–76.4%) in this study population. Table 3 shows the various family planning methods adopted by the eligible couples. Most common preferred method was tubectomy (81.6%), followed by condoms (11.4%), intrauterine devices (IUDs) (6.3%), and oral contraceptive pills (OCPs) (0.7%).

Not working	3044	68.6

Table 3: Various family planning methods adopted by eligible couples

Family Planning Method Adopted	Number (Percentage)
Tubectomy	2717 (81.64)
Condom	378 (11.36)
Intra Uterine Device (IUD)	210 (6.31)
Oral Contraceptive Pill (OCP)	22 (0.66)
Vasectomy	1 (0.03)
Total	3328 (100)

The demographic factors influencing the contraception acceptance is shown in Table 4. The significant predictors for contraceptive acceptance are higher age of women, those who are having two living children, women who are married after 19 years of age, and those who had given birth to first child after 19 years of age.

The social and economic factors influencing the contraception acceptance is shown in Table 5. Factors like higher educational level of women, working women, and higher socioeconomic class are significantly associated with adoption of any of the contraceptive method.

Discussion

Contraceptive use and unmet need for family planning are keys to understand profound changes in fertility pattern and also helps to improve reproductive health. By understanding the concept of unmet needs, the gap between women reproductive intentions and contraceptive behavior can be understood. In this study, Contraceptive Prevalence Rate among eligible couples was found to be 75%, which is higher than studies reported by NFHS IV (52.3%),[10] Patel AA (55.3%),[11] Singh *et al.* (68.4%),[1] Makade *et al.* (68.4%),[12] and Gupta *et al.* (71.1%).[13] The contraceptive acceptance is quite high among the study population.

Most common method followed by the eligible couples was permanent method, that is, tubectomy (81.6%) which is higher than other studies by Shree *et al.* (70.9%),[14] Patel AA, *et al.* (33.7%),[11] and Nanda *et al.* (30.5%).[15] In our study, 11.4% couples use condoms which is similar to study done by Chandra *et al.* (11.7%)[3] and higher than Nanda *et al.* (5.1%).[15] Usage of IUDs was 6.3% which is lower than study done by Nanda *et al.* (45.8%)[15] and Shree *et al.* (11.3%).[14] Another important finding as that only one male individual has undergone vasectomy. This clearly portrays that even though permanent sterilization method in male (i.e., vasectomy) is an easier procedure and has lesser postoperative symptoms the responsibility for birth control still traditionally rests with the woman since she has to undergo the physical and psychological burden of unplanned pregnancy.

In our study, contraception usage showed significant association with higher age of the women, religion, education of the women, higher socioeconomic class, working status of the women, presence of two living children, age at the time of marriage as well as first child birth more than 18 years of age. There was no significant association with type of family, educational status of husband and caste.

In this study, the usage of contraception was significantly higher among those who were aged 35–49 years. The contraceptive acceptance was three times higher than those of aged 15–24 years, probably these couples would have completed their family. Similar findings were reported by Patel AA,[11] Valekar SS, *et al.*,[16] and Prateek *et al.*[2] wherein women of age group 35–49 years are using better contraception. The

contraceptive usage was significantly low (34.5%) among Muslims than Hindus (75.3%) but the proportion of Muslims was low in this study. This result was consistent with other studies like Singh AK, *et al.*[1] and Chandra *et al.*[3] The reason for lower usage of contraception among the Muslim couples could be because of religious and cultural beliefs on contraception. Hence, religion still plays a predictor role on deciding the choice of contraception.

Education of women leads to a greater awareness and a significant effect on family planning behavior and use of contraception. Our study revealed significantly higher usage of contraception among literates when compared with the illiterates. The literates will be able to understand the pros of contraceptive usage which could have brought the behavioral change. This result was consistent with studies done by Singh AK, *et al.*[1] Patel AA,[11] Gupta *et al.*,[13] Kumar N, *et al.*,[17] and Oppong FB, *et al.*[18] Improving education status can pave way to delay a women's marriage age, she will be able to seek a job and can help to change the attitude toward birth spacing and family size and empowers women to make a better decision.

In our study, contraceptive use was significantly higher among working women as they are more likely to be educated and their socioeconomic status is supposed to be better than the non-working women. Working women are likely to be more knowledgeable; would have wide exposure to media and social contacts which can influence their contraceptive behavior. This finding was similar to study done by Mukherjee *et al.*[19]

In the present study, it was found that as the socioeconomic status decreases, the usage of contraception also decreases. Contraception usage is significantly higher among class I when compared to Class V. This may be due to the fact that the higher socioeconomic status individuals have better accessibility and availability of contraception and they have better awareness regarding contraception. Similar finding was reported by Prateek *et al.*[2]

Number of living children had a significant impact on contraceptive usage. Those women who had completed their family by getting at least two children (small family norm) are using contraception higher than others. This may be due to the fact that many couples decided to complete their family with two children and also female sterilization (after institutional deliveries) was emphasized for women after they bear two children. Government policies and advisory of two child norm and benefits announced could have favored contraception acceptance by these couples. This finding was consistent with study done by Singh *et al.*[1] Shree *et al.*[14] Valekar SS, *et al.*,[16] and Gothwal M, *et al.*[20] Contrastingly, it was also found contraceptive usage was higher among those having two children compared with couples having three or more

Working status of women					
Not Working	2190 (71.9)	854 (20.1)	1		
Working	1138 (81.6)	256 (18.4)	1.73	1.48-2.03	<0.01

children. This could be due to the fact the need for contraception is not well appreciated by these couples.

Age at the time of marriage and age at time of first child birth also showed significant association with contraceptive usage. Those women who got married or gave birth before the age of 18 years used less contraception when compared with those who got married or gave birth to child after the age of 18 years. This may be because the former individuals are less aware of the contraceptive methods and their maturity levels are not favorable. Hence delaying the age of marriage of women as well as delaying the age of first child birth more than 18 years could have a positive impact on contraceptive acceptance. But studies by Prateek *et al.*[2] and Valekar SS, *et al.*[16] did not show significant association between contraception usage and age at marriage or age at first child birth.

Our study did not reveal association of contraception use and educational status of husband. This result is consistent with study done by Valekar SS, *et al.*[16] But studies by Prateek *et al.*[2] and Shree *et al.*[14] has shown association between educational status of husband and contraception usage. The current study did not show significant association of contraception use with caste and type of family, but a study by Nanda *et al.*[15] has shown significant association of contraception with caste and studies conducted by Singh *et al.*[1] and Valekar SS, *et al.*[16] has shown individuals in nuclear family are accepting the family planning methods higher than those in extended family.

This study has few limitations because other confounders which can influence the contraceptive prevalence like knowledge about contraception, sex preference, female autonomy, and unmet needs of contraception were not studied. Despite the data being retrieved from the routine family health survey, the reliability of the data is not a major concern as it was collected by trained field workers for purpose of family health survey.

Conclusion and Recommendation

From our study, it is obvious that the contraceptive prevalence was high among the study population and epidemiological factors like higher age of the women, religion, education of the women, higher socioeconomic class, working status of the women, presence of two living children, age at the time of marriage, as well as first child birth more than 18 years of age are influencing the contraception acceptance. Measures to sustain the gains of the family planning program should be given priority to sustain population stabilization and to achieve Net Reproductive Rate of one. Hence, on the first-hand targeted health awareness among those who are not using contraception could help to bring about a behavioral change so contraception usage can be maximized. Secondly, outreach contraceptive services should be intensified and expanded for easy access without fear of stigma by the society. Thirdly, reproductive health programs and policies should adequately involve men, by encouraging and motivation to adopt vasectomy as an easy method of family planning.

Acknowledgements

The authors appreciate and thank the efforts put forth by the medical officers and field staffs who worked in the Rural Health Training Centre for carrying out the family health survey in the field practice area.

Evidence for a hyper-reductive redox in a sub-set of heart failure patients

Thiagarajan Sairam[2], Amit N. Patel[3], Meenu Subrahmanian[2], Rajendiran Gopalan[4], Steven M. Pogwizd[5], Sudha Ramalingam[2], Ramalingam Sankaran[2*] and Namakkal Soorapan Rajasekaran[1,2,6*]

Abstract

Background: Oxidative stress has been linked to heart failure (HF) in humans. Antioxidant-based treatments are often ineffective. Therefore, we hypothesize that some of the HF patients might have a reductive stress (RS) condition. Investigating RS-related mechanisms will aid in personalized optimization of redox homeostasis for better outcomes among HF patients.

Methods: Blood samples were collected from HF patients (n = 54) and healthy controls (n = 42) and serum was immediately preserved in − 80 °C for redox analysis. Malondialdehyde (MDA; lipid peroxidation) levels by HPLC, reduced glutathione (GSH) and its redox ratio (GSH/GSSG) using enzymatic-recycling assay in the serum of HF patients were measured. Further, the activities of key antioxidant enzymes were analyzed by UV–Vis spectrophotometry. Non-invasive echocardiography was used to relate circulating redox status with cardiac function and remodeling.

Results: The circulatory redox state (GSH/MDA ratio) was used to stratify the HF patients into normal redox (NR), hyper-oxidative (HO), and hyper-reductive (HR) groups. While the majority of the HF patients exhibited the HO (42%), 41% of them had a normal redox (NR) state. Surprisingly, a subset of HF patients (17%) belonged to the hyper-reductive group, suggesting a strong implication for RS in the progression of HF. In all the groups of HF patients, SOD, GPx and catalase were significantly increased while GR activity was significantly reduced relative to healthy controls. Furthermore, echocardiography analyses revealed that 55% of HO patients had higher systolic dysfunction while 62.5% of the hyper-reductive patients had higher diastolic dysfunction.

Conclusion: These results suggest that RS may be associated with HF pathogenesis for a subset of cardiac patients. Thus, stratification of HF patients based on their circulating redox status may serve as a useful prognostic tool to guide clinicians designing personalized antioxidant therapies.

Keywords: Hyper-reductive, Hyper-oxidative, Heart failure, Circulatory redox state, Reductive stress

Background

There is a general consensus that oxidative stress induces various pathophysiological processes including cardiovascular complications [1, 2]; however, counteracting antioxidant supplementations have failed to prevent the progression or curtail disease pathogenesis [3, 4]. At present, it is not clear whether oxidative stress is a cause or consequence in a given cell or organ system exhibiting a chronic disease state. Therefore, it is vital to critically analyze the global redox milieu of patients experiencing chronic illnesses including heart failure (HF). HF is a progressive condition in which the cardiac muscle weakens and becomes inefficient to meet the body's demand for blood and oxygen supply. The etiology of HF is multifaceted as several genetic, biochemical, electrical and inflammatory factors have been shown to underlie the structural and functional remodeling that develops over time [5–8]. Based on the currently available literature, a majority of

the HF conditions have been correlated with oxidative stress for the past several decades. In particular, ischemic heart disease and/or reperfusion injury have been shown to display a hyper-oxidative state wherein increased reactive oxygen and nitrogen species (ROS/RNS) generation correlates with a worsening of myocardial injury [9–11]. In spite of these observations, supplementation with antioxidants seems to be inefficient to treat such conditions in a failing heart [12–14]. In particular, pre-clinical observations using rodent models have documented that a forced induction of oxidative stress leads to "heart failure" and pre-treatment with potential antioxidants seems to be protective [15–17]. However, these findings were not reproducible in HF patients [18–20].

To the best of our knowledge, all HF studies have focused on documenting the differences between HF patients and healthy control groups, and have not examined the potential for individual variations in the context of redox status among HF patients. Importantly, findings based on a group may not be precise to each individual of that group. Therefore, considering the inconsistent effects of antioxidant trials in human patients, it is worth testing whether all HF patients experience similar redox state. The ROS/RNS produced during basal mitochondrial metabolism (oxygen consumption at resting state) or in response to physical activity are key modulators of cellular motility to maintain a redox homeostasis and preserve the dynamic function of the myocardium [21–24]. However, other factors including genetic or chronic stresses that modulate ROS/RNS may tip the redox milieu towards either direction of the redox spectrum (i.e. reductive or oxidative). Despite several studies demonstrating the futility and/or detrimental effects of antioxidants, there has not been a single study attempting to understand the mechanisms associated with failure of the antioxidants in over six decades of biomedical research. In the present study, we attempt to address this critical gap in knowledge and postulate that some HF patients may either exhibit a hyper-reductive or normal redox state potentially conferring vulnerability and inimical side effects to antioxidant treatment.

In the current study, we determined the circulatory redox state of HF patients by measuring glutathione redox (GSH:GSSG) ratio, lipid peroxidation (MDA) and the activities of key antioxidant enzymes to compare with the healthy control group. Moreover, we utilized the ratio of GSH/MDA as a peripheral redox index and focused on stratifying HF patients according to this measure. Our findings revealed a surprising but meaningful observation in that there appears to be distinct subsets of HF patients exhibiting divergent redox signatures. Therefore, our data indicates that not all HF patients have oxidative stress as traditionally reported. Our pilot observations in this small cohort of HF patients (n = 54) warrant a new redox-based classification in these patients for selecting an appropriate therapy.

Methods

Study population

Our study population included heart failure (HF) patients (n = 54) (with systolic or diastolic dysfunction, dilated cardiomyopathy or biventricular dysfunction) and healthy controls (n = 42) who attended the in-patient and out-patient department of cardiology in PSG Hospitals, Tamil Nadu, India. Their characteristics are tabulated in Table 1. Patients with HF who were diagnosed using Framingham criteria were considered for this study [25]. Patients on dialysis, as well as those exhibiting severe liver diseases, malignancies or consuming antioxidant supplements were excluded from the study. While 85% of patients were admitted to the hospital for the first time, the remaining were presented for follow-up visits. The patients were treated as per the existing guidelines at the time. Briefly, the patients were categorized into those displaying heart failure (HF) with reduced ejection fraction (HFrEF) and preserved ejection fraction (HFpEF). The patients with HFrEF received stage-appropriate medications such as ACE inhibitors or Beta Blockers or ARBS alone or in combination, along with diuretics. Mineralocorticoid Receptor Antagonists and Hydralazine were also added if required. Patients with HRpEF had diuretics as their main stay along with the treatment of underlying causes such as coronary artery disease, chronic kidney disease, HF, atrial fibrillation etc. The study was approved by the PSG Institutional Human Ethics Committee (IHEC) and all patients/subjects completed a written informed consent prior to their participation.

Reagents

Supplies and reagents were purchased from Sisco Research Laboratories (India) unless otherwise specified.

Clinical assessment and echocardiography

Validation and confirmation of HF in patients were made based on clinical and echocardiography assessment. One echocardiogram was selected for each patient at the time of enrollment. Two-dimensional and M-mode echocardiography, color flow and spectral Doppler as well as annular TDI data were obtained from all patients and healthy controls using an ultrasound system (Philips IE33, Netherlands). Standard views, including the parasternal long axis view, short axis at the papillary muscle level and apical four and two chamber views were recorded. Cardiac chamber dimensions, volumes and left ventricular mass were measured according to current recommendations [26]. Left ventricular ejection fraction (LV EF) was

calculated using the teichholz formula [27]. Mitral Doppler signals were recorded in apical 4 chamber view, with Doppler sample volume placed at the tip of the mitral valve leaflets. The following parameters were obtained: early diastolic mitral inflow peak velocity (E), late diastolic mitral inflow peak velocity (A) and their ratio.

Blood sampling

Blood samples were obtained by venipuncture using a 21-gauge needle from the patients and healthy control subjects in plain tubes. Serum was separated by centrifugation at 3000 rpm for 5 min at 4 °C and immediately aliquoted and frozen at − 80 °C. A fraction of the serum was

treated with 10% meta-phosphoric acid (MPA) to remove proteins and the MPA-supernatant was stored for glutathione redox analysis instantly after the blood collection for all the controls and patients. The stored aliquots of serum were used for analyzing redox status and the activities of antioxidant enzymes.

Lipid peroxidation

Serum malondialdehyde levels were measured by the DNPH (2,4-dinitrophenyl hydrazine) derivatization method [28]. Briefly, 125 µl of serum was diluted in 125 µl 1× PBS (pH 7.4), mixed with 50 µl of 6 M NaOH and incubated at 60 °C for 30 min. 125 µl of 35% perchloric acid was then added to the mixture. 250 µl of this mixture was combined with 25 µl of 5 mM DNPH (in 2 M HCl) and incubated in the dark for 30 min. An aliquot of 25 µl of the solution was injected into the HPLC system (Shimadzu, Japan). The mobile phase of 0.2% (v/v) acetic acid and acetonitrile (50:50 v/v) was run at a flow rate of 0.5 ml/min at 25 °C. A C18 column (Agilent, USA) was used and the chromatograms were obtained at 310 nm. Concentration of MDA was measured after comparing with a reference curve using TMP (1,1,3,3-tetramethoxypropane) as a standard.

Reduced glutathione levels

The spectrophotometric based glutathione reductase/5,5′-dithio-bis (2-nitrobenzoic acid) (DTNB) recycling assay was used to measure reduced glutathione (GSH) levels as per [29–31] with minor modifications. In short, metaphosphoric acid extracts of serum samples were prepared and treated with triethanolamine (TEAM reagent) to adjust the pH for total GSH quantification according to the manufacturers' protocols (GSH redox Kit #CS0260, Sigma-Aldrich). An aliquot of TEAM treated samples were mixed with 1.0 mM 2-vinyl pyridine and incubated for 1.0 h at room temperature for GSSG measurements. For enzymatic recycling, the processed samples were treated with a reaction mixture containing 0.25 mM dithiobis-nitrobenzoic acid (DTNB), 0.38 U/ml Glutathione reductase and 60 µl of 0.17 mM NADPH in 0.1 M sodium phosphate buffer (pH 7.4) with 5 mM EDTA. The rate of DTNB formation was measured at A412 nm. Similarly, GSH and GSSG standards were treated and measured to obtain a standard graph to extrapolate the values from serum samples. The concentration of reduced glutathione (GSH) was estimated by subtracting the measured oxidized (GSSG) glutathione levels from the measured total (GSH plus GSSG) glutathione. GSH/GSSG ratio was then determined.

Superoxide dismutase (SOD) activity

Superoxide dismutase activity in the serum samples were measured using the pyrogallal auto-oxidation method [32]. This assay was carried out in a microtiter plate and the readings were measured using multimode reader (Varioskan Flash, Thermoscientific, USA). Approximately 50 µl of serum was treated with 25 µl ethanol and 15 µl chloroform. The contents were vortexed and centrifuged at 8000 rpm for 5 min and the supernatant was analyzed for SOD activity by mixing with 50 mM Tris–HCl buffer with 1.0 mM EDTA, pH 8.2 and 2.0 mM pyrogallal (in 50 mM HCl). The rate of autoxidation was measured from the increase in absorbance at 420 nm and the values were expressed as U/ml.

Catalase activity

The activity of catalase in serum of HF and HC samples was measured by H_2O_2 decomposition kinetics using a spectrophotometer [33]. A mixture containing potassium phosphate buffer (50 mM, pH 7.0), 20 mM H_2O_2 and 2.0 µl serum was used to measure the rate of decrease in optical density at 240 nm. Catalase activity was expressed as U/l.

Glutathione reductase activity

Glutathione reductase activity was assayed by monitoring NADPH oxidation linked to GSSG reduction [34] using a spectrophotometer. The assay was performed by suspending 10 µl of the serum in sodium phosphate buffer (0.3 M, pH 6.8), 25 mM EDTA, 20 mM GSSG, 2 mM NADPH and measuring the decrease in absorbance at 340 nm over time. The oxidation of 1 µmol of NADPH/min was used as a unit of glutathione reductase activity. Glutathione reductase activity was expressed as U/l.

Glutathione peroxidase activity

Glutathione peroxidase (GPx) activity was measured by a spectrophotometric assay using 5,5′-dithio-bis (2-nitrobenzoic acid) (DTNB) according to [35] where the oxidation of GSH in the presence of H_2O_2 takes place, and the unused GSH reacts with DTNB whose absorbance was measured at 412 nm. The enzyme assay was performed by incubating the serum (25 µl) in sodium phosphate buffer containing sodium azide (10 mM), GSH (4 mM) and 2.5 mMH_2O_2 for 5 min. Protein was precipitated using 10% trichloroacetic acid, centrifuged at 5000 rpm for 5 min, and the supernatant was assayed. This assay was carried out in a microtitre plate and the readings were measured using multimode reader (Varioskan Flash, Thermoscientific, USA) after mixing with disodium hydrogen phosphate (0.3 M, pH 7.0) and 100 mM DTNB (in 1% sodium citrate) at 412 nm. GPx activity (U/l) was measured as the amount of GSH consumed/min/mg protein after reaction with GPx and DTNB.

Protein estimation

Serum proteins were estimated using Bradford method. A known volume (5 µl) of 1:100 diluted serum was incubated in Bradford reagent (#18004246723, Biorad, USA) and measured the absorbance at 595 nm. The absorbance was extrapolated with the appropriate standard reference curve using bovine serum albumin (0.031–0.5 mg/ml) and the protein concentration was calculated. Specific activity for the antioxidant enzymes were measured after normalizing with the respective protein concentration.

Statistical analysis

For comparing two groups, Mann–Whitney U test was used for non-normal data and for groups with normal distribution, group mean ± standard deviation (SD) were compared, homogeneity variance test (Bartlett's test) followed by one way ANOVA was carried out. A $p > 0.05$ was considered to be statistically significant. Fisher's exact test was performed to analyse statistical significance of EF fraction and E/A ratio among the different groups of HF patients. For data which was not normally distributed, a nonparametric test, Kruskal–Wallis test was carried out to obtain the p value. All the statistical analyses were carried out using GraphPad Prism software version 5.0 Windows (GraphPad Software, USA).

Results

Stratification of heart failure patients based on circulatory redox status

Circulatory redox state (CRS) was assessed by quantifying the levels of reduced glutathione (GSH), a ubiquitous, small molecular antioxidant redox couple and malondialdehyde (MDA), an end-product of lipid peroxidation (Fig. 1). Compared to the healthy controls (HC; n = 42), circulating GSH levels were unchanged in HF patients (n = 54) (0.09207 ± 0.1215 µM in HF patients vs. 0.06374 ± 0.04887 µM in HC; p = NS; Fig. 1a), suggesting a wide range of redox states among the HF patients. In addition to total glutathione levels, the ratio of reduced to oxidized glutathione (GSH:GSSG) did not differ between HF and HC (4.93 ± 7.25 in HF patients vs. 3.01 ± 1.78 in HC; p = NS; Fig. 1c). In contrast, MDA was significantly higher in HF patients vs. HC (4.342 ± 2.103 vs. 1.566 ± 0.3018 µM, respectively; $p < 0.0001$) (Fig. 1b), suggesting that increased lipid peroxidation is coupled with the development of HF. Therefore, we next assessed whether the redox index (reduction vs. oxidation) is significantly different between the groups. Comparisons of GSH/GSSG ratio revealed insignificant differences between the groups, indicating that the HF patients seem to exhibit a wide range of redox levels in relation to HC (4.93 ± 7.25 in HF patients vs. 3.01 ± 1.78 in HC; p = NS; Fig. 1c). Therefore, our approach for stratifying HF patients used CRS (i.e. GSH/MDA) to gain more knowledge and understand the pathogenesis. But, comparisons of GSH/MDA ratios between the HF and HC yielded a statistically significant result (0.02 ± 0.0345 in HF patients vs. 0.04 ± 0.028 in HC; $p < 0.0001$; Fig. 1d). Therefore, we were interested in stratifying the HF patients based on their circulating redox score (CRS) (Fig. 1d). The CRS of healthy subjects was designated as normal redox (NR). A CRS value in any patient lower than the NR displayed by HC was regarded as hyper-oxidative (HO) while a patient exhibiting a GSH/MDA ratio greater than the NR cutoff was classified as hyper-reductive (HR). Surprisingly, our CRS-based stratification revealed three distinct classes within our cohort of HF patients (Fig. 1e). Along these lines, 41% of HF patients were assigned to the normal redox (NR) group whose mean GSH/MDA ratio was similar to HC. Next, 42% of HF patients belonged to the hyper-oxidative (HO) class whose mean GSH/MDA ratio (0.004787 ± 0.002055) was lower than HC group (0.03969 ± 0.02857), and 17% of HF patients exhibited a hyper-reductive (HR) state in which mean GSH/MDA ratio (0.2271 ± 0.03192) was greater than HC group (0.03969 ± 0.02857). Interestingly, the GSH/MDA ratios were statistically significant among all three HF groups ($p < 0.0001$) by one way ANOVA analysis. These novel observations suggest that redox status plays a variable role in the progression of HF and that both extremes (e.g. oxidative and reductive) may contribute to disease pathogenesis.

Activities of antioxidant enzymes were significantly altered in HF vs. healthy controls

To assess the capacity of the endogenous antioxidant defense system in the periphery of HF patients, we further analyzed the activity of circulating antioxidant enzymes such as superoxide dismutase (SOD), glutathione reductase (GR), catalase, and glutathione peroxidase (GPx) among the various groups of HF patients (Fig. 2). SOD (Fig. 2a), Gpx (Fig. 2b), catalase (Fig. 2c), GR (Fig. 2d) did not show any statistically significant differences among NR, HO, and HR groups of HF patients. While the activities of SOD (6.455 ± 2.30 for HO, 6.646 ± 2.556 for NR, 6.400 ± 1.752 for HR vs. 2.571 ± 0.61 U/ml for HC; Fig. 2a), GPx (527.2 ± 343.4 for HO, 413.3 ± 243.7 for NR, 581 ± 310.2 for HR vs. 312 ± 141.4 U/l for HC; $p < 0.01$; Fig. 2b), and catalase (855.2 ± 776.5 for HO, 787.8 ± 454.9 for NR, 1068 ± 590.3 for HR vs. 689.1 ± 556.8 U/l for HC; $p < 0.05$; Fig. 2c) were significantly increased, GR activity was significantly lower (11.66 ± 5.5 for HO, 14.29 ± 9.86 for NR, 13.32 ± 6.79 for HR vs. 24.70 ± 28.22 U/l for HC; $p < 0.05$; Fig. 2d) in all HF patient groups (HO, NR and HR) relative to healthy controls.

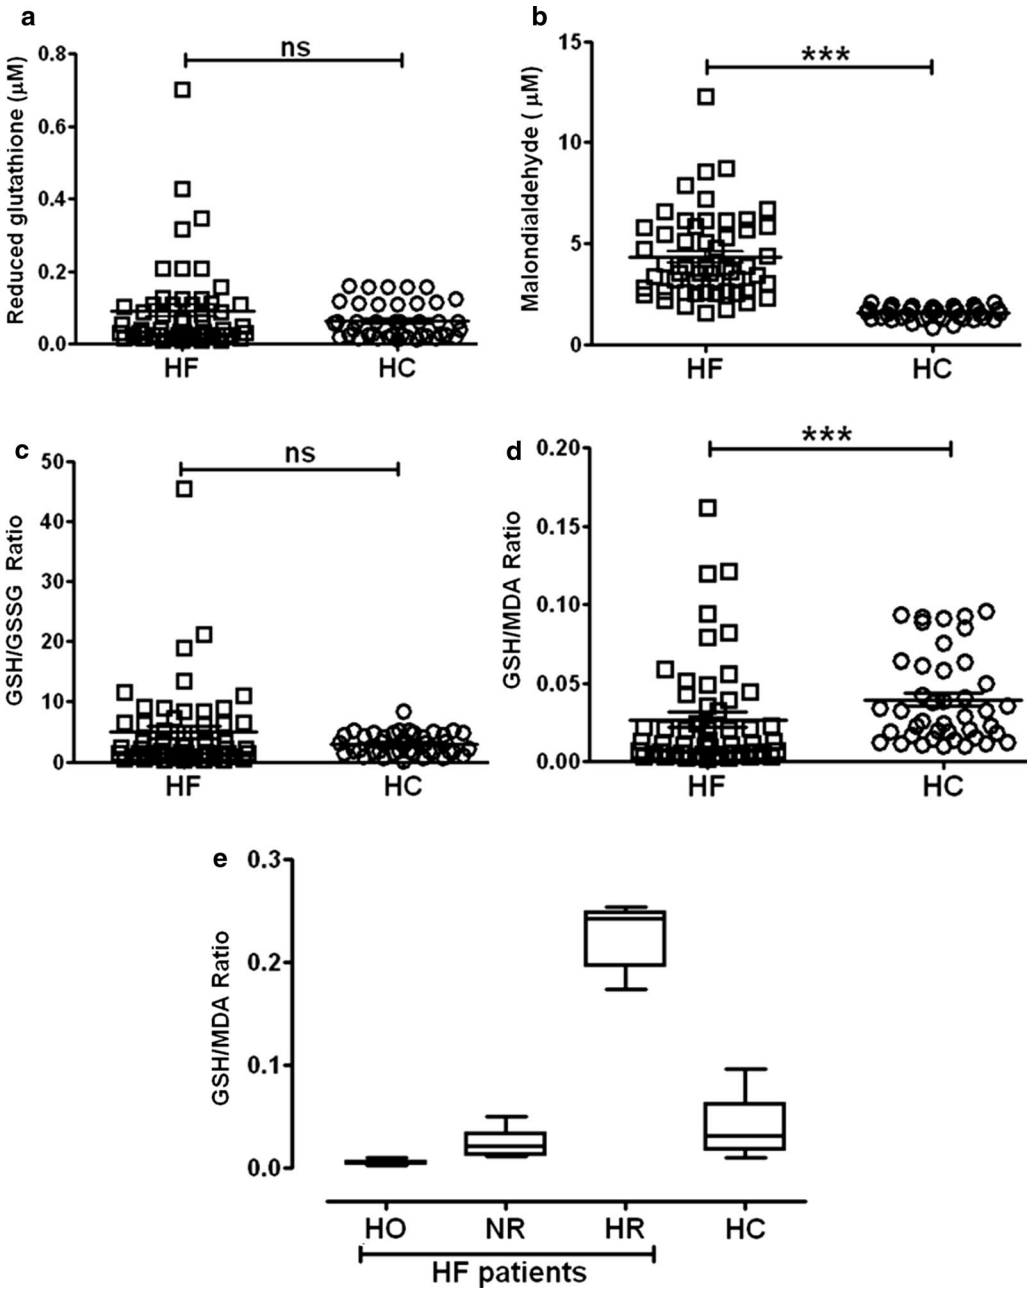

Fig. 1 Stratification of heart failure (HF) patients based on redox status. **a** Comparison of reduced glutathione (GSH) levels showing statistically insignificant GSH levels between HF patients and HC. **b** Significantly higher malondialdehyde levels in HF patients vs. HC. **c** Statistically insignificant GSH/GSSG ratio between HF patients and the healthy controls. **d** Statistically significant, higher GSH/MDA ratio in HC and lower values in HF patients. Mann–Whitney U test was carried out for statistical significance. ***$p < 0.001$. $n = 42$ HC and 54 HF patients. **e** Stratification of HF patients into hyper-oxidative (HO), normal redox (NR) and hyper-reductive (HR) groups based on comparison of GSH/MDA ratio with healthy controls (HC). Remarkably, higher GSH/MDA ratio in HR group, similar GSH/MDA ratio in NR and HC, and a significantly lower GSH/MDA ratio in HO group were observed. One way ANOVA was carried out with $p < 0.0001$ among all the heart failure patient groups ($n = 42$ HC, 23 HO, 22 NR, and 9 HR)

Redox associated changes in cardiac remodeling and systolic function in HF patients

To relate our biochemical redox observations in the distinct subsets of HF patient with myocardial structural and functional remodeling, we performed non-invasive echocardiography analyses to determine fractional shortening, ejection fraction and left ventricular (LV) mass. First, we confirmed that HF patients

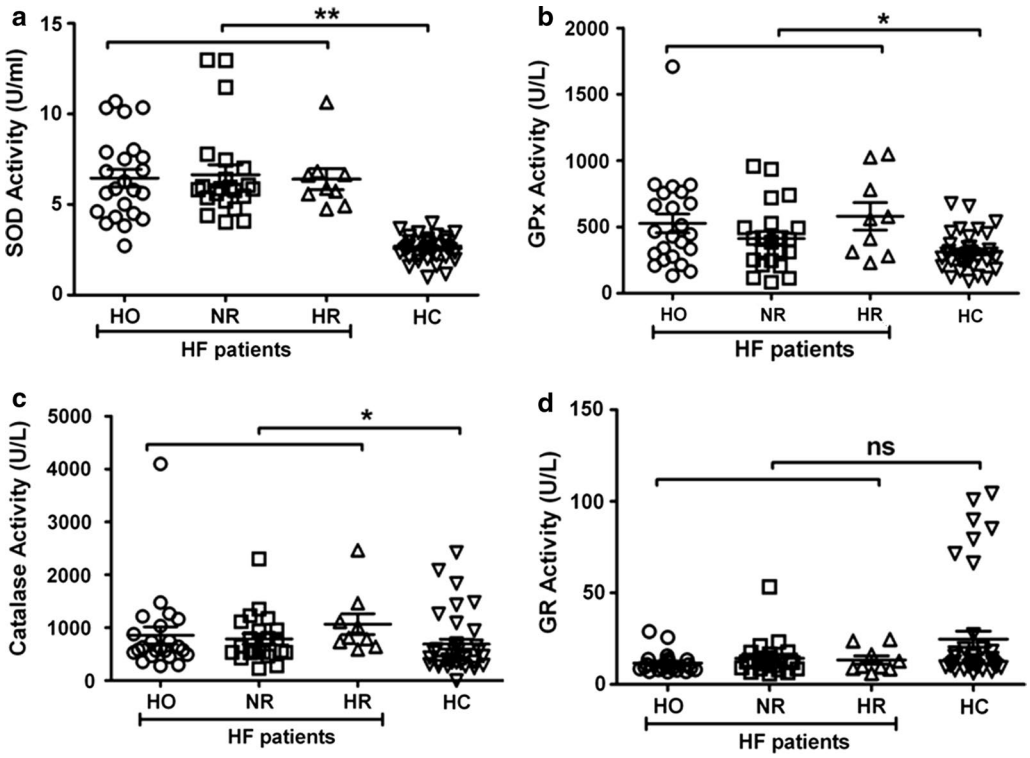

Fig. 2 Comparison of antioxidant enzymes between heart failure (HF) patients and healthy controls. **a** Statistically significant higher superoxide dismutase activity (SOD) in HF patients compared to healthy controls. **b** Statistically significant higher glutathione peroxidase activity (GPx) in HF patients compared to healthy controls. **c** Statistically significant higher catalase activity compared to HC. **d** Statistically significant lower glutathione reductase activity (GR) compared to HC. One way ANOVA was carried out (**$p < 0.001$, *$p < 0.05$) among all the heart failure patient groups (n = , 23 HO, 22 NR, and 9 HR 42 HC except for catalase and GPx, where n = 35 HC because of limited sample volume)

exhibit significantly distinct myocardial mass and systolic function when compared to HC (Fig. 3a–c). Fractional shortening (Fig. 3a), ejection fraction (Fig. 3b) and LV mass (Fig. 3c) did not show any statistically significant differences among the NR, HO, and HR groups of HF patients. However, when compared with HC, all HF patient groups (HO, NR and HR) showed significantly lower fractional shortening (17.03 ± 9.256 for HO, 15.40 ± 5.863 for NR, 16.54 ± 5.185 for HR vs. 36.13 ± 6.020 for HC; $p < 0.01$) and ejection fraction (33.78 ± 17.62 for HO, 32.47 ± 10.41 for NR, 32.57 ± 9.424 for HR vs. 65.46 ± 7.9 for HC; $p < 0.01$), but significantly greater LV mass (309.1 ± 107.9 for HO, 281.1 ± 128.2 for NR, 320.1 ± 103.8 for HR vs. 162.6 ± 13.72 for HC; $p < 0.01$). Representative M-mode echo images for systolic function analysis of NR, HO, HR and healthy control groups are shown in Fig. 3d.

Evidence for a wide range of diastolic abnormalities in HF patients

Primary measurements of trans-mitral inflow including the peak early filling (E wave), late diastolic filling (A wave) velocities and the E/A ratio were performed in HF patients as well as HC (Fig. 4a–c). Although there was no statistically significant difference between HF patients and the HC for ME, MA and ME/A ratio, their measures were widely distributed among the groups compared to the controls (Fig. 4d–f). Representative mitral valve Doppler analysis for diastolic function with graphs for ME/A ratios for HO, NR, HR and healthy control groups are shown in Fig. 4g. M E/A ratio differed according to age and gender [36, 37]. Based on this range, we grouped the HF patients into impaired relaxation and restrictive filling.

Proportion of patients based on systolic (EF) and diastolic (E/A ratio) functions suggest a hyper-reductive condition may be a detrimental factor in HF pathogenesis

Among the HF patients, the HO group (55%) had a higher percentage of patients with ejection fraction $\leq 30\%$ than the NR (44.5%) and HR groups (44.5%). Patients with an EF between 31 and 40% were more frequently assigned to the HR group (33.3%) compared to NR (28%) and HO groups (18%). In contrast, HF patients displaying an EF between 41 and 50% were

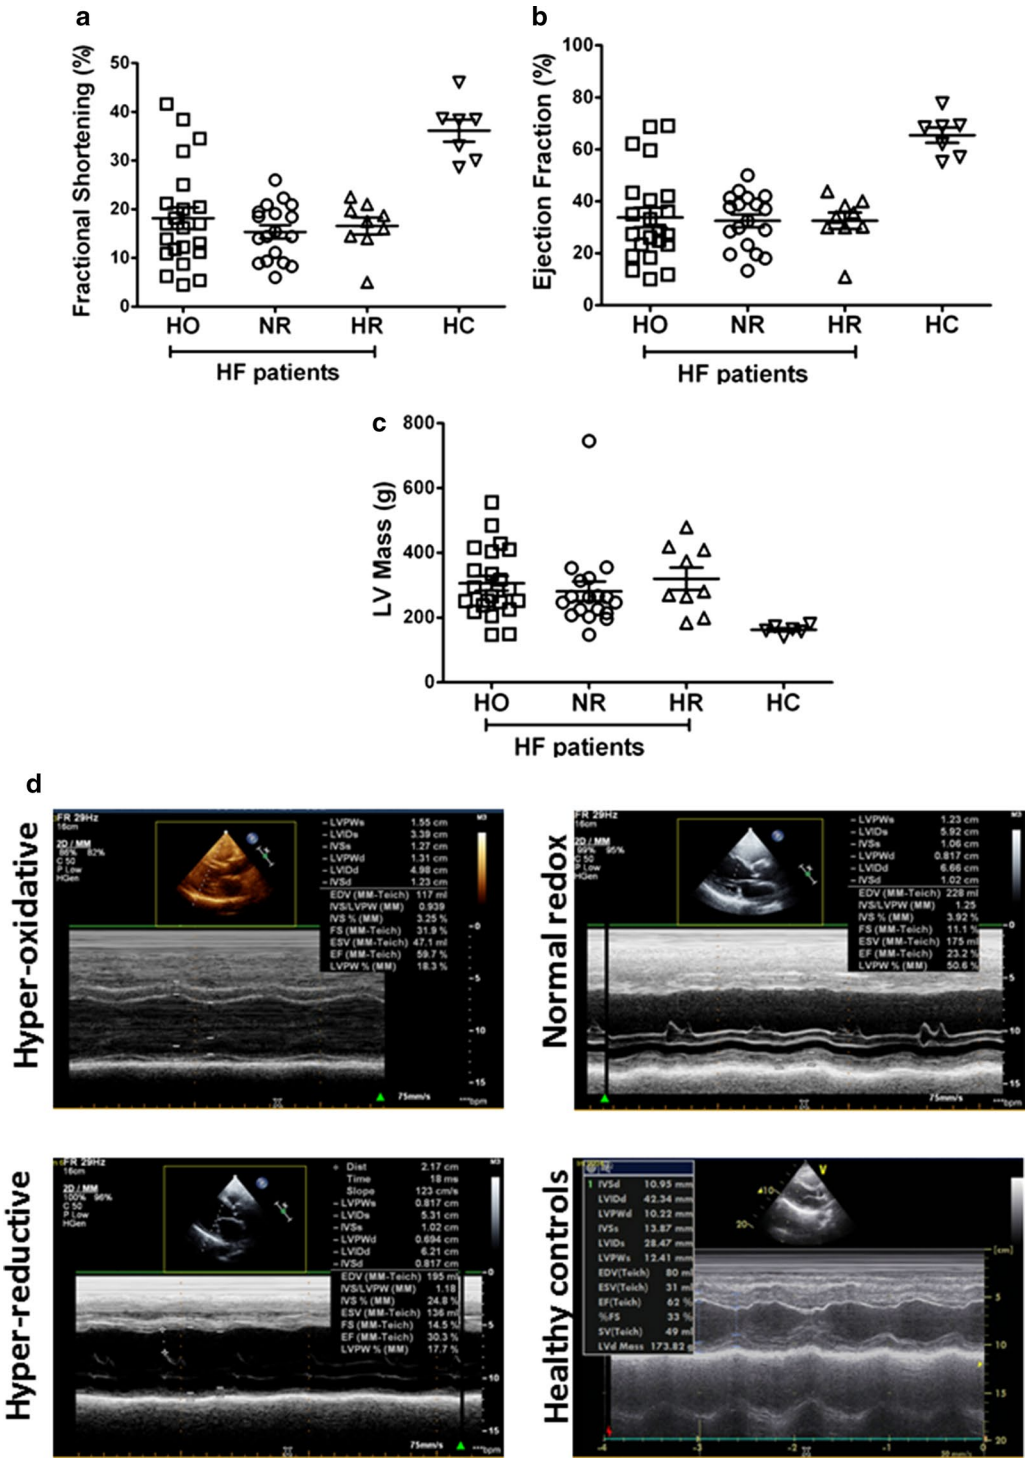

Fig. 3 Echocardiographic parameters for hyper-oxidative (HO), normal redox (NR), hyper-reductive (HR) and healthy controls (HC). **a** Statistically significant lower percentage of fractional shortening (FS) for HO, NR and HR groups of HF patients compared to HC. **b** Statistically significant lower percentage of ejection fraction for HO, NR and HR groups of heart failure patients compared to HC and **c** statistically significant higher LV mass for HO, NR and HR groups of heart failure patients compared to HC. One way ANOVA was carried out with a $p < 0.01$ vs. HC for **a**–**c** $n = 7$ HC, 22 HO, 18 NR and 9 HR. M-mode ECHO related parameters focusing on systolic functions and dimensions with ejection fraction (EF) and FS for **d** representative m-mode images for each group

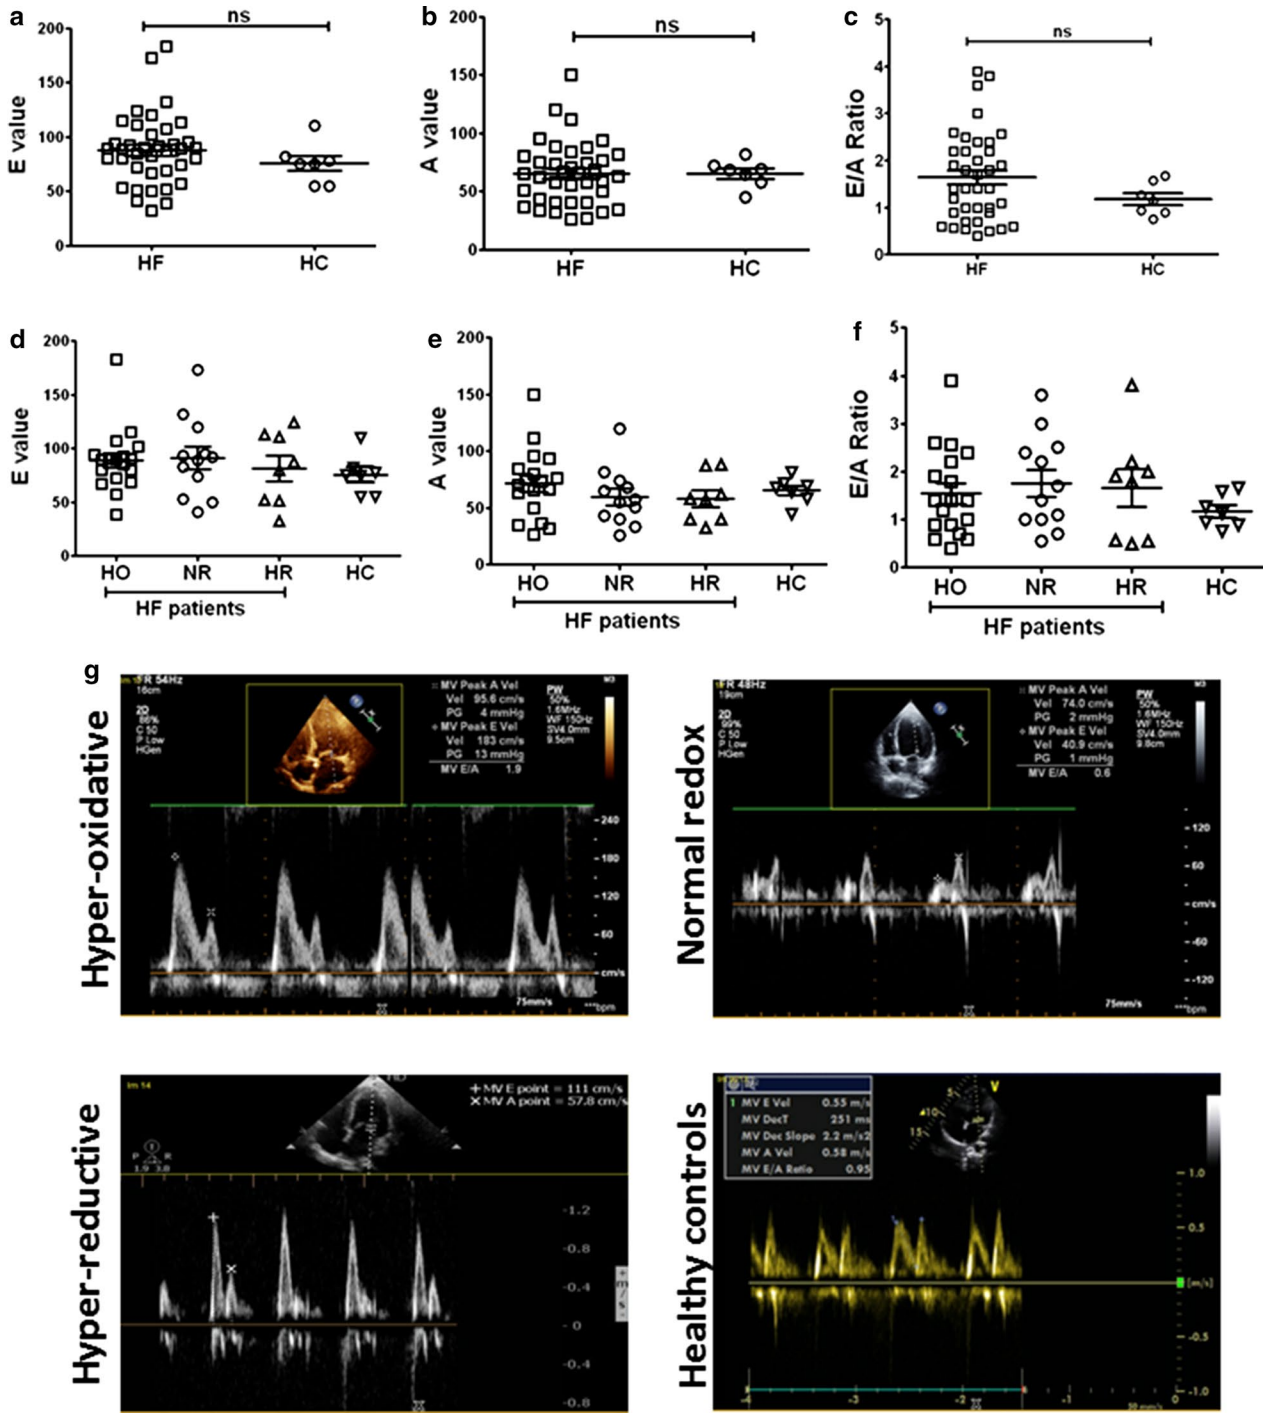

Fig. 4 Comparison of diastolic function abnormalities between HF patients and healthy controls. Similar values between HF patients and healthy controls were observed for **a** Early (E) filling, **b** late (A) filling and **c** E/A ratio. Mann–Whitney U test was carried out with no statistical significance among the groups for **a**–**c**, n = 7 HC and 38 HF patients. **d** Early (E) filling values were slightly higher in HF group patients (HO, NR and HR) than healthy controls. Relative to healthy controls, **e** late (A) filling values and were slightly higher in HO and lower in NR and HR. **f** E/A ratio were slightly higher in HF group patients (HO, NR and HR) than healthy controls. n = 7 HC, 18 HO, 12 NR and 8 HR. One way ANOVA was carried out with no statistical significance among the groups for **d**–**f**. Mitral valve Doppler analysis for diastolic function with graphs for M E/A ratios for **g**. Representative mitral valve Doppler images for each group

less prone to be classified as HO (9%) when compared to the NR (22%) and HR groups (22%). Intriguingly, HF patients with HFpEF were completely absent in HR groups relative to HO (18%) and NR patients (5.5%) (Fig. 5a).

Using the ME/A ratio as an index, diastolic function was compared between different HF groups and healthy controls (Fig. 5b). To our surprise, none of the HR patients exhibited normal diastolic function (E/A ratio 0.76–1.6); however, 41.3% of HO and 33% of NR patients revealed such E/A ratios. While only 17% of NR patients exhibited impaired relaxation (E/A ratio $\leq$ 0.75), the incidence of impaired relaxation in HR and HO patients were 37.5 and 23.5% respectively. Finally, the HR group had higher percentage of patients (62.5%) with restrictive filling (E/A ratio $\geq$ 1.61) as compared with HO (35.2%) and NR patients (50%). Fisher's exact test was carried out with no statistical significance for EF fraction and E/A ratio among the HO, NR, and HR group of HF patients.

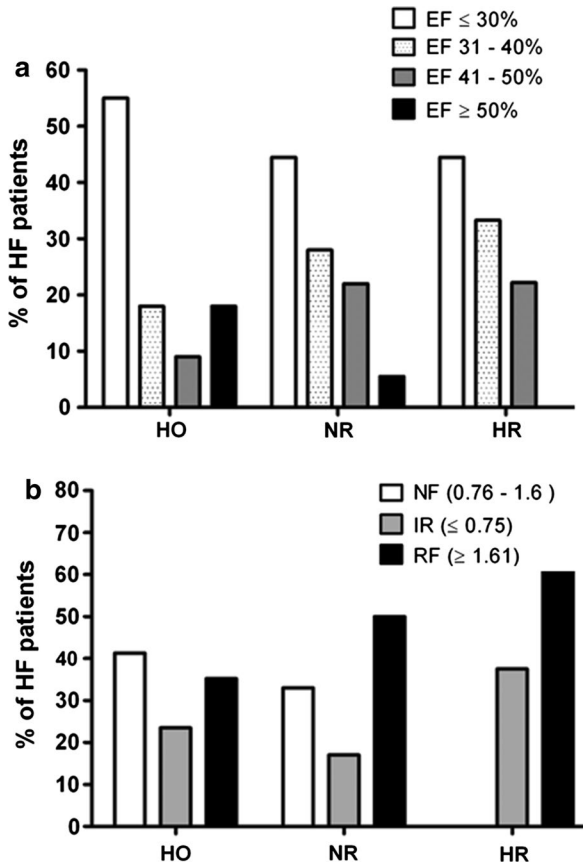

Fig. 5 Comparison of systolic functions (EF) and diastolic functions (E/A ratio) among hyper-oxidative, normal redox and hyper-reductive groups of HF patients. **a** Comparison of ejection fraction (EF) among hyper-oxidative (HO), normal redox (NR) and hyper-reductive (HR) groups of HF patients indicating higher number of HO patients have lowest range of EF $\leq$ 30% and patients with highest range of EF $\geq$ 50% are absent in HR group. **b** Comparison of E/A ratio among HO, NR and HR groups of cardiac failure patients with normal filling (NF), impaired relaxation (IR) and restrictive filling (RF) indicating that the HR group had higher number of patients with RF and HO group had higher patients with NF. Fisher's exact test was carried out with no statistical significance for EF fraction and E/A ratio among the HO, NR, HR group of HF patients

Discussion

The current understanding of redox changes during heart failure (HF) is centered on results obtained from a given group of HF patients compared to healthy controls. Importantly, this experimental approach assumes that redox imbalances during HF progression conform to the oxidative stress paradigm and neglect the potential for observations of individual redox responses in unique subsets of cardiac patients. Here, we attempted to investigate the individual differences of circulating redox biomarkers such as reduced glutathione (GSH), its redox ratio (GSH/GSSG), lipid peroxidation levels (i.e. MDA) and its normalization to reduced glutathione (i.e. GSH/MDA). In particular, we examined whether some HF patients exhibit a unique redox state that is likely to be stretched on either direction of the redox spectrum (i.e. hyper-reductive vs. hyper-oxidative). The development of HF might occur in response to various factors including a chronic oxidative stress/inflammation, infection, ischemic insult, genetic cues and other chronic stresses [38, 39]. Hither to, the redox-based classification of HF has not been implemented.

Generation of reactive oxygen/nitrogen species (ROS/RNS) and oxidative stress has been reported to be associated with the development of HF [40, 41]. However, the evidence for oxidative stress as a causal factor for chronic HF is ambiguous as oxidative stress is absent at the onset of HF in some patients while it appears as a consequence at the later stages of the disease in others. Therefore, we postulate that the oxidative stress may not be solely responsible for the development of HF, and that the other extreme of the redox continuum, reductive stress (RS; a hyper-reductive condition) may play an equally pathological role in certain instances. In the past decade, we and others have suggested that RS might also be an additional mechanism that causes pathological cardiac remodeling leading to heart failure [30, 42–44]. Notably, the existence of RS as a key driver of pathogenesis has been shown in a human mutant protein aggregation cardiomyopathy with augmented antioxidant capacity [30, 45]. Furthermore, other laboratories have reported that augmentation of HSP25, a molecular chaperone that co-regulates glutathione metabolism, promoted RS and resulted in cardiac hypertrophy in transgenic mice expressing Hsp25

[44]. Of late, it has been shown that significant upregulation of NADPH in the heart promotes reductive stress and exacerbates myocardial injury in a mouse model [46]. Nonetheless, such an evidence for RS or a hyper-reductive condition in human HF has not been demonstrated. Our current observations in a small cohort of HF patients (n = 54) have indicated that a distinct subset of HF patients exhibit a hyper-reductive condition in their circulation. Thus, we believe that our novel findings might be useful in stratifying HF patients based on the circulatory redox state (CRS) and in designing appropriate treatment strategies targeting antioxidants.

Based on the CRS (i.e. GSH/MDA), HF patients were stratified into three distinct groups, namely HF patients with (a) hyper-oxidative (HO), (b) normal redox (NR), and (c) hyper-reductive (HR) conditions. Interestingly, while a majority of the HF patients fall into the HO (42%) and NR (41%) categories, a small subset exhibited the HR (n = 17%). Of note, these observations suggest that not all HF patients experience oxidative stress. Therefore, a key question remains as to how and why NR or HR redox conditions contribute to the development of HF remains. Although these analyses seem to be novel and interesting, the mechanisms for NR and/or HR redox conditions in the development of HF are yet to be discovered. Importantly, changes in circulating redox biomarkers in a single group of HF patients appear to be insignificant when compared to healthy controls as the individual levels of CRS have a wide range, which masks the actual scenario in a given HF patient. Hence, our approach for stratifying HF patients based on their CRS will be appropriate to gain more knowledge and understand the pathogenesis of HF in a personalized manner that is likely to enhance the potential of a patient's treatment. Furthermore, we believe that a basic and simple biochemical clinical test for the CRS of a HF patient is a feasible strategy to improve the patient's health and increase their survival through selecting appropriate treatment strategies.

In the majority of the patients (> 85%), our CRS measurements were performed upon the first hospital admission. Critically, we meticulously confirmed that none of the subjects had consumed antioxidant supplements prior to this visit, thereby indicating a clear picture of a hyper-reductive condition associated with HF. In addition to providing the first evidence for an abnormally reductive state in human HF patients, another key finding of our study is the wide heterogeneity of the CRS in response to HF. Along these lines, the prevalence of NR and HR in a considerable number of participants contradicts the expected HO. Considering that ROS/RNS serve as key cellular signaling molecules for basal physiology and responses/adaptations to acute/chronic stress conditions [47–49], patients who exhibit NR or HR may have not gained protection from developing HF. Altogether, these results indicate that in contrast to the common understanding, oxidative stress is not the only factor inducing HF.

Next, our detailed analyses of cardiac structure and function among the 3 classes of HF patients revealed interesting information. Although there is no statistically significant differences among the groups, most of the HO patients displayed severe systolic dysfunction with an ejection fraction $\leq 30\%$ when compared with NR and HR group. It has been established that an over production of ROS/RNS adversely alters cardiac function eventually leading to diastolic and systolic dysfunction [50, 51]. Moreover, left ventricular (LV) dysfunction in HF patients correlates well with the extent of oxidative stress in the myocardium and plasma [50]. In the HR group none of the patients had HFpEF and only 5% in NR group. Hence, both the HR and NR groups predominantly have mild to moderate systolic dysfunction. As such, we speculate that oxidative stress could be a major cause for severe systolic dysfunction rather than reductive stress. In addition to systolic function, we assessed the grade of diastolic dysfunction among the three groups of HF patients utilizing noninvasive Doppler echocardiography mitral inflow (E/A ratio). Surprisingly, the HR group exhibited a higher percentage of patients with a restrictive filling pattern while none for normal filling pattern. However, all other groups had almost equal percentage of patients with normal filling pattern. From our data, it is apparent that patients with RS have severe diastolic dysfunction as compared with normal redox and oxidative stress conditions. Specifically, reductive stress imparts both mild to moderate systolic dysfunction and severe diastolic dysfunction among HF patient groups. There has been accumulating evidence indicating that HF with systolic dysfunction is associated with oxidative stress and nitric oxide (NO) signaling [52] whereas our observations suggest a novel role for reductive stress in the development of diastolic dysfunction.

Conclusion

In this study, we believe that we provided evidence supporting the presence of a hyper-reductive (i.e. reductive stress) condition in a subset of HF patients. Notably, we observed that the HR–HF group had a higher percentage of patients with diastolic dysfunction while the HO–HF group exhibited a higher percentage of patients with systolic dysfunction. Further, individual differences in CRS during the development of HF are apparent suggesting unique contributions of redox disequilibrium across distinct classes of patients. The exact nature of the mechanisms responsible for the heterogeneity in redox responses in the context of HF is presently unknown. We

consider that the wide inter-individual variability for CRS shown here is not limited to the two biomarkers (GSH and MDA) of the redox milieu. Remarkably, the data presented herein emphasize that the mean CRS of a group of HF patients can be misleading. We also acknowledge that this pilot study included a small (but tightly controlled for age and other comorbidities) and male dominant cohort of HF patients. Therefore, our future investigations will focus on larger groups including both genders with specific types of HF such as ischemic disease, hypertrophic cardiomyopathy, dilated cardiomyopathy, and rheumatoid cardiac diseases, and will accentuate differences in diastolic vs. systolic dysfunctions.

Authors' contributions
TS and NSR conceived the idea, performed the experiments and wrote the manuscript. MS performed experiments and collected data. RG, SR and SR provided samples, resources and processed ethical approvals. ANP and SMP critically reviewed and revised the clinical portion of the results. All authors read and approved the final manuscript.

Abstract

Background: Early or timely initiation of breastfeeding, specifically within 1 h of birth, refers to the best practice recommendation by the World Health Organization (WHO). Timely initiation of breastfeeding has the potential to prevent 22 % of neonatal deaths if all infants were breastfed within an hour after birth [1]. The primary objective of the paper is to estimate the prevalence of breast feeding initiation within first hour of life and the clinical correlates and socio demographic factors. **Material and methods:** This study was conducted at PSG Institute of Medical Science and Research, Coimbatore in the month of July 2018. Mothers with the children age below four years attending paediatric outpatient department were included in the study. Multivariate logistic analysis was usedto determine the factors associated with timely initiation breastfeeding practice. **Results:** The prevalence of timely initiation of breastfeeding within one hour was 56.5%. It was observed that the caesarean delivery, preterm delivery, sick condition of the baby, earlier breast surgery, lack of counselling after delivery and lack of skin to skin contact at birth were negatively associated with timely initiation of breastfeeding within one hour. **Conclusion:** The findings clearly indicated that nearly half of the mothers did not initiate breastfeeding within one hour of birth.

Key Words: breastfeeding, prevalence, sociodemographic factors, timely initiation.

Introduction

Timely initiation of breastfeeding is defined as putting the new born to the breast within one hour of birth [1] .Early or timely initiation of breastfeeding, specifically within 1 h of birth, refers to the best practice recommendation by the World Health Organization (WHO) [1]. Few studies revealed that breastfeeding initiation after the first hour of birth doubles the risk of neonatal mortality [2] and the promotion of breast feeding within one hour is a key component in child survival. In addition it has also been shown that a total of 71% of neonatal mortality could be prevented by using antenatal, intra-partum and post natal interventions related to breastfeeding. In addition, many studies reported that the initiation of breast feeding within 24 hours of birth was significantly associated with reduction in 'all cause of mortality'. Recognizing the importance of timely initiation of breastfeeding, the Ethiopian government had developed infant and young child feeding guidelines giving appropriate emphasis to key messages on timely initiation of breastfeeding in 2004. Early initiation of breastfeeding (EIBF) promotes the release of oxytocin that enables contraction of the uterus and decreases postpartum haemorrhage [3]. Though the breast feeding within first hour of life is considered as an indicator of excellence of breast feeding and only 39%

E-Mail:

of the new born in the developing countries are put to breast within one hour of birth. According to national family health survey 3, in India, the rate of early initiation of breast feeding stands low at 24.5% [4]. The characteristics associated with the practice have been little investigated. Hence the current aim is to estimate the prevalence of breastfeeding initiation within first hour of life and examine the factors associated with timely initiation of breastfeeding.

Materials and Methods

Study methods and participants

This study was conducted in the month of July 2018 at PSG Institute of Medical Science and Research, Coimbatore. Ethical clearance from the institution was obtained prior to the study. A total of 527 mothersof children under four years were participated in the study.Mothers with the children age below four years attending paediatric outpatient department were included in the study. Babies with congenital anomalies that interfere with breastfeeding were excluded from the study. A structured interviewer administered questionnaire was used to collect data from mothers about timely initiation of breast feeding related with youngest child. The mothers were asked how long after birth their babies were first put to the breast. Initiating breastfeeding within one hour was categorized as "yes", whereas later than one hour was categorized as "no".The socio-demographic characteristics considered were as education of the mother, age of the mother, occupation of the mother, education of the father, socio economic status, gender of the child, gestational age of the child, birth weight of the child, mode of delivery, condition of the child soon after delivery and counselling for breastfeeding after delivery. Modified BG Prasad socioeconomic scale has been inuse for determining the socio-economic status with people having per-capita income greater than or equal to Rs.6180 is included in class 1, class 2 ranging from Rs.3090-6179, class 3 ranging from Rs.1850-3089, class 4 ranging from Rs.930-1849 and below Rs.930 is included in class 5. The classification is done based on the Consumer Price Index (CPI) value of 279 for Coimbatore [5]. Each study participant was adequately informed about the objectives of the study and obtained consent for ensuring their confidentiality.

Statistical methods

The collected data were checked manually for completeness and entered in to SPSS (23) for analysis. Descriptive statistics was used to summarize and analyse the socio-demographic characteristics of the study participants and the prevalence of timely initiation of breast feeding. Proportions were compared by timely initiation of breast feeding using Chi-square test.To determine the factors associated with timely initiation breastfeeding practice, binary logistic regression analysis carried out. Variables that showed significant association with timely initiation of breastfeeding in the bivariate models were entered in a multivariable logistic model. Strength of association was measured using odds ratio and 95 % confidence intervals. p value < 0.05 was considered as statistically significant.

Results

A total of 527 women were studied. The socio-demographic characteristics of children and families were given in Table 1. The prevalence of timely initiation of breastfeeding within one hour was 56.5% (Table 2).

Table 1: Socio demographic characteristics of infants and Families

Characteristics		Number (%)
Infant characteristics Child's age(months) (Mean ± SD)		15.55 ± 11.92
Education of the Mother	Below 12th standard	138(26.2)
	Above 12th standard	389(73.8)
Mother's age (years)	15-24	108(20.5)
	25-34	388(73.6)
	35-44	31(5.9)

Mother's Occupation	House wife	403(76.5)
	Paid worker	124(23.5)
Education of the Father	Below 12th standard	129(24.5)
	Above 12th standard	398(75.5)
Socio economic status	Class 1 & 2	426(80.8)
	Class 3,4 & 5	101(19.2)
Gender of the child	Female	246(46.7)
	Male	281(53.3)
Gestational age of the child	Term	469(89.0)
	Pre term	58(11.0)
Birth weight of the child (gm)	<=2500	126(23.9)
	>2500	401(76.1)
Mode of delivery	Vaginal delivery	336(63.8)
	Caesarean	191(36.2)
Condition of the child	Well	454(86.1)
	Sick	73(13.9)
Counselling after delivery	Yes	326(61.9)
	No	201(38.1)

Table 2: Timely initiation of Breast Feeding (Hours)

Brest feeding in hours	Number (%)
Within one hour	298 (56.5)
Between 1-4hr	78(14.8)
After 4hr	151 (28.7)
Total	527 (100)

In logistic regression analysis, (Table 3) it was observed that the timely initiation of breast feeding was lower among caesarean delivery compared to vaginal delivery and the difference was statistically significant ($p<0.001$). The timely initiation of breastfeeding was more when the condition of mother was well as compared to those mothers with sick condition ($p<0.05$). Timely initiation of breastfeeding was lower among mothers having low birth weight children than children having normal birth weight ($p<0.001$). Late initiation of breast feeding was higher for pre- term babies than term babies($p<0.001$). It was also observed that the mothers with the well children tend to initiate breastfeeding within one hour than sick children ($p<0.001$). Increased number of antenatal visits had significantly higher prevalence of timely initiation of breastfeeding than less antenatal visits ($p<0.01$). The timely initiation of breastfeeding was less in mothers who had earlier breast surgery compared to mothers who had no earlier breast surgery ($p<0.05$). It was also observed that counselling about timely initiation of breastfeeding after delivery ($p<0.001$) and skin to skin contact at birth ($p<0.001$) were significantly associated with timely initiation of breastfeeding.

Table 3: Factors associated with timely initiation of breast feeding in univariate analysis

Variable		Total	Feeding started within one hour (%)	Feeding started after one hour (%)	odds ratio	p value
Total		527	298(56.5)	229(43.5)		
Age (mean, SD)		27.72,3.95	27.69,4.06	27.75,3.82		
Age of the mother (years)	35-44	31(5.9)	15(5)	16(7)	1.676	0.403

	<=2500	1		

Discussion

Globally, around four million new born die, most from preventable causes each year. Death in the neonatal period accounts for 41 % of all deaths in children below four years. Timely initiation of breastfeeding can help to prevent neonatal deaths caused by infections such as sepsis, pneumonia and diarrhoea[6].In India, a multipronged strategy including large scale programmes, effective capacity building initiatives, strong partnerships, community-

based action, and strategic mass media communication led to an increase in the rates of early initiation of breastfeeding from 24.5% in 2006 to 44.6% in 2014 (i.e. a 1.8-fold increase) [7]. More recently, analyses on a large cohort of almost 100 000 new born from three large trials in Ghana, India and Tanzania has shown that, compared with infants who initiated breast feeding within the first hour of life, the risk of neonatal death among children who initiated breast feeding between 2 and 23 hours after birth was 41% higher (RR 1.41; 95% CI 1.24 to 1.62), and 79% higher among those who initiated breast feeding at 24–96 hours of birth (RR 1.79; 95% CI 1.39 to 2.30) [7].

In thisstudy,caesarean delivery was associated with delayed breastfeeding initiation compared to vaginal delivery.Caesarean delivery is the most consistent predictor of late initiation of breastfeeding reported by many studies conducted in Ethiopia and abroad[8]. Mothers might be uncomfortable to breastfeed due to the pain experienced after surgery and the related factors associated with caesarean delivery.

It was observed that the gestational age of the child is a predictor of timely initiation of breastfeeding. The timely initiation of breastfeeding was significantly lower in preterm children. This result may be explained by the common problems, such as limited oral-motor skills, delayed lactogenesis in prematurely delivered mothers and babies and babies were used to give formula feed from hospital. Thus, effective antenatal care to prevent premature births will contribute to early breastfeeding initiation. The observational prospective study conducted on 500 new born delivered at Department of Rajkiya Mahila Chikitsalaya (RMC), Ajmer and out born section of Department of paediatrics, JLN MC, Ajmer reported that preterm infants had significantly lower rate of early initiation of breastfeeding than term infants[9].

Furthermore, condition of the baby was significantly associated with timely initiation of breastfeeding. It was observed that sick condition of the baby adversely affect the initiation of breastfeeding within one hour. Babies who may have sick at birth include those who experienced a difficult delivery, jaundice after delivery,those with birth defects, those born prematurely and these problems can lead to late initiation of breastfeeding. Fortunately for these babies special care is available. New born babies who need intensive medical attention are often admitted in to Neonatal intensive care unit (NICU) for hours after delivery.so mothers failed to initiate breastfeeding in the first hour after delivery.

Earlier breast surgery was found to be statistically significant with timely initiation of breastfeeding. Women undergo breast surgery for many reasons. Augmentations, reductions, mastectomies, lumpectomies, and biopsies, are often carried out on women of childbearing age. These surgeries can adversely affect timely initiation of breastfeeding and the ability to make healthy breast milk supply for a child.

In addition we have also observed a significant association between timely initiation of breast feeding and counselling about timely initiation after delivery. Counselling about timely initiation has a major impact on timely initiation of breastfeeding. The findings suggest that more efforts are needed to create awareness in providing counselling for the timely initiation during antenatal visits and delivery time. This might be related to the fact that mothers received breastfeeding information/counselling immediately after delivery which is the most appropriate time for delivering key messages about breastfeeding[10].

Baby put on mother's abdomen (skin to skin contact between mother and baby) is found to be an important factor to initiate breast feeding early. WHO recommends that early skin to skin contact between mother and baby helps to initiate early breast feeding.

Birth weight of the child is a predictor in the association of timely initiation of breast feeding in univariate analysis. Socio economic status did not have any association with timely initiation of breast feeding. Previous studies showed that initiations of breastfeeding in low birth weight children were significantly delayed [9]. Also, here educational status of mother did not have any significant association with timely initiation of breast feeding ($p>0.05$). Prior findings showed that education was found to have predominant importance for timely initiation of breastfeeding. Parity and initiation of breast feeding were found to have a lack of association in this study.

This study involves several limitations. One limitation is the recall bias caused by difference in the accuracy or completeness of the recollections retrieved by study participants regarding the breastfeeding practice from the past (retrospective reporting). Another limitation is that the region of study has a generally higher socio-economic status and it was a hospital based study. Community based study program is an approach that emphasize on community empowerment as an important tool in health promotion. Even though the study has several strengths. We have obtained a large number of demographic and clinical data which can influence the association of timely initiation of breastfeeding. All respondents are asked the same basic questions in the same order by the same interviewer tominimize the potential observer bias. Advanced statistical analysis was used to analyse the association

of socio demographic and clinical correlates with timely initiation of breastfeeding.

Conclusion

This study revealed that the prevalence of timely initiation of breastfeeding was significantly lower than the present WHO recommendations [11]. The findings clearly indicate that appropriate strategies are needed to minimize delays in initiation of breastfeeding and for practising better timely initiation of breastfeeding within one hour of birth.

Acknowledgement

The authors are extremely thankful to Dr.S Ramalingam, Dean, PSG Institute of Medical Sciences and Research for permitting us to do this study. The authors are also thankful to Dr. S L Ravishankar, Professor and HOD Community Medicine for his valuable comments and suggestions for improving the draft of this paper.

ABSTRACT

Background: *Workers in the transport industry are at greater risk for cardio vascular diseases (CVD) due to their increased diet and sedentary behavior.* ***Aims:*** *The aim of the present study is to estimate the prevalence of hypertension among truck drivers and its associated factors.* ***Methods and materials:*** *This study was conducted at Walayar check post which is located on a National highway of South India in August 2016. A detailed physical examination was conducted by a team of medical doctors. Socio demographic information were also elicited.* ***Results:*** *The prevalence of overweight was 50% and the prevalence of hypertension was 40%. In multivariate data analysis, only history of chronic disease was significantly associated with hypertension. Overweight was not significantly associated with hypertension when controlled for age, duration of driving, smoking, marital status, and history of chronic disease (odds ratio=1.987, P=0.054). On further stratified analysis, it was found that higher age (odds ratio=3.160 P<0.001) and longer duration of driving (odds ratio=1.076 P<0.001) were significantly associated with overweight. Overweight (odds ratio=2.210 P<0.05) and history of chronic disease (odds ratio=10.178 P<0.001) were significantly associated with high blood pressure after removing both age and duration of driving from this model. Receiver operating characteristic curve analysis relating age with overweight identified 38 years as the optimum cut off value.* ***Conclusions:*** *The truck drivers must be educated at their younger age preferably early thirties to prevent overweight and thereby to reduce hypertension.*

Keywords: Truck drivers, hypertension, overweight, obesity

INTRODUCTION

The social and economic effect of increased morbidity and mortality associated with cardiovascular diseases (CVD) is a great challenge in both developed and developing countries [1-3]. Many studies have demonstrated that there is a strong correlation between risk factors of cardiovascular diseases and occupational factors [4-7]. Workers in the transport industry are at greater risk of an increased diet and sedentary behavior [8,9]. Truck drivers in India have to travel long distances in their life time on an extensive spread of national and state high ways that range from well-engineered roads to complete absence of concrete roads. Their occupation pre-disposes them to multitude of risk factors such as prolonged sitting and driving, tight running schedules, reduced rest breaks, traffic congestion, the sedentary nature of job and resultant physical, psychological, and behavioral problems [8-10]. Thus, professional drivers in particular have higher mortality, morbidity and absenteeism rates due to obesity. Hypertension is one of the main outcomes of the disease and is common among professional drivers. Considering the inherent risks associated with the profession of truck drivers, the importance of truck drivers to the country's economy and scarcity of studies aimed at evaluating the cardiovascular risk profile among these professionals, the present study is aimed to assess the prevalence of hypertension and the factors associated with hypertension among long distance truck drivers.

METHODS

Study design

This was a cross sectional study conducted at Walayar check post which is located on a National highway of South India on August 2016.

Ethics

Ethical clearance for the study was obtained from Institutional Ethical Committee, PSGIMS&R, Coimbatore.

Sample size: With an expected prevalence of hypertension as 45% [9] and with 20% allowable error, the sample size required for this study was estimated as 122. With a non-response of 20%, the total sample was 153. We totally studied 175 truck drivers.

Inclusion and exclusion criteria

Drivers who came with valid driving license for submission of documents at the check post on the day of survey and those who gave informed consent were included. Drivers with known congenital heart disease and genetic disorders were excluded.

Methodology

A detailed physical examination was conducted by a team of medical doctors. Blood pressure was measured on right arm in sitting position using digital sphygmomanometer. Two readings were taken at 3 minutes interval and the mean of the two was recorded. The following variables were also evaluated: socio demographic characteristics (age, education, family history of CVD, prior diagnosis of chronic disease), physically active, eating patterns, consumption of alcohol or other stimulants and smoking habits.

The following criteria and definitions were used [9]:

- Family history of CVD: when the individual mentions the occurrence of heart disease in a first degree relative.
- History of chronic diseases: truck drivers were asked whether they had been previously being diagnosed with any chronic diseases and what medicines they were taking.
- Subjects were considered physically active if they are performing aerobic (walking, biking, dancing, and racing) or anaerobic activities (body building) at least 150 minutes in a week and moderately active if they do 10 to 150 minutes in a week and insufficient if they do less than 10 minutes in a week.
- Subjects were considered active smokers if they use tobacco daily in any quantity or at quit smoking in the previous 12 months. Subjects were considered non-smokers if they had not used tobacco for the past 12 months.
- For determining the body mass index (BMI) the truck drivers were weighed (in kg) without shoes on a 150 kg mechanical anthropometric scale and height in meter. The BMI levels were classified according to the WHO guidelines [11]; subjects were normal if their BMI was 18.5 kg/m^2 to 24.5 kg/m^2, overweight if their BMI was 25.0 kg/m^2 to 29.9 kg/m^2, grade 1 obese if the BMI was 30.0 kg/m^2 to 34.9 kg/m^2, grade 2 obese if the BMI was 35.0 kg/m^2 to39.9 kg/m^2 and grade 3 obese if the BMI $\geq$ 40.0 kg/m^2.

Statistics

Data were analysed using SPSS (19). Mean (SD) were calculated for continuous variables and percentages were calculated for categorical variables. Logistic regression analysis was done to estimate the odds ratio and its statistical significance. Hypertension was defined as present in those with systolic blood pressure greater than or equal to 140 mm Hg or those with diastolic blood pressure greater than or equal to 90 mm Hg. For statistical analysis, BMI>25 kg/m^2 were considered as overweight. Variables significantly associated ($P<0.2$) with hypertension were subjected to multivariate regression analysis. However, due to multicollinearity, stratified analysis was further done to observe the association. Receiver operating characteristic curve analysis was then done to find the optimum cut off value.

RESULTS

The mean age of the study participants were 39.38 years with the minimum age of 22 years and the maximum of 67

years. The prevalence of overweight was 50% and the prevalence of hypertension was 40% (Table 1). In univariate analysis, positive family history, overweight, history of chronic disease, smoking, longer duration of driving, marital status and older age were significantly associated with hypertension (P<0.2) (Table 2). However, in the multivariate analysis, only history of chronic disease was found to be significant. Overweight was not significantly associated with hypertension when controlled for age, duration of driving, smoking, marital status and history of chronic disease (odds ratio=1.987; P=0.054). On further analysis, it was found that higher age (odds ratio=3.160; P<0.001) and longer duration of driving (odds ratio=1.076; P<0.001) were significantly associated with overweight. Overweight (odds ratio=2.210; P<0.05) and history of chronic disease (odds ratio=10.178; P<0.001) were significantly associated with high blood pressure after removing both age and duration of driving from this model. Receiver operating characteristic curve analysis relating age with overweight identified 38 years as the optimum cut off value. Hence it is concluded that the truck drivers must be educated at their younger age preferably early thirties to prevent overweight and thereby to reduce hypertension.

Table 1 Prevalence of hypertension and obesity among the study population

Condition	Number N=175	%
Hypertension	70	40
Raised systolic blood pressure	48	27.4
Raised diastolic blood pressure	51	29.1
Overweight/Obesity	86	49.1

Table 2 Variables associated with hypertension

Variable	Status	Number	Prevalence	Odds ratio	P value

DISCUSSION

A number of studies have demonstrated that the high prevalence of obesity among workers in the transport industry. According to Moreno, et al. this category of workers has a higher incidence of obesity, physical inactivity, inadequate diet, smoking habits, higher levels of cholesterol and hypertension [12,13]. A study carried out in the United States involving more than six hundred thousand workers found the highest prevalence of obesity to be among male employees who work in the transport services [14]. The worldwide prevalence of hypertension was estimated at 1 billion individuals with approximately 7.1 million deaths occurring per year due to this condition [9]. According to the World Health Organization, systolic blood pressure greater than 115 mm Hg accounts for 62% of cases of cardiovascular disease and 49% of cases of ischemic heart disease. Moreover, arterial hypertension is one of the major risk factors of cerebrovascular accident. In our study, we observed a prevalence of 41%, with a prevalence of raised systolic blood pressure of 27.4% and a prevalence of raised diastolic blood pressure of 29.1% among truck drivers.

We observed that the truck drivers must be educated at their younger age particularly early thirties to prevent overweight and obesity and thereby to reduce hypertension. Young adulthood is a vulnerable period for weight gain and the health consequences of becoming obese during the life span are of serious concern. Unhealthy dieting habits include high sugar sweetened beverage consumption, lower vegetable intake and greater consumption of foods prepared outside

the home, which may place young adult long distance truck drivers at increased risk for overweight and obesity. To improve their nutrition and health, as they progress through the life cycle, it requires approaches specifically targeted to this group. Strategies and programs for obesity prevention of truck drivers should include both individual level and population level approaches. However, the evidence base for prevention of weight gain and halting overweight and obesity in young adulthood truck drivers is currently limited.

CONCLUSION

The data in the present study allow us to draw conclusion that long distance truck drivers are highly vulnerable to develop CVD because of the high prevalence of obesity and hypertension observed. The accumulation and association of risk factors and unique features of this profession indicate that traditional actions could not change the scenario. Appropriate health care actions based on comprehensive policies that focus on the truck drivers work environment and monitoring of these factors must be established. More research into programs tailored to the needs of young truck drivers is warranted.

ACKNOWLEDGEMENTS

The authors are extremely thankful to Dr. Arvind Pandey, Director, National Institute of Medical Statistics, New Delhi, Dr. Thomas V Chacko (Professor and Head), Dr. SL Ravi Shankar (Professor), Dr. M Sivamani (Professor), Dr. Sudha Ramalingam (Professor) and Dr. S Karthikeyan (Assistant Professor) of the Department of Community Medicine, PSG Institute of Medical Sciences and Research, Coimbatore for their valuable guidance at various stages of the study. The authors are also extremely thankful to Mr. Abdul Navas, Regional Transport Officer, Palghat for permitting us to do this study. We are also thankful to Mr. Vinod, Head of Marketing and Mr. Sirajudeen for helping us to conduct this study.

Front. Neurol. 11:524. doi: 10.3389/fneur.2020.00524

Over the past two decades, our understanding of Parkinson's disease (PD) has been gleaned from the discoveries made in familial and/or sporadic forms of PD in the Caucasian population. The transferability and the clinical utility of genetic discoveries to other ethnically diverse populations are unknown. The Indian population has been under-represented in PD research. The Genetic Architecture of PD in India (GAP-India) project aims to develop one of the largest clinical/genomic bio-bank for PD in India. Specifically, GAP-India project aims to: (1) develop a pan-Indian deeply phenotyped

clinical repository of Indian PD patients; (2) perform whole-genome sequencing in 500 PD samples to catalog Indian genetic variability and to develop an Indian PD map for the scientific community; (3) perform a genome-wide association study to identify novel loci for PD and (4) develop a user-friendly web-portal to disseminate results for the scientific community. Our "hub-spoke" model follows an integrative approach to develop a pan-Indian outreach to develop a comprehensive cohort for PD research in India. The alignment of standard operating procedures for recruiting patients and collecting biospecimens with international standards ensures harmonization of data/bio-specimen collection at the beginning and also ensures stringent quality control parameters for sample processing. Data sharing and protection policies follow the guidelines established by local and national authorities.We are currently in the recruitment phase targeting recruitment of 10,200 PD patients and 10,200 healthy volunteers by the end of 2020. GAP-India project after its completion will fill a critical gap that exists in PD research and will contribute a comprehensive genetic catalog of the Indian PD population to identify novel targets for PD.

Keywords: Parkinson's disease, genetic diversity, genome-wide association study, common genetic variation, biobank

BACKGROUND

Parkinson's disease (PD) is the second most common neurodegenerative disorder in adults over the age of 60 years (1). According to the Global Burden of Disease study (2018), the worldwide burden of PD has more than doubled over the past two decades from 2.5 million patients in 1990–6.1 million patients in 2016 (2). India is home to nearly 0.58 million persons living with PD as estimated in 2016, with an expected major increase in prevalence in the coming years (2). Despite the large number of people affected with PD, insights into the underlying genetic and environmental risk factors specific to the Indian population are limited. This is in contrast to the Caucasian population in whom easy access to the patient cohort and the population homogeneity have driven initial large scale genome-wide studies (3, 4). Despite the success, the constraints of performing studies in a single homogenous population became apparent as well. This is because the Caucasian population contains only a subset of genetic diversity (5). Populations vary in terms of allele frequency, linkage disequilibrium (LD) patterns, and differences in effect estimates. This provides a scientific rationale that no single population is sufficient to fully uncover the variants underlying disease in all populations, and makes it imperative to pursue genetic research in diverse populations to capture the genetic diversity of a disease.

About 5–10% of PD is monogenic and inherited in an autosomal dominant or recessive manner. The large majority of patients have a sporadic disease. To date, 90 PD loci have been identified explaining a missing heritability in a range of 16–36% (3). It is also increasingly recognized that additional loci with varying degrees of minor allele frequency and effect size remain to be discovered which might account for the remaining missing heritability. Most of the PD loci have been identified in cohorts that are heavily biased toward persons with Caucasian ancestry (3, 4). This generates issues of reproducibility in a global context. For instance, variants in leucine-rich repeat kinase 2 (*LRRK2*), glucocerebrosidase (*GBA*), and alpha-synuclein (*SNCA*) genes identified in the western population have been shown to pose negligible risk to the Indian patients (6–9). Novel variants in the known genes or novel genes may be associated with PD risk in the genetically more diverse Indian population (10). Variations in allele frequency in genetically heterogeneous populations may provide adequate power to GWA studies with smaller sample sizes for the enriched loci. For example, the discovery of an association at a new putative locus at chr1 (PARK16) in the Japanese population for PD underscores the need to study ethnically diverse populations. The associated SNP, rs823128, which was shown to be protective against the development of PD specifically in the Asian population has a minor allele frequency ∼20% in the Japanese population as compared to only 3% in the Caucasian population (11). With this minor allele frequency, individual GWAS in the Caucasian populations had very little power to detect an association, even though the SNP was well-tagged with arrays. The 1,000 Genomes project which uses the combinatorial approach of exome and whole-genome sequencing suggests that individuals from different populations carry different profiles of rare and common variants and that low-frequency variants show substantial geographic differentiation, thus arguing in favor of diversifying genetic research especially in populations which have so far been underrepresented in gene mapping such as the Indian population (12). In addition to the potential for new gene discovery, the inclusion of ethnically diverse cohorts provides an opportunity to cross-validate newly identified loci, which has direct implications for the global applicability and scalability of potential novel therapeutic targets.

We initiated the Genetic Architecture of Parkinson disease in India (GAP-India) project to provide for the first time, a large-scale genetic catalog of the Indian PD population. This paper describes the design of the GAP-India project including the study sites, subject recruitment, clinical assessments, biospecimens processing, plan for data analysis and sharing, capacity building, and the ethical and regulatory frameworks within which we operate.

STUDY DESIGN

GAP-Indiastudy aims to understand the genetic architecture of PD in the Indian population through large scale sample collection and federated data analysis models. The study aims to collect pan-Indian genetic and phenotypic data and will develop one of the largest clinico-genomic PD resources for the scientific community from India. To achieve our objectives, we have formed a trilateral consortium, the Luxembourg-German-Indian Alliance on Neurodegenerative diseases and Therapeutics (Lux-GIANT) (**Figure 1**). The "knowledge-sharing" model aims to build capacity and exchange programs to integrate clinical/genetic centers and harmonize data collection with Luxembourg and German centers. Lux-GIANT follows a decentralized model and based on expertise, different cores have been created (**Figure 2**). For example, the central clinical core in India is established at the Sree Chitra Tirunal Institute for Medical Sciences and Technology (SCTIMST), Trivandrum, Kerala. Given the diversity and vastness of India, apart from the central clinical core, three high volume academic movement disorders centers across India have been identified and established as nodal centers to recruit participants with a pan-India representation. These four clinical nodes are further connected to twenty clinical sub-centers which are spread throughout India. The central clinical core is responsible for coordinating patient recruitment and biospecimen collection with nodal centers. The nodal centers supervise the patient recruitment and biospecimen collection at the sub-centers. Similarly, genomics, functional and bioinformatics cores have been established in Luxembourg, Germany, and India. The functional core at the National Brain Research Center, Manesar, India, is mandated to develop the Lux-GIANT iPSCs biobank. The functional core in India coordinates its activities with the functional cores in Germany and Luxembourg. This has been done to share protocols and develop common functional protocols to perform functional studies. The array processing will be done at the Center for Cellular and Molecular Biology (CCMB), Hyderabad. The central genomics/bioinformatics core at Tubingen will coordinate data generation with the local center and subset of samples will be processed in Germany for quality control purposes.

PROJECTED COHORT AND STUDY SITES

The GAP-India study revolves around a network of clinical sites in India organized in a "hub and spoke" manner. Patient recruitment at each nodal or sub-center will be supervised by a neurologist with specific expertise in Movement Disorders. Subjects will be enrolled at all the sub-centers and the four nodal centers (SCTIMST, Trivandrum; All India Institute of Medical Sciences, New Delhi; National Institute for Mental Health and Neurosciences, Bengaluru and Nizams Institute of Medical Sciences, Hyderabad). The nodal centers are all high-volume academic centers with established movement disorders programs. The sub-centers include additional public sector teaching hospitals, larger multispecialty hospitals, and neurology clinics in the private sector.

Genetic evidence indicates that most Indians descended from a mixture of two divergent populations: Ancestral North Indians (related to Central Asians, Middle Easterners, and Europeans) and Ancestral South Indians (not closely related to other genetic groups) and almost all the current inhabitants are admixtures of these two broad groups to varying extents (13). Within the population, allele frequency changes between subgroups are larger than in European populations, owing to founder effects maintained by a transition to endogamy about 1,900–4,200 years ago (14). The 1,000 genomes project contains about 500 genomes from the Indian subcontinent (including India and geographically neighboring countries), from five diverse linguistic groups, yet the Ancestral North Indian component is prominent in this dataset (15). Within the linguistic groups too, population substructures were evident suggesting that careful matching of cases and controls from within the same ethno-linguistic groups is necessary to avoid false positive associations.

Geographical locations of the enrolling sites in India were chosen to consider this unique population structure and to enable a pan-Indian representation (**Supplementary Figure 1**). The study aims to enroll 10,200 PD patients and 10,200 healthy volunteers over 1 year. Furthermore, GAP-India aims to develop a cohort of 25,000 cases and 25,000 controls by 2024. The four nodal centers will directly enroll about 6,000 patients and the remaining subjects will be enrolled at the sub-centers. The sample size was chosen to take into consideration the statistical power to detect a risk associated variant in GWAS as well as the feasibility of attaining it within the timeframe of the project. The extensive multi-centric nature of the project helps in covering diverse genetic subgroups and meeting recruitment goals within the timelines.

SUBJECT RECRUITMENT

Subjects will be recruited from the Movement Disorder clinics or Neurology clinics run by the PIs of nodal and sub-centers. A detailed history and systemic and general neurological examination will be performed in all subjects. Research staff at all recruiting centers will be trained in the standard operating procedures including clinical assessments and familiarized with online data entry systems before site initiation. Subjects who meet all the following inclusion criteria will be recruited in the patient group: (1) clinical diagnosis of PD as per United Kingdom Parkinson's Disease Society Brain Bank (UKPDSBB) diagnostic criteria (16), (2) age more than 18 years and (3) Asian Indian ethnicity. Subjects meeting any of the following criteria will be

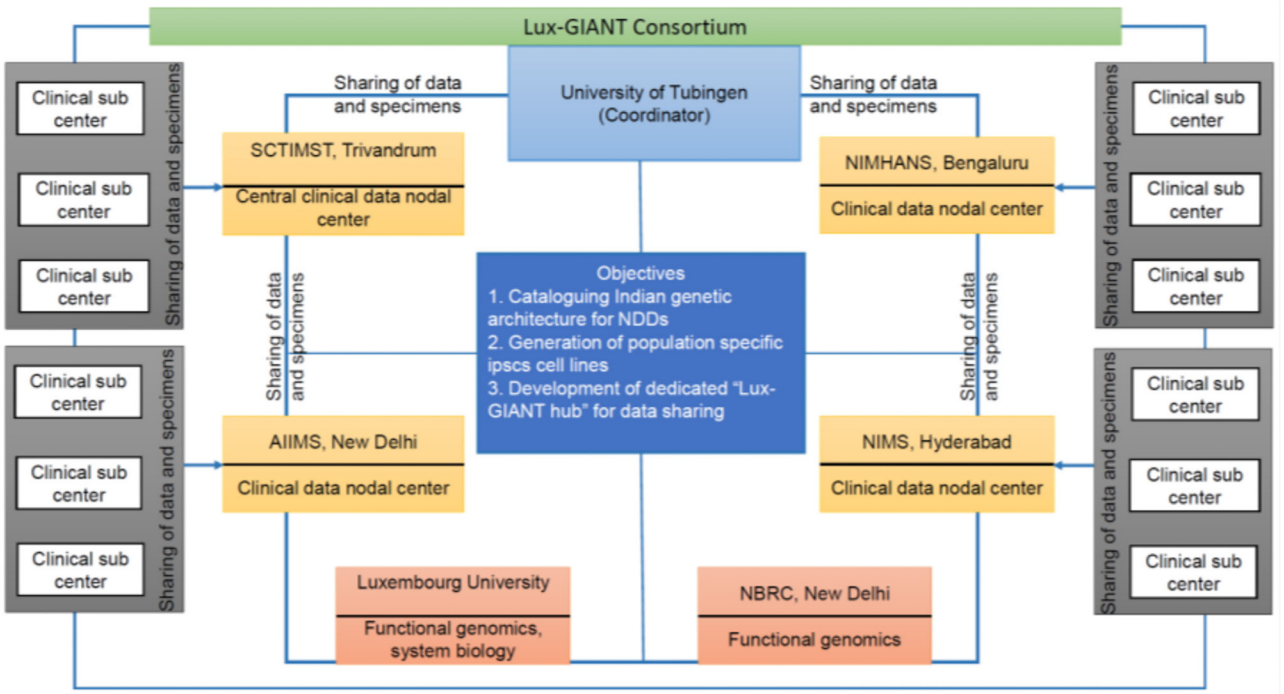

FIGURE 1 | Overall flow chart describing the details of the Lux-GIANT consortium. The consortium follows the "hub-spoke" model. The Lux-GIANT has established three main cores: genomics, clinical, and functional genomics. The University of Tubingen is the coordinator site. Luxembourg site aims to strengthen functional genomics and system biology. Functional core from India, National Brain Research Center, will be responsible for developing and maintaining iPSCs. Four main clinical-nodes capturing most of India are formed. These four nodes are connected to clinical sub-centers which span throughout India. The "central clinical node" aims to streamline the administrative process, which is required for clearance and sample shipment. The different nodes within India are connected with the main "central clinical node" for continuous update of cohort and members.

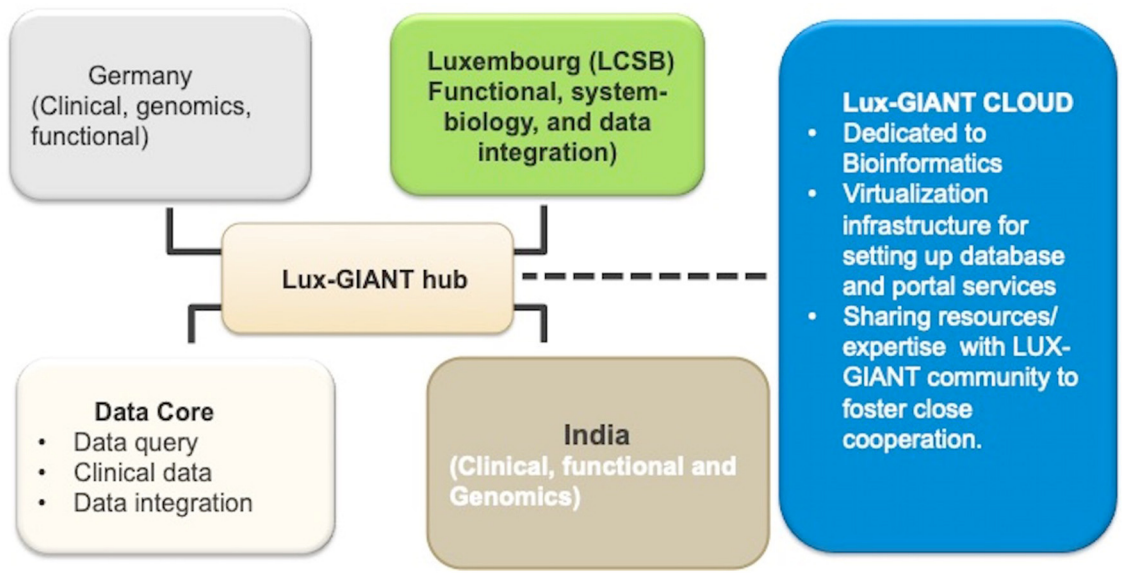

FIGURE 2 | Clinical, genomics, bioinformatics, and functional cores in the Lux-GIANT consortium.

excluded: (1) cognitive or psychiatric dysfunction sufficiently severe enough to impair the patient's ability to provide informed written consent (2) red flags or additional neurological signs raising suspicion of atypical Parkinsonism. Patients who have previously undergone surgical procedures such as pallidotomy, thalamotomy, or Deep Brain Stimulation will not be excluded. Healthy volunteers will be recruited through advertisements displayed on the hospital campus. They will be gender-matched and should belong to the same geographic–ethnic background as the patients. A detailed history and standard neurological examination will be performed before inclusion as controls. Volunteers with a family history of PD or other neurodegenerative diseases will be excluded from the control group. All subjects will be recruited after obtaining written informed consent and with the approval of the Institutional Ethics Committee. Centralized monitoring of recruitment rates and fidelity to operating procedures will be done by the clinical nodal center, SCTIMST.

CLINICAL ASSESSMENTS AND BIOSPECIMEN COLLECTION

Trained personnel at each clinical site will collect clinical and demographic data. The demographic data collected includes information on the geographical origin within India. Structured questions will capture information related to environmental exposures known to be associated with PD including pesticides, fungicides, insecticides, and other chemicals, smoking, caffeine, and head injury. Patients will be asked to report if they ever held a job requiring exposure to pesticides, herbicides, fungicides, insecticides, rodenticides, and fumigants and whether they were exposed to these chemicals at their place of residence through self-use or via another person. Lifetime smoking history of 100 or more cigarettes will be documented. History of head injury or concussion including falls, sporting activities, violence, and car or other accidents in childhood or adulthood will be queried. Patients will also be asked about exposure to caffeinated coffee in quantities more than once per week for 6 months or longer. Years of education will be documented. Furthermore, our environmental exposure data collection will align with the environmental questionnaire from the Genetic-Epidemiology of Parkinson disease (GEoPD) consortium to harmonize the dataset across the ongoing studies. A structured history and clinical examination will be conducted to collect data regarding onset symptoms, motor fluctuations, and dyskinesias, medications, and non-motor symptoms. Non-motor symptoms included in the interview are cognitive impairment, psychosis, depression, sweating abnormalities, seborrhea, sleep disorders including REM behavioral disorder, restless legs, hyposmia, orthostatic hypotension, constipation, dysphagia, and urinary/fecal incontinence. Data from Computerized Tomography (CT), Magnetic Resonance Imaging (MRI), Dopamine Active Transporter- Single Photon Emission Computed Tomography (DaT SPECT) will be collected if available. The family history will be probed for consanguinity and to identify any known relations with PD, dementia, tremor, or other neurological disorders. For patients who have undergone functional neurosurgery, the target, time since surgery and other details will be collected. The motor symptoms at the time of recruitment will be assessed by the Unified Parkinson's Disease Rating Scale (UPDRS Parts I- IV) (17). Subjects will be screened for cognitive dysfunction using the Montreal Cognitive Assessment (MoCA) and for depression using the Beck's Depression Inventory (BDI- II) (18, 19). Validated regional language versions of MoCA will be used for non-English speaking subjects. Demographic and risk factor information will be collected from the control group. Clinical terminologies have been standardized to enable data harmonization with existing research groups and also build a phenotypic information resource for this particular population of PD patients.

The whole blood samples will be collected at each recruiting center 10–15 ml of blood samples collected in EDTA tubes will be processed for DNA extraction using the *salting-out* method. The quantity and quality of DNA will be analyzed using a micro-volume UV/visible spectrophotometer (Nanodrop, Thermo Fischer). Additionally, the quality will also be checked by agarose gel electrophoresis. Those samples with an $A_{260/280}$ ratio of 1.8–2.0 and $A_{260/230}$ ratio of >2.0 will be stored in 1.2 ml screwcap cryovials barcoded with a unique sample ID at SCTIMST Biobank (−80°C), in aliquots. The samples received from the nodal centers and sub-centers will be again checked (using Nanodrop and agarose gel) at SCTIMST to ensure the quality and quantity of DNA that is required for the genotyping. For sequencing, 50 μl of 50–100 ng/μl DNA will be transported in 96-well microtiter plates sealed with peelable heat seals in a waterproof container and dry ice. At the time of collection, specimens will be de-identified by avoiding any personal identifiers on the label. Specimen labels and data collection instruments will be labeled by center-specific serial numbering. No direct personal identifiers will be stored in the online data capture system and quasi-identifiers like date of birth are flagged as such and de-identified by the system before export. Only the site PIs hold identifying information if required for re-identification at a later stage. The central clinical node and other investigators with access to the online database will not have access to direct personal identifiers. Biospecimens collected at the sub-centers will be transported to the nodal centers for DNA isolation. All biospecimens are finally routed to the clinical core at SCTIMST, Trivandrum for storage and in consenting subjects, longer-term bio-banking. In keeping with the existing regulatory framework in India, to promote capacity development, array processing and genotyping will be done at the Center for Cellular and Molecular Biology, Hyderabad. The genetic core at Tübingen will perform the bioinformatics analysis and a subset of specimens will be processed at the Lux-GIANT genotyping core facility in Munich for quality control purposes. All clinical and genetic data will be stored on a shared electronic platform with access restrictions and security protocols in place. Functional validation of putative pathogenic variants including patient-specific induced pluripotent stem cell modeling will be done at the National Brain Research Center, Gurgaon, India. In this way, the study is designed to comprehensively capture clinical and genetic information from a large Indian cohort in

a manner that enables integration with existing international cohorts. DNA isolation from whole blood will be done at the four nodal centers and centralized quality control monitoring at SCTIMST, Trivandrum. DNA specimens from consenting subjects will be maintained in a biorepository at SCTIMST for potential future research.

DATA ANALYSIS

For genetic analysis, a two-stage design will be followed. Currently, the arrays available for genotyping lack in-depth genetic variability information from the Indian population. GAP-India aims to address this issue by performing whole-genome sequencing (WGS) of around 500 subjects covering the north, south, east, and west of India.

Whole-Genome Sequencing

The data generated from whole-genome sequencing will be analyzed using the megSAP pipeline (https://github.com/imgag/megSAP) developed at the Institute of Medical Genetics and Applied Genomics, University Hospital of Tübingen (Tübingen, Germany). In brief, SeqPurge (v. 2020_03) will be used for adapter and quality trimming (20), Burrow-Wheeler Aligner mem (BWA mem (v.0.7.17) for read mapping (21), samblaster (v. 0.1.24) for duplicate removal (22), ABRA2 (v. 2.22) for indel-realignment (23), freebayes (v. 1.2.0) for calling of small variants (24), ClinCNV (v. 1.16.1) for CNV calling (25), Manta (v. 1.6.0) for structural variant calling (26), and Ensembl VEP (v. 96.3) for variant annotation (27). Furthermore, additional tools available from the ngs-bits toolset (https://github.com/imgag/ngs-bits) will be used for data cleaning.

GWAS Analysis

Study Population and Genotyping

The analysis cohort will represent ∼10,200 PD cases and 10,200 controls of Indian ancestry, genotyped with Illumina's Global Diversity Array (GDA) containing neurodegenerative specific content.

Quality Control

GenomeStudio will be used to cluster the genotyping array using the GenCall algorithm and preliminary QC will be implemented in GenomeStudio as described elsewhere (28). Data will be exported in the standard PLINK format and downstream QC procedures and statistical analysis will be conducted using the latest PLINK (http://pngu.mgh.harvard.edu/_purcell/plink) and R software packages (http://www.r-project.org/), installed on a Linux based computation resource (29). The post-GenomeStudio QC will be broadly divided into three main steps comprising of (i) Sample and genetic marker quality (ii) Population structure (iii) Genotyping consistency. Furthermore, QC will be implemented independently in each Indian subpopulation covering north, south, east, and west of India.

Sample and Genetic Marker Quality

Firstly, all samples and SNPs with missing rate>1% will be excluded. Concerning genetic marker quality, we would exclude SNPs with MAF<0.01 and HWE p-value $<1 \times 10^{-10}$ in cases as well as HWE $<1 \times 10^{-6}$ in controls (30). Allele frequencies will be checked with Indian sub-populations represented in the Haplotype Reference Consortium (HRC). Furthermore, allele frequency consistency across different batches of genotyping datasets will be checked to rule out the batch effect.

Population Structure

Individuals deviating ±3 SD from the samples' heterozygosity rate mean will be excluded. Only those males will be included which have an X chromosome homozygosity estimate of more than 0.8. On the other hand, only those females will be included which have an X chromosome homozygosity estimate of less than 0.2. Related samples will be filtered based on identity by descent (IBD) coefficient>0.1 (31). Principal component analysis (PCA) will be used to detect population outliers using the first ten principal components and the outlier samples will be removed. We identified five populations representing the Indian subcontinent in phase 3 1,000 Genomes Project (KGP): two from the northwestern region [Gujarati Indian in Houston, TX (GIH) and Punjabi in Lahore, Pakistan (PJL)], two from Southern region [Indian Telugu in the UK (ITU) and Sri Lankan Tamil in the UK (STU)] and one from Eastern region [Bengali in Bangladesh (BEB)]. The five Indian subcontinent populations marked as South Asain population in the PCA plot of the worldwide population showed a clear demarcation emphasizing the need to diversify the genomic research in under-represented populations to identify population-specific novel genetic loci for complex diseases (**Figure 3**).

Imputation

Imputation will be carried out using the Haplotype reference consortium (HRC) as a reference panel consisting of individuals from more than 26 worldwide populations (32). The SNPs with imputation info score of less than 0.7 will be discarded.

Association Analysis

Post-QC and imputation, association analysis will be conducted for each sub-population using binary logistic regression analysis assuming an additive genetic model adjusting for age, sex, and relevant principal components. A conventional genome-wide significance threshold of 5 × 10–8 will be used to identify the significant SNPs. The fixed meta-analyses inverse-variance weighting of log-ORs will be implemented in METAL to combine summary statistics across all the Indian sub-populations (33). Genome inflation factor λ will be computed using the median χ^2-statistics. Lastly, Manhattan and QQ plots will be constructed to visualize the results. All the summary statistics will be made available publicly. Heterogeneity in allelic effect sizes between different Indian sub-populations contributing to the meta-analysis will be assessed using Cochran's Q statistic.

Polygenic Prediction

We will further use genome-wide complex trait analysis (GCTA) to perform conditional and joint analysis to identify the top variants that account for heritable variation among different loci

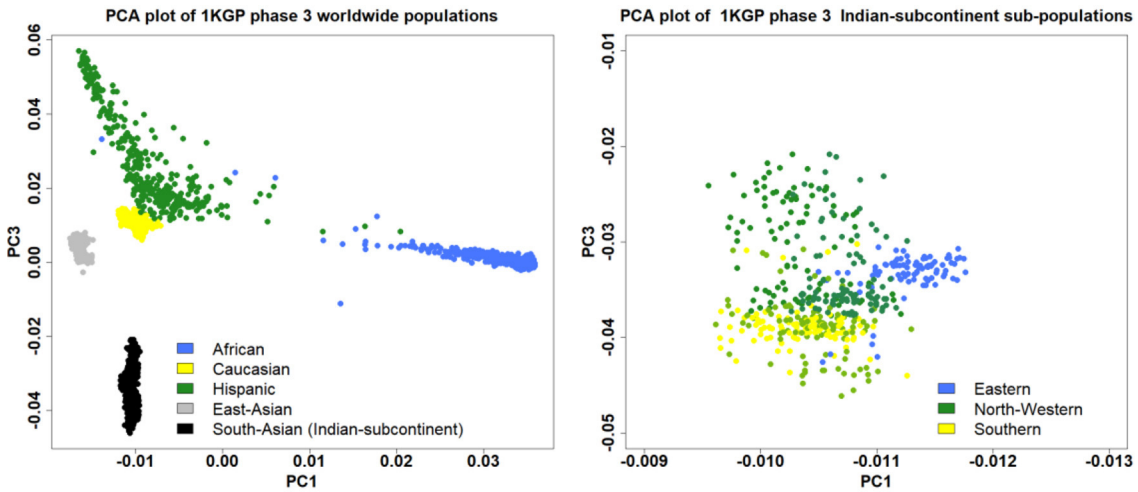

FIGURE 3 | The PCA plot using the phase 3 1,000 Genomes Project showing the distribution of the South Asian population among the worldwide populations (left), and sub-populations from different regions of the Indian subcontinent (right).

(34). Polygenic risk score profiling will be done in a standard weighted allele dose manner (35).

Biological Annotation

We will further integrate our GWAS summary statistics with expression and network data using Functional Mapping and Annotation of Genome-Wide Association Studies (FUMA) to perform the tissue specificity and pathway enrichment analysis (36).

The genomics/bioinformatics core in Tubingen will be responsible for data integration and analysis.

Data Management and Sharing

To ensure seamless data exchange among Lux-GIANT partners, we have established a secure data management and analysis platform. At this moment this platform is equipped with REDCap, a state-of-the-art EDC (Electronic Data Capturing) system (https://www.project-redcap.org) widely used in various clinical and translational projects and is hosted at the "clinical core" site, SCTIMST. The Lux-GIANT REDCap instance is aligned with the Genetic Epidemiology of Parkinson disease (GEoPD) consortium minimal dataset Case Report Forms (CRFs). This will ensure uniform clinical data collection across various participating countries in GEoPD that are spread across five continents. This will facilitate cross-study data pooling and analysis for future multinational projects. All Indian nodal centers and sub-centers taking part in this study are collecting pseudonymized data into this secure and access-controlled instance centrally. All the identifiable information of each study participant stored separately at each site in a corresponding hospital system and only authorized clinical people from that site to have access to it. This setup is aligned with European general data protection regulations (GDPR) as well as Personal Data Protection Bill (PDP) 2019. This pseudonymized clinical data, as well as the corresponding molecular data, will be served to all Lux-GAINT partners via the "data core" site established at Tubingen by leveraging the infrastructure established by the German Network for Bioinformatics and Infrastructure (de.NBI, https://cloud.denbi.de). Through the dashboard of the de.NBI Cloud Site Tubingen the allocation of the desired resources (number of virtual CPU cores, number of virtual machines (VMs), amount of storage and RAM) will be covered. Furthermore, to provide secure access to the VMs to researchers, so-called security groups will be created, which can be seen as a VM specific firewall to control incoming and outgoing network traffic connections. To provide an additional layer of security to Lux-GIANT genomics data, a private network will be added to the Lux-GIANT cloud project to protect the network traffic from and to the volume where the genomics data reside. In addition to the network traffic protection, a certificate-based approach will be used to grant specific permissions (read, write) on a per-user base. The certificates will be distributed to the particular person using a state-of-the-art asymmetric encryption technique. The whole process starting with the project application is illustrated in **Figure 4**. For further details, please see (37). The system-infrastructure, as created, will provide a secure environment to handle and process sensitive patient data in a restrictive and responsible way using cloud resources. To complement our cloud-based activities, the "data integration" site, ELIXIR-Luxembourg Node (ELIXIR-LU) will FAIRify this data by making them Findable, Accessible, Interoperable, and Reusable (38). All the meta-data will be shared through the ELIXIR data catalog (https://datacatalog.elixir-luxembourg.org) that facilitates the Findability of the data. Both clinical and associated molecular data will be curated, harmonized, and integrated into a discovery analytics system—Ada (https://ada-discovery.github.io). It will be hosted in the de.NBI cloud Tubingen and will facilitate the data exploration and analysis through intuitive web interface rich with dynamic visual analytics and advanced machine learning (Deep Learning).

GAP-India aims to share data at the end of a 2-year embargo period, consistent with guidelines followed by other consortia's

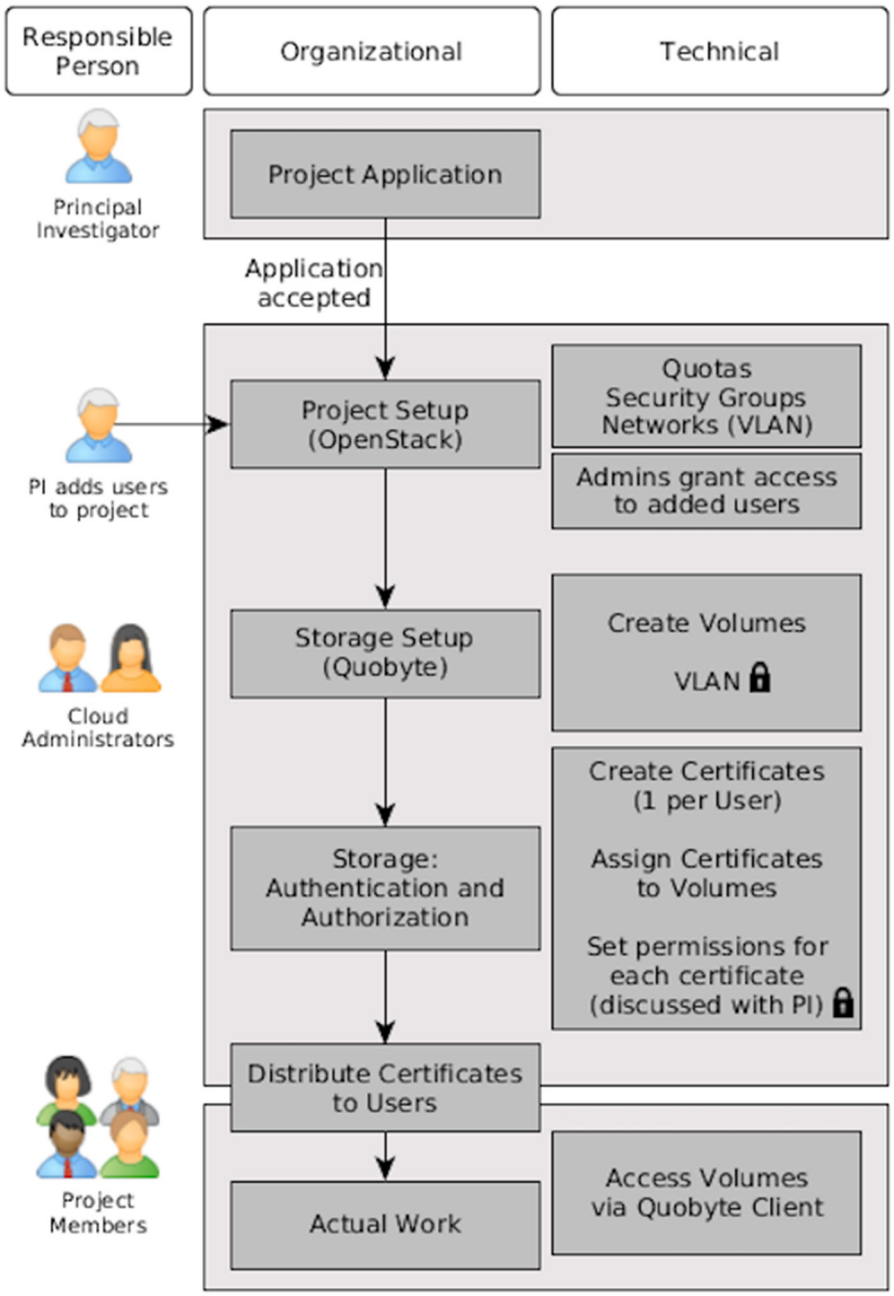

FIGURE 4 | Data management and access workflows in the Lux-GIANT network.

such as H3AfricaConsortium. The purpose of the 2-year embargo period is to give Lux-GIANT researchers a reasonable time-frame to analyze and publish their data before others do. The GAP-India project aims to develop an extensive data sharing plan designed to maximize the utility of its data for the scientific community. Lux-GIANT cloud portal through which GAP-India data will share data fall into two categories: (i) controlled access, and (ii) open access.

The controlled access via the Lux-GIANT portal hosted on the de.NBI Cloud will be given to researchers/institutes who will comply with the data protection and ethical regulations, as described in the GDPR, and PDP 2019. The open-access data which does not require prior ethical clearance will be made available to the scientific community either via the Lux-GIANT Portal or PDgene database.

Regulatory and Ethical Framework

GAP-India project aims to address two main issues: (1) To generate the most comprehensive PD genome-phenome catalog, including iPSC biobank of the Indian PD population, and (2)

to develop scientific and infrastructure capacities in India which have so far lagged in PD genomics research.

One of the major reasons that hinder the collaboration in the genomic era between various research consortia which are primarily led by institutions either in the USA and/or Europe and under-represented population such as India were concerns that data generated from the under-represented population will not be properly represented by the local stakeholders. GAP-India aims to dispel this notion of "scientific imperialism" by developing the "knowledge-sharing" model and also establishing the guidelines which adequately protect the interests of local investigators as well.

The data generated from the GAP-India project follows the strict ethical guidelines, as stipulated by the Indian Medical Council of Research (ICMR)- HMSC for international collaborative research and follows the provisions of ICMR guidelines for biomedical research in India (39). All the clinical recruiting sites obtain ethical approval from their specific ethics committee according to local protocols.

The GAP-India project involves multi-centers across India. There exists a considerable disparity in access to and protocols for regular health care among patients. Therefore, various ethical considerations have arisen during the development stage of the GAP-India project. Specifically, the following issues have been considered. (1) return of genetic results generated from the study, and how they will be received; (2) providing information about genetic findings to patients and care-providers; (3) concerns about stigmatization; and (4) ensuring equity and fairness in collaboration.

As per the Indian guidelines, we are mandated to return actionable results, with the potential to improve the health outcome of the participants. For this, a re-identification process will be followed through the PI of the recruiting center. Genetic counseling and guidance will be offered in case of such a return of results. Incidental findings that are not actionable will not be returned (39).

One of the major spin-offs from this study will create a core network of clinicians and researchers dedicated to PD genetics in India. A long-term biorepository and capacity building in terms of infrastructure and skill upgradation are additional advantages. Taken together, GAP-India aims to develop a dedicated pool of researchers and health care professionals to raise PD awareness in India.

The GAP-India study and the LUX-GIANT network aim to address a critical gap in knowledge regarding the genetic origins of PD, by leveraging the population diversity afforded by as a yet unaddressed population. We expect to generate novel data that may drive targeted therapies and make them applicable on a global scale.

ETHICS STATEMENT

The studies involving human participants were reviewed and approved by Institutional Ethics Committees of all participating clinical centers. The patients/participants provided their written informed consent to participate in this study.

AUTHOR CONTRIBUTIONS

RR conceived, designed, organized and wrote the first draft, reviewed, and critically revised the manuscript. KD, RMK, and RY conceived the project, reviewed, and critically revised the manuscript. VS, UM, PA, NK, TF, HK, AS, KS, SM, SD, SK, LP, MB, PW, SR, MH, GW, and SP reviewed and critically revised the manuscript. FB, MH, JK, AK-S, SG, PL, MSt, and JR reviewed, and critically revised the manuscript. VB, GC, JS, PS, TG, OR, and VG reviewed and critically revised the manuscript. PP, RK, and RB organized the research project, and reviewed and critically revised the manuscript. KB, NC, RC, CT, MD, CG, HM, NK, SK, PM, CS, AKS, and DW reviewed and critically revised the manuscript. AK and MSh conceived, organized, and executed the research project; designed, executed, reviewed, and wrote the first draft; and reviewed and critically revised the manuscript.

FUNDING

This study was funded by the Michael J Fox Foundation, USA Genetic Diversity in PD Program: GAP-India Grant ID: 17473 (AK and MSh). MSh was further supported by the grants from the German Research Council (DFG/SH 599/6-1 to MSh), MSA Coalition, and Michael J Fox Foundation (to MSh). This work at University of Luxembourg was also supported by Fonds National de Recherche de Luxembourg (FNR) within the PEARL programme [FNR/P13/6682797/Krüger] and the National Center for Excellence in Research on Parkinson's disease (NCER-PD), the European Union's Horizon 2020 Research and Innovation Program (WIDESPREAD; CENTER-PD; grant agreement no. 692320). The support for work at Department of Neurodegenerative Diseases, Hertie Institute for Clinical Brain Research, University of Tübingen also comes from Hertie Foundation. VB was also supported by ERC, DFG, and Volkswagen Foundation. JR was also supported by NIH and DFG. The investigators at National Brain Research Center are also supported by NBRC core funds. The authors acknowledge the support by the High Performance and Cloud Computing Group at the Zentrum für Datenverarbeitung of the University of Tübingen. Part of the work presented here was also supported through the BMBF funded project de.NBI (031 A 534A) and the MWK Baden-Württemberg funded project CiTAR (Zitierbare wissenschaftliche Methoden).

ACKNOWLEDGMENTS

We would like to thank all of the study participants for their time and biological samples to be a part of this study.

Genotype Phenotype Correlation of Genetic Polymorphism of PPAR Gamma Gene and Therapeutic Response to Pioglitazone in Type 2 Diabetes Mellitus- A Pilot Study

S. SHANMUGA PRIYA[1], RAMALINGAM SANKARAN[2], SUDHA RAMALINGAM[3], THIAGARAJAN SAIRAM[4], LS SOMASUNDARAM[5]

ABSTRACT

Introduction: Pro12Ala polymorphism is a missense mutation at codon 12 in peroxisome proliferator-activated receptor γ gene (PPARG). This polymorphism is known to be associated with increased insulin sensitivity. Pioglitazone, a thiazolidinedione, is an anti-diabetic drug which acts as an agonist at PPAR γ receptor.

Aim: To determine the association between Pro12Ala polymorphism of the PPARG and variation in therapeutic response to the PPARγ agonist, pioglitazone.

Materials and Methods: The study was done as a hospital based pilot project in 30 patients with type 2 diabetes mellitus, on treatment with sulfonylurea or metformin but without adequate glycaemic control. They were started on pioglitazone as add on therapy for a period of 12 weeks. The participants were categorized as responders and non-responders based on the change in HbA1C level after 12 weeks. Pro12Ala polymorphism was analysed by polymerase chain reaction-restriction fragment length polymorphism.

Statistical Analysis: Logistic regression analysis was done to evaluate the associations between age, baseline body weight, BMI, waist circumference, waist-hip ratio and Pro12Ala variants with the response to pioglitazone. The p-value< 0.05 was considered significant.

Results: The frequency distributions of PPAR gamma genotypes were 80% for Pro/Pro and 20% for Pro/Ala in the study population. Among the study participants, 30% were non-responders and 70% responders to pioglitazone. A significantly higher frequency of the polymorphism was detected in the responders (p=0.005) compared to non-responders group.

Conclusion: Our study suggests that there is a potential association between Pro12Ala polymorphism and glycaemic response to pioglitazone.

INTRODUCTION

Type 2 diabetes mellitus is considered as a heterogeneous syndrome of dysregulated glucose homeostasis. The world prevalence of diabetes in adults has been predicted to increase from 285 million in 2010 to 439 million in 2030 [1]. It is also increasingly recognized that adequate management of diabetes by appropriate drug therapy is essential in preventing complications.

The peroxisome proliferator–activated receptor γ gene (PPARG) encodes the PPARγ receptor, a transcription factor that belongs to the family of nuclear receptors and it regulates the carbohydrate and lipid metabolism. Among the two isoforms, PPAR-γ2 is specific for adipose tissue, where it plays a pivotal role in adipogenesis and is an important mediator of insulin sensitivity [2].

Pro12Ala polymorphism is the result of a CCA-to-GCA missense mutation in the codon12 of exon B of the PPARG gene. There is substantial evidence from various genetic studies that the Pro12Ala polymorphism improves insulin sensitivity in humans [3,4]. It is possible that alterations in transcriptional activity of the polymorphic gene in adipocytes primarily enhance insulin's action [4,5]. Pioglitazone is a thiazolidinedione, the pharmacological ligand for PPARγ receptor. The thiazolidinediones act by decreasing the insulin resistance in muscle, liver and adipose tissue.

The effect of Pro12Ala polymorphism (rs1801282) on the therapeutic response to pioglitazone has not yet been studied in the South Indian population. Hence our study was designed to investigate the association of PPARG gene Pro12Ala polymorphism and the therapeutic response to pioglitazone therapy in type 2 diabetes mellitus patients in a South Indian population. The secondary objectives were to determine the influence of patient characteristics like body weight, BMI, waist-hip ratio on glycaemic response to pioglitazone and also to identify the association between Pro12Ala polymorphism and these patient characteristics in the population studied.

MATERIALS AND METHODS

The present study was a hospital based prospective pilot study done in 30 patients. The study protocol was approved by the Institutional Human Ethics Committee before the start of the study. Patients who had already been diagnosed with type 2 diabetes mellitus and on regular treatment were included for the study. As per the current American Diabetes Association (ADA) guidelines, fasting plasma glucose ≥ 126 mg/dl or 2 hour postprandial plasma glucose ≥ 200 mg/dl or HbA1C ≥ 6.5% is the threshold for the diagnosis of diabetes [6].

Diabetic patients aged 30–85 years, of both sexes and already on treatment with sulfonylurea or metformin, but without adequate glycaemic control, as evidenced by HbA1C values of 7.5 to 9.5 % were selected for the study. Only those patients whose diabetic medications were not changed in the previous six months and those who had no previous history of PPAR agonist use were included.

Patients with type1 diabetes and known history of ischemic heart disease or congestive cardiac failure were excluded. Similarly

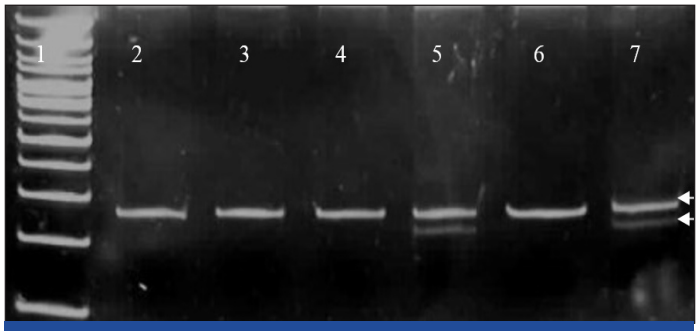
known cases of liver disease, bladder cancer or previous history of fractures were excluded from the study. Patients already on drugs which increase fluid retention like steroids, NSAIDs as well as pregnant and lactating women were excluded.

Written informed consent was obtained from each of the patients who met the above criteria. Basic demographic data like name, age, sex and anthropometric measurements of height, weight, body mass index, waist circumference, hip circumference and waist hip ratio were recorded. Baseline fasting blood glucose levels (by enzymatic reference method) and HbA1C levels (by immunoturbidimetry) were also determined during the first visit. Pioglitazone 30 mg once daily was added to the existing regimen without changing any other medication. The patients were counseled for self reporting of any adverse events. They were also instructed to maintain the same level of energy intake and physical activity as before. The next visit was scheduled after 12 weeks, during which the body weight was recorded in addition to repeating the fasting blood glucose and HbA1C. There were no significant adverse drug reactions reported by the participants during the study period.

The expected average reduction in HbA1C in type 2 diabetic patients with pioglitazone therapy is in the range of 0.5 to 1.4% [7]. Glycaemic response to pioglitazone was determined by the fall in HbA1C after 12 weeks of add-on pioglitazone therapy. If the absolute decrease in HbA1C was less than 0.5%, they were categorized as non-responders. During the same visit, blood was also drawn for genetic analysis.

Genotyping of the patients was performed to identify the Pro12Ala polymorphism in the PPAR gamma gene. The genomic DNA was first extracted from the blood samples of the study participants. The extracted DNA was rinsed with 70% alcohol and re-suspended in 40 µL of TE buffer (pH 8.0). Pro12Ala polymorphism was determined by polymerase chain reaction-restriction fragment length polymorphism (PCR-RFLP). The DNA was amplified by PCR using a sense primer (5'-GCCAATTCAAGCCCAGTC-3') and an antisense primer (5'-GA TATGTTTGCAGACAGTGTATCAGTGAAGGAATCGCTTTCCG-3') that flanked the region containing the 12-amino acid site of PPARγ2. The PCR product was 270 bp in length. The PCR conditions were an initial denaturation step at 94ºC for 8 min, followed by 35 cycles of denaturation at 94ºC for 50 sec, annealing at 59ºC for 50 sec, and extension at 72ºC for 1 min, with a final extension of 5 min at 72ºC.

After PCR amplification, the PCR product was subjected to restriction digestion by BstUI/Bsh 1236 I (Fermentas 10units/ µL) enzyme at 37ºC overnight, electrophoresed on a 12% polyacrylamide gel and stained with ethidium bromide. The digested RFLP products after gel electrophoreses was used to identify the study subjects with the Pro12Ala polymorphism. A single 270 bp fragment indicated the presence of CC (Pro12Pro) genotype while three fragments of 270, 227 and 43 bp product size confirmed the presence of GC (Pro12Ala) genotype [Table/Fig-1]. GG (Ala12Ala) genotype would be represented by two fragments of 227 and 43 bp [8]. Inorder to ensure validity, the samples were run in polyacrylamide gel using an internal positive and negative control and replicating 10% of the samples randomly. In addition, the gel was read by two independent blinded observers and the concordance rate was found to be 100%.



STATISTICAL ANALYSIS

The data was analysed using the SPSS version 19. All data were expressed as mean± standard deviation. Paired t-test was performed to assess the effect of pioglitazone treatment and an independent sample t-test to analyse if there was any significant difference in the body weight, BMI, waist circumference, waist-hip ratio, baseline fasting blood glucose or the baseline HbA1C between wild type (homozygous) and those with Pro12Ala polymorphism (heterozygous). Logistic regression analysis was used to evaluate the associations between age, baseline body weight, BMI, waist circumference, waist-hip ratio and Pro12Ala variants with the response to pioglitazone. The p-value< 0.05 was considered significant.

RESULTS

The mean age of the study participants was 53.2 ± 10.95 years, of which 46% were males and 54% females. At baseline, the mean body weight of the study population was 66.83 ± 10.492 kg and the mean BMI 26.247 ± 3.71. The mean waist circumference and mean waist-hip ratio were 90.50 ± 9.343 cm and 0.9033 ± 0.0649 respectively. Using 'paired t-test', a significant decrease in mean fasting blood glucose and HbA1C levels was seen after 12 weeks of add-on treatment with pioglitazone whereas mean body weight and BMI did not change significantly [Table/Fig-2]. The PPARγ (rs1801282) genotype frequency distributions were 80% for Pro/Pro, 20% for Pro/Ala and 0% for Ala/Ala in the study population. An independent sample t-test [Table/Fig-3] showed that there was no statistically significant difference found in the body weight, BMI, waist circumference, waist-hip ratio, fasting blood glucose or HbA1C between wild type (homozygous) and those with Pro12Ala polymorphism (heterozygous) at baseline. Interestingly, after pioglitazone treatment, the fasting blood glucose between wild type (125.92 ± 21.549) and heterozygous (106.33 ± 5.645) was statistically significant with p-value of 0.03. A similar statistically significant difference in HbA1C between the wild type (7.158 ± 1.007) and heterozygous (6.300 ± .4690) genotypes was found. However, the difference in other parameters after treatment was not statistically significant.

Among the study participants, 30% were non-responders and 70% responders to pioglitazone add-on therapy. At baseline, 22

Variable	Odds ratio	p-value
Age	0.015	0.90
Body Weight	4.933	0.02
BMI	3.199	0.07
Waist circumference	0.985	0.30
Waist hip ratio	2.717	0.09
Pro12Ala (rs1801282)	7.763	0.005

[Table/Fig-4]: Multiple logistic regression analysis for the influence of clinical and genetic factors on the response to pioglitazone treatment.

patients in the study were receiving metformin while the rest were on treatment with sulfonylureas, among which, five patients were on glimepride and three on glibenclamide treatment. Also, it was noted that amongst those with the Pro12Ala polymorphism, five were on pre-existing metformin therapy while only one patient was on glibenclamide therapy.

Logistic regression analysis performed showed that there was no statistically significant association between the age, BMI, waist circumference or waist-hip ratio with the glycaemic response to pioglitazone therapy in the study population. But a statistically significant association was detected both for baseline bodyweight of the patients and PPARγ genotype Pro12Ala with the therapeutic response to pioglitazone [Table/Fig-4]. An analysis based on different pre-existing treatment regimes of the patients was not done for two reasons. First, we had included only those patients whose treatments were not changed in the previous six months implying that any change in their glycaemic response after the addition of pioglitazone was due to the add-on treatment. In addition, the smaller sample in the sulfonylurea group precluded direct comparison with the metformin group.

DISCUSSION

In this study, the Pro12Ala polymorphism has been detected in 20% of the study population. This is similar to the frequency of the polymorphism reported in other studies [9-12] done in the Indian population. The current study has illustrated that there is no significant difference in the body weight between the wild type and heterozygous population [Table/Fig-3]. Likewise, there is no statistically significant association between the polymorphism and parameters of adiposity like BMI, waist circumference and waist hip ratio. Various studies done in different ethnic populations have established that the effect of Pro12Ala polymorphism on body mass index is complex. A higher BMI has been demonstrated in the Pro12Ala heterozygotes in certain populations like the white Americans, Iranians and other Caucasian populations [10,13,14] while few studies have also demonstrated a lower BMI in the Pro12Ala polymorphic individuals [13,15]. Genetic heterogeneity due to differences in ethnicity could be contributory to the discrepancies [13,16].

A metanalysis in British subjects has shown that the Pro12Ala polymorphism has an apparent effect on BMI only in markedly obese individuals. When BMI of the three genotype groups are compared, it is found that the Ala12 homozygotes have significantly higher BMI than heterozygotes and Pro12 homozygotes indicating that the Ala12 allele is associated with increased BMI, particularly in the obese individuals [17].

The effect on BMI can be ascribed to an increased PPAR γ expression in the adipose tissue of obese subjects, but this expression can be down-regulated by low-calorie diet. It has been shown that, when the dietary polyunsaturated fat to saturated fat ratio is low, the BMI in Ala12 carriers is greater than that in Pro12 homozygotes, but when the dietary ratio is high, the opposite is seen. This gene–nutrient interaction may, in part, explain the differential effects of the polymorphism on the body mass index in obese and lean individuals [18].

In addition, studies in the Indian population have largely shown that there are no differences in BMI, waist-hip ratio and waist circumference between the carriers of the polymorphism and the wild-type genotype in contrast to the Caucasians [10,11]. Contradictorily, a higher BMI has also been observed [12]. However, the BMI of individuals with the Pro12Ala genotype did not significantly differ from individuals with the Pro12Pro genotype in the global analysis implying only a modest effect of the polymorphism [9,17].

The first evidence for an association between the Pro12Ala polymorphism in PPARG gene and increased insulin sensitivity was reported by Debb et al., [15]. A reduced transcriptional activity of the PPARG2 gene as a result of Proline to Alanine aminoacid substitution has been demonstrated but however the mechanism by which the reduced transcriptional activity of PPARγ influences insulin sensitivity is still unclear [15].

Moreover, multiple studies have proven that Pro12 Ala polymorphism reduces the risk of type 2 diabetes mellitus [19-21]. In addition, the progression from normal glucose tolerance to clinical type2 diabetes in which insulin resistance plays a major risk factor, is genetically influenced by this polymorphism [20]. Currently it is also recognized that this polymorphism plays an important role in the risk of nephropathy in diabetes patients [21].

On the contrary, studies have also revealed that reduction in the risk of diabetes is not conferred by the polymorphism in the Indian population unlike that seen in Caucasian population [10,12]. It is interesting to note that some studies also refute such differential effects of the polymorphism ascertaining that the increased insulin sensitivity and protective role of the polymorphism in reducing the risk of diabetes is also evident in the Asian Indians [11,16]. The disparate results are attributed to the diversity in ethnicity of the Indian sub-populations [11].

This is the first study in the South Indian population evaluating the effect of the Pro12Ala polymorphism on therapeutic response to pioglitazone, a PPAR gamma agonist. A statistically significant genetic association between Pro12Ala polymorphism and therapeutic response to pioglitazone [Table/Fig-4] was detected implying a potentially significant contribution of the PPARG2 gene in determining the response to the drug. It has been difficult to explain why paradoxically, both reduced transcriptional activity due to Pro12Ala polymorphism and pharmacological activation of PPARγ by thiazolidinediones result in improved insulin sensitivity. Yamauchi et al., have proposed that the supra-physiological activation of PPAR gamma by thiazolidinediones markedly increases the triglyceride content of white adipose tissue, thereby decreasing triglyceride content of liver and muscle [22]. This in turn leads to amelioration of insulin resistance at the expense of obesity whereas a moderate reduction of PPAR gamma activity by Pro12Ala polymorphism decreases triglyceride content of white adipose tissue, skeletal muscle, and liver due to increased leptin expression and fatty acid combustion along with decreased lipogenesis, thereby ameliorating high fat diet induced obesity and insulin resistance. Thus even though different mechanisms appear to be involved, both act to reduce insulin resistance. This additive effect could be the possible mechanism by which the study participants with Pro12Ala polymorphism have demonstrated a better therapeutic response compared to those with Pro12Pro genotype.

Similar studies done in other populations have yielded conflicting evidence [23-25]. These studies were performed in different ethnic populations like the Chinese, Iranian, and German. A study done in thirty, type 2 diabetes patients in a North Indian population revealed a better glycaemic response of those with Pro12Ala polymorphism to pioglitazone monotherapy [26]. A metanalysis of five studies in which the effect of Pro12Ala polymorphism on the pharmacodynamics of pioglitazone was examined, showed that three studies proved a genotype phenotype correlation while the rest did not reveal such association. According to the metanalysis, this disparity in the results could be attributed to factors like heterogeneity of the patient population in the studies included in the metanalysis, their inclusion/ exclusion criteria, different pioglitazone treatment regimens and presence of other anti-diabetic treatments. Thus PPARG2 gene Pro12Ala polymorphism could be contributory to the inter-individual variability observed in therapeutic response to pioglitazone, even though the variability cannot be completely explained by the polymorphism indicating the possible involvement of other genetic and environmental factors [27].

CONCLUSION

The current study has demonstrated a significant association between the Pro12Ala polymorphism and a better glycaemic response to pioglitazone. But the major limitation of the study is small sample size. Therefore the results require confirmation in larger trials involving larger sample before establishing the genotyping for Pro12Ala polymorphism as a predictor of response to pioglitazone therapy in diabetes. Thus the study emphasizes that genotyping could, in future, guide in optimizing diabetes management in individual patients and that pharmacogenetics has an important role to play in achieving the goal of individualized therapy in patient care.

ABSTRACT

Background: *Malnutrition is a serious and frequent condition among older adults. However, older adults are poorly assessed for malnutrition although it is not an uncommon problem in this population. Age related decline in food intake, is associated with various psychological, physiological, and social problems.* ***Aims:*** *The study was aimed to conduct more comprehensive nutritional assessment tests among malnourished and among normal elders to assess other geriatric syndromes and to investigate the association of geriatric syndromes with malnutrition.* ***Methods and Material:*** *An earlier community survey was conducted at the urban field practice area of PSG Institute of Medical Sciences and Research, Coimbatore on 154 households and 190 elders aged 60 years and above were interviewed. Malnutrition was assessed using mini nutritional assessment test (MNA) in which 37 were found to be malnourished, 47 were found to be at risk of malnutrition and 106 were found to be normal. The present cross sectional study included 30 malnourished elders and 30 normal elders randomly selected from this population. The geriatric syndromes were assessed and compared between malnourished and normal.* ***Results:*** *It was observed that, the presence of visual disturbances (86.71% vs. 53.3% x^2=7.937, P<0.01), dizziness, (60.0% vs. 16.7% x^2=7.937, P<0.01), hearing loss (40.0% vs. 10.0% x^2=7.200, P<0.01), dementia, (30.01% vs. 3.3% x^2=7.680, P<0.01) and depression (60.0% vs.13.8% x^2=13.464, P<0.01) were significantly higher in malnourished compared to normal elderly. The functional dependence mean + standard deviation (for GUGT (2.16+0.83 vs. 1.36+0.49 t=4.530 P<0.001 and Barthel index (83.50+12.18 vs. 90.66+6.91 t=2.801 P<0.01) were also significantly different between malnourished and normal elderly.* ***Conclusion:*** *The presence of various geriatric syndromes was significantly higher in malnourished elderly compared to normal. Thus, the interventional programs for malnutrition among elderly should also identify and address their geriatric syndromes.*

Keywords: Barthel index, elderly, geriatric syndrome, malnutrition

INTRODUCTION

Malnutrition is a serious and frequent condition among older adults [1]. The ageing process is a biological reality which has its own dynamic, largely beyond human control. However, it is also subject to the constructions by which each society make sense of old age. Aging is presumed to be process starting from infancy and continuing until death. On the other hand, being elderly is an unpreventable process that has biological, chronological, and social aspects and problems. Aging is a multidimensional change involving the physical, psychological as well as social aspects for an individual. It can be described as a progressive deterioration of the physical and mental functions resulting in a simultaneous decline in both the capacity of the body to maintain homeostatic balance as well as the adaptability of the individual to various stressors thereby consequently increasing the chances of illness and mortality. Many changes occur as people enter old age and these changes decrease quality of life.

Malnutrition is a condition that results from eating a diet in which nutrients are either not enough or are too much such that the diet causes health problems. It may involve calories, protein, carbohydrates, vitamins, or minerals. Malnutrition is often used specifically to refer to under nutrition where there is not enough calories, protein, or micronutrients. Poor nutritional status and malnutrition in the elderly population are important areas of concern.

Malnutrition and unintentional weight loss contribute to progressive decline in health, reduced physical and cognitive functional status, increased utilization of health care services, premature institutionalization, and increased mortality. Nonetheless, many health care practitioners inadequately address the multi factorial issues that contribute to nutritional risk and to malnutrition. A common assumption is that nutritional deficiencies are an inevitable consequence of aging and disease and that intervention for these deficiencies are only minimally effective [2]. Hence, despite the high prevalence of malnutrition among elderly, nutritional problems were not yet acknowledged by health professionals. The need for nutritional assessments and interventions are particularly crucial in this age group.

To determine the nutritional status, an earlier community survey was conducted at the Urban field practice area of PSG Institute of Medical Sciences and Research, Coimbatore on 154 households and 190 elders aged 60 years and above were interviewed. Malnutrition was assessed using mini nutritional assessment test (MNA) in which 37 were found to be malnourished, 47 were found to be at risk of malnutrition and 106 were found to be normal [1]. The predictive validity of mini nutritional assessment test has been validated in several studies by demonstrating its association with adverse health outcomes, social functioning, mortality, and higher rates of visit to general practitioner. Besides, this test has the advantage that without any laboratory test, nutritional status of elderly can be determined with questions and anthropometric measurements [1].

There were very few studies in which malnutrition is correlated to functional capacity in the elderly. Oliveira, et al. studied nutritional status and functional capacity in hospitalized elderly [3]. Li-Chin, et al. were able to show that MNA assessment could predict activity of daily living (ADL) and instrumental activity of daily living (IADL) status in community-dwelling elderly in Taiwanese population [4]. However, they did not do a comprehensive assessment of other parameters of functional capacity and nutrition. In order to suggest more appropriate measure to improve the health of the elders, further geriatric comprehensive assessment tests are needed to assess other geriatric syndromes. The present study was undertaken to compare the prevalence of other geriatric syndromes among malnourished and normal elders living in a community.

METHODS

Study design

This was a cross sectional study conducted to do an in depth comprehensive assessment among a sample of malnourished and normal elders.

Ethics

We have obtained the institutional ethical committee clearance prior to the study.

Sample size

We have used the sample size calculation for two sample means. With an expected standard deviation of Barthel index in the normal group as 4 and expecting 3 units decrease in the malnourished group, with α=0.05 and β=0.20, the sample size required for this study was 30 in each group.

Inclusion and exclusion criteria

The present study was conducted during June-August 2016 at the urban field practice area of PSG Institute of Medical sciences and Research, Coimbatore. India. The urban health centre of PSG Institute of Medical Sciences and Research has six areas on which three areas were randomly selected. An earlier community survey was conducted in these areas to estimate the prevalence of malnutrition [1]. The selected areas were HUDCO colony, AD colony, and Pattalmman Kovil street. The total number of households in these areas were 762. In 565 houses, there were no elderly people and non-response was obtained in 43 houses. Hence, we surveyed 154 households and 190 elders were examined in which 37 were found to be malnourished, 47 were found to be at risk of malnutrition and 106 were found to be normal [1]. From this study population, 30 malnourished and 30 normal adults were randomly selected.

Methodology

We have conducted a detailed comprehensive geriatric assessment after obtaining informed consent. Dementia was assessed using ‘mini-cog test” which include word recall score with a range of 0 to 3 and clock drawing score with range of 0 to 2. A total score of 0 to 2 indicates positive screen for dementia and 3 to 5 indicates negative screen for dementia [5]. Depression was assessed using validated “Geriatric depression scale” [6,7]. Barthel index test was done to measure the activity of daily living (ADL) [8]. This include a pre fixed score for feeding, bathing, grooming,

dressing, bowels, bladder, toilet use, bed to chair and back transfers and mobility on level surfaces and on stairs. In addition, we have conducted get up and go test (GUGT) [9]. Other established geriatric syndrome studied were visual disturbance, hearing loss, urinary incontinence, insomnia, dizziness, hearing loss and fall.

Statistics

The mean and Standard deviation (SD) of, ADL and GUGT were calculated and compared between malnourished and normal using independent t-test. Similarly, the prevalence of geriatric syndrome between normal and malnourished were compared using Chi square test. The data were analyzed using SPSS. $P<0.05$ was considered as statistically significant.

RESULTS

The mean (SD) of age in this subsample population for malnourished people was 71.33 (7.41) years and normal was 68.67 (5.91) years. The mean (SD) of MNA score for malnourished was 15.38 (1.23) and normal was 24.9 (2.48) (Table 1).

Table 1 Characteristics of the sample population by nutritional status

Variables		Normal (Mean (SD))	Malnourished (Mean (SD))	P value
Age		68.67 (5.91)	71.33 (7.41)	0.129
MNA		24.9 (2.48)	15.38 (1.23)	P<0.001
Sex (%)	Men	7 (23.3%)	12 (40.0%)	0.165
	Women	23 (76.7%)	18 (60%)	-

The presence of various geriatric syndromes was significantly higher in malnourished elderly compared to normal. We observed that the prevalence of visual disturbances (86.71% vs. 53.3% $x^2=7.937$, $P<0.01$), dizziness, (60.0% vs. 16.7% $x^2=7.937$, $P<0.01$), hearing loss (40.0% vs. 10.0% $x^2=7.200$, $P<0.01$), dementia, (30.01% vs.3.3% $x^2=7.680$, $P<0.01$) and depression (60.0% vs. 13.8% $x^2=13.464$, $P<0.01$) were significantly higher in malnourished compared to normal elderly. The functional dependence mean + standard deviation (for GUGT (2.16+0.83 vs. 1.36+0.49 t=4.530 $P<0.001$ and Barthel index (83.50+12.18 vs. 90.66+6.91 t=2.801 $P<0.01$) were also significantly different between malnourished and normal elderly (Table 2).

Table 2 Association of geriatric syndromes with malnutrition

Geriatric syndromes	Normal (N=30)	Malnourished (N=30)	P value
Visual disturbance	16 (53.3%)	26 (86.71%)	P<0.01
Urinary incontinence	1 (3.3%)	2 (6.7%)	0.554
Insomnia	11 (36.7%)	16 (53.3%)	0.194
Dizziness	5 (16.7%)	18 (60.0%)	P<0.01
Deafness	3 (10.0%)	12 (40.0%)	P<0.01
Fall	9 (30.01%)	11 (36.7%)	0.584
Dementia	1 (3.3%)	9 (30.01%)	P<0.01
Depression	4 (13.8%)	18 (60.0%)	P<0.001
Get Up and Go Test (GUGT Score) (Mean + SD)	1.36+0.49	2.16+0.83	P<0.001
Barthel index score (Mean + SD)	90.66+6.91	83.50+12.18	P<0.001

DISCUSSION

The world health organization has stated that aging population will present new challenges for health care [10]. The health of the elderly will be an important issue defining the health status of the population [11]. The mini nutritional assessment scale (MNA) is a widely used international questionnaire to evaluate the nutritional state of elders with high sensitivity (98.9%), specificity (94.3), and diagnostic accuracy (97.2%) [1]. However in India, only very few community studies were conducted to estimate malnutrition among elderly [1]. Both its reliability and validity were assessed by Mathew, et al. and found reliable and valid in Indian context [11,12].

The elderly is the fastest growing segment of the population including in India. Malnutrition has emerged as an important problem among elderly. In our earlier study, we have reported an estimated prevalence of 19.47% in the general population. There are different mechanisms involved in the development of malnutrition in elderly include gastrointestinal and endocrine system disorders, loss of taste and smell, decreased appetite and inadequate dietary

intake that is related to both disease state and psychosocial factors [12]. Many studies reported sarcopenia, immobility, social isolation, and dementia were also associated with decreased oral food intake [13]. The term 'geriatric syndrome' is used to cover functional impairment, cognitive impairment, malnutrition, incontinence, falls, depression, psychosis, insomnia, vertigo, and other related disorders [13].

In our study, nutritional status of malnourished patients was found correlated with the number of established geriatric syndromes. Dementia was one among them which had significantly higher proportion in malnourished group compared to normal group. Many studies reported that cognitive deterioration in the elderly affects daily functional status and instrumental activities which result with disability, dependence and decreased oral intake [14]. Many studies found greater impairment in both simple and instrumental daily living activities and a more severe ideomotor praxis deficit in patients at risk of malnutrition [15]. Activity of daily living measured through GUGT test and Barthel index test was associated with nutritional status in this study. We have also observed a significant association between visual disturbance and malnutrition. Visual activities can lead to fall which can affect the activity of daily living [3]. In an earlier study, it was observed that ADL was shown a relation between dietary quality and geriatric outpatients. Lower self-efficacy, a lower score of attitudes toward health and difficulty with meal preparation were found to be the common problems in many reported studies [2].

Depression has been proven to be a very common cause of weight loss in the older patients [16]. It was observed in some studies that weight loss in depression occurs in 90% in older patients, compared with only 60% in the youngsters [17]. It was also observed that causes of malnutrition in depressed patients mainly involve lack of appetite, loss of interest in self-care, apathy, and physical weakness [17]. In general, inadequate nutritional intake is associated with various conditions of older people, in particular, with subjective conditions such as mood and functional status and with objective situation such as living alone, income and education [18].

However, causal relationships between the factors and the nutritional status were unclear. Another limitation of the study is the collection of data from a small sample population. Large scale studies are needed for confirmation of findings. Another limitation of the study is dementia was assessed using mini cog test which was not followed up by confirmatory MMSE [18] as it is difficult to use in rural illiterate population. Despite these limitations, our study has several strengths. We have used validated tests to assess the geriatric syndrome. Many of these earlier studies were hospital based and not much studies were done at community. In addition, cases and controls were selected through a well-defined sampling procedure.

CONCLUSION

The presence of various geriatric syndromes was significantly higher in malnourished elderly compared to normal. This association between malnutrition and the presence of geriatric syndromes needs further study as either could be causative or a sequel of each other. An understanding of these causes is essential to formulate appropriate treatment strategies. Although an adequate nutrition supply is the key to the treatment of malnutrition, it alone may not necessarily be successful. Other causative factors must also be addressed and treated. In conclusion, the interventional programs for malnutrition among elderly should also identify and address their geriatric syndromes.

Abstract

A simple, reproducible and sensitive liquid chromatography (HPLC) method has been developed and validated for estimation of bisphenol A (BPA) in human urine. A simple liquid–liquid extraction technique was used in BPA sample preparation. The analyte was chromatographed on a Shimadzu Prominence HPLC system using isocratic mobile phase conditions at a flow rate of 0.500 ml/min and a Hypersil Gold C_{18} column maintained at 40°C. Quantification was performed on a fluorescence detector set at excitation 275 nm, emission 313 nm and bisphenol B was used as internal standard. The total run time was 8 min. The method was found to have acceptable sensitivity, selectivity, accuracy (98.82–103.64%), precision (1.17–5.36) and stability in the validation experiment carried out as per the USFDA guidelines. The method sensitivity was as low as 0.50 ng/ml. The applicability of the validated analytical method was established in human patient urine samples. The mean human urine BPA concentrations were 1.18 ± 2.11 ng/ml in the control group and 5.76 ± 6.00 ng/ml in the patient group ($P < 0.001$). Therefore, this method could be considered as an alternative for routine bio-monitoring of BPA which is less expensive and feasible in resource-poor settings.

KEYWORDS
bisphenol a, breast cancer, HPLC–FLD, human urine, patients

1 | INTRODUCTION

Bisphenols are a heterogenous class of phenolic chemical compounds, formed by aromatic condensation of two phenol rings (Rochester, 2013). About 18 bisphenolic compounds have been synthesized and named as per the synthetic functional groups with which the phenols condense. Bisphenol A (BPA) is formed when two phenol groups react with acetone, whereas bisphenol S is formed after sulfur trioxides react with phenols groups. However, the efficiency of their overall radioactive degradation is high (76%) (Rochester, 2013).

Bisphenols have been used as either polycarbonate or epoxy resin polymers in various applications (Peller et al., 2009). For example, epoxy bisphenol resins have been used in floorings, varnishes, printed circuit boards and beverage cans, among many applications, whereas polycarbonate polymers have applications in housing electronics, optical devices and other important industrial uses (Corrales et al., 2015). Many of these industrial applications are due to their favorable chemical properties and their superiority over alternative chemicals. For example, their use in medical equipment as reflectors is unavoidable and no alternatives are available, owing to their favorable optical properties. The use of BPA in dental fillings, brake fluids, flame retardants in electronic equipments, rubber and thermal paper industries is allowed up to a permitted level.

List of Abbreviations: BPA, bisphenol A; FLD, fluorescence detection; HPLC, high-performance liquid chromatography; TBME, *tert*-butyl methyl ether; USFDA, United States Food and Drug Administration.

Certain bisphenols can enter the body of fishes through contaminated water, and when these fishes are consumed by humans, they can enter the higher levels of the food chain. Bisphenols can also enter the body via food cans when they react with hot water and are consumed. Epoxy resin polymers of bisphenols can also penetrate the body via food when foodstuffs with additives containing phenolic chemicals are consumed. Other industrial chemicals like tetra-bromobisphenol A, which are manufactured in large quantities, are degraded to bisphenolic chemicals in the environment. Bisphenols are known to be toxic and to pollute the environment. Two such bisphenols, BPA and bisphenol S are proven to be endocrine disruptors (Ribeiro et al., 2017). Certain bisphenols like BPA are potent carcinogens, and have been shown to either induce cancers or be associated with the risk of cancer progression in animal and human models (Stossi et al., 2014). This has been attributed to their interaction with the nuclear receptors like aryl hydrocarbon receptors in endocrine tissues. Their etiological role in the causation and progression of hormone-positive cancers like breast cancer has been proven to be because of the ability of the BPA–aryl hydrocarbon receptor complex to induce estrogen-modulated developmental reprogramming (Dang et al., 2007; Fernandez & Russo, 2010). Owing to their toxicological profiles as environmental pollutants, their production, supply and use are regulated by the United Nations Basel and Stockholm Conventions as industrial chemical pollutants (Haffner & Schecter, 2014).

Recent evidence indicates that, more than the glucuronide metabolite levels in urine, the levels of the parent BPA is highly indicative of bisphenolic toxicity profiles, although the urinary levels of the metabolite are generally higher (Foster et al., 2019). Although the estimation of phase II BPA metabolites indicates the source of exposure in humans as compared with urinary BPA levels (Gerona et al., 2016), there may be significant inter-species variation in the metabolite concentrations in urine, leading to variations in both total BPA and metabolite BPA levels in urine (Völkel et al., 2002). Hence, in this study, we hypothesize a probable association of urinary BPA levels in cancer patients with the risk of breast cancer.

The biomonitoring of BPA and its metabolites in urine was evaluated using high-performance liquid chromatography coupled with fluorescence detection (HPLC–FLD) after chemical derivatization with *p*-nitrobenzoyl chloride (Mao et al., 2004). Other methods to estimate these compounds in biological matrices have also been developed as high-throughput alternatives to HPLC, like ultra-high-pressure liquid chromatography–mass spectromentry (UPLC–MS; Anderson et al., 2014), liquid chromatography–tandem mass spectrometry (LC–MS/MS; Lee et al., 2013; Li & Franke, 2015) and SPE-UPLC–MS (Jing et al., 2011). However, these methods are neither cost-effective nor time-efficient, and hence cannot be employed in regular biomonitoring of both environmental and biological samples in a routine manner. While LC–MS/MS methods are beneficial in several ways, the costly instrumentation and restricted accessibility for regular hospital practice and laboratories are their major limitations.

In this study, the association of urinary BPA concentrations and the risk of breast cancer was assessed in patients. To achieve this objective, an HPLC–FLD method for BPA was developed and validated. Additionally, the method was designed using an isocratic mobile phase proportional with a light buffer and better reproducibility with less interference. An LC–MS/MS compatible buffer and chromatographic conditions were used; if required, the method can be easily adapted to suit LC–MS/MS. The method and chromatographic conditions employed are high-throughput, cost-effective and time-efficient for estimating BPA in human urine. The proposed method was successfully applied to estimate the exposure of BPA in human urine samples in breast cancer patients and a comparable control group.

2 | MATERIALS AND METHODS

2.1 | Chemical and reagents

Acetonitrile and methanol HPLC grade were purchased from Sigma-Aldrich, India. Ammonium acetate of HPLC grade was purchased from Fisher Scientific, India. The reference standard BPA and bisphenol B (internal standard, IS) were purchased from Sigma-Aldrich, India. Methyl *tert*-butyl ether (TBME) and acetic acid of HPLC grade were obtained from Himedia, India. Blank urine was obtained from the blood bank services of PSG Hospitals, Coimbatore, India. Ultrapure water (18.2 MΩ cm), used in all experiments, was obtained from a MilliQ water purification system (Millipore, Milford, MA, USA).

2.2 | Instrumentation and chromatography conditions

The bioanalytical method was developed using an HPLC instrument consisting of a Shimadzu Prominence HPLC system equipped with an isocratic solvent delivery unit LC–20A pump and column oven CTO-20A coupled with a fluorescence detector (Shimadzu, RF-20A, Japan). The chromatographic separation was performed on a Thermo Hypersil Gold C_{18} column from Thermo-Fisher (3.0 × 150 mm; 5 μm). The column temperature was set at 40°C. The mobile phase was composed of a mixture of solvent A (80% acetonitrile in water, 60%, v/v) and solvent B (10 mM ammonium acetate, 40%, v/v) at a flow rate of 0.5 ml/min. Before analysis the mobile phase was filtered through a 0.45 μm membrane filter and degassed by ultra-sonication. A 20 μl injection of each sample was loaded onto the system and total analysis time was 8 min. The calibration curve was linear over the concentration range 0.5–100 ng/ml. The fluorescence detector set at excitation 275 nm and emission 313 nm. Data acquisition was done using LC solution software (Shimadzu).

2.3 | Preparation of calibration standard and quality control samples

The BPA and IS stock solutions were prepared in methanol at a concentration of 1,000 μg/ml. The series of BPA working stock solutions

in the concentration range of 10–1,000 ng/ml were obtained by further diluting the stock solution with methanol–water (50:50, v/v). The stock solution of BPA and IS were stored at 4°C until analysis. The calibration standards of BPA in urine with final concentrations of 0.50, 2.0, 5.0, 15.0, 30.0, 50.0, 70.0, 90.0 and 100 ng/ml were prepared by spiking a 450 µl aliquot of blank urine with a 50 µl aliquot of BPA working standard stock solutions. Quality control samples (QC) were prepared at four concentration levels of 0.50 ng/ml (lower limit of quantification, LLOQ), 2.50 ng/ml (low quality control, LQC), 35.0 ng/ml (middle quality control, MQC) and 80.0 ng/ml (high quality control, HQC). These samples were stored at −80 ± 10°C.

2.4 | Sample preparation

Sample preparation was carried out by the liquid–liquid extraction procedure. To a 500 µl of aliquot of urine, 50 µl of IS working solution was added into a 5 ml polypropylene tube and mixed for 30 s on a Spinix vortex shaker (Tarsons, India). To this was added 3.0 ml of TBME and it was vortex mixed for 5 min. The solution was centrifuged at 3,000 rpm for 5 min at 4°C on an Eppendrof 5810R centrifuge (Eppendrof AG, Hamburg, Germany). The clear organic layer was transferred into 5 ml clean glass tubes and evaporated to dryness at 40°C using nitrogen evaporator (Turebovap®, Biotage, USA). The residue was reconstituted in 250 µl of the mobile phase, vortex mixed for 1.0 min and centrifuged at 10,000 rpm for 5 min. Finally, the clear supernatant was injected onto the HPLC system for analysis.

2.5 | Development of an HPLC method

Different buffers, ionic strengths and pHs were used as an aqueous solvent during method development. Acetonitrile and methanol were used at different compositions to optimize and evaluate the organic content of the mobile phase. A C_{18} column was used to attain optimum retention, resolution and good peak shape for BPA and IS.

2.6 | Development of sample extraction method

Different extraction methods were employed, such as protein precipitation and liquid–liquid extraction, to obtain maximum recovery and good peak shape without interferences. Methanol, acetonitrile and trichloroacetic acid were used as the precipitating solvent for protein precipitation. Dichloromethane, hexane, ethyl acetate and TBME solvents were used in the liquid–liquid extraction method with different acidic, basic and neutral conditions.

2.7 | Bioanalytical method validation

The validation procedures were carried out according to US Food and Drug Administration guidelines (USFDA, 2018) as explained previously (Siva Selva Kumar & Ramanathan, 2016). The method was validated for selectivity, specificity, recovery, linearity, accuracy, precision and stability using US Food and Drug Administration (USFDA) guidelines[17] for assay in human urine.

2.8 | Selectivity and specificity

Selectivity of the method was assessed by analyzing 10 separate human urine samples that were collected and injected at the beginning of the validation and the potential interferences at the LC peak region for analytes and IS were subsequently investigated. At least eight out of 10 lots should have a response less than 5 times the lower limit of quantification (LLOQ) level response in the same matrix as per USFDA guidelines (USFDA, 2018).

2.9 | Carryover

Carryover effects were assessed by injecting the HQC samples just before the blank human urine to check for potential interference. As per the USFDA guidelines, carryover assessed by injection of high concentration should be <20% of the area of the LLOQ (USFDA, 2018).

2.10 | Sensitivity

Sensitivity of the method was evaluated by spiked urine samples at LLOQ level injected six times and the area of the BPA peak at LLOQ level should be at least 5 times greater than the blank peak area, as recommended by USFDA guidelines. As per the USFDA guidelines, the injected LLOQ samples accuracy should be ±20% and the precision, expressed as the coefficient of variation, should be <20% (USFDA, 2018).

2.11 | Extraction recovery

The recovery was evaluated to demonstrate the reproducibility of the extraction procedure. The recovery of the BPA in LQC, MQC and HQC samples (six extracted QC samples) was evaluated relative to six extracted blank samples spiked with neat standards containing concentrations equivalent to low, mid and high concentrations of BPA with the intended standard concentration (200 ng/ml) corresponding to 100% recovery.

2.12 | Linearity

Linearity was evaluated by linear regression analysis with the use of working standard solutions and spiked urine samples containing the BPA of interest at different concentrations within the range

0.50–100 ng/ml for BPA. The calibration curves were constructed by plotting the ratio of the peak area of BPA to the peak area of internal standard vs. the nominal BPA concentration. The slopes and intercepts were calculated with least square linear regression analysis of the data with the use of a $1/x^2$ (where x is concentration) weighting factor. The acceptance criteria for each back-calculated standard concentration were ±15% deviation from the nominal value except at the LLOQ, which was set as ±20% (USFDA, 2018).

2.13 | Accuracy and precision

The validation methods for evaluation of the accuracy and precision in the experiments were performed as four independent series (including ruggedness) in urine. The intra- and inter-day assay accuracy and precision were estimated by analyzing six replicates containing analytes at four different QC levels, that is, 0.50, 2.5, 35.0 and 80 ng/ml. The accuracy, which represents the closeness of the agreement between the mean values obtained from the series of measurements by the method and the actual value, should be within 85–115% of the nominal value, except at the LLOQ, where it should not deviate by <20% (USFDA, 2018). Precision, which represents the closeness of agreement among a series of measurements obtained from multiple sampling, was estimated with variances in repeatability (intra-day variances) and intermediate precision (sum of intra- and inter-day variances). The precision should not exceed ±15% relative standard deviation (RSD), except for at the LLOQ, where it should be within ±20% of the RSD (USFDA, 2018).

2.14 | Stability

Stability tests were performed to evaluate the stability of analyte in urine samples under different conditions that might be encountered during processing of patient sample analysis. The bench-top stability study assessed the stability of the analyte in urine at room temperature for 8 h, whereas a post-preparative stability study assessed the stability of the analyte in the treated samples (refrigerator stability for 24 h at 10°C) at low (2.5 ng/ml) and high (80 ng/ml) QC concentrations. Freeze–thaw stability was determined after three freeze–thaw cycles and long-term stability was determined by asessing QC samples stored at −80°C for 30 days against a freshly spiked calibration curve and quality control samples.

2.15 | Participants

The present study was a hospital-based case–control study which included 50 breast cancer cases and 50 healthy control subjects. The study was approved by the Institutional Human Ethics Committee and all consenting participants were included. Clinically confirmed breast cancer subjects were recruited from the Department of Medical Oncology, PSG Hospitals, Coimbatore. The age-matched controls were those who had undergone mammogram screening for a routine health checkup during the same period, and not been diagnosed with breast cancer. Informed consent was obtained for all the participants and during the hospital visit we collected 5 ml of urine from each subject in a sterile container and stored it at −80°C until use.

2.16 | Statistical methods

Data analysis was performed using SPSS (IBM SPSS, version 24.0). Comparisons of BPA urinary concentrations among the groups were conducted using nonparametric procedures, including *t*-tests and Mann–Whitney *U*-test. Statistical significance was set at $P < 0.05$. Data was reported as mean ± SD.

3 | RESULTS AND DISCUSSION

3.1 | Optimization of the chromatographic conditions

Method development was initiated for the determination of BPA in human urine samples using reverse-phase liquid chromatography coupled with fluorescent detection. The HPLC–FLD method development was performed to achieve adequate resolution of BPA and endogenous interferences in matrix with simple buffers and short run time. This method has certain advantages over those which were used earlier for BPA quantification in urine samples. In the method development, different mobile phases comprising a number of combinations of buffers (e.g. acetate buffers and phosphate buffers) and organic solvents (methanol and acetonitrile) along with different flow rates (0.350–0.800 ml/min) were tested to optimize for a successful chromatographic resolution of BPA and IS. In the mobile phase optimization, methanol solvents produced an asymmetric peak shape and long run time. Acetonitrile was used as the organic solvent in the mobile phase, and peaks were sharp and symmetrical and the run time was reduced. The good resolution of peaks attained with isocratic mobile phase consisted of a mixture of 80% acetonitrile in water (60%, v/v) and 10 mM ammonium acetate (40%, v/v) at a flow rate of 0.5 ml/min on a Hypersil Gold C_{18} column. Compared with phosphate buffers, volatile buffers like ammonium acetate in mobile phase give good column life and can be suitable for mass spectrometry.

3.2 | Development of sample extraction method

Poor recovery was observed with precipitation extraction for BPA (23.48%). For liquid–liquid extraction, BPA recovery was 31.88 and 38.28% for dichoromethane and ethyl acetate. TBME was used as the extraction solvent in neutral, acidic and basic conditions. However, a reproducible and good recovery (>90%) was obtained in TBME with neutral conditions for BPA and the IS. Therefore, liquid–liquid

extraction using TBME was the preferred method for human urine sample preparation in this study.

3.3 | Bioanalytical method validation

3.4 | Selectivity and specificity

Selectivity of the method was evaluated by analyzing pooled BPA-free human blank urine, blank urine spiked with IS and with analyte injected at the beginning of the validation, and the possible interferences at the LC peak region for analyte and IS were investigated (Figure 1). At least eight out of 10 lots should have a response <5 times the LLOQ level response in the same matrix.

3.5 | Carryover

There was no peak response observed when the highest calibration standard was analyzed just before the blank urine. This indicated that the washing step of the column at the end of the chromatography separation was adequate to remove potential residues of the analyte. The BPA peak response in blank was <20% of the LLOQ.

3.6 | Sensitivity

The analyte peak area at LLOQ was found to be >5 times higher compared with the peak area of the blank sample. The mean accuracy for BPA for the six LLOQ injections was 101.82% and the precision value for BPA was 3.57 (CV). Hence, the developed method was sensitive at LLOQ level (0.50 ng/ml).

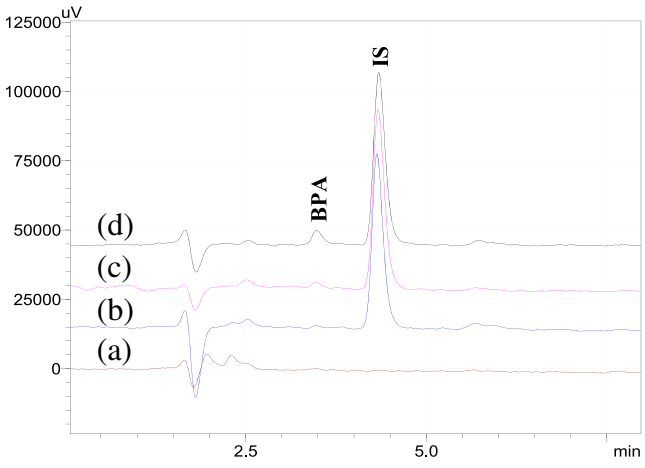

FIGURE 1 Representative HPLC chromatograms of bisphenol a (BPA) and internal standard (IS) in human urine. (a) Blank urine sample; (b) blank urine spiked with IS; (c) blank urine spiked with analyte (0.50 ng/ml) and IS; and (d) sample collected from breast cancer patient

3.7 | Recovery

The liquid–liquid extraction technique gave adequate recovery and cleaner samples. The results of the evaluation neat standard vs. urine extracted standard were estimated for BPA (2.50, 35.0 and 80.0 ng/ml) and the mean recovery was 96.07 ± 8.42%. The recovery of the IS at 200 ng/ml was 79.12 ± 4.45%.

3.8 | Linearity

The calibration curves were constructed using nine calibration standards in human urine and exhibited excellent linearity with regression correlation coefficient (r^2 > 0.996) over the concentration range of 0.50–100 ng/ml for BPA. A typical regression equation was prepared by determining the best fit of peak-area ratio (peak area analyte/peak area IS) vs. nominal BPA concentration. The slopes and intercept were calculated with least square linear regression analysis of the data with use of a $1/x^2$ weighting factor. The lowest concentration with the RSD <20% was taken as the LLOQ and was found to be 0.50 ng/ml for BPA. The percentage accuracy observed for the mean back-calculated concentration for four calibration curves for the BPA was within 95.40–105.30%.

3.9 | Accuracy and precision

The accuracy and precision of the method were evaluated as intra-day (repeatability) and inter-day (intermediate) human urine for BPA samples, as summarized in Table 1. The intra- and inter-day precisions were <5.36% and the accuracy ranged from 98.82 to 103.64% at all levels. All the values were within the accepted range and the method was accurate and precise.

3.10 | Stability

The stability of BPA in human urine was investigated under a variety of storage and process conditions, in urine at room temperature for 8 h, in the refrigerator for 24 h at 10°C, after three freeze–thaw cycles and after long-term storage at −80°C for 30 days, as summarized in Table 2. The results indicated that BPA was stable under the conditions described.

3.11 | Regular practical applicability of the validated analytical method in patient samples

An association study between the prevalence of breast cancer and urine BPA concentrations was successfully undertaken. To achieve this objective, patient samples were analytically processed to estimate the BPA levels in urine and these were later correlated with the patient's phenotype status with emphasis on breast cancer.

TABLE 1 Intra- and inter-day precision and accuracy of bisphenol A (BPA) in human urine

	Intra-day ($n = 6$)			Inter-day ($n = 18$)		
Nominal concentration (ng/ml)	Measured concentration (mean ± SD, ng/ml)	CV (%)	Accuracy (%)	Measured concentration (mean ± SD, ng/ml)	CV (%)	Accuracy (%)
0.55	0.57 ± 0.03	5.26	103.64	0.56 ± 0.03	5.36	101.82
2.54	2.58 ± 0.12	4.65	101.57	2.51 ± 0.10	3.98	98.82

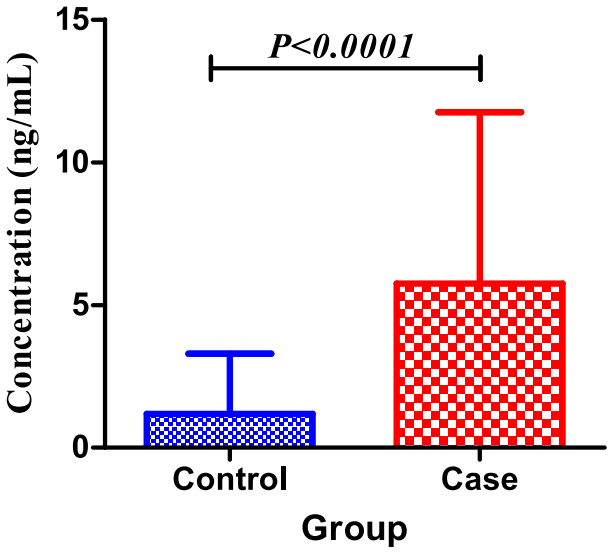

FIGURE 2 The mean urinary BPA levels in control vs. case group

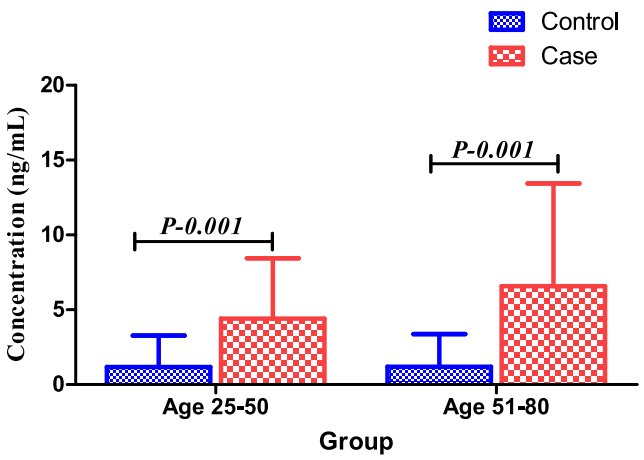

FIGURE 3 The mean urinary BPA levels in control vs. case in the age groups 25–50 and 51–80 years

Moreover, 84% of cases and 64% of controls in our study had detectable levels of BPA in the biological matrix cross-section.

The mean urinary BPA level in the control group was 1.18 ± 2.11 ng/ml, whereas it was 5.76 ± 6.00 ng/ml in the patient group ($P < 0.0001$; Figure 2). The mean ages of the study population were cases, 52.68 ± 10.99 years, and controls, 48.48 ± 10.07 years. The sample of study volunteers was then divided into two age groups for subgroup analysis. In the 25–50 year age group, the mean urinary BPA concentrations in the control and patient groups were 1.18 ± 2.09 and 4.41 ± 4.04 ng/ml ($P < 0.001$; Figure 3). These were 1.19 ± 2.19 and 6.58 ± 6.87 ng/ml in the 51–80 years control and patient group populations ($P < 0.0001$). The data are summarized in Table 3.

3.12 | Current status of BPA biomonitoring in breast cancer patients

Bisphenol A is used as a plasticizer in rubber and chemical manufacturing units, and it is useful as a chemical reagent in the synthesis of epoxy resins and polyvinyl chloride. It is also useful in healthcare industrial sectors, for example in dental extraction units

TABLE 3 Comparisons of BPA concentration and age in case vs. control study in breast cancer patients

Groups	Case (mean ± SD)	*N*	Control (mean ± SD)	*N*	*P*-Value

(Konieczna et al., 2015). However, it is an environmental pollutant, specifically classified as a Persistent Organic Pollutant by the United Nations Stockholm Convention and as a grade 2B as a possible carcinogen in humans by the International Agency for Research on Cancer (IARC) (Seachrist et al., 2016). However its potential risk as an endocrine disruptor is greater in causing breast cancer and neuroendocrine toxicities. We have investigated the association between prior BPA exposure, cross-sectionally quantified in the urine of patients, and the breast cancer phenotype in different age groups.

Bisphenol A increased the risk of trans-generational epigenetic transfer when Sprague–Dawley rats were fed with graded doses in a high-fructose diet for 2 weeks (Holmes, 2017), which increased breast cancer incidence in female offspring rats. Indeed BPA is a known carcinogen and environmental endocrine disruptor. The carcinogenic ability of BPA is apparently expressed in mice exposed prenatally to ≥0.25 μg/kg b.w./day, on embryonic day 18, by increased chronic inflammatory processes in the breast adipocytes and tissue (Wang et al., 2017). It exhibits carcinogenic potency in breast tissue by increasing the expression of hormone and proliferation of hormone-positive breast tissue cell, both *in-vitro* and *in-vivo*. Since BPA is an estrogenic compound with endocrine disruption potential, it is hypothesized to increase the proliferation of estrogen-positive breast cells, specifically of the MCF-7 lineage (Soto et al., 1995; Vandenberg et al., 2009; Wang et al., 2017). Being structurally similar to estrodiol, BPA increases wet uterine weight and lactoferrin expression and has other effects in estrogen-specific screens (Markey et al., 2001). Being also chemically similar to diethylstilbestrol, it can increase the risk of *in-utero* estrogenic effects in both animal models and humans, causing trans-generational endocrine disruption (Seachrist et al., 2016). Although it can bind to both forms of nuclear receptors for estrogen, its affinity to bind to orphan estrogen-related and GPR-30 receptors stimulates the genomic and nongenomic cascades of cellular proliferation in the breast tissue. Low-dose BPA can also additionally suppress androgen synthesis and thyroid hormone actions, both of which can further contribute to the endocrine disrupting effect of this pollutant.

The geometric mean of BPA concentrations across seven countries was 1.20 ng/ml, and it was found to be the highest in India with a median urinary level of BPA reaching 1.71 ng/ml in the general population (Zhang et al., 2011). Although the range of creatinine-clearance-adjusted BPA levels in urine in volunteer samples was broad (0.31–39.2 μg/g), it was reported to be nearly equal in male and female genders. In this study, the mean BPA urinary concentration in the volunteers was 1.18 ± 2.11 ng/ml, which approximates previously reported exposure levels in the general population. In breast cancer patients, there was a 3- to 4-fold increase in this value (mean urinary level was 5.76 ± 6.00 ng/ml in cases). This was higher than previously reported values in cases with breast cancer (after adjusting for creatinine clearance), approximating nearly 0.71 ± 0.31 ng/g in breast adipocytes (Reeves et al., 2018). The level was higher in the blood samples of cancer patients in another case–control study (mean blood BPA was 13.87 ng/L (Yang et al., 2009), and in the general population (noncancer volunteers) in urine (0.37 ng/g creatinine in rural areas vs. 0.46 ng/g in urban areas) owing to chronic low-dose environmental exposures (Battal et al., 2014).

The current study proposes a biomonitoring method that could be routinely used for urinary estimation of BPA in both control populations and breast cancer patients as a toxicology biomarker. It is a cost effective and less expensive alternative to other methods used for BPA estimation. For example, studies reporting effective methods for BPA estimation like gas chromatography–mass spectrometry, LC–MS/MS (Caban & Stepnowski, 2020; Kato et al., 2005). Most of these reported methods also have used the highly expensive solid-phase extraction in BPA biomonitoring, using environmental samples for research outcomes (Caban & Stepnowski, 2020; Murphy et al., 2019). Moreover, this study reports a less time-consuming method of BPA estimation in patients for the first time in a South Indian population using robust case–control design compared with previous reports (Murphy et al., 2019). Other studies reported in India have developed and applied expensive method alternatives to the one developed, and have reported their application in patient plasma biomonitoring for other diseases (Pednekar et al., 2018). Finally, this method has been validated in 100 healthy volunteers and patients, with a higher degree of precision and extrapolatibility to human biomonitoring, owing to higher statistical confidence. This reported method hence could be used for routine risk assessment and biomonitoring of both environmental samples and patient matrices, with minor variations in method optimization, in a high-throughput, cost-effective and time-gaining manner, in contrast to previous reports in an Indian population.

To conclude, a high-throughput, cost-effective routine alternative to LC–MS (HPLC–FLD) without compromising on the analytical

accuracy was developed as an easier low-cost alternative for screening BPA in urine samples.

4 | CONCLUSION

A reliable, simple and sensitive HPLC method has been developed and validated for BPA analysis and applied to obtain a significant association in breast cancer patients' urinary samples. This method has significant advantages, including adequate recovery and good peak shape with shorter run time.

We have developed a rapid and reliable method to estimate the BPA in human urine and applied it for quick and cost-effective routine biomonitoring in breast cancer patients exposed environmentally to BPA. This method has similar sensitivity to other methods developed using LC–MS/MS.

Background: According to the recommendations from The World Health Organization, exclusive breast feeding (EBF) should be given to infants for the first six months for healthy growth and development. However, developing countries have a wide range of variation in the practice of EBF. From this study, we aim to estimate the duration of EBF and find the impact of socio-demographic characteristics on EBF.

Materials and Methods: This study was conducted at PSG Institute of Medical Sciences and Research, Coimbatore in the month of July 2018. Mothers with children aged below 4 years attending the paediatric outpatient department were included in the study. Kaplan-Meier curve analysis and logistic regression analysis were employed.

Results: Our analysis indicates that the prevalence of EBF was 58.4% among infants up to 6 months of age with mean duration of EBF 4.52 months. It was observed that mothers of a younger age (15-24 years) and with lower socio-economic status were negatively associated with the practice of providing EBF to infants up to six months of age.

Conclusion: The findings clearly indicate that the interventions related to EBF up to six months of age should be targeted at women in the lower socio-economic status and at younger ages.

Keyword: Exclusive breast feeding, socio-economic status, mother's age.

Introduction

According to the recommendation of the World Health Organization (WHO), exclusive breastfeeding (EBF) should be given to infants for the first six months of life and continued breastfeeding up to two years of age or beyond for the healthy growth and development [1-3]. Recent literatures have suggested exclusive breastfeeding as a cost-effective intervention to reduce infant mortality rate in less developed countries [4, 5]. Globally, it is estimated that the lack of providing exclusive breast feeding to infants in the first 6 months of life results in 1.4 million deaths and 10% of disease in under-five children [6]. On the other hand, poor school performance, reduced productivity and impaired intellectual and social development are reported to be much higher due to the lack of EBF in the first 6 months of life.

In India, a large number of children, nearly 20 million, were not able to receive EBF for the first six months, according to the reports from National Family Health Survey (NFHS) [7]. Over the past several years, India has failed to witness any remarkable achievements in infant feeding practices. Only a small increment was recorded in EBF rates amongst infants in the 0-6 month age group from 41.2% in 1998-99 (NFHS 2) to 46.3% in 2005-2006 (NFHS 3). The mean duration of EBF among last born children is as brief as two months.

In 2016, the Government of India started various initiatives to tackle the health issues among children due to inappropriate breast-feeding practices. The Government of India developed the infant and young child feeding guidelines in 2016 in view of this initiative. However, more studies are needed to explore the factors associated with the low proportion of EBF. The present study aims to estimate the duration of EBF and to find the impact of socio-demographic characteristics influences on EBF practice.

Methodology

Study design and setting

A cross-sectional study was conducted at PSG Institute of Medical Sciences and Research, Coimbatore in the month of July 2018. The mothers of infants less than four years of age, who attended the paediatric outpatient department, were included in the study. The selected mothers were broadly classified into two groups: EBF and non-EBF. Mothers having children aged below 6 months and who were given only breast milk in the 24 hours preceding the survey were considered as EBF and others were in non-EBF group [8].

Sample size estimation

In order to estimate the EBF with the precision of 20% of the expected prevalence of 30%, with 95% CI, we require a minimum sample size of 300 for the study.

Data collection

Data were collected using direct interview method. Mothers were interviewed about the duration of EBF in months with respect to youngest child. The socio-demographic characteristics and breast-feeding related information were elicited from the selected mothers. The characteristics studied were educational status of the mother, age of the mother, working status of the mother, educational status of father, socio-economic status of the household, child's gender, gestational age of the child, birth weight of the child, mode of delivery, condition of the child soon after delivery, and counselling for breastfeeding after delivery. The socio-economic status was calculated using Prasad classification with class 1 as the person having per-capita income greater than or equal to Rs.6180, class 2 ranging from Rs.3090-6179, class 3 ranging from Rs.1850-3089, class 4 ranging from Rs.930-1849, and class 5 as person having per-capita income below Rs.930. The classification was done based on the Consumer Price Index (CPI) value of 279 for Coimbatore [9].

Exclusion criteria

Babies with congenital anomalies that interfered with breastfeeding were not included in the study.

Ethical approval

The study was approved by the Institutional Human Ethics Committee, PSG Institute of Medical Sciences and Research, Coimbatore.

Outcome variable

The outcome variable was the exclusive breast feeding (EBF) status of infants up to six months of age.

Explanatory variables

Mother's age, educational status of mother and father, working status of mother, gender, gestational age and birth weight of the child and socio-economic status of the household were the explanatory variables.

Statistical analysis

To estimate the mean and median duration of exclusive breast feeding among infants under study, the Kaplan-Meier Survival analysis method was applied and conditional probability of survival at monthly interval of time was then obtained. The termination of EBF was considered as outcome of the event of the occurrence. Accordingly, those women who fed their babies exclusively with breast feeding on the date of interview were considered as censored cases. In such cases, the duration of EBF was recorded as it was not known when they would discontinue EBF and start introducing adult diet. The duration of exclusive breastfeeding was sub grouped into smaller time intervals and for each interval all those who have been observed at least that long were used to calculate the probability of a terminal event occurrence in the interval. Then the overall probability of the event occurrence at different time

periods were estimated using the probabilities estimated from each interval. Survival probabilities, standard error, hazard rate, and mean and median survival time have been calculated. Log rank test was applied to compare the statistical significance for the equality of duration of exclusive breast feeding for different groups. In addition, logistic regression analysis was done to find the association of socio-demographic characteristics with EBF categorized as Yes or No. Odds ratio and then 95% confidence intervals were then calculated. Multivariate logistic regression analysis was done for those variables found significantly associated with the outcome variable of interest in the Univariate analysis. $p<0.05$ was considered as statistically significant. The data were analysed using SPSS (Ver. 23).

Results

A total of 527 women were studied. The socio-demographic characteristics of infants and families are given in Table 1. The prevalence of exclusive breast feeding was 58.4% among infants up to 6 months of age with the mean duration of EBF as 4.52 months.

On testing equality of the duration of EBF, it was observed that the mean duration of EBF was higher in mothers of age group 35-44 years than those aged 15-24 years and 25-34 years ($p<0.05$). The mean duration of EBF was more in class 1 and 2 of the socio-economic status than class 3,4, and 5 of the socio-economic status ($p<0.05$). The mean duration of EBF was more in children whose father's education was above 12th standard than those less than 12th standard ($p<0.05$). It was also observed that the mothers with the sick children tend to do less EBF than those with well children ($p<0.05$). The findings are presented in Table 2.

In the logistic regression analysis (Table 3), the prevalence of EBF was higher among the mothers of age group 25-34 years than those aged 15-24 years ($p<0.05$) and it was significantly higher among class 1 and 2 of the socio-economic status than class 3, 4, and 5 of socio-economic status ($p<0.01$). The multivariate logistic regression analysis also shows that the socio-economic status of class 1 and 2 had significantly higher prevalence of exclusive breast feeding than class 3, 4, and 5 of the socio-economic status ($p<0.01$) with an odds ratio of 1.788 (95% CI: 1.153-2.775). In addition, the prevalence of EBF was higher among the age group 25-34 years than in the aged group 15-24 years ($p<0.05$) with an odds ratio of 1.572 (95% CI: 1.021-2.421).

During the interviews, 47 (8.9%) mothers reported the problem of inverted nipple as a constraint for EBF. Seventy-seven (14.6%) mothers perceived to have the problem of low breast milk and 124 (23.5%) mothers had employment outside home. In addition, 151 (28.6%) mothers had no supportive family members at home (Table 4). It was also observed that there was a statistically significant association between perception of low breast milk and lower socio-economic status ($p<0.05$) (Table 4).

□ □□□□□□□□□□

□r □□□□□□□□□□□□□□□□□□□□□□□□□r □□□□□□□d □□□□□

Breast feeding is universally recognized as the best way of feeding infants which helps in their healthy growth and development. Therefore, several countries, especially developing nations, have started implementing health promotion interventions to support successful breastfeeding by taking into account the factors influencing breast feeding outcomes. For infants till the first six months of life, the WHO strongly recommends EBF without any additional food or water. The WHO also suggests providing complementary diet at 6 months along with breast milk and sustaining breast feeding until the age of 2 years. However, whether an infant is breastfed or formula fed depends on several factors like social, psychological, and environmental scenarios.

Despite several efforts made for EBF up to six months, in our study, 42% of the mothers were still not following EBF up to six months. The mean duration of EBF was 4.52 months which is much lower than the findings reported by Chudsama et al. [5]. Infants not exclusively breast fed up to six months are at risk of higher occurrence of associated infections, malnutrition deficiencies, and under-development [10, 11]. Most of the recent studies regarding EBF come out with the similar fact that the practice of EBF tends to decline and highlight the tremendous progress in the marketing of industrial milk products as well as the lack of awareness of this serious issue among mothers.

□□□□□□□□□□□ □□□□□□□□□□□□d □□□□□□□□□□□□□□□□□□□□ □□□□□□□□□□□□□□□□□□□□ □r □□□□□□□□□d □□□□□

A significantly lower prevalence of EBF was observed among mothers with lower socio-economic status, which is controversial with the result obtained from an Ethiopian demographic health survey that explained a declining trend of EBF with the higher maternal educational and socio-economic

status [12]. Furthermore, our study found that the duration of EBF was significantly lower among mothers with lower socio-economic status. The findings of our study clearly acknowledge socio-economic status of the household as a major influencing factor for longer breastfeeding practice among mothers in a higher income bracket. In addition, we have also observed a significant association between the perception of low breast milk and lower socio-economic status. The findings clearly suggest that interventions should be tailored to target women with lower socio-economic status.

[illegible]

It was observed that age of the mother is a predictor of EBF. The mean duration of EBF was significantly lower in the age group of mothers with 15-24 years. The findings suggest that more efforts are needed to create awareness about the need for EBF in younger aged mothers.

Education and occupation of the parent's and its [illegible]

We could not find statistical significance between the father's education and increased prevalence of EBF in the multivariate analysis though we observed a statistical significance in the univariate analysis. Maternal educational status was also found statistically not significant with EBF, which is a controversial observation with the findings of the Ethiopian demographic health survey which indicated a declining trend of EBF practices with higher maternal educational status but supports the findings observed by Tesfaye Setegn et al. [10].

[illegible]

The findings clearly indicate that the interventions related to EBF up to six months of age should be targeted to women in the lower socio-economic status and at younger ages.

[illegible]

Our study relies on retrospective reporting, which may result in inaccurate recall and this can be point out as a major limitation. However, most of the recent literature also followed the similar maternal recall mode for elucidating breast-feeding practices. Since this was a hospital-based study, the study population was representative of generally higher socio-economic status and which also reflects as a limitation of our work. A community-based cross-sectional study with a large sample size can provide more light in this field. Despite these limitations, the study has several strengths. We have elicited a large number of demographic and clinical data which can influence the association of duration of EBF. The same interviewer collected all information which reduces the inter observer bias. Advanced statistical methods were employed to analyse the association of socio-demographic and clinical correlates with EBF.

[illegible]

Our results can help to create more awareness about the need for EBF in the younger age group and the mothers in lower socio-economic status.

[illegible]

To the best of our knowledge, not many studies were conducted in Tamil Nadu to examine the socio-demographic and clinical correlates of exclusive breastfeeding. Results of this study indicate a need to create awareness to mothers regarding the need of providing EBF to infants up to six months of age.

[illegible]

India has undergone a rapid transition. Contradictory to our expectations, higher socio-economic status mothers are now aware about the need for EBF. More efforts are needed for those mothers in lower socio-economic status and those at younger ages. Secondly, apart from mother's education, father's education also plays a great role in breast feeding practices. In conclusion, it was observed that lower socio-economic status and young age of the mother have negative impact on EBF for six months of age.

Characterization of cardiac autonomic function in COVID-19 using heart rate variability: a hospital based preliminary observational study

https://doi.org/10.1515/jbcpp-2020-0378
Received November 13, 2020; accepted February 18, 2021; published online March 12, 2021

Abstract

Objectives: The novel corona virus disease, which was initially reported in China in late 2019, has become a global pandemic affecting 330 million cases. COVID-19 affects predominantly the respiratory system, in addition to other organ systems, mainly the cardiovascular system. One of the hypotheses is that virus entering the target cells by binding to angiotensin converting enzyme 2 affecting hypothalamic pituitary axis could lead to dysautonomia which is measured by heart rate variability (HRV). HRV is a non-invasive measure of autonomic function that facilitates identification of COVID-19 patients at the risk of developing cardiovascular complications. So, we aimed to assess HRV in COVID patients and compare between COVID patients and normal controls.

Methods: In a case control design, we compared 63 COVID-19 infected patients with 43 healthy controls matched for age and gender. Along with clinical characterization, heart rate variability was evaluated using ambulatory 5 min ECG in lead II and expressed in frequency and time domain measures. Statistical analysis was performed using SPSS 17.0.

Results: Mean age of the study population was 49.1 ± 14.2 years and 71 (66.9%) were males. Frequency domain measures high (HF) and low (LF) frequency powers were significantly decreased in COVID-19 patients compared to controls. HF/LF and LF/HF ratios were not different between groups. Time domain measures rMSSD (root mean square of successive RR interval differences) and SDNN (standard deviation of NN intervals) were significantly increased among COVID-19 subjects. COVID-19 infection was associated with increased parasympathetic activity as defined by rMSSD>40 {adjusted odds ratio 7.609 (95% CI 1.61–35.94); p=0.01} and SDNN>60 {adjusted odds ratio 2.620 (95% CI 1.070–6.44); p=0.035} after adjusting for age, gender and comorbidities.

Conclusions: Our study results showed increased parasympathetic tone in COVID patients. Early diagnosis of autonomic imbalance in COVID patients is needed to plan management and limit progression of disease.

Keywords: heart failure; pulmonary hypertension; right heart.

Introduction

In December 2019, a novel coronavirus disease (nCoV) epidemic emerged in Wuhan City, Hubei Province, China. Owing to its high transmissibility and infectivity rate it spread across the world and WHO declared it as a pandemic on March 11, 2020 [1, 2]. As this virus predominantly affects the respiratory system it has been renamed as severe acute respiratory syndrome coronavirus 2 (SARS CoV-2) and the disease caused by this virus has been named as corona virus disease 19 (COVID-19) [3].

COVID-19 shows wide range of clinical presentations ranging from asymptomatic/mild symptoms (fever, cough, dyspnea, myalgia, fatigue, anosmia, dysgeusia and diarrhea) to severe illness like acute respiratory distress syndrome (ARDS), arterial and venous thrombosis, myocarditis and varieties of neurological manifestations [4–7]. A report from WHO says that “80% of infections are mild or asymptomatic, 15% are severe infections and 5% are critical infections” [8]. Co-morbid conditions like obesity, type 2 diabetes mellitus, coronary artery disease, chronic liver disease, chronic kidney disease and chronic respiratory disease are known to be risk factors for developing severe disease [9–11]. Wide spectrum of manifestations is explained by SARS CoV-2 having target cells in multiple organs and systems like respiratory tract including lung parenchyma,

ileum, bladder, esophagus, heart, kidney, hypothalamus, pituitary, adrenal glands etc. These target cells have angiotensin converting enzyme-2 (ACE2) receptors in their cell wall. ACE2 binding affinity of the SARS CoV-2 spike protein ectodomain is one of possible mechanisms by which entry to these cells is facilitated [1, 12]. Histopathological and immune histochemical studies have clearly demonstrated a direct assault on these organs/systems by the SARS CoV-2 virus [13].

Though main portal of entry is respiratory system and hence the dominantly affected one, SARS CoV-2 reaches other systems through mechanism yet unknown. Neuroinvasive potential of SARS CoV-2 has been discussed in recent literature in the context of plausible explanation for variety of neurological manifestations of COVID-19 [14–16]. Earlier studies have demonstrated that SARS CoV-1 and MERS CoV (Middle east respiratory syndrome CoV) have the potential to enter and invade central nervous system, dominantly in brainstem structures [12, 17, 18]. Owing to the similarities in viral structure and receptor binding domain, neurotropism of SARS CoV-2 can be speculated from the evidence found from SARS CoV-1. Though sparse, direct evidence of neurotropism of SARS CoV-2 is emerging in literature. A recent report by Paniz–Mondolfi et al. [19], demonstrated by electron microscopy, presence of viral particles in postmortem brain tissues of a COVID-19 patient. Another report by Moriguchi et al. [20], evidenced the presence of SARS CoV-2 in cerebrospinal fluid. It has been postulated that SARS CoV-2 can enter the central nervous system by several mechanisms such as invasion through olfactory epithelium [21], synapse-connected route from terminal nerve endings [22] and transmission across blood-brain barrier by endothelial damage [19]. Clinical implications of neuropropensity of SARS CoV-2 range from mild symptoms like headache, dizziness etc., to severe manifestations like seizures, encephalitis, Guillain-Barre syndrome and cerebrovascular events. Involvement of autonomic nervous system (brainstem and hypothalamus) can lead to dysfunction of vital organs including cardiovascular system, thereby significantly influencing the outcome in COVID-19 patients. Cardiovascular system is also affected by the virus leading to manifestations like acute myocardial infarction, myocarditis and arterial & venous thrombosis. Monitoring the cardiac autonomic function of patients with COVID-19 can help us identify the individuals who are at risk of developing adverse cardiovascular outcomes.

Autonomic dysfunction has been reported in viral infections like retrovirus (human immunodeficiency virus, human T-lymphotropic virus), herpes viruses, flavivirus, arbovirus, enterovirus 71 and lyssavirus [23]. Current literature on autonomic dysfunction in COVID-19 patients is very sparse, barring a few case reports [24, 25]. Though various other methods were employed in these clinical settings to elicit dysautonomia, heart rate variability (HRV) measurement was seldom used for this purpose. During last two decades, HRV is considered most objective, reproducible and validated tool for demonstration of autonomic dysfunction [26]. Frequency and time domain measures of HRV have emerged as the most promising markers of balance between parasympathetic and sympathetic activity of autonomic nervous system that controls homeostasis of all vital organs.

Eliciting an association between autonomic dysfunction and COVID-19 could clarify the genesis of many clinical manifestations and importantly the unpredictable natural course of the illness. In this study, we intended to evaluate for autonomic imbalance and the direction of its deviation in COVID-19 subjects by measuring HRV and comparing the differences in HRV metrics between SARS CoV-2 positive and negative individuals.

Methods

This was an analytical cross-sectional study involving adult COVID-19 patients admitted for treatment in PSG Institute of Medical Sciences, Coimbatore, a specialized COVID-19 treating center in South India during March to June 2020. Sample frame during this period was approximately 500 inpatients whose COVID-19 status was confirmed by reverse transcription-polymerase chain reaction (RT-PCR) test of nasopharyngeal and oropharyngeal swab. Eligible inpatients (test group) of both genders, aged between 25 and 60 years were recruited from the sample frame by convenient sampling method. Patients with uncontrolled hypertension, coronary artery disease, cerebrovascular accident, family history of young myocardial infarction were excluded. Similarly, those patients on treatment with beta-blockers, inhaled or oral beta-mimetics, theophylline and other drugs with potential chronotropic effects were excluded. Patients with severe disease (those requiring oxygen support and/or intensive care) were also excluded. The comparison group included age and gender-matched healthy individuals from among the employees of medical school who tested negative for SARS CoV-2 by RT-PCR of their nasopharyngeal and oropharyngeal swab and fulfilled above mentioned selection criteria. This study was cleared by the institutional human ethics committee, and all study participants gave written informed consent. All such subjects recruited for the study underwent a detailed clinical examination.

Assessment of HRV

Study participants in both the groups were instructed to refrain from smoking, caffeine intake for 2 h and alcohol intake for 36 h. They should have had adequate rest, at

least 8 h of uninterrupted sleep on the night before the assessment of HRV and normal breakfast on the day of assessment. They were made to lie quietly in a couch in supine position for 5 min to alleviate the anxiety in a sound attenuated room with dim lighting and the temperature ranging from 20 to 25 °C.

After explaining the procedure to the subject, HRV, a quantitative marker of the autonomic activity was assessed using an ambulatory ECG system (INCO digital NIVIQURE, Bangalore, India) in lead II for 5 min. It is a multichannel digital data acquisition system which enables to acquire, analyze and store ECG data. ECG data was obtained at a sampling rate of 1,024 Hz in standard lead II configuration. The interface RS232C-compatible module was used to transfer data from the recording unit to the computer. The transferred data was analyzed using inbuilt software system. The series of RR intervals obtained were subjected to frequency and time domain analysis. Time domain indices of HRV indicate the amount of variability in measurements of interbeat interval (IBI), which represent time period between successive heartbeats. Time domain measures include standard deviation of NN intervals (SDNN), root mean square of successive RR interval differences (rMSSD) and percentage of successive RR intervals (pNN50). Frequency domain measurements estimate the distribution of absolute or relative power into frequency bands. Frequency domain measures include low frequency (LF) and high frequency (HF) [26]. HF component indicates the parasympathetic activity, whereas LF represents both sympathetic and vagal activity, and SDNN, rMSSD and pNN50 measure parasympathetic activity [26, 27].

Statistical analysis

The data were examined initially for normality of distribution and homogeneity of variance and expressed in terms of mean ± SD or percentage. Data with wide dispersion were expressed in log transformed values. Data from continuous variables were compared between study groups using Student's *t*-test whereas categorical variables were compared using Chi-Square test. Mann–Whitney *U* test was performed for variables that were not normally distributed. HRV variables that were significantly different between the groups were used as dependent variables for logistic regression analysis. For this purpose, HRV measures were dichotomized to categorical variable (artificial categorization using median split [28]) using an arbitrary cut-off value that was close to the median as reported by Nunan et al. [27] in their systematic review of studies involving normal subjects. Stepwise logistic regression analysis was employed to identify significant covariates and to evaluate association between HRV measures and SARS CoV-2 status after adjusting for important confounders like age, gender and comorbidity. Subgroup analysis was performed to characterize clinical and HRV profiles of SARS CoV-2 infected subjects based on symptom status. A p value of <0.05 was considered significant. All statistical analyses were carried out using SPSS version 17 software.

Results

In total, 106 participants were recruited for the study, which included 63 (59.4%) COVID-19 subjects and 43 (40.6%) healthy individuals who tested negative for SARS CoV-2. Among COVID-19 patients 33 (52.3%) had mild to moderate symptoms and 30 (47.6%) were asymptomatic. Mean age of the study population was 49.09 ± 14.21 years with 71 (67%) male subjects and 35 (33%) female subjects (Figure 1).

Comparing COVID-19 patients and healthy subjects, both groups were age and gender matched. Vital parameters like heart rate, SPO_2 at room air, systolic and diastolic blood pressure showed no difference between the study groups. Among frequency domain HRV parameters, HF and LF powers were significantly decreased among COVID-19 patients as compared to healthy individuals. HF/LF ratio and LF/HF ratio were not different between the groups (Table 1). Among time domain parameters, mean rMSSD was significantly higher in the COVID-19 group compared to healthy individuals (Figure 2). Mean SDNN value was higher among COVID-19 subjects with a trend toward statistical significance.

In the above graphical representation, the box spans the interquartile range, ends of the box represent upper and lower quartiles, bold horizontal line within the box represents the median value and the whiskers show the

Adjusted for age, gender and presence of comorbidities	2.620 (1.070–6.44)	0.035

minimum and maximum values. The circles with numericals are outliers.

Based on the published data on range of observations and median value of normal subjects, we defined parasympathetic overtone when subjects had rMSSD more than 40 and SDNN more than 60 [27]. These dichotomous variables indicated that COVID-19 patients had higher parasympathetic overtone than the healthy subjects (Table 1). Stepwise logistic regression analysis revealed a significant association between SARS CoV-2 infection status and parasympathetic overtone after adjusting for age, gender, T2DM or the presence of one or more comorbidities (Table 2).

Subgroup analysis was performed comparing the characteristics between symptomatic and asymptomatic subjects with COVID-19 (Table 3). Symptomatic COVID-19 patients were elderly and predominantly males as compared to asymptomatic patients. Symptomatic patients more frequently had at least one co-morbidity. Common

co-morbidities among symptomatics were DM type 2 (36.7%), Systemic hypertension (33.3%), obesity (10%), hypothyroidism (13.3%) and psychomorbidity (10%). Both frequency and time domain HRV parameters showed no difference between the subgroups.

Discussion

Our study clearly demonstrated an increased parasympathetic activity in COVID-19 patients, independent of important confounders like age, gender and comorbidities including diabetes mellitus. Autonomic dysfunction in COVID-19 subjects in our study was best demonstrated by time domain measures of HRV namely rMSSD and SDNN with predefined cut-off values. HF and LF powers in frequency domain were significantly decreased in COVID-19 subjects, though their ratios were not significantly different when compared to the healthy uninfected subjects. In a subgroup analysis of COVID-19 subjects, HRV measures were not different between asymptomatics and mild to moderate symptomatic. To our knowledge, our study was the first to demonstrate higher rate of autonomic imbalance among COVID-19 patients as compared to uninfected healthy group.

Our search through literature yielded scanty reports on autonomic dysfunction among COVID-19 patients. Ritwik Ghosh et al. [24] reported in one case of COVID-19, clinical features of autonomic dysfunction in the form of sinus arrhythmia, postural hypotension, intermittent profuse sweating, constipation, erectile dysfunction and squeezing sensation in the chest. Cardiac dysautonomia was not studied in this report. In another case report, Reiner Buchhorn et al. [25], studied a 58-year-old COVID-19 patient with 24 h ECG monitoring and found a significant decrease in heart rate and a paradoxical decline in HRV. But for these two case reports suggesting a possible autonomic dysfunction, no studies have yet, evaluated the presence of this important physiological disharmony in COVID-19 patients.

Though scanty in the context of COVID-19, plethora of evidence available in the literature demonstrating autonomic dysfunction in other infectious diseases like human immunodeficiency virus [29–31] human T Cell lymphotropic virus [32], Epstein Barr virus [33], cytomegalovirus [34], West Nile virus [35], Chagas disease [36, 37], diphtheria [38], leprosy [39], dengue[40], tetanus [41] and botulism [42]. Methodological differences in evaluating autonomic function as well as variations in study design do not allow head-to-head comparison of these studies with our findings in COVID-19 patients**.** In our search through literature, we found only two reports using HRV to link autonomic dysfunction with infection. Jeevagan Vijayabala et al. [43] postulated sympathetic dysfunction as one of the pathogenetic mechanisms in Dengue shock syndrome . Robert Carter et al. [40] examined HRV of 27 children during defervescence in dengue viral infection and found that cardiac parasympathetic activity was the major cause for reduction in heart rate during this period of illness. Their observations were mainly based on frequency domain measures of HRV after correcting for baseline changes in heart rate. Contradictory to the above observations, La-Orkhun et al. [44] found no significant changes in various time and frequency domain metrics of HRV at least 24 h after defervescence, and follow-up conducted at least 14 days after defervescence. Our findings are consistent with Jeevagan Vijayabala et al. and Robert Carter et al., that we too found an increased parasympathetic activity in COVID-19 patients as demonstrated by the increase in time domain variables of HRV. This study further substantiates

two cases as cited above that reported autonomic dysfunction due to COVID-19. Proposed mechanisms of viral infection induced autonomic dysfunction include invasion of the central nervous system and the direct viral, toxin-mediated or immune-mediated involvement of the peripheral and autonomic nervous system [45].

Unlike the time domain variables, we found that frequency domains of HRV, specifically the LF/HF ratio were not different between the COVID-19 subjects and the healthy subjects. Traditionally LF/HF ratio was considered a marker of sympatho-vagal balance in cardiovascular system. However recent evidence this ratio merely indicates one part of complex non-linear interaction between sympathetic and parasympathetic nervous systems confounded by multiple physiological and mechanical factors [46]. Some of these confounders may have been missed in our study protocol. Also, smaller sample size may explain our inability to detect subtle difference in LF/HF ratio between the groups.

Our study involved a standardized measurement of heart rate variability using an ambulatory 5 min ECG recording in lead II. Precision of our evaluation was further augmented by stringent selection of subjects and optimal conditions for HRV measurement during conduct of the study. Our study is limited by participation of only asymptomatics and mild to moderate symptomatic patients with SARS CoV-2 infection. Severely ill COVID-19 patients were excluded from the study because we believed that factors like stress, cytokine storm, drugs like steroids, vasopressors etc., positive pressure ventilation, prolonged hospitalization and related psychomorbidity that typically characterize these patients may have a confounding effect on our observations. None of our study subjects had any of these factors that could have possibly altered our findings. Sample size of the study was not adequate to provide enough statistical power to our findings. But we believe that this preliminary report can serve a stimulus for future research in this direction. A larger sample size could have facilitated further evaluation of association between symptoms and autonomic function in our subjects.

In conclusion, this study has found that COVID-19 is associated with autonomic dysfunction whose mechanism and prognostic implications need to be evaluated further. HRV measurement, being a simple, noninvasive, inexpensive tool, its utility in clinical practice as a possible rapid diagnostic and prognostic marker needs to be assessed in future research.

Abstract

Background: There is a substantial interest in the potential role of chocolate consumption and its association with the risk of type 2 diabetes mellitus. The objective of this study was to examine the association of consumption of chocolate with the risk of type 2 diabetes mellitus.

Methods: A case control study was conducted at PSG Hospitals between 1st June 2017 and 1st July 2017. All those who had newly diagnosed type 2 diabetes and attended Department of Endocrinology for follow-up visit were the cases and the relatives accompanying them without the history of diabetes were the controls. Chocolate consumption and other dietary factors were elicited. The mediating factors studied were age, sex, Body Mass Index (BMI), educational levels, smoking status, alcohol consumption, family history of diabetes, potassium intake, magnesium intake and use of statins.

Results: After adjusting the potential confounders, chocolate consumption was inversely associated with risk of type 2 diabetes ($p<0.05$) with odds ratio of 0.564 (95% CI = 0.32 - 0.98).

Conclusions: Our findings suggest that moderate consumption of chocolates (preferably 1 to 2) per week has a decreased risk of type 2 diabetes mellitus. Potential applications of this knowledge include recommendations by health care professionals to encourage individuals to consume a wide range of phytochemical rich foods include chocolates in moderate amounts. The results from our study also suggest that adjusting for mediating factors did not alter the results and hence other unknown factors may explain inverse relation between chocolate consumption and type 2 diabetes mellitus.

Keywords: Chocolate consumption, Potassium intake, Type 2 diabetes mellitus, Tea consumption

Introduction

There is a substantial interest in the potential role of chocolate and one of its primary bioactive compounds, flaven-3-ols in prevention and management of cardio vascular disease (CVD).[1-5] Few randomized controlled clinical trials (RCT) have examined mechanisms by which chocolate in cocoa and flaven-3-ols potentially reduce CVD risk.[6-10] However, the predominant focus of these studies has been blood pressure effects and many of these studies examined its effects on systolic and diastolic blood pressure, LDL and HDL cholesterol. In addition,

some of these RCT's reported a reciprocal relation between insulin resistance and chocolate consumption.

There were few observational studies which supported the association between cocoa intakes and reduced diabetes risk. Chocolate contains caffeine, flavonoids and minerals such as magnesium that could influence the risk of diabetes mellitus. An inverse association between the consumption of caffeine, flavonoids and magnesium with the role of diabetes mellitus has been reported with inconsistent results.[11-12] In contrast, cocoa and chocolate have beneficial effects in insulin resistance, oxidative stress and inflammation which play important roles in pathogenesis of diabetes mellitus. However, it is still unclear, whether chocolate consumption is associated with risk of diabetes mellitus and whether this association differs according to the characteristics of the study population. The present study is aimed to find the association between chocolate consumption and risk of diabetes mellitus.

M□□□□□□□

Study population and design

A case-control study was conducted at PSG Hospitals. All those who have newly diagnosed in the past 1 year as type 2 diabetes and attending the Department of Endocrinology for follow up between 1stJune 2017 and 1st July 2017 were considered as cases. Controls were those who accompany with them and do not have history of diabetes. We then retrospectively evaluated their food practices and other demographic information.

General assessments

The general assessment survey was conducted at the outpatient Department of Endocrinology, PSG Hospitals, Coimbatore. The general questionnaire contained questions on demographic characteristics. Body weight (in kg) and height (in meter) were also measured. However, in few cases, we were not able to measure height. Food intake was assessed using a validated Food Frequency Questionnaire in this population and from this magnesium intake and potassium intake were estimated.[13] The questionnaire also asked about chocolate consumption, coffee intake, tea intake, smoking status, practice of alcohol intake, whether previously diagnosed as diabetes, other medical histories and medications taken.

Statistical analysis

To examine the association between chocolate consumption and incidence of type 2 diabetes, we used four logistic regression models. In the first model, odds ratio and 95% confidence intervals for type 2 diabetes mellitus were calculated against a reference group of low consumers of chocolate adjusted for age (continuous) and gender (male/female).

A second logistic regression model corrected the other known diabetes risk factors include smoking status (present/absent), BMI, education attainment (classes up to 12th standard/college and above), family history of diabetes (present/absent); alcohol intake (gm. per week). Body mass index was calculated by the formula, body weight (kg) divided by the square of the body height (meter). A third model corrected for coffee and tea consumption. Mediating factors were included in the final model. The mediating factors considered were daily intake of magnesium and potassium which were elicited from their food consumption practices and the effects of long term medications like the use of statins.

□□□□□□□□

The study included 150 cases and 150 controls. Demographic characteristics of the study participants among cases and controls were presented in Table 1.

Odds ratio	0.559	0.601	0.540	0.564
95% CI for diabetes	0.336 - 0.932	0.352 - 1.026	0.312 - 0.936	0.324 - 0.980
p Value	0.026	0.062	0.028	0.042

Among the variables studied, all differences between case subjects and control subjects were comparable except for age, educational level and family history of diabetes. Cases were slightly older in age compared to controls. The mean and standard deviation of age (years) among cases were 53.29±11.52 and that of controls were 41.75±12.44. This difference was statistically significant ($p < 0.05$).

The mean and standard deviation of potassium intake among cases were 624.11±151.14 and that of controls were 661.14±209.54. This difference was statistically significant ($p < 0.001$). 72% of the participants among diabetic were having education up to 12th standard whereas the similar value for non-diabetic was only 56.7%. This difference was statistically significant ($p < 0.001$). Among diabetic, 60.7% of them had family history of diabetes whereas the similar value for non-diabetic was only 34.0%. This difference was statistically significant ($p < 0.001$).

87.3% of the cases do not take chocolate on a weekly basis whereas the similar value for controls was only 68%. 11.3% of the cases take 1 to 2 chocolates on a weekly basis whereas the similar value for controls was 25.3 % (Table 2). In the multivariate regression model (Table 3), it was observed that the participants who consume more chocolate had a significantly decreased risk of diabetes compared with those who do not take chocolate on a weekly basis (odds ratio = 0.564, 95% CI = 0.324 - 0.980).

[illegible]

In our study, self-reported chocolate intake was significantly inversely associated with diabetes mellitus. Many studies supported our findings that chocolate consumption may lower risk of diabetes mellitus. The recent Maine- Syracuse Longitudinal Study (MSLS) reported that persons who eat chocolate at least once a week have a lower prevalence of diabetes and are at lower risk for a diagnosis of diabetes for five years later.[14]

Beneficial effects of cocoa and chocolate on risk factors related to diabetes mellitus were reported in short term randomized clinical trials as well as long term experimental studies5,8. It was reported in same studies that cocoa or chocolate improves insulin resistance, oxidative stress and inflammation. However, whether these results are the possible mechanisms resulting in an inverse association between chocolate consumption and risk of diabetes is still unclear. It is also uncertain that which substance in chocolate is responsible for the inverse association with diabetes mellitus that we have observed.

However, it is important to differentiate between the natural product cocoa and the processed product chocolate which is an energy dense food. In addition, physical activities, diet and other life style factors must be carefully balanced to avoid differential weight gain over time.

Our study has several limitations. Since this was a case - control study, cause and effect relations between chocolate consumption and diabetes cannot be established. This has not been established in any study in the literature also. A bidirectional relationship could not be ruled out, modest amounts of chocolate protect against diabetes but some diabetic patients chose to eat modest amounts of chocolates.

It is also unclear if the benefits of the chocolates are limited only to dark chocolate. It is widely hypothesized that cocoa flavonols, found in larger amounts in dark chocolate, responsible for its health benefits and more large scale prospective studies are required to provide more information on whether only dark chocolate is beneficial or chocolate in general is beneficial. It is also possible that chocolate consumption may represent an overall marker for a cluster of favorable socio demographic profiles and thereby healthier life style behaviors and better health status. This could explain, at least in part, the observed associations with the insulin biomarkers.

[illegible]

Study findings suggest that moderate consumption of chocolates (preferably 1 to 2) per week has a decreased risk of type 2 diabetes. Potential approach of this knowledge includes recommendations by health care professionals to encourage individuals to consume a wide range of phytochemical rich foods include chocolates in moderate amounts.

The results from our study also suggest that adjusting for mediating factors did not alter the results and hence other unknown factors may explain inverse relation between chocolate consumption and type 2 diabetes mellitus. Continued studies are necessary to study the role of specific factors regarding the association of chocolate consumption and type 2 diabetes mellitus.

Abstract

Background

Female genital tuberculosis often faces diagnostic challenges due to the asymptomatic nature of the disease. Our study aims at comparing the microbiological and histopathological results with PCR in diagnosing genital tuberculosis in endometrial curettage specimens.

Methods

Around 139 patients with diverse gynaecological complaints were recruited for the study, and endometrial curettage specimens were collected. The specimens were subjected to microbiological culture and staining, histopathological examination and PCR to look for the presence of *M. tuberculosis*. Statistical analyses of the PCR results include calculating sensitivity, specificity, positive and negative prediction values and positive and negative likelihood ratios.

Results

PCR yielded a detection rate of 41.7% (58/139) when compared to the microbiology (2.15%) and histopathology results (1.43%). PCR with *hsp65* and *cfp10*, in combination, detected 20% of the cases. Statistical analyses were suggestive that PCR with *hsp65* showed a higher sensitivity and specificity of 50% and 92.59% respectively.

Conclusion

The results obtained in this study suggest that for a definitive diagnosis, combinations of the results from various diagnostics techniques can only be considered.

Keywords: PCR, Female genital tuberculosis, Culture, Histopathology

Introduction

Female genital tuberculosis continues to be an important cause for infertility, especially in developing countries like India accounting for about 7–15% [1]. This is a form of secondary tuberculosis after a primary encounter of tuberculosis, either pulmonary or extrapulmonary [2]. *Mycobacterium tuberculosis* remains abeyant for a longer duration, reactivates and causes harmful effects on female genital tract which develops as female genital tuberculosis. Among the various sites, fallopian tubes and endometrium are affected the most, followed by ovary, cervix and vagina [3]. Tubal obstruction, impairment of implantation and ovulatory failure occur as a result of genital tuberculosis [4]. Therefore, infertility, chronic abdominal pain and menstrual dysfunctions are often found associated with this disease. On the other hand, 11% of women affected are asymptomatic [5] and so remain underdiagnosed.

Various diagnostic procedures like microbiological culture, smear microscopy, histopathology, hysterosalpingography (HSG) and ultrasonography are in use, though each of which had proven unhelpful in diagnosing certain cases. PCR is emerging as an important tool in view of its rapidness, sensitivity and specificity reported by many researchers [6, 7]. Since endometrial tuberculosis leaves only traces of bacilli, molecular techniques are potentially considered important for mycobacterial demonstration.

In our study, we have made an attempt to compare the results between PCR, microbiology and histopathology as well as correlate its results with the phenotype displayed by the patients. This investigation would help us in understanding the epidemiology of this disease, commonly appeared clinical evidences and superiority of techniques that can be employed in its diagnosis.

Materials and Methods

Patient Enrollment

Around 139 women belonging to the reproductive age group who attended the Obstetrics and Gynecology clinic in PSG Hospitals featuring symptoms suggestive of genital TB like chronic pelvic inflammatory disease, infertility, tubo-ovarian mass, secondary amenorrhoea and history of pulmonary tuberculosis were recruited for this study. Ethical committee approval was obtained for this study from Institutional Human Ethics Committee, PSG Institute of Medical Sciences & Research, Coimbatore (IHEC No: 10/214). Pregnant women and patients in whom dilatation and curettage (D&C) were contraindicated were excluded in this study. Informed consent was obtained from all individual participants included in the study and detailed history, and gynaecological examination were done on

the patients. Endometrial curettings collected from the patients were subjected to microbiological culture in Lowenstein–Jensen's (LJ) medium, acid fast staining, histopathological examination and PCR for detecting *M. tuberculosis.*

Microbiological Examinations

The endometrial curettings suspended in saline were vortexed in the presence of glass beads to obtain an even suspension, and the samples were subjected to Ziehl Neelson (acid fast) staining technique for smear positivity. The samples were inoculated onto Lowenstein–Jenson's medium and incubated for 4 weeks at 37 °C. To confirm the absence of growth, incubation was extended to 2 weeks more.

Histopathological Observations

The endometrial curettings were suspended in 10% formalin and processed. The samples were stained with haematoxylin and eosin to look for the presence of caseating granulomas with epitheloid cells, lymphocytes, plasma cells and giant cells which is suggestive of tuberculosis.

Polymerase Chain Reaction from Endometrial Curettings

The endometrial curettings were suspended in lysis buffer (50 mM KCl, 10 mM TrisHCl pH 8.3, 1.5 mM $MgCl_2$, 0.1% Nonidet P-40, 0.5% Tween-20) and homogenized. DNA was extracted using the standardized protocol [8]. PCR for amplifying three mycobacterial gene segments was carried out. The primer sequences and the amplicon length are mentioned in Table 1. 20 µl of PCR mix consisted of 50 ng of DNA mixed with 0.2 mM of each of the four dNTPs (dATP, dCTP, dGTP, dTTP), 10 mM Tris–HCl (pH 8.3), 50 mM KCl, 0.01% gelatin, 1.5 mM MgCl2, 0.05 µM of each forward and reverse primers, 1 U/µl *Taq* polymerase and nuclease free water. The reaction was supplemented with positive and negative controls. The PCR parameters followed were 35 cycles of denaturation (94 °C for 5 min), primer annealing (60 °C for 50 s) and extension (72 °C C for 1 min). The final extension was carried out at 72 °C C for 5 min, and the samples were put on hold at 4 °C C. The PCR products were run on 1.5% agarose gel, and the bands were visualized under UV light using a gel documentation system.

Table 1

Primer details of three mycobacterial gene segments

S. no	Gene segment	Primer sequences (FP – Forward primer, RP – Reverse primer)	Size of PCR product (bp)
1	*Hsp65*	FP-5′ ACCAACGATGGTGTGTCCAT 3′ RP-5′ CTTGTCGAACCGCATACCCT 3′	441
2	*Cfp10*	FP-5′ GGCAGAGATGAAGACCGATG 3′ RP-5′ GCTTATTGGCTGCTTCTTGG 3′	191
3	*Esat6*	FP-5′ CATGACAGAGCAGCAGTGG 3′ RP-5′ CCCTATGCGAACATCCC 3′	291

Statistical Parameters

Statistical parameters like sensitivity, specificity, positive and negative prediction values and positive and negative likelihood ratios were calculated.

Results

Clinical Presentations of the Patients

The common presenting symptoms found in the study population were primary infertility (60%) and irregular cycles (47.5%). Secondary infertility and abdominal pain account for about 16.5% and 10%, respectively. White discharges (7.2%), secondary amenorrhoea (6.5%), dysmenorrhoea (5.7%) and fibroid uterus (4.3%) were manifested by the patients too. Hypomenorrhoea (1.4%), oligomenorrhoea (3.6%), menorrhagia (2.9%), ectopic pregnancy (1.4%) and history of tuberculosis (1.4%) constituted to a meagre amount (Fig. 1).

Open in a separate window

Fig. 1

Frequency of presenting symptoms in the study population. The percentage of different clinical presentations observed in the patients recruited for this study was depicted. Primary infertility and irregular cycles were presented more frequently, while ectopic pregnancy and oligomenorrhoea were presented the least

Correlation of Microbiological and Histopathological Results with PCR

For PCR detection, primers specific for three mycobacterial gene segments, namely *hsp65, cfp10* and *esat6*, were used. *Hsp65* is the mycobacterium genus-specific gene segment was employed for the diagnosis of genital TB [9]. *cfp10* and *esat6* were the gene segments present in *M. tuberculosis*, *M. africanum* and virulent *M. bovis,* thus comprising the *M. tuberculosis* complex [10, 11].

Overall, 58/139 samples were positive at least for one primer through PCR with a detection rate of 41.7%. On the contrary, only 2/139 samples were positive for histopathology with a detection rate of 1.43%. Microbiological examinations detected two cases of *M. tuberculosis* and a case of non-tuberculous mycobacteria with a positivity rate of 2.15%. Based on the PCR results, positive samples were grouped into four categories depending on the number of gene segments amplified for each sample (Table 2).

Table 2

Analysis of PCR-positive samples

Gene segments amplified	No of samples positive	Percentage
hsp65, cfp10 and *esat6*	4/139	2.9
hsp65 and *cfp10*	28/139	20
hsp65	12/139	8.6
cfp10	14/139	10

Out of 139 samples, four samples were positive for all the three gene segments. Both histopathological findings and microscopic techniques (acid fast staining & culture) yielded the negative results for these samples. *Hsp65* and *cfp10* gene segments were identified in 28/139 samples. Among 28 samples, only one sample detected tubercle bacilli through culture on LJ medium. Histopathological examinations yielded the negative results. In 12/139 samples, *hsp65* alone was detected. In 1/12 sample, mycobacterial culture and histopathology results were positive for *M. tuberculosis*. Non-tuberculous mycobacterium was detected in one sample. *cfp10* was detected in 14/139 samples which showed the negative results for microbiology and histopathology. There were 81/139 samples which gave the negative results for PCR. Out of this, one sample was positive for histopathology.

Overall, it is clear from the data that *hsp65* and *cfp10* either alone or in combination have been successful in detecting 58/139 samples. In combination, *hsp65* and *cfp10* have detected up to 20% of cases which microbiological and histopathological assays were unable to detect (Table 2).

Correlation of Clinical Symptoms with PCR Results

The varied clinical clues exhibited by the patients and their respective PCR results were compared (Table 3). The predominant clinical symptoms associated with the PCR-positive samples were irregular menstrual cycles and primary infertility accounting for 50–75% of the cases. Secondary infertility,

secondary amenorrhoea, hypomenorrhoea, dysmenorrhoea, oligomenorrhoea, chronic abdominal pain and white discharges were found in 10–25% of the cases. History of tuberculosis and fibroid uterus constitute a very meagre percentage of 3.5–7% (Table 3).

Table 3

Correlation of clinical symptoms with PCR results

Clinical features	PCR amplicons found			
	hsp65*, *cfp10* and *esat6	***hsp65* and *cfp10***	***hsp65***	***cfp10***
Primary infertility (%)	50	75	66	50
Secondary infertility (%)	–	21.4	8.3	20
Secondary amenorrhoea (%)	25	7.1	8.3	7.1
Hypomenorrhoea (%)	25	3.5	–	–
Oligomenorrhoea (%)	25	–	8.3	20
Dysmenorrhoea (%)	25	7.1	–	7.1
Menorrhagia (%)	–	3.5	–	–
White discharges (%)	25	10.7	–	21.4
Irregular cycles (%)	75	39	25	50
Abdominal pain/PID (%)	–	3.5	8.3	21.4
Ectopic pregnancy (%)	–	7.1	–	–
History of tuberculosis (%)	–	3.5	–	3.5
Fibroid uterus	–	7.1	8.3	7.1

The patients in whom all the three gene segments of mycobacteria were amplified belonged to the reproductive age group 27–31, marked with irregular menstrual cycles, primary infertility, hypomenorrhoea, dysmenorrhoea, oligomenorrhoea and white discharges.

The 28 patients in whom *hsp65* and *cfp10* gene segments were amplified belonged to the age group of 19–47. They indicated gynaecological irregularities like primary infertility (75%), secondary infertility (21.4%), secondary amenorrhoea (7.1%), white discharges (10.7%), fibroid uterus (7.1%) and ectopic pregnancy (7.1%). 39% of these 28 patients had irregular menstrual cycles. A previous history of abdominal tuberculosis was found in a patient. 3.5% of these patients had chronic pelvic inflammatory disease (PID). Other menstrual problems like menorrhagia, hypomenorrhoea and dysmenorrhoea were also associated in these patients.

Hsp65 alone was amplified in 12 samples. Primary infertility (66%), irregular cycles (25%), 8.3% each of secondary infertility, secondary amenorrhoea, abdominal pain, fibroid uterus and oligomenorrhoea were the clinical symptoms associated in these patients.

In 14 samples, only *cfp10* was amplified. A history of pelvic tuberculosis was also associated with a case. 50% of these patients had irregular cycles and primary infertility. White discharges, chronic abdominal pain and PID were observed in 21.4% of patients. 20% of patients had secondary infertility

and oligomenorrhoea. 7.1% of the patients had complaints like secondary amenorrhoea, fibroid uterus and dysmenorrhoea.

Sensitivity and Specificity of TB PCR

Microbiological culture was considered as the gold standard technique to diagnose endometrial TB. All culture-positive cases in our study were considered as positive cases. Based on this, the sensitivity, specificity and positive and negative predictive values for the TB PCR were calculated (Table 4). Using any one of the primers, the sensitivity and specificity of PCR were found to be 75% and 59.2%, respectively. The sensitivity and specificity were high for primer set *hsp65* when compared with other combinations of primers.

Table 4

Sensitivity, specificity and predictive values for the TB PCR

PCR primers	Statistical parameters					
	Sensitivity (%)	Specificity (%)	Positive predictive values (%)	Negative predictive values (%)	Positive likelihood ratio	Negative likelihood ratio
PCR Positive (for any one of the primer)	75	59.26	5.17	98.77	1.84	0.42
PCR positive for all the three primer sets (*hsp65*+ *esat6*+ *cfp10*+)	0.00	97.04	0.00	97.04	0.00	1.03
PCR positive for two primer sets (*hsp65* and *cfp10*)	20	82.91	3.57	97.04	1.17	0.96
PCR positive for one primer set (*hsp65* alone)	50	92.59	16.67	98.43	6.75	0.54
PCR positive for one primer set (*cfp10* alone)	0.00	89.63	0.00	96.80	0.00	1.12

Discussion

Our results indicated lower detection rates for culture (2.15%) and histopathological analyses (1.43%) and higher identification rates for PCR. The similar results were obtained for histopathology (1.87%) and microbiology (2.05%) findings recorded earlier [12]. Other studies reported a higher detection rate of 65% for PCR with endometrial biopsies [13].

PCR-positive four samples (for all three gene segments) showing the negative results for microbiology and histopathology may be due to the lower sensitivity of culture and histopathological analyses. The possible reason for culture insensitivity may be poor recovery of bacilli as the sparse number of bacilli is a characteristic feature of genital TB [14]. The false-negative histopathology results may be due to the shedding of endometrium leaving insufficient time for granuloma formation or damaged endometrium [2, 15].

A PCR and culture negative sample displaying positive result may be due to the co-presence of other pathogens which might have precipitated the lesions. This also confirms the fact that the PCR results correlate with that of culture and have shown reliability.

Review of available data on microbiological diagnosis of genital TB indicates that BACTEC 460 TB culture had a sensitivity of 7.14–40% and a specificity of 90–100% [16–18] which improved upon usage of PCR as an additional tool in diagnosing genital TB. The histopathological method showed a sensitivity of 10.7% and specificity of 100% [16]. These figures reveal that there was a need for development of a better sensitive method for genital TB with subtle presentations and lower bacterial load. In our setting, around 20% of the positive cases were spotted positive by *hsp65* and *cfp10*. Statistical parameters indicate a higher sensitivity and specificity of PCR when any one of the primers was used. Among the primer combinations, *hsp65* primers demonstrated higher probabilities of finding mycobacteria with higher specificity of 92.59% as it is a mycobacterium genus-specific gene, but it showed a lower sensitivity rate of 50% possibly because of the presence of both the endometrial DNA and the mycobacterial DNA in the sample which might give rise to more inhibitory effects on PCR. Lower sensitivity range of 55% in detecting *M. tuberculosis* through PCR was also reported earlier [19] where the usage of low-cost PCR reagents was the reason for lower sensitivity, though it was developed for applications in low income settings [20]. Similarly, lower sensitivity of PCR (57%) in diagnosing genital TB was reported in another study where combination of many sets of primers was suggested to be used to improve the sensitivity.

Conclusion

The gold standard test to diagnose endometrial tuberculosis remains the culture technique: LJ medium and MGIT liquid culture. In the current scenario, all the clinical decisions are best made depending on the culture results although collaborative tests may be supportive. Therefore, PCR can only be used as an additional method along with histopathology, microbiology and imaging tools.

Acknowledgements

We thank all the faculty members of the Department of Histopathology, PSG Institute of Medical Sciences and Research, Coimbatore, for their contribution in reporting the results of the endometrial biopsies.

Abstract

Aims

We aimed to assess the incidence of the BRAF V600E mutation in thyroid neoplasms at a tertiary care center and its association with various phenotypic features.

Methods and material

We included all cases diagnosed as thyroid neoplasm in the past decade at the Department of Pathology of our institute and obtained their clinical details from the medical records department of the institute after obtaining permission from the authorities and due International Human Epigenome Consortium clearance. We included data on age, sex, clinical presentation, hormone status, and T and N status of the malignant neoplasms. Hematoxylin and eosin (H&E) slides of all cases were evaluated for the type

of neoplasm, nuclear features, invasion into the capsule and vascular spaces, extrathyroidal extension, lymph node metastases, mitoses, necrosis, and presence/absence of amyloid. Paraffin blocks of sections with high tumor density and less normal tissue were chosen for evaluation after H&E staining. The slides showing tumors with large areas of hemorrhage, cystic change, or necrosis were excluded. Two primers were used to amplify a 339-bp fragment containing the V600E mutation in exon 15 of BRAF. Tissues were prepared from formalin-fixed paraffin-embedded (FFPE) blocks, and DNA was isolated using a standard protocol BRAF NF and BRAF NR Primer Standardized Protocol For FFPE Tissue DNA. Percentages and tables have been used for data presentation.

Results

Among 47 identified cases, 14 were positive for the BRAF V600E mutation and had papillary carcinoma (n = 9) or follicular neoplasms (n = 5; follicular adenoma, n = 3; follicular carcinoma, n = 2). In the BRAF-positive papillary carcinomas, five cases were aged 20-30 years, eight were female, eight (88.88%) were euthyroid, and one was hypothyroid. Furthermore, 55.55% (5/9 cases) of BRAF-positive cases were stage I, 33.3% (3/9 cases) were stage II, and 0.02% (1/9 cases) were stage III.

Conclusions

In our cohort, 31% of cases of papillary thyroid carcinoma (PTC) and 18.72% of follicular neoplasms expressed the BRAF V600E mutation.

BRAF V600E mutation-positive papillary thyroid carcinomas consistently showed all characteristic nuclear features, such as nuclear crowding, overlapping, and grooves.

Considering the greater prevalence in the younger age group, the importance of mutation surveillance in PTCs for a total thyroidectomy may be warranted in mutation-positive patients.

Keywords: braf v600e mutation, papillary carcinoma, thyroid gland, thyroid neoplasms, thyroid malignancies

Introduction

Thyroid cancers account for approximately 1% of all malignancies and are one of the most common malignancies of the endocrine system [1,2]. The development of malignancy in the thyroid is influenced by both environmental factors as well as genetic factors. Specifically, the thyroid is vulnerable to genotoxic effects of radioactive iodine and nongenotoxic effects (thyroid-stimulating hormone stimulation) of iodine deficiency both of which can lead to neoplastic lesions in the thyroid [3].

Most thyroid tumors can be diagnosed based on morphological assessment and immunohistochemical findings [4,5] As altered gene expression can be discovered before morphological changes, knowledge regarding the genetic background helps in understanding thyroid carcinogenesis and facilitates the planning of appropriate therapeutic strategies and development of drugs that target specific molecules.

Thyroid tumors are classified based on the 2004 World Health Organization guidelines [3]. Recently, the RAS-RAF-MAP kinase signaling pathway has been implicated in many cancers, particularly more frequently in thyroid carcinomas, with the BRAF V600E mutation playing a vital role in papillary thyroid carcinoma. Furthermore, the BRAF mutation is specific for papillary carcinoma, is associated with poorer outcomes, and is frequently noted in high-grade tumors [6-8]

BRAF: an overview

BRAF is a serine-threonine kinase belonging to the family of RAF proteins. It acts upstream of MEK1/2 kinases in response to RAS signals. BRAF mutations are involved in early thyroid carcinogenesis and are somatic genetic alterations rather than germline mutations [9,10]. BRAF mutations occur early and play an important role in the pathogenesis of papillary thyroid carcinoma (PTC). Point mutations of BRAF are the most common types of mutations and occur in approximately 40%-45% of cases [11,12]. Other studies have reported [13,14] BRAF mutation rates of 35%-69% in PTC. The most common BRAF mutation is V600E, which is from missense thymine (T) to adenine (A) transversion at nucleotide 1799 in exon 15. This results in the substitution of valine by glutamate at residue 600. A less common mutation is the K601E mutation found in thyroid cancer [15,16]. Structurally, the RAF protein is divided into two functional domains, namely, the N-terminal and C-terminal regulatory domains, with three conserved regions (CR 1,2, and 3). CR1 and CR2 are present in the N-terminal domain and CR3 in the C-terminal domain [17].

Normally, RAS proteins are attached to the plasma membrane on the cytoplasmic side of the cell, endoplasmic reticulum, and Golgi membrane and are activated by growth factors binding to receptors at the plasma membrane. In an inactive state, RAS proteins bind to guanosine diphosphate (GDP), and upon activation, exchange GDP with guanosine triphosphate (GTP), leading to a conformational change that produces active RAS [2]. This activated RAS binds to the RAS-binding domain in CR1 of RAF, recruits RAF to the membrane, and activates a downstream signaling cascade wherein RAF phosphorylates mitogen-activated protein kinase (MAPK) [17]. Extracellular signal-regulated kinases 1 and 2 (MEK 1 and 2) become activated, which consecutively phosphorylate and activate extracellular signal-regulated kinases 1 and 2 (ERK 1 and 2). Activated ERK migrates to the nucleus where it activates various transcription factors that trigger cell cycle progression and result in cell proliferation and differentiation [8]. The RAF protein has three isoforms, ARAF, BRAF, and CRAF. Among these, BRAF is the most common isoform and most commonly mutated isoform because it has higher basal kinase activity [17] Additionally, BRAF protein expression is higher in hematopoietic cells, neurons, and testicles; is the predominant isoform [18,19] in thyroid follicular cells; and is the most potent activator of the MAPK pathway. Gain-of-function BRAF mutations function as an alternate pathway for aberrant activation of ERK signaling, resulting in constitutive activation of BRAF kinase, i.e., it can phosphorylate MEK as monomers in a RAS-independent manner. Such chronic stimulation of the MAPK pathway results in increased proliferation but reduced survival and differentiation of cells [11]. This signaling cascade is implicated in the etiology of several human cancers including malignant melanoma; thyroid, colorectal, and ovarian carcinomas; and carcinomas of the biliary tract, ovary, and cervix [9,20]

BRAF expression in thyroid carcinomas

Thyroid malignancies are predominantly diagnosed based on morphological assessment alone, and an immunohistochemical study is beneficial in confirming the diagnosis and establishing prognosis if tumor(s) exhibits unusual patterns. A significant improvement has been noted in the knowledge of molecular alterations over the past two decades in all tumors, including thyroid malignancies, and oncogenic BRAF activation represents one of the most prevalent molecular alterations. Reportedly, BRAF mutations are associated with poorer clinicopathological outcomes [21,22]. Among its various subtypes, BRAF most commonly occurred in the tall cell variant of PTC, followed by conventional PTC, and less commonly in the follicular variant of PTC. The tall cell variant is the most aggressive tumor, indicating that BRAF mutations are associated with poorer outcomes [9,23]. Other factors associated with the mutation and aggressive tumor phenotype include older age, extrathyroidal tumor invasion, lymph node, and distant metastasis, higher tumor stage, and poorly differentiated cancer [21,22,24-26].

Frasca et al [27] found that the presence of the BRAF V600E mutation in PTC is associated with aggressive tumor behavior and that tumor aggressiveness is independent of tumor size, suggesting that even small BRAF-positive tumors carry a higher risk of progression and invasiveness than BRAF-negative tumors.

BRAF mutations can be readily tested on thyroid tissue samples obtained by fine-needle aspiration with high preoperative clinicopathological prognostic capabilities in PTC. However, they have limited diagnostic value because [28-30] of low sensitivity in cytologically indeterminate specimens that are mostly non-PTC and therefore do not harbor the BRAF mutation. Nonetheless, controversies regarding BRAF mutations with poorer clinicopathological outcomes in papillary thyroid cancers have been reported in some studies [31,32]. In the thyroid, apart from papillary carcinomas, BRAF mutations are expressed in anaplastic carcinoma and poorly differentiated carcinoma (prevalence, 20%-30%, and 10%-15%, respectively).

BRAF-mutated, poorly differentiated, anaplastic carcinoma will have a papillary component, suggesting that these tumors progress from BRAF-positive papillary carcinoma [33-36]. The BRAF V600E mutation is not found in follicular thyroid cancers and benign thyroid nodules [23]. However, the other BRAF mutation, K601E, has been detected in follicular adenoma, carcinoma, and follicular variants of PTC. However, Kebebew et al reported a BRAF V600E mutation in one case of follicular carcinoma [22]. Newly developed mitogen extracellular kinase (MEK) inhibitors are particularly promising therapeutic agents for thyroid cancer. With these advances, it has become clearer that BRAF mutation will likely have a significant impact on the clinical management of PTC. Thus, this study aimed to assess the incidence of the BRAF V600E mutation in thyroid neoplasms at a tertiary care center and its association with various phenotypic features.

Materials and methods

We included all cases diagnosed as thyroid neoplasm in the past decade at the Department of Pathology of our institute and obtained their clinical details from the medical records department of the institute after obtaining permission from the authorities and due International Human Epigenome Consortium clearance (IRB number/Proposal number: 10/098). We included data on age, sex, clinical presentation, hormone status, and T and N status of the malignant neoplasms. Hematoxylin and eosin (H&E) slides of all cases were evaluated for the type of neoplasm, nuclear features, invasion into the capsule and vascular spaces, extrathyroidal extension, lymph node metastases, mitoses, necrosis, and presence/absence of amyloid. Paraffin blocks of sections with high tumor density and less normal tissue were chosen for evaluation after H&E staining. The slides showing tumors with large areas of hemorrhage, cystic change, or necrosis were excluded. Two primers were used to amplify a 339-bp fragment containing the V600E mutation in exon 15 of BRAF. Tissues were prepared from formalin-fixed paraffin-embedded (FFPE) blocks, and DNA was isolated using a standard protocol BRAF NF & BRAF NR Primer Standardized Protocol For FFPE Tissue DNA (Figures 1-4). Percentages and tables have been used for data presentation.

Results

Of the 50 identified cases, DNA could only be extracted from 47 because extraction proved futile in the remaining three cases (Table 1).

Table 1

Master chart showing demographic variables, morphologic subtype of thyroid neoplasms, stage, and mutant status.

PTC: papillary thyroid carcinoma; FN-LMP: follicular neoplasm - low malignant potential

S.No	Age/ Sex	Hormone Status	Size	Other features	Diagnosis	Stage	BRAF

Discussion

The BRAF V600E mutation is most often expressed in stage III (30%). Importantly, its expression, particularly in the early stages, indicates an aggressive course and warrants a total thyroidectomy, whereas its expression in the later stages is associated with poor outcomes.

In our group of 30 papillary carcinoma cases, DNA could be extracted from 29 and only nine expressed the BRAF V600E mutation. Its prevalence is lower than that reported in the literature, i.e., 40%-45% of PTCs harbor the mutation.

We found that five of the nine cases of BRAF V600E-positive papillary carcinoma were in the 20-30-year age group. Rossella et al found that V600E was expressed more in an older age group [6]. Given the greater prevalence in the younger age group, the importance of mutation surveillance in PTCs for a total thyroidectomy may be warranted in mutation-positive patients.

We found five cases of stage I (55.55%) and three cases of stage II (33.33%) showing BRAF positivity, indicating a significantly higher expression in stages I and II lesions. Therefore, we reanalyzed the reports of PTC.

This high incidence of V600E mutation can be explained by the fact that at a tertiary care hospital, the radiologist and cytopathologist could probably detect PTC at an early stage. Furthermore, the strongest argument against using BRAF mutation as an independent prognostic and predictive factor in PTC is its high prevalence (30%-80%). As the V600E mutation is associated with poor outcomes, these patients require very close follow-up. We found no correlation between nuclear features and BRAF V600E mutations; however, the characteristic nuclear crowding, overlapping, and grooves were consistently observed (Tables 6, 7).

The incidence of the BRAF V600E mutation in follicular neoplasms was 31% (five out of 16 cases). In contrast, the literature shows that the V600E mutation is rarely seen in follicular neoplasms, with very few reports that have identified this mutation in follicular neoplasms with minimal incidence [37]. Therefore, a reanalysis of routine H&E slides identified two cases of focal papillary architecture with nuclear features, which might have been overlooked during the morphological assessment. Despite their exclusion, the percentage incidence of the V600E mutation in follicular neoplasm was 18.72% (three out of 16 cases). Nonetheless, papillary carcinoma, particularly the microfollicular type, was possibly missed on routine evaluation as specimens were not extensively sampled, rather were only drawn from the most representative areas of the lesion.

Overall, we show that a significant number of cases of papillary carcinoma (31%; 9/29) and follicular neoplasms (18.7%; 3/16) express the V600E mutation. A larger prospective study, including preoperative cytology specimen and surgically resected specimens of the same patients, is needed to establish the utility of the V600E mutation as a routine diagnostic tool. After development, the primers would be cost-effective to patients.

An increase in the incidence of papillary carcinoma in areas where there is high iodine intake has been reported [3,38,39] and there is high iodine supplementation to correct iodine deficiency, particularly in the population with an existing V600E mutation. This raises the question of establishing dietary iodine supplementation levels to prevent the incidence of non-neoplastic conditions including multinodular goiter. Furthermore, papillary carcinoma usually remains intra-thyroid and few cases may present with rapid onset of clinical manifestations with enlargement of multiple cervical lymph nodes [40]. Therefore, a larger, multicenter, prospective study that includes cytology specimens collected preoperatively and following surgical resection is essential to establish the relationship between the incidence of papillary carcinoma and V600E mutation in the background of iodine supplementation and deficiency and to prove the utility of BRAF in routine diagnosis. However, the most recent

American Thyroid Association (ATA) recommendations do not indicate a routine application of BRAF status for initial risk stratification in differentiated thyroid cancer due to a lack of evident confirmation of a direct influence of mutation on the increase in relapse risk.

Further, considering the increase in the prevalence of the BRAF V600E mutation in follicular neoplasms, a larger study of the V600E mutation in follicular neoplasms is vital to observe changes in the expression patterns of mutations in the Indian population.

Conclusions

In our cohort, 31% of cases of PTC and 18.72% of follicular neoplasms expressed the BRAF V600E mutation.

BRAF V600E mutation-positive PTCs consistently showed all characteristic nuclear features, such as nuclear crowding, overlapping, and grooves.

Considering the greater prevalence in the younger age group, the importance of mutation surveillance in PTCs for a total thyroidectomy may be warranted in mutation-positive patients.

ABSTRACT

Introduction; Depression is an illness that may affect and be affected by diabetes mellitus. The clinical guidelines for older adults with diabetes mellitus have recognized this by recommending screening for and management of depression in diabetic elderly people. The aim of this study was to find out the prevalence of depression using PHQ -9 questionnaire among elderly diabetics in peripheral primary health care centres attached to a Private medical college. **Objectives:** 1. To find out the prevalence of depression among elderly diabetics 2. To find out the factors associated with depression among elderly diabetics **Methodology:** This cross sectional study was conducted among known diabetics above 60 years of age attending the NCD clinic of Peripheral health centres at Peelamedu, Vedapatti, Neelambur during December 2017 – April 2018. The socio demographic factors and morbidity factors such as fasting blood sugar, duration of diabetes, history of hypertension, past history of diabetes related complications, hours of sleep were included to find out the association with levels of depression. **Results:** Among the study population, 40.4 % were having the signs of depression in which the majority have only minimal symptoms of depression. The factors such as Female Gender, Fasting blood sugar >126 mg/dl and hours of sleep < 7 hours found to be statistically significant association with depression. **Conclusion:** The prevalence of depression using PHQ 9 is 40.4% and the factors such as female gender, fasting blood sugar more than 127 mg/dl and sleep at night less than 7 hours were found to have statistically significant association with depression.

Key word: Depression, PHQ-9, Screening, Prevalence, Elderly diabetics.

INTRODUCTION

Depression is an illness that may affect and be affected by diabetes mellitus. Depression is an independent risk factor for the onset of type 2 diabetes mellitus. It negatively affects the course of diabetes and is associated with increased risk of complications, hyperglycemia, and mortality. Depression may exert its negative effect through hormonal, neuronal, or immune system changes that directly affect the body's ability to produce or use insulin or, the effect of depression may be indirect, by resulting in poor self-care behaviours, such as overeating, drinking alcohol, not exercising, skipping medications, or failing to keep medical appointments. Thus, identifying and treating depression in diabetes is strongly recommended.[1]

Evidence suggests that depression may relate to poorer glycaemic control[2] and that poorer control predicts a poorer course of depression in adult samples.[3]There is some evidence that depression does not prospectively predict worsening of blood glucose control in the elderly, but more research needs to be done to understand this relationship in this group.

In interactions with the health care system, the presence of depression may influence decisions made by health care providers concerning medical outcomes (e.g., blood glucose and blood pressure). For example, providers may set goals that are easier to achieve, yet are less stringent, when they believe that depression will interfere with a patient's ability to adhere to a stricter regimen. Depression can also have an effect on patients' own goals and preferences for treatment, because depressed patients may feel too hopeless or helpless to embark on the lifestyle changes that are most beneficial for diabetes self-care.

Thus, in many different ways, diabetes may become more difficult to manage for elderly people who are also depressed, and depression may become more difficult to resolve in those who have diabetes, resulting in higher health care utilization and medical costs for those with this comorbidity.[4] The clinical guidelines for older adults with diabetes mellitus have recognized this by recommending screening for and management of depression in diabetic elderly people.

Tools such as the short form of the Geriatric Depression Scale, the Patient Health Questionnaire-9, and the newly

developed Depression and Suicide Screen are useful. [5] The present study used PHQ – 9 questionnaire to arrive at a provisional diagnosis of depression as patients with minimal symptoms (score 5-9), minor depression (score 10-14), moderate Major depression (score 15-19), severe major depression (score >20).

The objectives of this study were to find out the prevalence of depression using PHQ -9 questionnaire among elderly diabetics in peripheral primary health care centres attached to a Private medical college and to find out the factors associated with depression.

METHODOLOGY

The Department of community medicine of PSG Institute of Medical sciences and Research has one Urban (Peelamedu) and Two Rural health training centres (Vedapati and Neelambur) to deliver primary health care to people. These centres have basic laboratory services to manage Non communicable diseases (NCD). All these three centres run NCD clinic on a particular day of the week and maintain NCD register. This cross sectional study was conducted among known diabetics above 60 years of age attending the NCD clinic of Peripheral health centres at Peelamedu, Vedapatti, Neelambur during December 2017 – April 2018. By purposive sampling, 104 elderly diabetics who came for review during the study period at NCD clinic were selected. All registered diabetics above 60 years of age attending the NCD clinic were included and those who were on treatment for pre-existing major and minor mental illness were excluded.

After obtaining approval from Institutional Human Ethics Committee, informed consent obtained from the patients at NCD clinics of peripheral health centres. Study Questionnaire with PHQ-9 administered to the patients till the sample size of 100 reached. Questionnaire contains the following items i.e. Socio demographic variables, fasting blood sugar, presence of hypertension, complications related to diabetes and hours of sleep at past night to find out the association of above factors on depression among the study population.

Those patients found to be having depression will be followed up based on degree of depression at the peripheral health centres. Proportions, test of statistical significance (Chi square) and odds ratio with 95% confidence interval (CI) using SPSS version 24 were calculated.

RESULTS

Table 1: Distribution of study population at Peripheral Health Centres

Peripheral Health centres	Study population	Percent (%)
UHTC (Peelamedu)	46	44.2
VHTC (Vedapatti)	29	27.9
NHTC (Neelambur)	29	27.9
Total	104	100

The present study intended to find out the prevalence of depression among elderly diabetics and the factors associated with depression. There were 104 elderly

	No	26(45.6%)	31(54.4%)	(0.27-1.36)	0.231

* Statistically significant (p< 0.05)

diabetics (Table. 1) included in the study. Among the study population, 40.4 % were having the signs of depression (Table.2), of which 24% have only minimal symptoms of depression (Table.3).

The socio demographic factors i.e. age, gender, education, income per capita per month and morbidity factors such as fasting blood sugar, duration of diabetes, history of hypertension, past history of diabetes related complications, hours of sleep and PHQ -9 score are shown in Table.4.

Each of the above variables were categorized into two to find out the statistically significant (p< 0.05) association with depression among the study population using chi square test (Table. 5) in SPSS version 24. The factors such as Female Gender, fasting blood sugar >126 mg/dl and hours of sleep < 7 hours found to be statistically significant association with depression in the present study.

DISCUSSION

In the present study the prevalence of depression among elderly with diabetes mellitus was found to be 40.4%. The study conducted by SA Black et al showed that 31.1% of the older diabetic individuals reported high levels of depressive symptoms. [6] Prevalent major depressive episodes were present in 15.4% of the subjects with diabetes, which was significantly higher than in nondiabetic subjects in a study conducted among community-dwelling elderly persons with diabetes mellitus by P. de Jonge et. al. [7] In a study conducted by Manjiri D Pawaskar et al. among Medicare enrolled elderly population with type 2 diabetes mellitus, 17% had depressive symptoms. [8] In a study conducted by Kee-Lee Chou et al, on Prevalence of depression among elderly Chinese with diabetes, 26% of elderly diabetics reported elevated levels of depressive symptoms. [9] Elderly female diabetics are more among depressed (OR 3.2, 95%CI: 1.40-7.48) than men in this study which is statistically significant. Finkelstein EA et al reported diagnosed annual prevalence rates of major depression more among elderly female diabetics. In our study there is no significant association between the subjects with duration of diabetes less than 10 years and more than 10 years whereas in a study done by Yu-Ling Bai et al. a significant difference was found for depression scores between subjects with diabetes for <1 year and those with diabetes for >10 years.[10] Elderly with high Fasting blood sugar >127 mg/dl have higher risk of depression (OR 2.5, 95%CI: 0.99-6.33) than those with Fasting blood sugar <126 mg/dl in the present study. PJ Lustman et al reported in the meta analytic review of 24 studies that Depression is associated with hyperglycemia in patients with type 1 or type 2 diabetes[3]. However, association of depression with hyperglycemia in elderly diabetics is not documented. Elderly diabetics who slept more than 8 hours at night had lesser risk of depression (OR 0.279, 95%CI: 0.08-0.89) than those who slept less than 7 hours at night in this study. The factors such as age, education,

© Community Medicine Faculties Association-2019
NJRCM: www.commedjournal.in

income, marital status, past history of diabetes related complications and hypertension were not found to be significant in this study. This study has few limitations like very small sample size, FBS is taken as an indicator for glycemic control instead of Hb A1C and PHQ 9 administered by different doctors at three health centres.

Conclusion:

This cross sectional study among elderly diabetics in primary health centre setting of a private medical college revealed that prevalence of depression using PHQ 9 is 40.4% and the factors such as female gender, fasting blood sugar more than 127 mg/dl and sleep at night less than 7 hours were found to have statistically significant association with depression.

Brief Communication

Needs Assessment of Ophthalmology Education for Undergraduate Medical Students – A Study from a Medical College in South India

Karuppannasamy Divya[1], Kannappan Suvetha[2], Alo Sen[1], Devisundaram Sundar[1]

Departments of [1]Ophthalmology and [2]Community Medicine, PSG Institute of Medical Sciences and Research, Coimbatore, Tamil Nadu, India

ABSTRACT

Background: Adequate ophthalmic diagnostic and clinical skills are essential for practitioners in primary care settings as well as specialty care physicians. The objectives of this study were to assess the adequacy of ophthalmology teaching in undergraduate medical education and to evaluate the comfort of medical students in diagnosing common eye problems and performing ophthalmic skills. **Methods:** A questionnaire based, cross-sectional survey was conducted among third-year undergraduate students from a medical college in South India at the end of ophthalmology training from February 2014 to December 2014. The main outcome measures were hours of classroom-based instruction and clinical exposure to ophthalmology received by the students and their comfort level in diagnosing common eye problems and performing ophthalmic skills. **Results:** 134 students participated in the study. They had received an average of 96.2 ± 5.9 and 112.5 ± 11.3 hours of classroom and clinic-based instruction, respectively. The participants' comfort in diagnosing eye problems was satisfactory for cataract and eyelid disorders but not for ophthalmic emergencies. Only 45.5% had satisfactory knowledge in community ophthalmology. Respondents were more proficient in visual acuity testing (93.3%) and assessment of pupillary reaction (80.6%) than direct ophthalmoscopy (41%). **Discussion:** Undergraduate medical students from India received a greater amount of ophthalmology instruction compared to the International Council of Ophthalmology task force recommendations. Gaps in community ophthalmology and knowledge-skills discrepancies were noted. Review of curriculum, appropriate training resources, and effective teaching methods tailored towards primary care may be useful to improve the training.

Keywords: Comfort, knowledge, ophthalmology, undergraduate medical education

Background

Ophthalmology makes up a significant proportion of primary care consultations.[1] A basic knowledge of ophthalmology is essential in the management of several neurologic, endocrine, rheumatic, and infectious conditions. Despite the relevance of ophthalmology to medical practice, little time is allocated to teaching of ophthalmology in undergraduate medical education and the majority of primary care physicians do not feel that they have received adequate undergraduate ophthalmic education.[2] Also several studies have noted that medical students receive too little ophthalmic training.[3-5]

In India, the five and one-half year undergraduate medical training consists of four and one-half years of teaching of subjects comprising the medical curriculum and one year of internship. Ophthalmology is being taught in the third year after preclinical and paraclinical subjects.

The state of undergraduate ophthalmology training from medical colleges in India has not been studied so far. Evaluation

of ophthalmic knowledge and skills of undergraduates at the end of ophthalmology training would help in generating critical feedback on undergraduate ophthalmic curriculum planning. The objectives of this study were:

1. To assess the adequacy of ophthalmology teaching in undergraduate medical education
2. To assess the comfort level of medical students in diagnosing and treating common eye problems and performing ophthalmic skills.

Methods

After approval from the institutional review board, undergraduate medical students from a medical college in South India were included in the study at the end of their ophthalmology training (February 2014 to December 2014). The adequacy of ophthalmology education was quantified by determining the hours of classroom-based instruction and clinical exposure to ophthalmology received by the students and comparing these with the recommendations of the Medical Council of India (MCI) as well as the International Council of Ophthalmology (ICO).

A validated questionnaire [Appendix 1] was given to the students and their responses collected anonymously. The questionnaire consisted of three parts. Parts 1 and 3 assessed the students' comfort with respect to diagnosing specific ophthalmology conditions and performing ophthalmology-related skills on a Likert scale from 1 to 5 (1 = not at all comfortable, 2 = somewhat comfortable, 3 = moderately comfortable, 4 = comfortable, and 5 = very comfortable). In terms of comfort level, we examined the ease with which study participants reported they were able to diagnose common eye problems and perform ophthalmic skills.

The second part assessed knowledge on certain topics on a Likert scale, also from 1 to 5 (1 = very poor, 2 = poor, 3 = average, 4 = good, and 5 = very good). The conditions and skills covered in the questionnaire were based on the topics covered in the undergraduate ophthalmology curriculum recommended by the MCI.[6]

Participants were also asked about the number of hours spent in self-directed learning and how comfortable they felt in managing ophthalmology-associated issues overall.

Likert scale-based responses were subsequently dichotomized and reduced to proportions by categorizing scores 1–2 as unsatisfactory or inadequate and 3–5 as satisfactory or adequate. Data were entered using the Statistical Package for the Social Sciences (version 19 (SPSS, Inc., Chicago, IL, USA) and examined using descriptive and analytical statistics to yield frequencies, percentages, and proportions.

Results

Of the 150 undergraduate medical students, 134 responded to the questionnaire (response rate = 89.6%).

The main modes of ophthalmology exposure were didactic lectures (35 hours), tutorials (37.5 ± 3.8 hours), seminars (23.7 ± 2.2 hours), and clinic-based learning. Our study participants had received an average of 96.2 ± 5.9 hours of classroom-based instruction. They also had received 112.5 ± 11.3 hours of clinic-based instruction in the eight weeks of clinical posting. 121 participants (90.3%) had spent up to 10 hours in self-directed learning while 13 participants (9.7%) had spent more than 10 hours in self-directed learning.

The results of the participants' comfort in diagnosing ophthalmic conditions are presented in Figure 1. Figure 2 shows the students' adequacy of knowledge in community and systemic ophthalmology as well as indications for ophthalmic referral. Figure 3 shows the study participants' comfort in performing MCI recommended clinical skills. Tables 1-3 show the numerical data for the corresponding figures. Finally, 101 participants (75.4%) felt comfortable in managing ophthalmology associated issues overall.

Discussion

This cross-sectional observational study attempted to quantify the adequacy of undergraduate ophthalmic education and students' comfort with regard to the management of ocular conditions.

In comparison with MCI recommendations, our study participants received a satisfactory number of hours of both classroom and clinic-based instruction. The MCI recommends clinical training of 8 weeks and a total of 100 teaching hours in ophthalmology, which includes 30 h of didactic lectures,

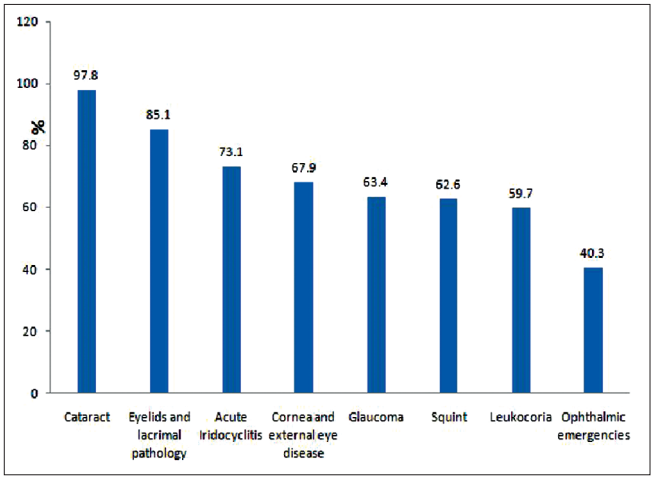

Figure 1: Medical students' comfort in diagnosing common ophthalmic conditions

[Downloaded free from http://www.educationforhealth.net on Monday, April 23, 2018, IP: 192.168.30.113]

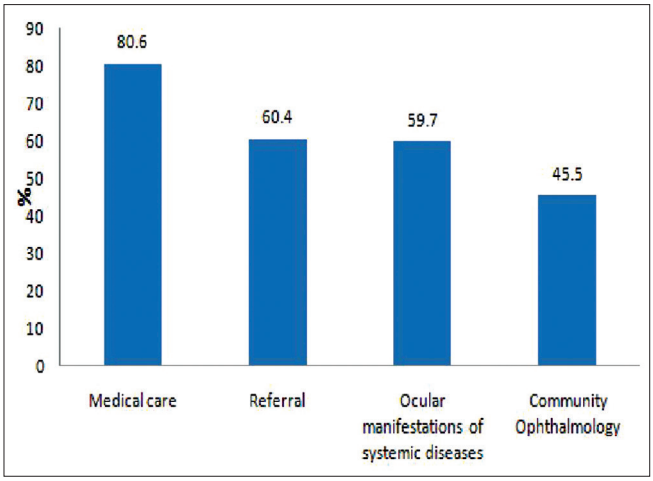

Figure 2: Students' adequacy of ophthalmic knowledge

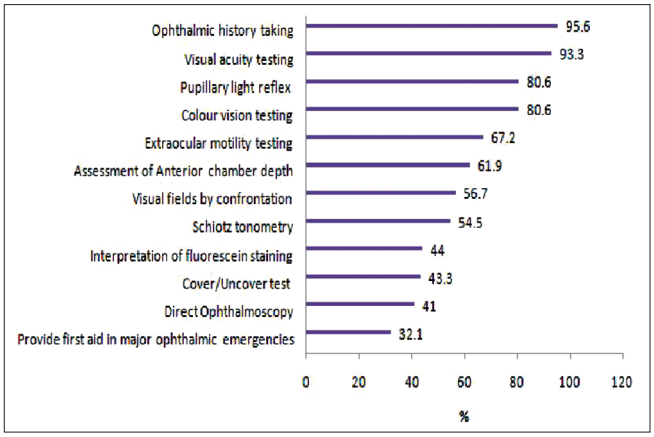

Figure 3: Students' self-reported proficiency in performance of ophthalmic skills

Table 1: Students' comfort in diagnosing common ophthalmic conditions

Ophthalmic conditions	Participants with adequate comfort in diagnosing common ophthalmic conditions (n=134), n (%)
Cataract	131 (97.8)
Eyelids and lacrimal pathology	114 (85.1)
Acute iridocyclitis	98 (73.1)
Cornea and external eye disease	91 (67.9)
Glaucoma	85 (63.4)
Squint	84 (62.6)
Leukocoria	80 (59.7)
Ophthalmic emergencies	54 (40.3)

60 h of tutorials and seminars (including integrated learning), and 10 h of self-directed learning.[7] These guidelines suggest a greater amount of ophthalmology exposure in undergraduate medical education in India when compared with ICO guidelines. The ICO recommends 40–60 h of ophthalmology exposure during undergraduate training.[8]

According to the curriculum recommended by the MCI, the goal of teaching ophthalmology to undergraduate medical students is to provide such knowledge and skills to the students that shall enable them to practice as a clinical and primary eye care physician.[6] The curriculum provides a list of competencies which need to be demonstrated by the student at the end of ophthalmology training. These include knowledge of common eye problems in the community; ability to manage common eye problems and identify indications for referral; recognize visual impairment and blindness in the community; and implement the National programme as applicable in the primary care setting.[7]

Most of the participants in the study reported a satisfactory level of comfort in diagnosing common ophthalmic problems. The fact that 97.8% reported a satisfactory level of comfort in diagnosing cataract is encouraging since cataract is the leading cause of preventable blindness in the developing world. Yet, despite this satisfactory level of comfort in managing common eye problems, most study participants' comfort in diagnosing ophthalmic emergencies such as endophthalmitis, rupture globe, and chemical injuries was found to be inadequate.

Nearly 60% reported to have adequate knowledge in ocular manifestations of systemic diseases. This could be because of better teaching resources as well as integration of ophthalmology topics into other subjects of the medical curriculum horizontally and longitudinally. The self-rated knowledge of more than one-half of the study participants was found to be unsatisfactory in community ophthalmology. With greater emphasis placed on teaching disorders of the eye, in theory lectures as well as in hospital settings, community ophthalmology is often neglected. A study on the status of ophthalmic medical education in the South-East Asia Region of World Health Organization has also highlighted this concern, where students have little exposure to community ophthalmology.[9]

The knowledge of most study participants on the indications of medical treatment and referral to eye clinics was adequate. With a significant shortage of ophthalmologists in developing countries, an adequate level of comfort of primary care physicians in providing medical care and accuracy in referral is essential. A high rate of referral places pressure on the limited resources of ophthalmic casualty departments and outpatient clinics.

More than 80% reported competency in ophthalmic history taking, visual acuity and color vision testing, and pupil examination. These are relevant not only in ophthalmology but also in general medicine, neurology, and trauma care. However, only 44% reported an adequate level of comfort in interpretation of fluorescein staining and 54.5% in Schiotz tonometry. This is an area of concern because corneal blindness

Direct ophthalmoscopy	55 (41)
First aid in major ophthalmic emergencies	43 (32.1)

and glaucoma contribute to a major extent to the burden of blindness in India; adequate proficiency of the primary care physician in these skills will help in early diagnosis and treatment or referral, thereby reducing the risk of visual loss.

Only 41% of respondents indicated that they had adequate proficiency in performing direct ophthalmoscopy which is consistent with studies elsewhere.[2,10] This could be because of the limited time devoted to teaching ophthalmoscopy in the medical school curriculum as well as the technical challenges involved.

Although most students were comfortable in managing ophthalmology associated issues overall, gaps were noted in certain key areas. Review of the curriculum with greater emphasis on community eye care and blindness control strategies, adequate training resources, and effective teaching methods tailored toward primary care would help to increase the medical students' comfort in managing common eye problems.

Since our observations are from a single center, generalization of results is limited. Subjective bias due to the candidates varying ability to accurately self-evaluate is also a limitation. The choice of the study population was medical students at the end of ophthalmology training rather than interns because of the possibility of recollection bias. A similar study on interns or junior medical officers would provide more insight into the knowledge and gaps in training.

In spite of these limitations, this needs assessment study is the first of its kind in India to assess the adequacy of ophthalmic teaching and the knowledge and clinical skills of undergraduate medical students. Ophthalmology in India is being taught as part of the essential undergraduate medical curriculum and not exclusively as an elective. Students receive adequate exposure to ophthalmology, and the undergraduate curricular hours are greater than the guidelines published by the ICO. Since ophthalmology related topics and examination skills are included in most of the standardized medical licensing examinations and internal medicine boards, medical graduates from India are at a distinct advantage.

Appendix

Appendix 1: Questionnaire

1. Using the table below, please indicate how comfortable You feel diagnosing the following issues based on your present knowledge:
   (1 = not at all comfortable, 2 = somewhat comfortable, 3 = moderately comfortable, 4 = comfortable, 5 = very comfortable)
   Conjunctiva/cornea 1 2 3 4 5
   Viral conjunctivitis
   Allergic conjunctivitis
   Subconjunctival hemorrhage
   Pterygium
   Corneal abrasion/ulcer
   Keratomalacia
   Corneal blindness
   Eyelid/lacrimal sac 1 2 3 4 5
   Blepharitis
   Chalazion
   Stye
   Dacryocystitis
   Lens/Uvea 1 2 3 4 5
   Cataract
   Acute iridocyclitis
   Glaucoma 1 2 3 4 5
   Primary open-angle glaucoma
   Acute angle-closure glaucoma
   Ophthalmic emergencies 1 2 3 4 5
   Globe rupture
   Chemical injuries
   Endophthalmitis
   Pediatric ophthalmology 1 2 3 4 5
   Strabismus
   Leukocoria

2. Using the table below, please indicate your knowledge on the following issues:
   (1 = very poor, 2 = poor, 3 = Average, 4 = good, 5 = Excellent)
   Ocular manifestations of systemic diseases 12345
   Diabetic retinopathy
   Hypertensive retinopathy
   Tuberculosis
   Toxemia of pregnancy
   HIV
   Community ophthalmology 1 2 3 4 5
   Magnitude of blindness in India
   NPCB and implementation at various levels
   Functions of ophthalmic assistant
   Organization of eye camp
   Medical care/referral 1 2 3 4 5
   Indications of topical antibiotics
   Indications of topical steroids
   Indications of antiglaucoma drugs
   Indications of ophthalmology referral

3. Using the table below, please indicate how comfortable You feel performing the following ophthalmology-related skills:
   (1 = not at all comfortable, 2 = somewhat comfortable, 3 = moderately comfortable, 4 = comfortable, 5 = very comfortable)
   Clinical assessment 1 2 3 4 5
   Ophthalmic history taking
   Visual acuity testing
   Test color vision
   Cover/uncover test
   Assessment of anterior chamber depth
   Pupil examination/swinging flashlight test
   Visual field testing by confrontation
   Extraocular movements
   Interpretation of fluorescein staining
   Schiotz tonometry
   Direct ophthalmoscopy
   Provide first aid in major ophthalmic emergencies

4. How many hours would you have spent in self-directed learning in ophthalmology?
   ("self-directed learning" describes a process by which individuals take the initiative, with our without the assistance of others, in diagnosing their learning needs, formulating learning goals, identify human and material resources for learning, choosing and implement appropriate learning strategies, and evaluating learning outcomes)
   1. 0–2 h 2. 2–5 h 3. 5–7 h
   4. 7–9 h 5. 0 > 10 h
5. How comfortable do you feel managing ophthalmology associated issues overall?
   1. Not comfortable at all 2. Somewhat comfortable
   3. Moderately comfortable 4. Comfortable 5. Very comfortable

THE END

Thank you for taking time for our survey.

Practical Advice Paper

Academia–Industry Collaboration to Provide Interdisciplinary Experiential Learning Opportunities in Public Health Professions Education and Improve Health of Female Factory Workers

Suvetha Kannappan[1], Thomas V. Chacko[2]

[1]Department of Community Medicine, PSG Institute of Medical Sciences and Research, Coimbatore, Tamil Nadu, [2]Department of Community Medicine and Medical Education, Believers Church Medical College and Hospital, Thiruvalla, Kerala, India

ABSTRACT

Background: The community medicine department of our medical school, in addition to addressing its mandate to prepare undergraduate students for primary care and graduate students for careers in public health, administers several community-based interventions. An international organization involved with improving health of female factory workers globally invited us to partner in their efforts locally. We used the Precede-Proceed model to design an intervention to deliver the desired project outcomes. **Activities**: Recognizing that this partnership with industry would provide a learning opportunity to our Master's degree program students, we involved them in a needs assessment survey in order to make an educational diagnosis to identify the influencing and reinforcing factors. Our faculty and students interfaced with a multidisciplinary team including mid-level factory managers, health-care staff, and peer health educators within the textile industry. **Outcomes**: Through this industry–academia collaboration, our health professions training institution was able to provide supplementary experiential learning opportunities to students in our Master's degree in Community Medicine program by involving them in all the project stages from planning based on health needs assessment, to module design, implementation, and program evaluation along with interdisciplinary teams from the textile industry. Students then reflected on their learning experience using a modified Kolbe's experiential learning cycle to improve their performance when they replicated the intervention with the next factory under the same project. **Conclusion:** The use of PRECEDE–PROCEED model in the industry–academia collaboration and Kolb's framework provided supplementary experiential learning opportunities for deliberate practice, receiving feedback, and reflecting on their learning to our Master's in Community Medicine degree students.

Background

The Department of Community Medicine at our medical school in South India is involved in a number of community-based activities and programs that cater to the health needs of different population groups in urban and rural settings and also provide hands-on experiential learning opportunities to future public health specialists. One such program is directed toward promoting the health of women in the textile industry. Tirupur, a textile city in South India, is one of the leading exporters of garments. Recent years have seen a high inflow of migrant female workers, most of whom are between 18 and 25 years old.[1] These women workers often suffer from anemia, poor hygiene, inadequate pre- and post-natal care, sexual violence, and exposure to infections and illness.[2]

Business for social responsibility (BSR) is a network of more than 250 member companies all over the world that promotes various sustainable initiatives. Among the many strategies they use for ensuring sustainability is the "peer education model," which brings together international brands, academia, and top management of factories to educate women who work in these factories.[3] This model advocates for better conditions for workers with owners and is called "health enables returns." The project is also known as HERproject which serves as an acronym for "health enables returns" and also refers to the targeted beneficiaries who are the vulnerable women factory workers.

The Master's Degree program in Community Medicine (Public Health) administered by the department provides learning opportunities for acquiring core public health skills that enable graduates to function as public health consultants, educators, leader–managers, and researchers for improving the health of defined population groups.[4] The 1st year of the Master's Degree program introduces students to the foundation courses in epidemiology, nutrition, demography, biostatistics, and environment health. The 2nd and 3rd years provide them with opportunities to apply these skills and also to further develop leadership and management skills in the defined population groups as well as research competency (a community-based thesis is required). The Master's Degree students use structured experiential learning opportunities for deliberate practice, reflection on practice, and receiving feedback from faculty on the job as well as on their reflective log [Figure 1][5] to equip them with skills that they will be using for continuing professional development.

Context

Master's Degree students generally get opportunities to learn about health program planning and program evaluation in health systems or community settings serving defined population groups. Workers in factories are a defined

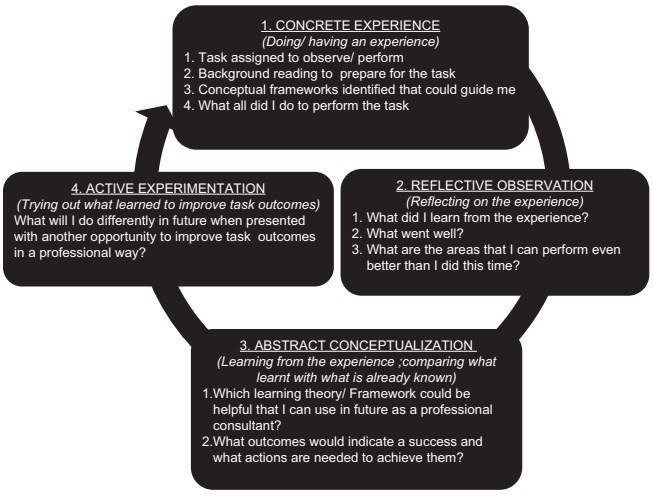

Figure 1: Reflective log using modified Kolb's cycle to optimize experiential learning

population group, so a collaborative partnership has been entered into between our medical school and BSR to address the health issues of the women workers and to promote good health. This academia–industry collaboration helped develop a need-based intervention, with academia contributing its expertise and industry, allowing its personnel and premises to function as resources to facilitate the implementation of the project. The community medicine department administering the Master's degree program involved the students in all the stages of the program planning, implementation, and evaluation.

The entire process of how the faculty and postgraduate students in the department of community medicine systematically designed and implemented the program within the industry is described in detail. We also describe how we built upon a well-known PRECEDE–PROCEED model by incorporating the concepts of community diagnosis and educational diagnosis to design a tailor-made intervention to improve the health of factory workers and thereby benefit the factory. It is hoped that sharing our experience will provide other health professions educational institutions with an alternate model of industry-based learning experience that they may be interested in replicating or adapting as an additional venue for community-based learning.

Activities

We chose to use the PRECEDE–PROCEED conceptual model to plan and apply the health behavioral theories for behavioral change.[6] We used the World Health Organization-recommended process of identifying the main health problems and their underlying social and other determinants known as "community diagnosis."[7,8] Based on the community diagnosis, we were able to identify the predisposing and enabling factors in the working environment. This means we could

[Downloaded free from http://www.educationforhealth.net on Wednesday, March 10, 2021, IP: 103.224.34.2]

make an "ecological diagnosis" as well as identify behaviors that are contributing to ill health by making an "educational diagnosis" (PRECEDE phase 1 through 3). Once these two diagnoses were made, the tailor-made "treatment" – the health education program (Phase 4: Health promotion educational strategies, program implementation) was designed to correct the faulty behaviors and predisposing conditions in the working environment and thereby lead to improvement in health.

The "team-academia," comprising of faculty project advisor, faculty project coordinator, consultants, Master's Degree Public Health students, and social workers, was drawn from the department of community medicine of our medical school. Following an orientation meeting with the top and middle management of the industry, a team consisting of the top- and middle-level managers, the factory's basic health-care nursing team, and the peer leaders as peer educators was formed at the factory level. The female factory workers were the beneficiaries or target population of the initiative. A brief summary of the various steps involved in the program implementation and expected outcomes based on the PRECEDE–PROCEED model is shown in Figure 2.

Outcomes

Benefits and outcomes for the industry

The model as shown in Figure 2 in its phase 6–8 guides the user to plan and put in place a system for program monitoring and evaluation. We used Kirkpatrick's Training evaluation framework[9] to capture the effectiveness of the educational intervention program outcome. Table 1 summarizes the different outcomes of the program in the short term.

Table 1 shows how the peer educators found the program to be useful (Kirkpatrick Level 1). This influences program acceptance and its sustainability. It also captures their learning in terms of gain in knowledge (Kirkpatrick Level 2) and change in behavior (Kirkpatrick Level 3), thereby showing that capacity-building of peer educators was achieved. Successful transfer of learning to workplace (Kirkpatrick Level 4) was indicated by the peer educators being able to gain confidence and conduct several training sessions, which contributes significantly to program sustainability. Similarly, the program impact as demonstrated by bringing in return-on-investment (Kirkpatrick Level 5) in terms of health benefits to the workers translating to reduction in sickness absenteeism has convinced the factory management to institutionalize the program. Acceptance by another set of 25 factories in the region is a clear indicator of widespread recognition of the utility of the intervention and so ensures its sustainability.

Beneficial learning opportunities and outcomes for the academia

Table 2 shows the learning opportunities for the Master's Degree students in the industry that are unique to the project and are listed across the various phases of the model used.

Table 1: Effectiveness of the peer educators' training program

Kirkpatrick's level	Outcome indicators/measurement	Results from factories postintervention
Level 1: Reaction of the peer educators (satisfaction, usefulness, suggestions etc.)	Verbal and written feedback immediately after the peer educators' training session	"The program was very useful; earlier I used to be shy talking about HIV/AIDS. Not anymore
Level 2: Learning	Learners gain in knowledge was assessed by verbal questioning, conducting quiz sessions at the end of the training, etc. An end-line assessment done using the standard survey form among 10% of the workers	Most of the peer educators were able to reply quickly and correctly Awareness score on nutritious diet has improved from 40% to 75% Awareness score on necessity for doctors visit during pregnancy has increased from 85% to 33%
Level 3: Change in behavior Level 4: Transfer of learning to workplace	Number of outreach sessions conducted by peer educators Periodicity of interaction with workers on various modules Case studies from peer educators and workers Periodic meetings and interview with management	Confidence: " I am now confident in doing "Self Breast Examination" An average of 70 outreach sessions conducted by peer educators per factory varying from 60 to 80 based on workers strength Workers practicing regular exercise has increased from 30% to 55%
Level 5: Return on investment: Program impact	Monitoring certain indicators such as sickness-related absenteeism, trends in food wastage every month, worker turnover, and pattern of illness Willingness of the management to internalize the program and continue to provide resources for the sustainability of the program Program scaleup and expansion	Health benefits Menstrual problem-related absenteeism has decreased from 30% to 20% Complaints of musculoskeletal problems has decreased from 35% to 22% Management 's feedback regarding the program "Absenteeism due to health reasons is declining. It is helpful to reach our production target" "Posttraining we have seen visible changes among our workers. They are more energetic at and after work" Changes brought in the factories Change in the canteen menu, availability of nutritious snacks within the premises improved linkage with public health system for utilizing national programs for anemia prevention, deworming and other health services Started with three factories in 2012 the HERproject is scaled up to 25 factories in 7 years

[Downloaded free from http://www.educationforhealth.net on Wednesday, March 10, 2021, IP: 103.224.34.2]

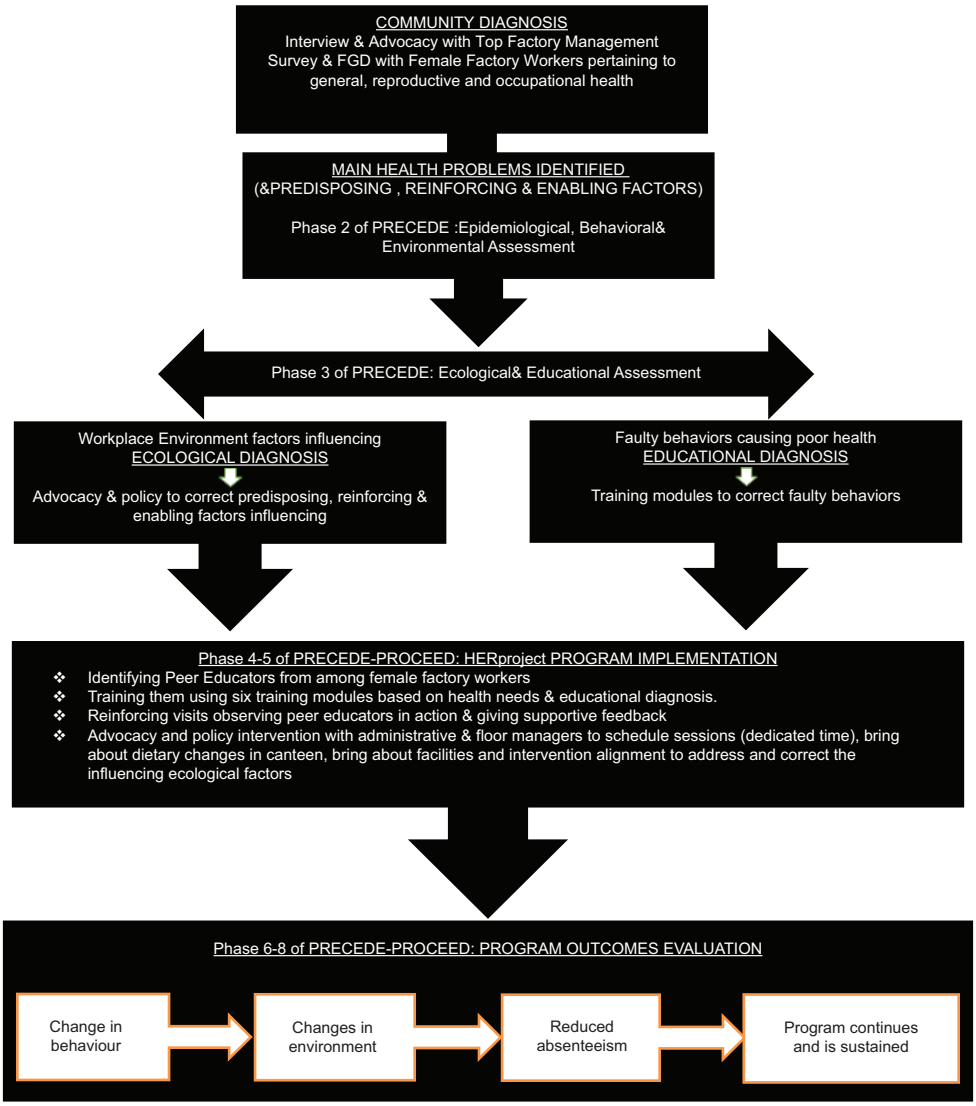

Figure 2: Flow diagram showing planning and implementation of the educational intervention

The concrete learning experiences in the second column are tagged with their resultant specific public health competencies and tools listed in the third column. They are effective communication, community diagnosis, educational diagnosis, training module design, working with interdisciplinary teams, use of adult learning principles, providing supportive feedback to peer educators, use of logic model for program planning, and identifying indicators to measure outcomes of any intervention.

Table 2 in its extreme right column captures the learning outcomes that emerged from the structured learning experiences stated in the column on its left and provides more insights about the benefits students reaped than any quantitative research would have elicited. These responses were captured from reflective logbooks students submitted after each learning experience they were involved in as part of their course. As shown in Figure 1, these reflective observations (step 2 in the Kolb's cycle) then provoke them to search for other conceptual frameworks that would illuminate and guide their next step in the step 3 namely "abstract conceptualization." This helps them to be better prepared for undertaking a similar professional activity by encouraging them to go through step 4 of "active experimentation" so that improved outcomes result.

Future Directions

The main factors that contributed to program sustainability are stated below and should find a place in project planning in future.

Contribution of the model for its sustainability

As indicated in Figure 2, it is clear that in addition to serving as a model to design an intervention, it facilitates, through the component of community diagnosis, in making an ecological

[Downloaded free from http://www.educationforhealth.net on Wednesday, March 10, 2021, IP: 103.224.34.2]

Table 2: The PRECEDE-PROCEED model: Learning opportunities and learning outcomes for students in academia

PRECEDE-Proceed model for guiding and planning		Concrete experiences in industry	Concrete experiences in public health learning	Reflections by students on their learning experience (extracted from their Kolb's Reflective logbook) Student's reflections on learning
Phases of the model	Components of the model			
PRECEDE Phase 1	Social assessments, participatory planning, situational analysis	Advocacy with top level and middle management	"2-min elevator talk": Articulating the need for intervention, the intervention and benefits to industry	*"Got insight into ways for influencing policy, interagency collaboration, using research for developmental activities" "learnt the importance of getting all the stakeholders on board for the success of the program*
PRECEDE Phase 2	Epidemiological, behavioral, and environmental assessments	Site visits to industry for identification of priority health needs and behavioral and environmental determinants	Community diagnosis: HNA survey design, administration and analysis; prioritizing needs; design and do focus group discussion with stakeholders	*"learnt importance of HNA questionnaire - as an effective method to prepare tailor-made intervention" "Learned more about the needs and how to prioritize them Highlighted the areas of unmet need and provided a clear set of objectives to work towards to meet these needs*
PRECEDE phase 3	Educational and ecological assessments	FGD about predisposing, reinforcing and enabling factors	Educational diagnosis: Identifying faulty behaviors leading to ill health and their predisposing, reinforcing and enabling factors Health promotion theories for designing program strategies	*"Learnt to be a good listener, take down notes quickly while conducting FGDs" "I could motivate the silent non respondents in the group to respond and not allow a few to dominate the discussion" "Using the FGD helped in eliciting the predisposing and enabling factors" "I understood how the moderators skills play a major role in getting rich data from the FGDs"*
PRECEDE phase 4	Intervention alignment	Modules based on needs identified: Health behavior, ergonomics, diet in canteen	Use of ADDIE framework for module design (analyze need, design instruction, develop material, implementation of peer educator training and evaluation)	*"Before conducting any health activity in (the) field, structured (prior) planning helps achieve desired outcomes" "Use of standard frameworks helps achieve desired outcomes and we have the satisfaction of having used globally used instructional design frameworks." "how using a framework makes the intervention more structured and organized"*
PRECEDE-PROCEED phase 5	Implementing educational strategies and planning evaluation of process, impact and outcomes of program	Identification of peer trainers from among the factory workers, training of trainers, time scheduling for training sessions Used mid-level managers to identify and finalizing evaluation indicators	Working and leading interdisciplinary team within academia and the industry use of adult learning principles and interactive teaching, supportive ongoing feedback Use of logic model for identifying activities to be monitored for process evaluation	*"While interviewing the workers at the end of the study itself we became aware that the workers had become empowered with knowledge and sounded confident. Shows peer education as a strategy works" "Learnt importance of peer health education as a strategy to sustain the benefits of the intervention longer" "Got an opportunity to practice pedagogical skills and adult learning principles"*
PROCEED phase 6	Process evaluation	Measuring indicators of success of processes needed to carry out tasks and activities	Use of survey and focus groups to collect indicators of success Document study to corroborate evidence in support	*"Great opportunity to learn about (ways for) identifying indicators for evaluation" "helps to understand how important is to identify the right indicator that reflects the outcome expected from the program"*
PROCEED phase 7	Impact evaluation	Used top-level managers to identify indicators of success arising from carrying out project tasks and activities	Use of logic model for identifying short term indicators for impact evaluation	*"HERproject peer educators develop communication and leadership skills, and they use those skills to share their knowledge with their co-workers, with their communities, and with their families" "It helped me understand how targeted health education can impact the health of the workers in the long run"*

HNA=Health needs assessment, FGD=Focus group discussion, ADDIE=Analysis, Design, Development, Implementation and Evaluation

and educational diagnosis (Phase 3 of the PRECEDE–PROCEED model). It thus addresses "the need" for the program as reflected by the "diagnosis" and so the continuing need for the intervention ("treatment") contributes to its sustainability. From Figure 2, it also becomes clear that in the Phase 4–5 of the PRECEDE–PROCEED model as applied to the project, the strategy of using peer educators from among the factory workers, training them using the modules developed by academia based on the ecological and educational diagnosis described in the Phase 3 of the model, reinforcing visits for supportive supervision of the peer educators, together with advocacy and policy intervention by academia with administrative and floor managers are all program components that contribute to sustainability of the intervention.

Successful outcomes (return on investment) as a driver to ensure sustainability

Even after these phases of the program were completed, the outcomes were sufficiently compelling to convince the factory management in terms of "return on investment"

[Downloaded free from http://www.educationforhealth.net on Wednesday, March 10, 2021, IP: 103.224.34.2]

to mainstream it along with other routine activities at the factory. Phases 6 through 8 of the model shown in Figure 2 highlight this result. Team academia, by consciously involving the factory administration to devise a feasible strategy of setting up the "peer education process" as well as having master-trainers at staff level within the factory, contributes significantly to the sustainability of the program.

Conclusion

Using a defined population group in an industrial setting provides a novel population group for students to apply theory to public health practice and helps them realize that irrespective of the target group they work with, the generic guiding principles are the same.

The PRECEDE–PROCEED model commonly used in health promotion program planning and evaluation was found to be helpful and demonstrated its usefulness to the students. Involving postgraduate students in the industry–academia collaboration provided supplementary experiential learning opportunities for deliberate practice, receiving feedback, and reflecting on their learning to our Master's in Community Medicine degree students. By involving them in all the stages from project planning based on health needs assessment, to implementation starting with advocacy with top-level management, training module design, training of peer educators, leadership and management of a multidisciplinary team in industry and program evaluation, they were able to apply their knowledge in a new context. The insights about their learning captured from their reflective portfolio logs using Kolb's experiential learning framework show that participation has enabled them to learn systematically prior to the intervention (PRECEDE phases), to implement the intervention tailored to the identified needs, and to devise program evaluation (PROCEED phases).

Use of Kolb's framework for their reflective log helped postgraduates to reinforce their learning and encouraged them to do background reading and plan for the tasks to be accomplished. It also helped them become reflective practitioners. These enhanced personal development practices help them to engage in continuing professional development to improve the quality of health-care delivery.

In addition, the industry provided another avenue to work collaboratively with multidisciplinary teams and thereby reinforced the value of collaborative learning and respecting team members and project stakeholders for the particular competencies and contributions that they bring together to deliver care and improve service effectiveness.

Acknowledgment

We acknowledge the financial, conceptual, and business network support of BSR and HER project for providing an opportunity to do a value addition to their project and implement it on such a wide scale. The concept and intellectual inputs for designing this tailor-made health promotion intervention using conceptual frameworks and theories for health promotion interventions are our own contribution as they were neither a requirement nor part of the guideline given by BSR and their HER project.

ABSTRACT

Background: Some studies suggested that a high rate of caesarean deliveries results in suboptimal breastfeeding outcomes. The relationship between mode of delivery and breastfeeding outcomes has been considered important given the rising prevalence of caesarean deliveries globally. The present study is to examine the relationship of mode of delivery with breastfeeding outcomes. **Materials and Methods:** This study was conducted at PSG Institute of Medical Science and Research, Coimbatore in the month of July 2018. Ethical clearance was obtained from the institution prior to the study. Chi square test was done to assess the association between socio-demographic variables, timely initiation of breastfeeding and exclusive breastfeeding with mode of delivery. The effect of caesarean on duration of breastfeeding was obtained by applying Kaplan-Meier method. **Result:** Prevalence of caesarean delivery was 36.2% and of vaginal delivery was 63.8%. A statistically significant association was obtained between caesarean deliveries and timely initiation of breastfeeding. However mode of delivery was not significantly associated with exclusive breastfeeding and duration of breastfeeding. **Conclusion:** The findings of our study indicates that caesarean deliveries have been associated with lower timely initiation n rates compared to vaginal deliveries.

Keywords: caesarean delivery, duration of breast feeding, exclusive breastfeeding, initial breastfeeding, vaginal delivery.

Introduction

Breastfeeding is a dynamic process comprising regulation between the mother's and infant's interconnected physiological, psychological, and behavioural systems [1]. Optimal infant and young child feeding is crucial for health and development.

Women are recommended to breastfeed exclusively for 6 months and to continue breastfeeding until the child is 2 years. Breastfeeding is widely acknowledged as the best and safest form of infant feeding [2].

The global average caesarean delivery rate is 12.4% with an average annual rate of increase of 4.4%.The use of caesarean delivery has increased in the last few decades particularly in middle- and high-income countries [3]. According to a recent analysis of national health survey data, caesarean deliveries in India has gone up from 10% to 30 % raising the country's average caesarean section rates from 5% to 18%. An independent analysis of data from the National Family Health Survey (NFHS) (199293 to 2015-16) and Rapid Survey on Children 2013-14,India's caesarean-section rate was at 18 per cent which was higher than the

Lancet report's estimate of 10 per cent[4]. It is necessary to find whether the mode of delivery affect the breastfeeding outcomes.

The primary aim of the study was to examine the association between mode of delivery and subsequent breastfeeding outcomes – initiation of breastfeeding within one hour of birth, exclusive breastfeeding up to six months and duration of breastfeeding.

Materials and Methods

This study was conducted at PSG Institute of Medical Science and Research, Coimbatore in the month of July 2018. Ethical clearance was obtained from the institution prior to the study. Informed consent was obtained from all mothers interested in participating. Questions about mode of delivery and breastfeeding were collected using questionnaire. A total of 527 mothers were studied. Eligible mother include those who with the children age below four years attending paediatric outpatient department. Babies with congenital anomalies that interfere with breastfeeding were excluded from the study. Socio economic status was measured using Prasad classification. The classification is done based on the Consumer Price Index (CPI) value of 279 for Coimbatore [5]. Class 1 include people having per-capita income greater than or equal to Rs.6180. Class 2, class 3, class 4 include the people having range of pre-capita income Rs.3090-6179, Rs.1850-3089, Rs.930-1849 respectively and class 4 include people having per-capita income less than Rs.930.

WHO recommends that for those children less than six months of age, who fed only on mother's milk in the 24 hours preceding the survey were considered as exclusive breastfeeding.

Chi square test was done to assess the association between mode of delivery with socio-demographic variables, initiation of breastfeeding and exclusive breastfeeding. p value<0.05 was considered as statistically significant.

The effect of caesarean on duration of breastfeeding was obtained by using Kaplan-Meier method. The duration of termination of breastfeeding was the outcome event and those mothers who are continuing the breastfeeding during the survey were considered as censored. Total probability of termination of breastfeeding till that time interval was calculated by multiplying all the probabilities of termination of breastfeeding at all time intervals preceding that time. The log rank test was used to assess the equality of survival curves of vaginal and caesarean delivery. The data were analysed using SPSS[5].

Results

The sample included 527 mothers. 36.2% of mothers were delivered by caesarean and 63.8% of mothers gave birth by vaginal delivery.

Table 1 depicts the various socio-demographic and clinical variables according to mode of delivery. Increased number of antenatal visits (p<0.05) and term delivery (p<0.01) were negatively associated with caesarean delivery.

Table 2 describes the association of mode of delivery with timely initiation of breastfeeding, exclusive breastfeeding and duration of breastfeeding. Timely initiation of breastfeeding was lower among caesarean deliveries compared to vaginal deliveries and the difference was statistically significant (p<0.001).The prevalence of exclusive breastfeeding was 60.1% for vaginal delivery and 55.5% for caesarean. However the difference was not statistically significant (p=0.301).There was no difference between duration of breastfeeding and mode of delivery (p=0.851).

Table1: Distribution of socio-demographic variables by modes of delivery

Characteristics		**Vaginal delivery (%)**	**Caesarean (%)**	**p value**
Mother's age	15-24	76(22.6)	32(16.8)	0.190
	25-34	243(72.3)	145(75.9)	
	35-44	17(5.1)	14(7.3)

Duration of breastfeeding	Mean Duration (Months)	18.357	18.680	0.035 *	0.851

*chi-square mentioned as log rank chi-square.

Discussion

We found that 56.5% of mothers surveyed reported initiating breastfeeding within one hour of birth and 58.4% reported exclusive breastfeeding for 6 months. The median duration of breastfeeding was 18 months. We observed a negative association between breastfeeding initiation within one hour and caesarean delivery. This contradicts the findings of Sara N K et al 2017[6] and supports the findings of Prior et al 2012 [7] and Hira Palla et al 2017 [8].

Despite the well-known benefits of nourishing infants exclusively with mother's milk, the rates of breastfeeding initiation, continuation and exclusive breastfeeding are still lower in India. Mothers and infants experiences during labour and delivery may affect lactation and breastfeeding outcomes. In this study we observed that caesarean deliveries have been associated with lower initiation rates compared to undergoing vaginal delivery. This may be due to the delay in mother-infant skin to skin contact, mother's post-surgery physical complications and effects of anaesthesia.

Research evidences showed that delayed onset of lactation is significantly higher among women with caesarean delivery compared to those with vaginal delivery. In addition, early contact with between mothers and infants during the first few hours after birth is important for forming a mother-infant bond that can lead to breastfeeding successful outcomes. Apart from it, operative care routines for post caesarean delivery can delay mothers from holding their infants and disrupt bonding between mother and infant. The mothers who undergo caesarean delivery stay longer in

hospital than mothers who experience vaginal delivery. Therefore a negative impact of surgical procedure delays breastfeeding initiation and babies were used to give formula feed from hospital.We did not find any association between mode of delivery and exclusive breast feeding. This supports the findings of Sara N K et al 2017[6] and contradicts the findings of Emily prior et al [7]. We did not find any association between mode of delivery and duration of breastfeeding which contradict the finding of Perez-Escamilla et al [9] and Amy J. Hobbs [10]. It has been suggested in these studies that lower duration of breastfeeding rates on women with caesarean delivery might be associated with physiologic mechanism that affect lactogens. However, in our study we could not establish a statistically significant association between type of delivery and duration of breastfeeding. The limitation of our study include response bias that contribute inaccurate information due to retrospective reporting. Another limitation is that the region of study has a generally higher socio-economic status and it was hospital based study. Further studies should address the obstacles based on delivery mode and other factors such as medical problems, women's knowledge around breastfeeding benefits, latching, and lifestyle changes on initiation of breastfeeding, exclusive breast feeding and duration of breastfeeding. In addition to mode of delivery, other factors that may influence breastfeeding initiation includes challenges encountered during nursing, availability of support systems, recommendation and attitudes of family, peers and health care professionals. Furthermore, large scale prospective cohort studies can provide more light in this area.

Conclusion

The findings of our study indicates that caesarean deliveries have been associated with lower timely breastfeeding initiation rates compared to mothers undergoing vaginal delivery.

Acknowledgement

The authors are extremely thankful to Dr.S. Ramalingam, Dean, PSG Institute of Medical Sciences and Research for permitting us to do this study. The authors are also thankful to Dr. S L Ravishankar, Professor and HOD Community Medicine for his valuable comments and suggestions for improving the draft of this paper.

Abstract

Introduction:

End of life care of terminally ill is a sensitive topic in our socio cultural ethos. In a country where Euthanasia policies are widely debated, dignified death is a desired form of death. Euthanasia literally means “good death”. In India the debate still continues on practices related to euthanasia and its legalization until recently when the verdict on the passive euthanasia has been passed by the supreme court. In addition, lack of an effective palliative care system has led to complex situations towards the end of life. Globally, it is estimated that palliative care is needed in 40-60% of all deaths. However there is no training or facility to meet this demand.

Methodology:

A focus group discussion (FGD) was carried out among 22 residents in a rural area of Tamilnadu to identify the social and cultural determinants of end of life care practices. A FGD guide was prepared and after an informed consent the study was undertaken. An in depth interview was carried out among a sub group of participants.

Results:

The FGD and the IDI revealed several end of life practices in the rural areas such as Thalaikoothal, Feeding the ill with holy water and sand etc. The study also revealed the major determinants leading to such practices such as the social, and cultural beliefs in addition to economical and emotional factors.

Conclusion:

Several factors determine the end of life decisions in a family ranging from economical to social and cultural factors. While we are examining these factors, it is important to strengthen the palliative care provision in the country by building capacity and integrating it in primary care.

Keywords: End-of-life practices, euthanasia, palliative care

Introduction

End-of-life care of terminally ill is a sensitive topic in our sociocultural ethos. In a country where euthanasia policies are widely debated, dignified death is a desired form of death. Euthanasia literally means “good death.” It is also popularly known as “mercy death” as it is practised to lessen the pain of an individual and ensure a dignified death. In India, only recently a landmark verdict on the passive euthanasia has been passed by the Supreme Court.[1] In addition, lack of an effective palliative care system has led to complex situations toward the end of life. Globally, it is estimated that palliative care is needed in 40%–60% of all deaths.[2] Home-based palliative care models have been successfully implemented globally. The ultimate goal of these home-based care is to “promote, restore, and maintain a person's maximum level of comfort, function, and health, including care toward a dignified death”.[3] However, still it is an unmet need in the community leading to several practices intertwined with cultural and religious beliefs. These practices which are widespread do not come into the limelight for well-known reasons. Many individuals who are believed to be terminally ill are taken home to die a “peaceful” and “dignified” death surrounded by their loved ones. In addition, there are several social, religious, and cultural beliefs and factors embedded in this decision to take care of the terminally ill at home and end-of-life practices.[4] There are also traditional practices which are sparsely reported in several parts of the country which claim to liberate the elderly from a painful death and providing them relief, thereby making their death “dignified”.[4,5,6,7] Such practices have become firmly entrenched as social customs and may not be considered as euthanasia by the concerned people. However, there is a dearth in the literature which documents these practices and the several determinants which lead to these practices in rural Tamil Nadu. This study explores the several end-of-life care practices and the social, cultural, and religious dimensions associated with those practices in rural Tamil Nadu.

Methodology

The study was conducted in rural areas as defined by the Government of India in and around Coimbatore.[8] Two focus group discussions (FGDs) and four in-depth interviews (IDIs) were conducted. Ethical approval was obtained from the Institution Human Ethics Committee, and written informed consent was obtained from the study participants who are permanent residents of the area and aged >40 years and had experience in taking care of any elderly or terminally ill individuals in their household. They were selected by convenience sampling. The field guide was prepared before the FGD. The FGDs were led by a moderator and an observer for taking notes and observation. All FGDs were recorded with the participant's permission and transcribed.

Based on the FGD findings, IDIs were conducted among four women who were involved in end of life practices for people who are terminally ill.

Data collection and analysis

The FGDs and IDIs were conducted using a field guide to facilitate probing and sharing of the relevant information. Interviews, which lasted between 45 and 55 min, were audio recorded with participant's permission. The field guide included the following prompts to elicit participant views and experiences: (i) reasons for home care of the terminally ill (ii) the end-of-life rituals or practices (ii) reasons behind such rituals (their beliefs and customs) (iii) how do they feel about these practices, and (iv) what are their perceptions on dignified death. Using an framework approach, the data were managed, described, and explored. The interview transcripts were indexed and mapped on the basis of recurring themes. The transcripts were reviewed by both the authors, and a consensus was reached regarding the themes.

Results

The study revealed the various end-of-life practices in the rural area when a person is terminally ill and the common social, religious, and cultural beliefs associated with such practices. The FGD also brought out several practices and rituals that were prevalent in a community to end the life of an individual who is terminally ill to bring about a peaceful death and alleviate their suffering. Similar rituals are reported sporadically elsewhere.[5,6,9,10]

The rituals that are practised are as follows:

a. Oil bathing otherwise called as "*Thalaikoothal*" means giving a shower on the head in the regional language in which the terminally ill person is given an oil bath using gingelly oil and cold water several times in a week

b. Feeding with holy water or milk: Feeding water or milk to the bedridden, semi or unconscious person with an intention to end the suffering. Tender coconut water, "*Theertham*" – holy water, from different temples and Kasi temple and the holy water used for bathing the deity in a temple are all used for such rituals

c. Practices to address the attachment toward materialistic things: Water with soil or mud from the land owned by the terminally ill person is used with the notion that the terminally ill person is attached to his/her materialistic possession. This water mixed with the mud is fed to the ailing individual several times until the death occurs.

All these rituals hasten death by causing hypothermia, renal failure, and aspiration pneumonia, etc.

Transcription of the recordings revealed various reasons behind practising such rituals which fell under the following major themes [Figure 1]. (i) Socioeconomical, (ii) cultural, (iii) moral, and (iv) spiritual.

Figure 1

Major themes evolved during focus group discussion

Socioeconomical reasons

Most of them cited the huge costs involved in the hospitalization of terminally ill. Since death is almost inevitable they felt there is no reason to keep them in the hospital and pay huge bills.

"*I do not have enough money and facilities to take care of her, and she developed bed sores*."

"*Doctor said that she has to undergo treatment that will be expensive and cannot guarantee her good quality of life*"

Some also said that the hospitals do not accommodate very terminally ill patients for whom treatment options are limited.

"*The hospital asked us to take him home; they said they can't keep him in hospital*"

Some also expressed that it affected their social life they could not go anywhere for any social gatherings or attend other personal work since they always had to attend to the sick person. They could not be left alone, and there was no one else to take care of them.

"*I cannot go out leaving her and was not able to attend to my personal needs and work*"

Thus, socioeconomic condition, especially in the rural area came out as one of the major factor influencing the care of the elderly in their last stages of life resorting to rituals to end the life soon.

Customs and culture

Most participants believed in traditional customs and practices. They believed that the end-of-life practices/rituals as a custom done during the last stage of life to assure their loved ones a peaceful death.

"*Thalaikoothal is a tradition done to an elderly person in their last stages of life*"

The participant also said that it was a tradition done for old people who are bedridden for a long time. There were different customs followed to expedite and ensure a peaceful and dignified death to the person.

Customs such as giving milk and holy water are done, and it is believed that all family members and grandchildren of the ill have to perform that tradition to ensure peaceful death. It is also believed only when all the loved ones do so the deceased soul will be satisfied.

"*Milk and holy water should be given by all members of the family and close kin of the diseased, including grandchildren*"

The discussion also brought out that these traditions are carried out by the family members themselves or based on the suggestions of relatives and neighbors.

"*My relatives and neighbors said that by giving water mixed with mud from my land will give my mother peaceful death as she may be thinking about our l*and"

Moral duties

The study participants often cited about their moral duties toward parents and elders.

The discussion showed that people perceived these practices as moral duties toward their parents and elders and by doing such practices they help them attain peaceful death.

Spiritual

Some of the practices such as holy water and using water that is being used for bathing the idol of God are believed to help the dying person attain God. They also believe when all the members of the household give that holy water and pray the terminally ill person is relieved from suffering and will join their deceased ancestors after death.

"*When holy water is given God will call them to heaven*"

"*Kasi theertham (holy water) is kept at homes of the elderly to be given at the last stages of life*"

To reach God and to reach heaven after death were the most commonly cited reasons for giving holy water. These reasons are widely believed in the rural community (from both Hindu and Christian faiths).

Discussion

The article has explored the views and perception behind end-of-life practices and rituals. The study has highlighted various determinants and beliefs such as the socioeconomic, cultural, spiritual, and moral views behind the practices leading to the death of an individual who is terminally ill. In addition to end of life practices when a person is nearing death (e.g., feeding them holy water etc,) some practices are deliberately followed to hasten death to minimize further suffering and ensure a peaceful exit. It is important to know and understand such practices and the context behind them, to educate and design interventions to prevent those which cause deliberate death such as Thalaikoothal. Exploration of the various themes emerged shows that apart from the socioeconomic causes, customs, and cultural reasons among the closed communities encourage such practices. Moreover, the moral obligation of the son or daughter of a family to ensure that their parents or the elderly die a peaceful and dignified death is very evidently a strong-rooted belief. Therefore, they resort to such practices/rituals to alleviate the suffering of their dear ones. The discussion also brought out the community's perception that only good death can help people reach God. This was very evident when people who execute these rituals in the community said that they felt content in helping those who are suffering reach God. On another dimension, this study also undermines the need for an effective palliative care approach during the end of life. A community-based palliative care approach involving the multidisciplinary health team or the neighborhood network in palliative care model adopted in Kerala which is a community owned and driven by volunteers can be considered.[11]

Conclusion

The study has brought out the various end-of-life practices that are followed in rural areas to hasten death of their dear ones who are terminally ill. It also highlights the perception behind such practices. These insights can be targeted on giving awareness to the people and bring about changes in rural society. However, strong are these practices intertwined in our society under the cover of "dignified death," it has to be considered as an act of euthanasia and the sufferings of the elderly cannot be neglected. Hence, such practices have to be curtailed by bringing about awareness and penalizing such acts. Effective elderly care and whenever facilities are available, the Government should consider offering home-based care for the elderly. It should be incorporated into the primary health-care system.

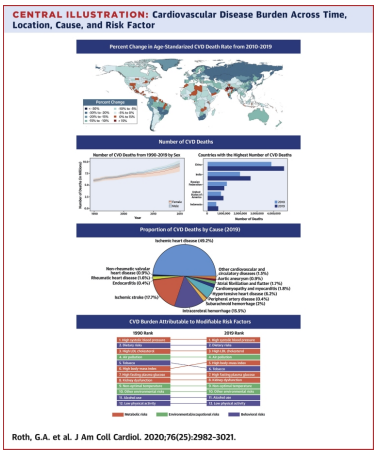
Abstract

Cardiovascular diseases (CVDs), principally ischemic heart disease (IHD) and stroke, are the leading cause of global mortality and a major contributor to disability. This paper reviews the magnitude of total CVD burden, including 13 underlying causes of cardiovascular death and 9 related risk factors, using estimates from the Global Burden of Disease (GBD) Study 2019. GBD, an ongoing multinational collaboration to provide comparable and consistent estimates of population health over time, used all available population-level data sources on incidence, prevalence, case fatality, mortality, and health risks to produce estimates for 204 countries and territories from 1990 to 2019.

Prevalent cases of total CVD nearly doubled from 271 million (95% uncertainty interval [UI]: 257 to 285 million) in 1990 to 523 million (95% UI: 497 to 550 million) in 2019, and the number of CVD deaths steadily increased from 12.1 million (95% UI:11.4 to 12.6 million) in 1990, reaching 18.6 million (95% UI: 17.1 to 19.7 million) in 2019. The global trends for disability-adjusted life years (DALYs) and years of life lost also increased significantly, and years lived with disability doubled from 17.7 million (95% UI: 12.9 to 22.5 million) to 34.4 million (95% UI:24.9 to 43.6 million) over that period. The total number of DALYs due to IHD has risen steadily since 1990, reaching 182 million (95% UI: 170 to 194 million) DALYs, 9.14 million (95% UI: 8.40 to 9.74 million) deaths in the year 2019, and 197 million (95% UI: 178 to 220 million) prevalent cases of IHD in 2019. The total number of DALYs due to stroke has risen steadily since 1990, reaching 143 million (95% UI: 133 to 153 million) DALYs, 6.55 million (95% UI: 6.00 to 7.02 million) deaths in the year 2019, and 101 million (95% UI: 93.2 to 111 million) prevalent cases of stroke in 2019.



Cardiovascular diseases remain the leading cause of disease burden in the world. CVD burden continues its decades-long rise for almost all countries outside high-income countries, and alarmingly, the age-standardized rate of CVD has begun to rise in some locations where it was previously declining in high-income countries. There is an urgent need to focus on implementing existing cost-effective policies and interventions if the world is to meet the targets for Sustainable Development Goal 3 and achieve a 30% reduction in premature mortality due to noncommunicable diseases.

Key Words: cardiovascular diseases, global health, health policy, population health

Abbreviations and Acronyms: AC, alcoholic cardiomyopathy; AF, atrial fibrillation; AFL, atrial flutter; BMI, body mass index; CAVD, calcific aortic valve disease; CHA, congenital heart anomalies; CKD, chronic kidney disease; CVD, cardiovascular disease; DALYs, disability-adjusted life years; GBD, Global Burden of Diseases, Injuries, and Risk Factors Study; HAP, household air pollution; HHD, hypertensive heart disease; HICs, high-income countries; ICD, International Classification of Diseases; IHD, ischemic heart disease; IKF, impaired kidney function; IS, ischemic stroke; LDL, low-density lipoprotein; LMICs, low- and middle-income countries; LPA, low physical activity; MV, mitral

valve; PAD, peripheral artery disease; PM, particulate matter; RHD, rheumatic heart disease; SBP, systolic blood pressure; SDI, sociodemographic index; TMREL, theoretical minimum risk exposure level; UI, uncertainty interval; YLDs, years lived with disability; YLLs, years of life lost

Central Illustration

Cardiovascular disease (CVD) remains a major cause of premature mortality and rising health care costs (1,2). Cardiometabolic, behavioral, environmental, and social risk factors are major drivers of CVD. Consistent, comparable, and systematic analysis of long-term trends and patterns in global CVD are essential to guide public policy and provide benchmarks for decision makers. Beginning with ischemic heart disease (IHD) and stroke, this article provides information on the burden of CVD, including 13 underlying causes of cardiovascular death and 9 related risk factors at the global, regional, and national levels (Supplemental Figure 1).

This paper explores CVD trends from 1990 to 2019 and examines the extent to which population growth and aging explain the observed trends, sex differences, and regional patterns and how the epidemiology of the disease itself is changing. These trends show us where in the world CVD mortality and burden are increasing or declining and where progress has stalled (3). For each of the contributing causes of cardiovascular death and risk factors examined, we identify which regions and countries have the highest and lowest estimates of prevalent cases and number of deaths, as well as summary measures including number of years of life lost (YLLs), number of years lived with disability (YLDs), and the magnitude and temporal trends in disability-adjusted life years (DALYs) (1). For each section, the article also addresses how the summary measures of health and disease discussed inform investments in cardiovascular research, their implications for clinical and public health practice, and implications for health system development and national and regional policy.

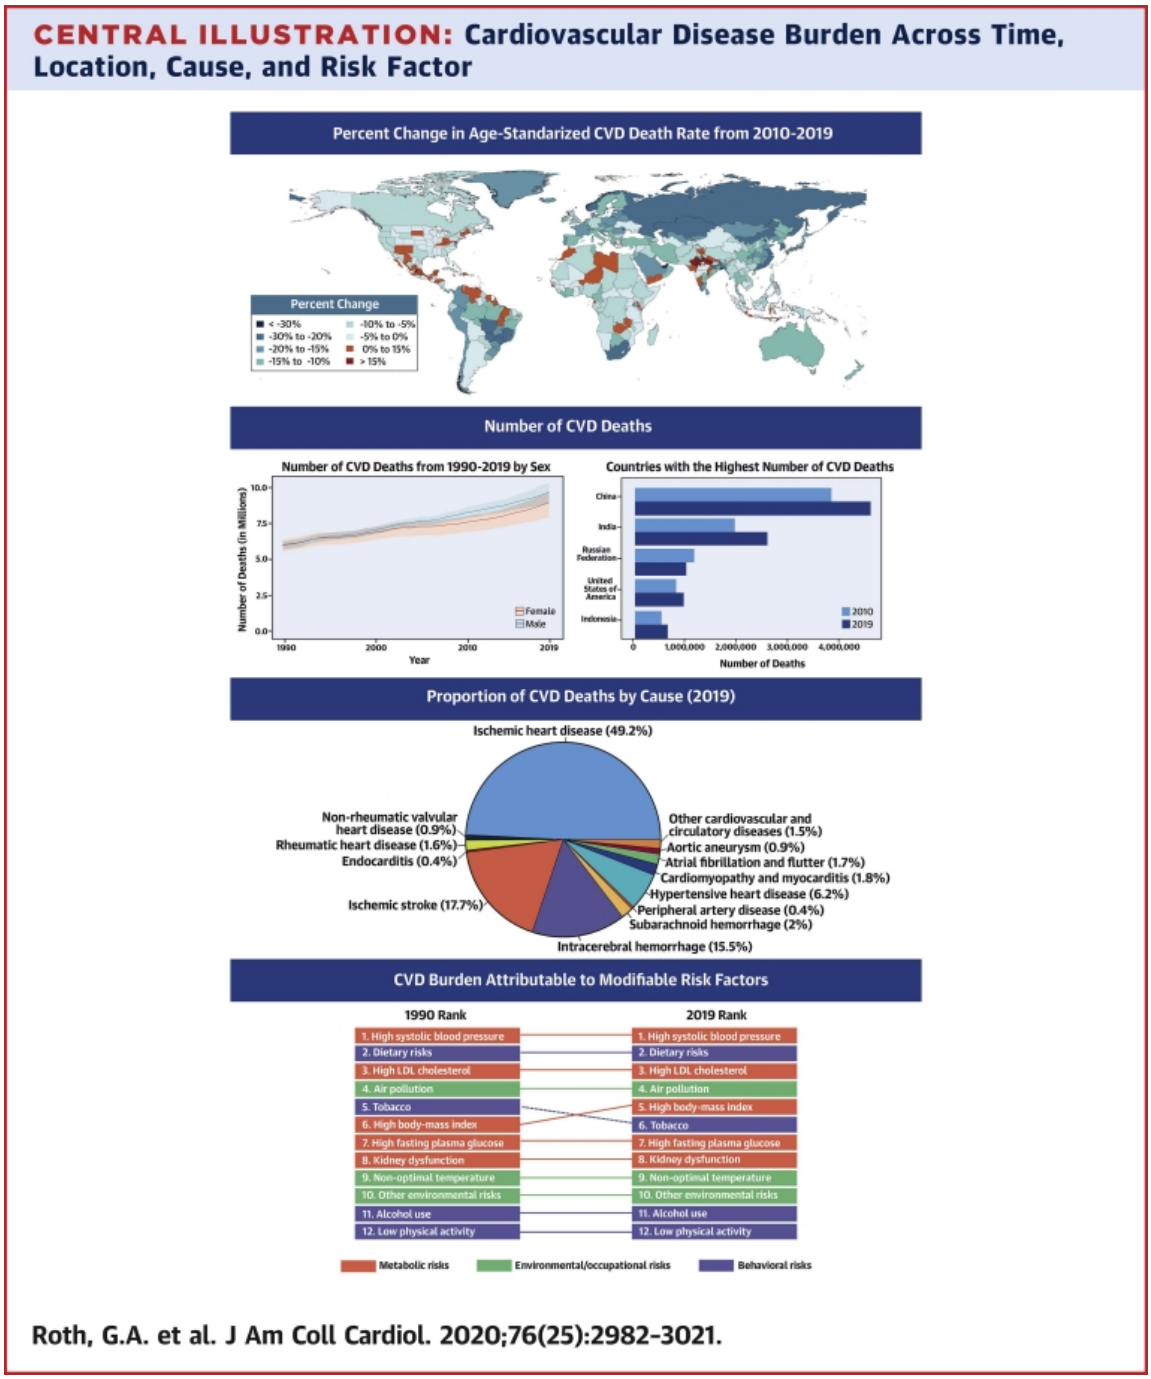
To improve accessibility across a wide range of audiences, we have structured the review such that each section can be read independently for those most interested in a subset of causes or risks. Discussion pertinent to each topic is included within every section. This article is a collaborative effort involving the *Journal of the American College of Cardiology*, the National Heart, Lung, and Blood Institute, and the Institute for Health Metrics and Evaluation at the University of Washington designed to provide crucial population-level information that can guide action for CVD and risk factor prevention, treatment, and control (2).

Global Burden of Disease Study Methods

GBD 2019 is a multinational collaborative research study that estimates disease burden for every country in the world (1,4). The study is an ongoing effort, updated annually, and is designed to allow for consistent comparison over time from 1990 to 2019, by age and sex, and across locations. The study produces standard epidemiological measures such as incidence, prevalence, and death rates as well as summary measures of health, such as DALYs. DALYs represent the sum of years of life lost prematurely and years lived with disability; can be estimated from life tables, estimates of prevalence, and disability weights; and may be expressed as counts or rates. Annual updates to the study include new diseases, new data sources, and updates to methods. All results are available via the GBD Compare website (5), and all input data is identified via the Global Health Data Exchange website (6). The study is performed in compliance with Guidelines for Accurate and Transparent Health Estimates Reporting (GATHER) guidelines for reporting health estimates (1). Detailed methods of GBD 2019 are reported in the Supplemental Appendix and summarized here.

Each CVD cause and related health states were identified with standard case definitions. IHD represented acute myocardial infarction, chronic stable angina, chronic IHD, and heart failure due to IHD. Myocardial infarction was defined according to the Fourth Universal Definition of Myocardial Infarction and was adjusted to include out-of-hospital sudden cardiac death. Stable angina was defined according to the Rose Angina Questionnaire. Stroke was defined according to the World Health Organization definition and was estimated separately for 3 subcategories: 1) ischemic stroke (IS); 2) intracerebral hemorrhage; and 3) subarachnoid hemorrhage (7). Lower extremity peripheral artery disease (PAD) was defined by an ankle brachial index of <0.9. Symptomatic PAD was defined as self-report of symptoms of claudication among those with an ankle brachial index of <0.9. Atrial fibrillation (AF) and atrial flutter (AFL) were defined by electrocardiogram. Hypertensive heart disease (HHD) was defined as symptomatic heart failure due to the direct and long-term effects of hypertension. Cardiomyopathy was defined as symptomatic heart failure due to primary myocardial disease or toxin exposure to the myocardium, such as alcohol. Acute myocarditis was defined as an acute and time-limited condition due to myocardial inflammation using health system administrative data. Endocarditis and rheumatic heart disease (RHD) were defined by their clinical diagnosis. Estimates of RHD include cases identified by clinical history and physical examination, including auscultation or standard echocardiographic criteria for definite disease.

Mortality was estimated by using vital registration data coded to the International Classification of Disease (ICD) system or household mortality surveys known as verbal autopsy. Statistical methods were used to increase the comparability of mortality data sources, including the reclassification of codes that are nonspecific or unspecified, noise reduction algorithms, and Bayesian geospatial regression software (CODem, the cause of death ensemble model, Institute for Health Metrics and Evaluation, Seattle, Washington) that used location-specific covariates to create smoothed time trends for 204 countries and territories by borrowing strength over age, space, and time. GBD 2019 allowed for the production of estimates with uncertainty intervals (UIs) for all locations in every year, even when data were sparse or missing. Disease incidence and prevalence were produced by using a broad range of population-representative data sources identified by literature review and via study collaborations, including scientific reports of cohorts and registries, population surveys, microdata from registry and cohort studies, and health system administrative data. Consistent disease estimates were produced by using epidemiologic state-transition disease modeling software, DisMod-MR (Institute for Health Metrics and Evaluation), and Bayesian meta-regression software, MR-BRT (Institute for Health Metrics and Evaluation), that adjusted for study-level differences in measurement



methods and case definitions. Risk factor exposures were estimated by using population-representative survey and surveillance data and geospatial Gaussian process regression models that borrowed strength across time and geography.

DALYs were calculated as the sum of YLLs, based on a reference maximum observed life expectancy, and YLDs based on standardized disability weights for each health state. Population-attributable fractions were calculated independently by risk factor by using risk exposures, estimates of relative risk based on meta-analyses, and theoretical minimum risk levels determined for each risk-outcome pair. Adjustment was made for comorbidity by simulating 40,000 individuals in each age-sex-country-year exposed to the independent probability of acquiring conditions based on their prevalence. The 95% UIs reported for each estimate used 1,000 draws from the posterior distribution of models, reported as the 2.5th and 97.5th values of the distribution. Age standardization was performed via the direct method, applying a global age structure from the year 2019. The University of Washington Institutional Review Board Committee approved the Global Burden of Diseases, Injuries, and Risk Factors Study (STUDY00009060).

Cardiovascular Diseases

Total CVDs

CVDs are common, have poor survival, and are increasing worldwide (Central Illustration). Prevalent cases of total CVD nearly doubled from 271 million (95% UI: 257 to 285 million) in 1990 to 523 million (95% UI: 497 to 550 million) in 2019, and the number of CVD deaths steadily increased from 12.1 million (95% UI: 11.4 to 12.6 million) in 1990, reaching 18.6 million (95% UI: 17.1 to 19.7 million) in 2019 (Figure 1A). The global trends for DALYs and YLLs also increased significantly, and YLDs doubled from 17.7 million (95% UI: 12.9 to 22.5 million) to 34.4 million (95% UI: 24.9 to 43.6 million) over that period.

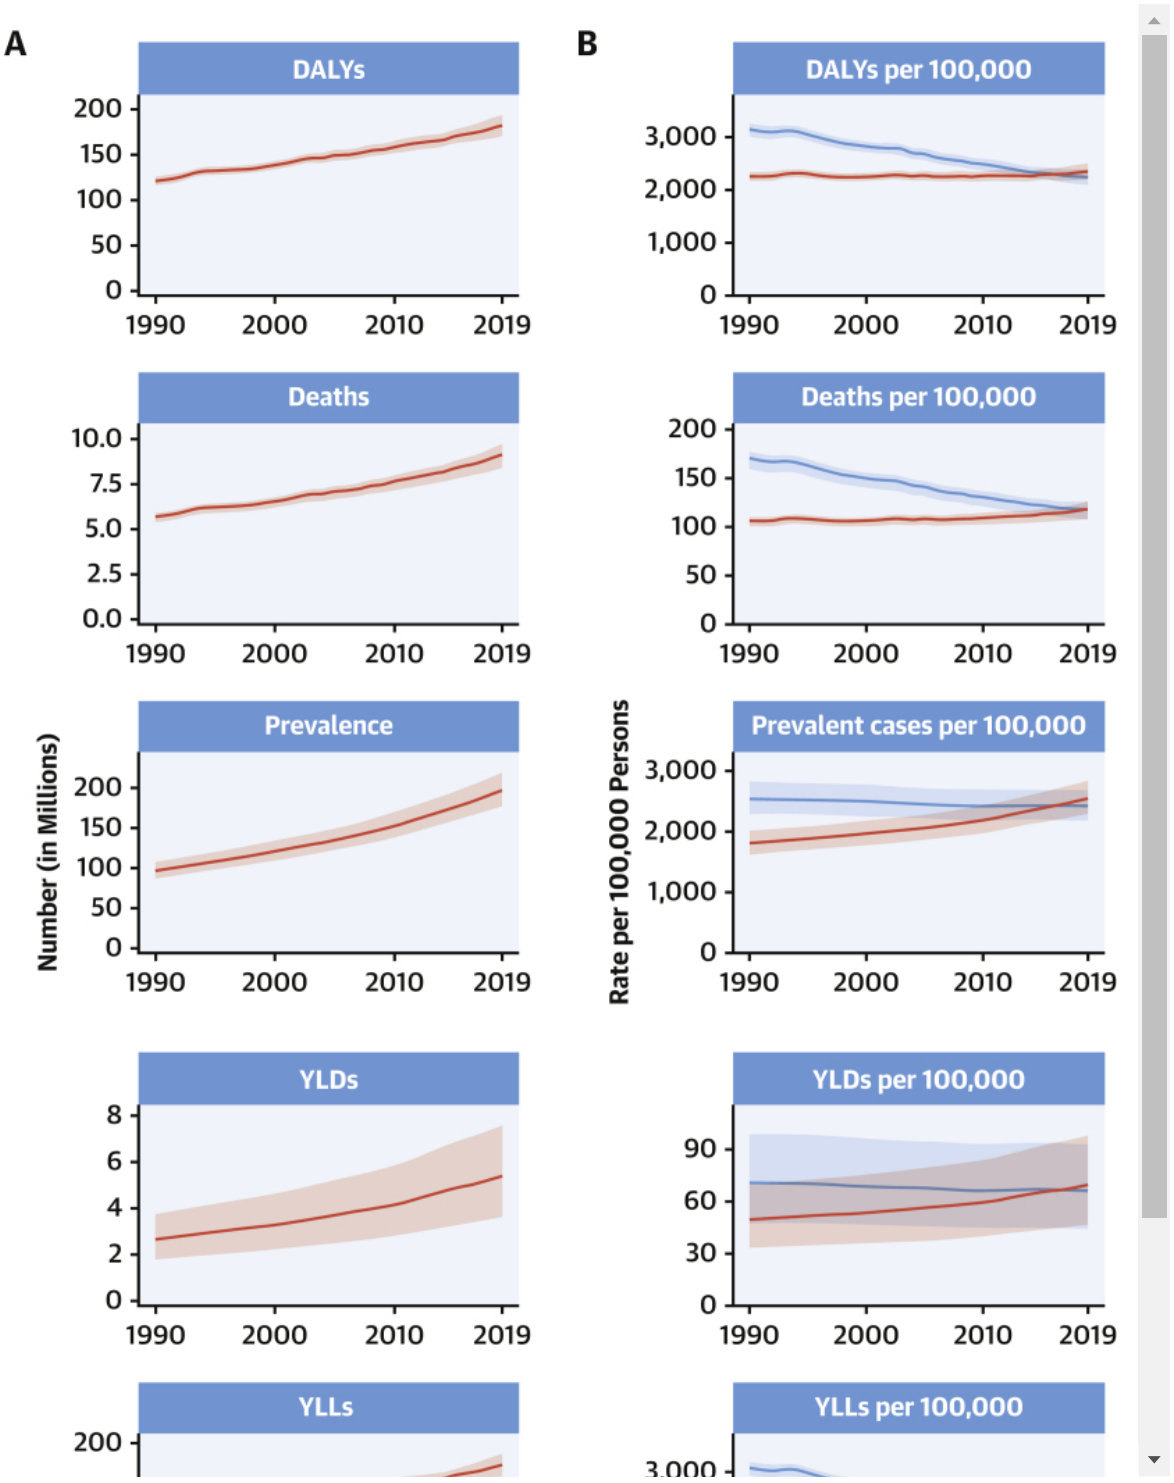
Figure 1

Total Numbers and Rates of Cardiovascular Diseases

(A) Total number of DALYs, deaths, prevalent cases, YLDs, and YLLs due to cardiovascular diseases, 1990 to 2019. **Shaded region**s represent 95% uncertainty intervals. **(B)** Age-standardized and all-ages DALY, death, prevalence, YLD, and YLL rates of cardiovascular diseases, 1990 to 2019. **Shaded regions** represent 95% uncertainty intervals. DALYs = disability-adjusted life years; YLDs = years lived with disability; YLLs = years of life lost.

At the country level, age-standardized mortality rates for total CVD were highest in Uzbekistan, Solomon Islands, and Tajikistan and were lowest in France, Peru, and Japan, where rates were 6-fold lower in 2019. From 1990 to 2019, large declines in the age-standardized rates of death, DALYs, and YLLs, together with small gradual reductions in age-standardized rates for prevalent cases and YLDs, suggest that population growth and aging are major drivers of the increase in total CVD (Figure 1B).



In 2019, total CVD DALYs were higher in men than women before age 80 to 84 years (Supplemental Figure 2). After this age, the pattern reverses. The sex differences in DALYs is most striking between ages 30 and 60 years (men greater) and age >80 years (women greater). The excess CVD deaths in women beginning at ages 80 to 84 years should focus attention to cause-specific mortality at older ages and have implications for secondary prevention strategies.

Among women, the age-standardized rates for DALYs were highest in Central Asia, Oceania, North Africa and the Middle East, and Eastern Europe; and lowest in High-Income Asia Pacific, Australasia, and Western Europe (Supplemental Figure 3). Among men, age-standardized rates for DALYs were highest in Central Asia, Eastern Europe, and Oceania; and lowest in High-Income Asia Pacific, Australasia, Western Europe, and Andean Latin America. At the country level, the highest age-standardized rates were estimated for many of the islands of Oceania, Uzbekistan, and Afghanistan, while the lowest rates for DALYs were seen in Japan, France, and Israel (Supplemental Figure 4). These regional and national differences in total CVD burden and mortality reflect differences in prevalence of CVD risk factors as well as access to health care (8). Differences in access to effective primary and secondary prevention strategies may also play a role in differences in total CVD burden, especially in low- and middle-income countries (LMICs) (9).

Global patterns of total CVD have significant implications for clinical practice and public health policy development (10). Prevalent cases of total CVD are likely to increase substantially as a result of population growth and aging, especially in Northern Africa and Western Asia, Central and Southern Asia, Latin America and the Caribbean, and Eastern and Southeastern Asia, where the share of older persons is projected to double between 2019 and 2050 (11,12). Increased attention to promoting ideal cardiovascular health and healthy aging across the lifespan is necessary (13). Equally importantly, the time has come to implement feasible and affordable strategies for the prevention and control of CVD and to monitor results (14).

Ischemic heart disease

The total number of DALYs due to IHD has risen steadily since 1990, reaching 182 million (95% UI: 170 to 194 million) DALYs and 9.14 million (95% UI: 8.40 to 9.74 million) deaths in the year 2019 (Figure 2A). GBD 2019 estimated 197 million (95% UI: 178 to 220 million) prevalent cases of IHD in 2019.

Open in a separate window

Figure 2

Total Numbers and Rates of Ischemic Heart Disease

(A) Total number of DALYs, deaths, prevalent cases, YLDs, and YLLs due to ischemic heart disease, 1990 to 2019. **Shaded regions** represent 95% uncertainty intervals. **(B)** Age-standardized and all-ages DALY, death, prevalence, YLD, and YLL rates of ischemic heart disease, 1990 to 2019**. Shaded regions** represent 95% uncertainty intervals. Abbreviations as in Figure 1.

Global age-standardized rates for DALYs, deaths, and prevalent cases declined over this time period, indicating that, on average, global increases in IHD have been due to population growth and aging, although even the age-standardized death rate is estimated to be increasing in many locations across South, East, and Southeastern Asia, including China (Figure 2B). Increasing absolute numbers of incident and prevalent IHD cases in most countries mean that national health systems will need to address increasing demand for IHD-related preventive and therapeutic services as these trends continue.

At the global level, substantially more total DALYs due to IHD were experienced by men than women. IHD DALYs rose rapidly for men beginning at age 30 years (Supplemental Figure 5). Men ages 45 to 49 years had almost as many DALYs due to IHD as women ages 65 to 69 years.

Age-standardized DALY rates due to IHD were highest in Eastern Europe, Central Asia, Oceania, and the Middle East/North Africa regions (Supplemental Figure 6). At the country level, extremely high rates were estimated for Uzbekistan, Ukraine, Tajikistan, and many of the islands of Oceania, with the lowest levels in Japan, Republic of Korea, and France (Supplemental Figure 7). Higher exposure to risks including tobacco and excessive alcohol use and restricted access to preventive health care may partly explain these patterns.

IHD remains a major threat to public health, and overall burden is increasing globally. In some locations over the past 5 years, including parts of the United States and United Kingdom, age-standardized IHD death rates are increasing, suggesting that long-term declines in IHD due to improved prevention and health care are no longer occurring in these locations. Health systems and countries need to focus on delivering effective interventions that will reverse these trends, including those that prevent and control diabetes, decrease obesity and high cholesterol, improve diet and physical activity, reduce tobacco and excessive alcohol use, integrate “polypills” for elevated blood pressure and related conditions, improve pre- and in-hospital care for acute coronary syndrome, and improve survival and quality of life for those living with the long-term sequelae of IHD, including heart failure. Social and economic factors remain fundamental drivers of IHD, suggesting that multisectoral interventions are needed to eradicate this disease (15).

Stroke

The total number of prevalent strokes, deaths, and DALYs due to stroke increased steadily from 1990, reaching 101 million (95% UI: 93.2 to 111 million) prevalent (85.3% [95% UI: 82.6% to 88.2%] increase) stroke survivors, 6.55 million (95% UI: 6.00 to 7.02 million) deaths from stroke (43.3% [95% UI: 31.0% to 55.4%] increase), and 143 million (95% UI: 133 to 153 million) DALYs due to stroke (32.4% [95% UI: 22.0% to 42.2%] increase) in 2019, with the bulk of the burden outside of the high-income world (Supplemental Figures 8A and 9A). Of 12.2 million (95% UI: 11.0 to 13.6 million) incident stroke cases, 7.63 million (95% UI: 6.57 to 8.96 million) (62.4%) were IS, 3.41 million (95% UI: 2.97 to 3.91 million) (27.9%) were intracerebral hemorrhages, and 1.18 million (95% UI: 1.01 to 1.39 million) (9.7%) were subarachnoid hemorrhages (Supplemental Figures 10A, 11A, and 12A).

Globally, age-standardized rates for deaths and DALYs due to stroke substantially declined over the same period of time (Supplemental Figures 8B, 10B, 11B, and 12B), suggesting that: 1) preventive measures are very effective at lowering risk of both ischemic and hemorrhagic stroke; and 2) on average, global increases in stroke burden have been largely due to population growth and aging.

Importantly, age-standardized rates for prevalence of stroke survivors have increased since 1990 in several locations including in China, Indonesia, and parts of the United States. Age-standardized death rates also increased in some locations, including Indonesia and the Philippines.

Age-standardized rates of DALYs and deaths due to stroke were substantially greater in men compared to women, but prevalence was greater in women, suggesting the possibility of greater risk of death and disability in men but better stroke survival in women. Similar patterns were observed in men and women with IS, intracerebral hemorrhage, and subarachnoid hemorrhage.

There is tremendous regional disparity in the burden of stroke. Age-standardized rates of deaths and DALYs due to stroke were highest in Oceania, Central Asia, East Asia, Southeast Asia, Eastern Europe, and sub-Saharan Africa (Supplemental Figure 13), and prevalence of stroke survivors was highest in Oceania, Southeast Asia, East Asia, and the Middle East/North Africa regions (Figure 3). These data suggest that applying preventive strategies, such as treatment of elevated blood pressure and cholesterol levels, can have major health benefits where stroke burden remains high, especially in those regions that did not show substantial decline over the past decades (i.e., Central Asia, Southern sub-Saharan Africa).

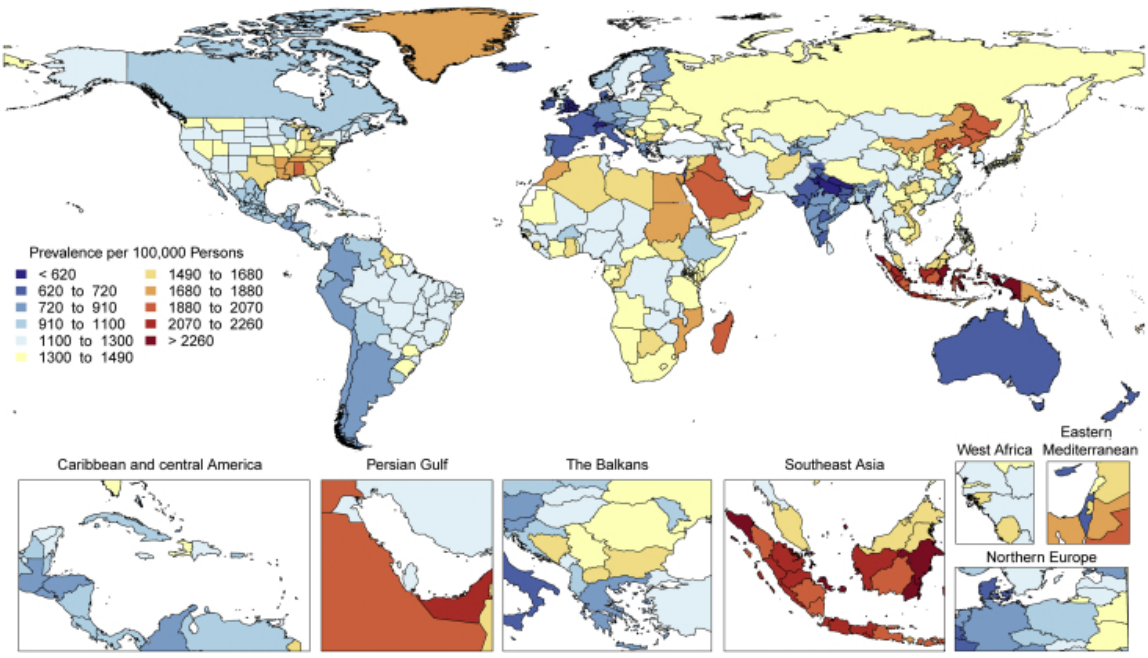


Figure 3

Map of Age-Standardized Prevalence of Stroke Survivors in 2019

Stroke remains the second-leading cause of death, and stroke burden in terms of DALYs is increasing. Primary stroke prevention strategies are not sufficiently effective as currently implemented in many countries. Large (15- to 20-fold) geographic variations in age-standardized stroke DALYs and mortality rates and moderate (4-fold) geographic variations in age-standardized prevalence may be related to the variations in stroke risk factors or the quality of and/or access to preventative care, acute stroke care, and stroke rehabilitation across the globe. Global and national health systems need to focus on new

approaches for delivering stroke prevention that can reverse these trends, including strategies to provide equal access to quality health care and prevention across all populations, and proven effective interventions that reduce mortality and improve outcomes post-stroke.

Hypertensive heart disease

The global prevalence of HHD has risen steadily over the last 3 decades, as have the total number of deaths, DALYs, YLLs, and YLDs due to this disease. In 2019, HHD was the main cause of 1.16 million (95% UI: 0.86 to 1.28 million) deaths and 21.5 million (95% UI: 16.4 to 23.9 million) DALYs annually, with a global prevalence of 18.6 million (95% UI: 13.5 to 24.9 million) cases (Supplemental Figure 14A).

The age-standardized prevalence and YLDs of HHD per 100,000 persons have been constant over time, and corresponding age-standardized rates of deaths, DALYs, and YLLs declined steadily until the mid-2000s and have leveled off since then (Supplemental Figure 14B). The trends for the absolute and age-standardized estimates closely resemble those for high blood pressure. Taken together, the increasing global prevalence and rates of HHD can be explained by population growth and aging, but the declining age-standardized rates of adverse outcomes are similar to those for IHD and stroke and are likely an effect of improved secondary prevention.

The age distributions of DALYs due to HHD are very similar in women and men until age 70 years (Supplemental Figure 15). This contrasts to the age distributions for high blood pressure, in which men are overrepresented at younger ages. The similarities by sex in DALYs calls for an equal attention to the clinical prevention and treatment of HHD in women and men.

The highest age-standardized rates of DALYs due to HHD are noted in Africa (Figure 4). DALYs due to HHD are particularly higher in Central sub-Saharan Africa, followed by most of Africa except Western sub-Saharan Africa, and Oceania. A similar geographic pattern exists for high blood pressure (with the exception of high rates of DALYs in men from high blood pressure in Central Asia and Eastern Europe). An overrepresentation of DALYs due to HHD in women can be noted in Central and Eastern sub-Saharan Africa (Supplemental Figure 16). The significance of this is uncertain because no such peaks are noted for high blood pressure or other contributing factors, and it can represent regional differences in disease coding, including that of peripartum cardiomyopathy. Inequalities in access to both primary and secondary prevention are a potential cause of these regional and sex differences.

Open in a separate window

Figure 4

Map of Age-Standardized DALYs Due to Hypertensive Heart Disease in 2019

DALYs = disability-adjusted life years.

The global prevalence of HHD and absolute rates of adverse outcomes are expected to continue to rise due to population growth and aging. The age-standardized rates of adverse outcomes due to HHD are no longer decreasing, and with continuing global increases in obesity and diabetes, corresponding increases in left ventricular hypertrophy and other aspects of HHD are likely. Intensified global and

regional efforts to lower blood pressure and control other risk factors are needed, for example with population-wide reductions in dietary sodium intake. Continued surveillance of inequalities in adverse outcomes due to high blood pressure are necessary to inform such efforts.

Congenital heart anomalies

A total of 3.12 million (95% UI: 2.40 to 4.11 million) babies were born with congenital heart anomalies (CHA) in 2019, representing 2,305.2 per 100,000 live births (95% UI: 1,772.9 to 3,039.2 per 100,000 live births), a total of 13.3 million (95% UI: 11.5 to 15.4 million) people were living with CHA, and CHA was the underlying cause of 217,000 deaths (95% UI: 177,000 to 262,000 deaths), of which 150,000 deaths (95% UI: 120,000 to 184,000 deaths) were in infants <1 year (Figure 5A). The all-ages rates of DALYs, YLLs, and YLDs for CHA in 2019 were 241.6 per 100,000 (95% UI: 196.1 to 292.7 per 100,000), 234.0 per 100,000 (95% UI: 189.8 to 285.7 per 100,000), and 7.6 per 100,000 (95% UI: 3.7 to 12.7 per 100,000), respectively (Figure 5B).

Open in a separate window

Figure 5

Total Numbers and Rates of Congenital Heart Anomalies

(A) Total number and number among children younger than 1 year of DALYs, deaths, prevalent cases, YLDs, and YLLs due to congenital heart anomalies, 1990 to 2019. **Shaded regions** represent 95% uncertainty intervals. **(B)** Age-standardized and all-ages DALY, death, prevalence, YLD, and YLL rates of congenital heart anomalies, 1990 to 2019. **Shaded regions** represent 95% uncertainty intervals. Abbreviations as in Figure 1.

Between 1990 and 2019, the global CHA birth rate was largely unchanged, but the all-ages death rate due to CHA declined 60.4% (95% UI: –71.9% to –41.4%) from 7.1 per 100,000 (95% UI: 5.0 to 10.5 per 100,000) in 1990 to 2.8 per 100,000 (95% UI: 2.3 to 3.4 per 100,000) in 2019. Age-standardized prevalence, death, and DALY rates remain lower than all-ages rates in low-income countries because of younger populations, higher birth rates of CHA, and much less access to the intervention that is needed to allow for the survival of children born with CHA.

The proportion of all infant deaths caused by CHA increased in all quintiles of the sociodemographic index (SDI) since 1990 except the highest because improvement in CHA mortality has lagged behind that of other causes, most notably infectious, respiratory, and diarrheal diseases (16). In low-SDI regions, CHA death rates have declined by 42.1% (95% UI: –61.9% to 12.1%) since 1990, compared with declines of 71.3% (95% UI: –74.7% to –64.6%) in high-SDI subgroups. Unlike other CVDs, prevention has limited ability to reduce the burden of CHA after birth; improvements in early diagnosis and access to cardiac surgery are the only solutions.

The total number of global CHA births remained steady, global CHA deaths decreased by 42.7% (95% UI: –59.3% to –15.2%), and the global number of individuals living with CHA increased by 28.2% (95% UI: 26.3% to 30.1%). There were increases in the 15- to 49-year and the 50- to 69-year age groups, in which the number of individuals living with CHA grew by 41.6% (95% UI: 40.0% to 43.2%) and 117.3% (95% UI: 114.7% to 120.0%) to 4.21 million (95% UI: 3.67 to 4.76 million) and

1.31 million (95% UI: 1.13 to 1.51 million), respectively, reflecting a cohort effect from the time of birth. Most of the prevalence increase occurred outside of high-income countries (HICs) and was due to improvements in survival and population growth. Health systems will be increasingly burdened with adolescents and adults needing care for their congenital heart conditions.

The very young age distribution in LMICs and large burden of YLLs due to CHA should drive a global mandate for investment in data collection and resources to expand access to infant heart surgery in regions in most need. In low-income countries with very young populations, the prevalence and mortality from RHD parallel lack of access to cardiac surgery services for CHA, and pooling resources to care for both of these diseases makes a stronger case for investment in surgical services (that includes both in-country surgical personnel and nongovernmental organizations) than for either disease alone.

Rheumatic heart disease

The prevalence of RHD has been rising steadily since 1990, reaching 40.5 million (95% UI: 32.1 to 50.1 million) currently affected in 2019 (Supplemental Figure 17A). Deaths decreased until 2012 but have stabilized since then and even started increasing since 2017 (306,000 [95% UI: 259,000 to 340,000] in 2019). DALYs and YLLs have slowly decreased to 10.7 million (95% UI: 9.21 to 12.1 million) and 8.68 million (95% UI: 7.43 to 9.77 million), respectively, in 2019, whereas YLDs have increased to 1.99 million (95% UI: 1.20 to 3.04 million).

Age-standardized rates for RHD prevalence have closely tracked with all-age rates, but age-standardized mortality has exceeded all-age mortality until the past few years, highlighting the differential mortality risk due to RHD observed in regions with differing age structures and levels of development (Supplemental Figure 17B). The narrowing of this differential tells a positive story about RHD care, although the dominance of China and India in the overall figures may mask persistent differentials in other high-prevalence countries and regions. The continuing increase in prevalence cannot be attributed to changes in age structure but likely reflects increased global awareness, the increasing availability of echocardiography for case definition, improved survival in some places, and the chronic nature of RHD.

Globally, the prevalence of RHD is estimated to peak between 20 and 29 years, remain relatively stable until 40 years, and then begin a steady decline, likely reflecting decreasing survival at older ages. Sex distribution is equal until the age of 15 years, after which women bear a higher burden in terms of prevalence across nearly all world regions. Higher rates of RHD in post-pubertal females are well described, but incompletely understood, and may reflect the interaction of biological, social, and environmental risk factors.

RHD burden continues to show substantial global heterogeneity (Supplemental Figure 18). The highest age-standardized DALY rates are seen in Oceania and South Asia (627.4 per 100,000 [95% UI: 404.1 to 918.0 per 100,000] and 348.5 per 100,000 [95% UI: 272.4 to 412.2 per 100,000], respectively) with the lowest in the highest-income regions (<25 per 100,000). Furthermore, although some regions have shown large declines between 1990 and 2019 (Eastern and Central Europe, East Asia, Central Latin America, high-income Asia Pacific, and North Africa and the Middle East), there are also regions with only modest improvements and regions where very little improvement has been seen (Oceania, South Asia, the Caribbean, and sub-Saharan Africa). There is also substantial within-region national and subnational variability in RHD DALYs, some examples of which include substantially higher RHD DALYs in Guyana and Haiti compared to the rest of Latin America and the Caribbean and the heterogeneity seen in the subnational data on RHD DALYs from India (Figure 6).

Open in a separate window

Figure 6

Map of Age-Standardized DALYs Due to Rheumatic Heart Disease in 2019

DALYs = disability-adjusted life years.

RHD burden is highest among the world's most disadvantaged populations. The most marginalized and poorest populations regionally, nationally, and at a subnational level are not showing signs of improvement and continue to die early from RHD. Health systems in LMICs should support the recommendations of the 2018 World Health Assembly Global RHD Resolution with increased multisector investment in primary health care, improved sanitation and housing, infrastructure, secure medication supply chains, evidence-based RHD screening, prevention and management, and tertiary capacity to care for patients at the severe end of the RHD spectrum. RHD burden could be greatly decreased with an effective group A streptococcal vaccine, with several promising candidates currently in development (17). Future data collection is needed at subnational levels to identify and monitor populations with ongoing high RHD burdens.

Cardiomyopathy and myocarditis

DALYs due to cardiomyopathy and myocarditis have increased from 7.06 million (95% UI: 6.30 to 8.63 million) to 9.14 million (95% UI: 7.86 to 10.0 million) over the past 30 years, a pattern that is also seen in the rise of deaths from 238,000 (95% UI: 212,000 to 257,000) to 340,000 (95% UI: 285,000 to 371,000) (Supplemental Figure 19A). However, over the same period, the age-standardized rate of death has decreased from 8.0 per 100,000 (95% UI: 6.4 to 8.6 per 100,000) to 5.6 per 100,000 (95% UI: 4.5 to 6.3 per 100,000) in men and 5.8 per 100,000 (95% UI: 4.4 to 6.4 per 100,000) to 3.3 per 100,000 (95% UI: 2.7 to 3.6 per 100,000) in women. The age-standardized morbidity and mortality for men and women in 2019 remains different, at 6.5 per 100,000 YLDs (95% UI: 4.3 to 9.3 per 100,000 YLDs) and 4.2 per 100,000 YLDs (95% UI: 2.8 to 6.0 per 100,000 YLDs) and 148.9 per 100,000 YLLs (95% UI: 120.2 to 168.7 per 100,000 YLLs) and 71.4 per 100,000 YLLs (95% UI: 61.0 to 79.9 per 100,000 YLLs), respectively.

The prevalence and related mortality of cardiomyopathy and myocarditis increase throughout adulthood in both sexes, with a larger proportion of cases in men than in women. When myocarditis alone is considered, a similar trend was observed. Referring to 2019, in the age between 35 and 39 years, when myocarditis can commonly occur (18,19), the rate of myocarditis is 6.1 per 100,000 (95% UI: 4.2 to 8.7 per 100,000) in men and 4.4 per 100,000 (95% UI: 3.0 to 6.3 per 100,000) in women. Similar figures can be found in the range of ages between 20 and 44 years.

The increased prevalence associated with aging is more pronounced in cardiomyopathies than in myocarditis. Approximately a 6-fold higher age-related increase of other cardiomyopathy was observed in men between 35 and 39 years (10.8 per 100,000 [95% UI: 6.5 to 17.4 per 100,000]) versus those between 80 and 84 years (698.5 per 100,000 [95% UI: 429.6 to 1064.8 per 100,000]) compared with myocarditis in men of 35 to 39 years (6.1 per 100,000 [95% UI: 4.2 to 8.7 per 100,00]) versus those of 80 to 84 years (63.0 per 100,000 [95% UI: 43.6 to 87.9 per 100,000]). The relatively greater rise of other cardiomyopathy compared to myocarditis prevalence with age is constant, from 1990 to 2019.

Myocarditis-related mortality rate between 35 and 39 years was 0.2 per 100,000 (95% UI: 0.2 to 0.3 per 100,000) in men compared to 0.1 per 100,000 (95% UI: 0.1 to 0.2 per 100,000) in women in 2019. Alternatively, myocarditis resulted in death in 1 in 72 men (585 deaths per 42,200 incident cases) and 1 in 87 (324 deaths per 28,100 incident cases) women in this age bracket who were diagnosed in 2019. Between ages 80 and 84 years, the rate was higher, at 1 death for every 19 incident cases of myocarditis in men (1,800 deaths per 34,400 incident cases) and 1 death for every 15 incident cases of myocarditis in women (2,260 deaths per 34,900 incident cases).

Marked regional variations in other cardiomyopathy in age-standardized DALYs in both sexes were observed in 2019 (Supplemental Figure 20). These ranged from 5 to 46 DALYs per 100,000 in South Asia, East Asia, Andean Latin America, high-income Asia Pacific, and Central Latin America to 96 to 147 per 100,000 in Oceania, the Caribbean, high-income North America, and Western and Eastern sub-Saharan Africa to 230 to 271 per 100,000 in Central Asia, Eastern Europe, and Southern and Central sub-Saharan Africa. These regional variations may be explained by a higher prevalence of peripartum cardiomyopathy in Africa, Chagas disease in Central and South America, and alcohol-related cardiomyopathy in parts of Central Europe and Russia (20).

Although the morbidity and mortality rates from cardiomyopathies and myocarditis collectively present a substantial global disease burden in 2019, the regional differences in the burden (Figure 7) suggest that public health interventions should be tailored to the specific etiologies of cardiomyopathy to lower these rates in the future.

Open in a separate window

Figure 7

Map of Age-Standardized DALYs Due to Cardiomyopathy and Myocarditis in 2019

DALYs = disability-adjusted life years.

Alcoholic cardiomyopathy

The global prevalence of alcoholic cardiomyopathy (AC) estimated by GBD 2019 was 708,000 cases (95% UI: 545,000 to 924,000 cases), approximately 9.1 cases per 100,000 (95% UI: 7.0 to 11.9 cases per 100,000) (Supplemental Figure 21A). Globally, AC was responsible for 71,700 deaths (95% UI: 60,200 to 82,000 deaths), 2.38 million YLLs (95% UI: 2.00 to 2.73 million YLLs), and 60,100 YLDs (95% UI: 38,500 to 88,300 YLDs). The total number of DALYs due to AC was 2.44 million (95% UI: 2.05 to 2.78 million). After a rapid increase from 1999, DALYs, deaths, and YLLs started decreasing from 2005 to 2019. The global prevalence and YLDs due to AC are increasing.

All-age and age-standardized rates of DALYs, deaths, prevalent cases, YLDs, and YLLs declined from 2005 to 2019 (Supplemental Figure 21B). This indicates that the global increase in AC prevalence is related, in part, to population growth and aging. Several countries in East Asia and the Caribbean regions showed opposite trends, with increasing age-standardized values for almost all indicators. Factors that might explain these regional differences remain incompletely understood.

At the global level, substantially more total DALYs due to AC were experienced by men than women. DALYs from AC rose rapidly among men beginning from age 25 years, being significantly higher in men than women across all ages (Supplemental Figure 22). Women are generally considered more susceptible to alcohol-induced damages than men, which may reflect sex-specific differences in alcohol consumption, type, blood level, distribution, or metabolism. However, the higher level of alcohol consumption and the higher frequency of alcohol problems among men could justify the observed higher rate of DALYs.

Age-standardized DALYs due to AC were higher in Central Europe as well as in the Caribbean (Cuba), followed by Australasia, North America, Central Asia, Western Europe, and tropical Latin America (Figure 8). Extremely high rates were seen in Eastern Europe, particularly in Russia and Kyrgyzstan. The lowest levels were observed in sub-Saharan Africa, Andean Latin America, and North Africa and the Middle East. Geographic differences reflect drinking patterns among regions, for example, rates of binge drinking, as well as social and cultural behaviors, such as abstaining from alcohol.

Open in a separate window

Figure 8

Map of Age-Standardized DALYs Due to Alcoholic Cardiomyopathy in 2019

DALYs = disability-adjusted life years.

AC represents substantial morbidity and mortality among young and middle-age people, particularly men. The age-standardized DALYs are high in several countries, and the true burden of disease could be underestimated because alcohol consumption is often underreported (21). Additional policy support for public education and awareness is needed to reduce the harmful use of alcohol. Because alcohol negatively affects cardiovascular function, increased clinician emphasis on eliminating alcohol use among people with coexisting CVD is advisable. Research should be aimed at understanding the exact mechanisms of disease, susceptibility to alcohol damage, effective public health interventions, and treatments for AC.

AF and AFL

The total number of DALYs due to AF and AFL increased progressively from 3.79 million (95% UI: 2.96 to 4.83 million) in 1990 to 8.39 million (95% UI: 6.69 to 10.5 million) in 2019 (Supplemental Figure 23A). GBD 2019 estimated 59.7 million (95% UI: 45.7 to 75.3 million) prevalent cases of AF/AFL in 2019, about a doubling compared to the prevalent cases in 1990.

When standardized for age, prevalence of AF/AFL, DALYS, and death rates did not display marked changes between 1990 and 2019 (Supplemental Figure 23B). The age-standardized AF/AFL prevalence rate was 775.9 per 100,000 (95% UI: 592.4 to 990.8 per 100,000) in 1990 and 743.5 per 100,000 (95% UI: 571.2 to 938.3 per 100,000) in 2019. Age-standardized rates for DALYs did not change substantially between 1990, when they were 110.0 per 100,000 (95% UI: 87.7 to 139.2 per 100,000), to 2019, when they were 107.1 per 100,000 (95% UI: 86.2 to 133.7 per 100,000). Similarly, the age-standardized death rates per 100,000 were similar in 1990 at 4.3 per 100,000 (95% UI: 3.7 to 5.1 per 100,000) and 4.4 per 100,000 (95% UI: 3.7 to 5.0 per 100,000).

Comparing total numbers with age-standardized numbers suggests that global increases in AF/AFL are largely attributable to aging of the population and population growth.

Globally, under the age of 70 years, more total DALYs due to AF were experienced by men than women (Supplemental Figure 24). Between 70 and 74 years, men and women had similar DALYs. However, at age 75 years and older, this trend was reversed, with higher total DALYs experienced by women. These trends were observed in 1990 as well as 2019. These findings point toward sex-specific, age-related targets for the prevention and management of AF/AFL.

Age-standardized DALY rates due to AF/AFL were highest in high-income North America, Australasia, Central Asia, and Europe and were observed to be lowest in the high-income Asia Pacific region (Figure 9). Also, Andean and Central Latin America, the Caribbean, sub-Saharan Africa, and North Africa and the Middle East displayed low rates. However, because of a general lack of data from these regions, more detailed studies should be performed. The reasons for this significant regional variation may include increased ascertainment in high-income regions, differential control of risk factors, and genetic factors. A detailed comparison of potential differentiating features between highest DALY rate versus lowest DALY rate regions could yield valuable additional information.

Open in a separate window

Figure 9

Map of Age-Standardized DALYs Due to Atrial Fibrillation and Flutter in 2019

DALYs = disability-adjusted life years.

AF/AFL are the most common arrhythmias and continue to make a progressive and substantial impact on public health at a global level. In most regions, prevalence rates are increasing, suggesting that more effort is needed to improve prevention and health care for AF/AFL at a global level. Health systems and countries will need to focus their efforts to reverse these trends by aggressive attention to the reduction of risk factors such as hypertension, diabetes, and obesity; better treatment of individuals with IHD and heart failure; and improved access to medications for thromboembolism prophylaxis.

Aortic aneurysm

The total number of YLLs due to aortic aneurysm, including both thoracic and abdominal types, has increased steadily since 1990, reaching 3.32 million YLLs (95% UI: 3.11 to 3.52 million YLLs) and 172,000 deaths (95% UI: 157,000 to 183,000 deaths) in 2019 (Figure 10A).

Open in a separate window

Figure 10

Total Numbers and Rates of Aortic Aneurysm

(A) Total number of deaths and YLLs due to aortic aneurysm, 1990 to 2019. **Shaded regions** represent 95% uncertainty intervals. **(B)** Age-standardized and all-ages death and YLL rates of aortic aneurysm, 1990 to 2019. **Shaded regions** represent 95% uncertainty intervals. YLLs = years of life lost.

Age-standardized rates for YLLs and deaths declined over this period, indicating that, overall, global increases in aortic aneurysm have been due to population growth and aging (Figure 10B). This likely reflects improvement in diagnosis and treatment of risk factors.

At the global level, men bore a substantially higher burden of YLLs due to aortic aneurysm compared with women. YLLs from aortic aneurysm rose most steeply in the sixth decade of life for men, peaking by age 70 years (Supplemental Figure 25). Women younger than age 75 years accounted for less than one-half of YLLs due to aortic aneurysm. The gap between men and women narrowed with increasing age, with YLLs in women overtaking those of men at age 90 years. This could be explained by the generally longer lifespan of women compared with men. Despite the lower prevalence of abdominal aortic aneurysm than men, growth rate in women has been shown to be more rapid, rupture during surveillance 4 times more likely, and likelihood of fatal rupture 3 times as high, even after adjustment for age (22, 23, 24). For thoracic aortic aneurysms, women have a lower incidence but are more likely to have fatal consequences than men (25).

Age-standardized YLLs due to aortic aneurysm were highest in Eastern and Central Europe as well as Southern and Tropical Latin America, with extremely high levels noted in Montenegro and parts of Brazil (Supplemental Figure 26). The lowest levels were observed in Andean Latin America, North Africa and the Middle East, and East Asia, including Mexico, Iraq, and China. Risk factors, including tobacco use and hypertension, as well as access to screening and preventive health care, may partially explain these patterns.

Aortic aneurysm remains a major public health issue, with the overall burden in terms of number of YLLs and deaths increasing globally. Because age-standardized rates for YLLs and death due to aortic aneurysm declined from 1990 to 2019, the increase may be attributable to population growth and aging. However, because the risk factors for this disease remain common, most national health systems will need to address increasing demand for preventive care, including low-cost screening modalities for abdominal aneurysms in the high-burden regions mentioned earlier. The risk factors underlying the development of aortic aneurysm are common to other CVDs, such as IHD. As such, investing health system resources in these risk factors, including hypertension management and smoking cessation, could reduce the burden of other diseases in addition to aortic aneurysm. Combined with implementation of inexpensive screening technology, such as ultrasonography, where indicated, the morbidity and mortality due to aortic aneurysm can be significantly decreased globally.

Nonrheumatic valvular heart disease: calcific aortic valve disease

Calcific aortic valve disease (CAVD) occurs commonly among older adults with a normal trileaflet aortic valve and with a greater frequency among those with a congenital bicuspid aortic valve. CAVD is clinically important because severe obstruction causes symptoms and left ventricular dysfunction warranting surgical or transcatheter valve replacement (26). The prevalence of CAVD increases with age and is >1,000 per 100,000 beyond the age of 75 years.

Globally, both the prevalence and age-standardized prevalence of CAVD have increased steadily over the last 3 decades (Supplemental Figure 27B). In 2019, the age-standardized prevalence rose to approximately 116.3 cases per 100,000 (95% UI: 100.4 to 134.5 cases per 100,000) people, from about 45.5 cases per 100,000 (95% UI: 37.6 to 54.7 cases per 100,000) people in 1990. This increase may be attributable to increased prevalence of atherosclerotic risk factors associated with the development and progression of CAVD (27). Although age-standardized YLDs due to CAVD have increased in parallel with prevalence, there has been no significant change in age-standardized DALYs, most likely because most of the DALYs due to CAVD accrue from YLLs, whereas deaths due to CAVD (and consequently, age-standardized YLLs) have not increased over the years. The ready availability of aortic valve replacement in regions of the world where CAVD is most prevalent may be an important check on mortality.

In HICs, the age-standardized prevalence of CAVD is similar among both men and women, while the prevalence among men exceeds that among women to varying degrees in the other regions of the world. Population-based studies of the prevalence of nonrheumatic valvular heart disease remain rare, and further research is needed to understand if sex differences in prevalence are due to differences in disease burden, health-seeking behavior, or rates of diagnosis.

There is substantial heterogeneity among countries in age-standardized prevalence and DALYs due to CAVD (Figure 11). Prevalence is low (<20 per 100,000) in several regions of the world, notably, sub-Saharan Africa (excluding the south), most of Asia (including South and Southeast Asia), North Africa and the Middle East, and Oceania. In contrast, age-standardized prevalence is much higher (>200 per 100,000) in Australasia; high-income Asia Pacific and North America; and Central, Eastern, and Western Europe. The difference may reflect higher prevalence of other competing illnesses and lack of testing for CAVD in LMICs. Despite the low prevalence of CAVD in LMICs, DALYs due to CAVD are disproportionately high, possibly reflecting the limited access to timely aortic valve replacement (28).

Open in a separate window

Figure 11

Age-Standardized DALYs Due to Nonrheumatic Calcific Aortic Valve Disease in 2019 by Region

Age-standardized DALY rate of nonrheumatic calcific aortic valve disease by region and sex with 95% uncertainty intervals, 2019. DALYs = disability-adjusted life years.

As populations age, CAVD becomes an increasingly important cause of morbidity and mortality. The increase in reported prevalence of CAVD may be a consequence of both an increase in the prevalence of risk factors for atherosclerosis and an increased awareness and investigation to detect disease. Although major advances have been made in the treatment of end-stage CAVD, research on ways to prevent the onset and progression of disease requires additional investments. In the populous regions of

the world such as South Asia and Africa, despite the low prevalence of CAVD, the absolute number of people with CAVD is large. Countries will need to invest in health care infrastructure and health workers to provide timely valve interventions for these patients to reduce related morbidity and mortality.

Nonrheumatic valvular heart disease: degenerative mitral valve disease

The major cause of nonrheumatic degenerative mitral valve (MV) disease is MV prolapse (29,30). Untreated, this can lead to chronic mitral regurgitation, AF, and heart failure (31). The total number of DALYs due to degenerative MV disease has increased since 1990 and is responsible for 883,000 DALYs (95% UI: 754,000 to 1,090,000 DALYs) and 34,200 deaths (95% UI: 28,300 to 43,300 deaths) in 2019 (Supplemental Figure 28A). GBD 2019 estimated 24.2 million (95% UI: 23.1 to 25.4 million) prevalent cases of degenerative MV disease in 2019.

Age-standardized rates for DALYs, deaths, and prevalent cases of degenerative MV disease declined over this time period, suggesting that the global increases in MV disease have been due to population growth and aging (Supplemental Figure 28B). The regions with the largest reductions in age-standardized DALYs between 1990 and 2019 are high-income Asia Pacific, North Africa and the Middle East, and Australasia. However, for some regions—for example, in Eastern Europe and Central Asia—age-standardized rates have not declined.

At the global level, substantially more total DALYs due to MV disease were experienced by women than men. For almost all age groups, MV disease DALYs were higher in women than men (Figure 12). Globally, women and men had similar DALYs in the 40- to 44-year age groups, but the levels diverged after age 65 years, when women had more than one-third more DALYs due to MV disease than men, peaking at age 75 to 79 years. Prior studies have found that women with severe regurgitation have higher mortality and lower surgery rates than men, which may account for some of the increased DALYs in older women (32).

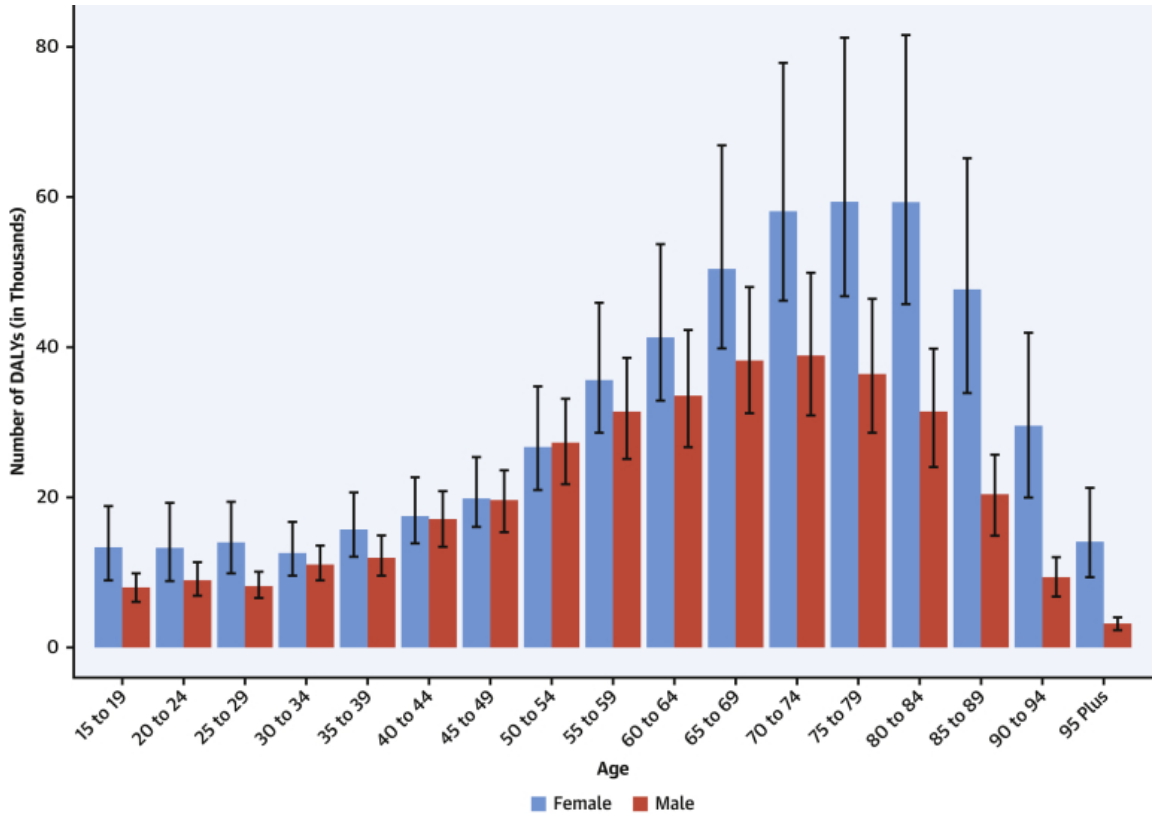

Figure 12

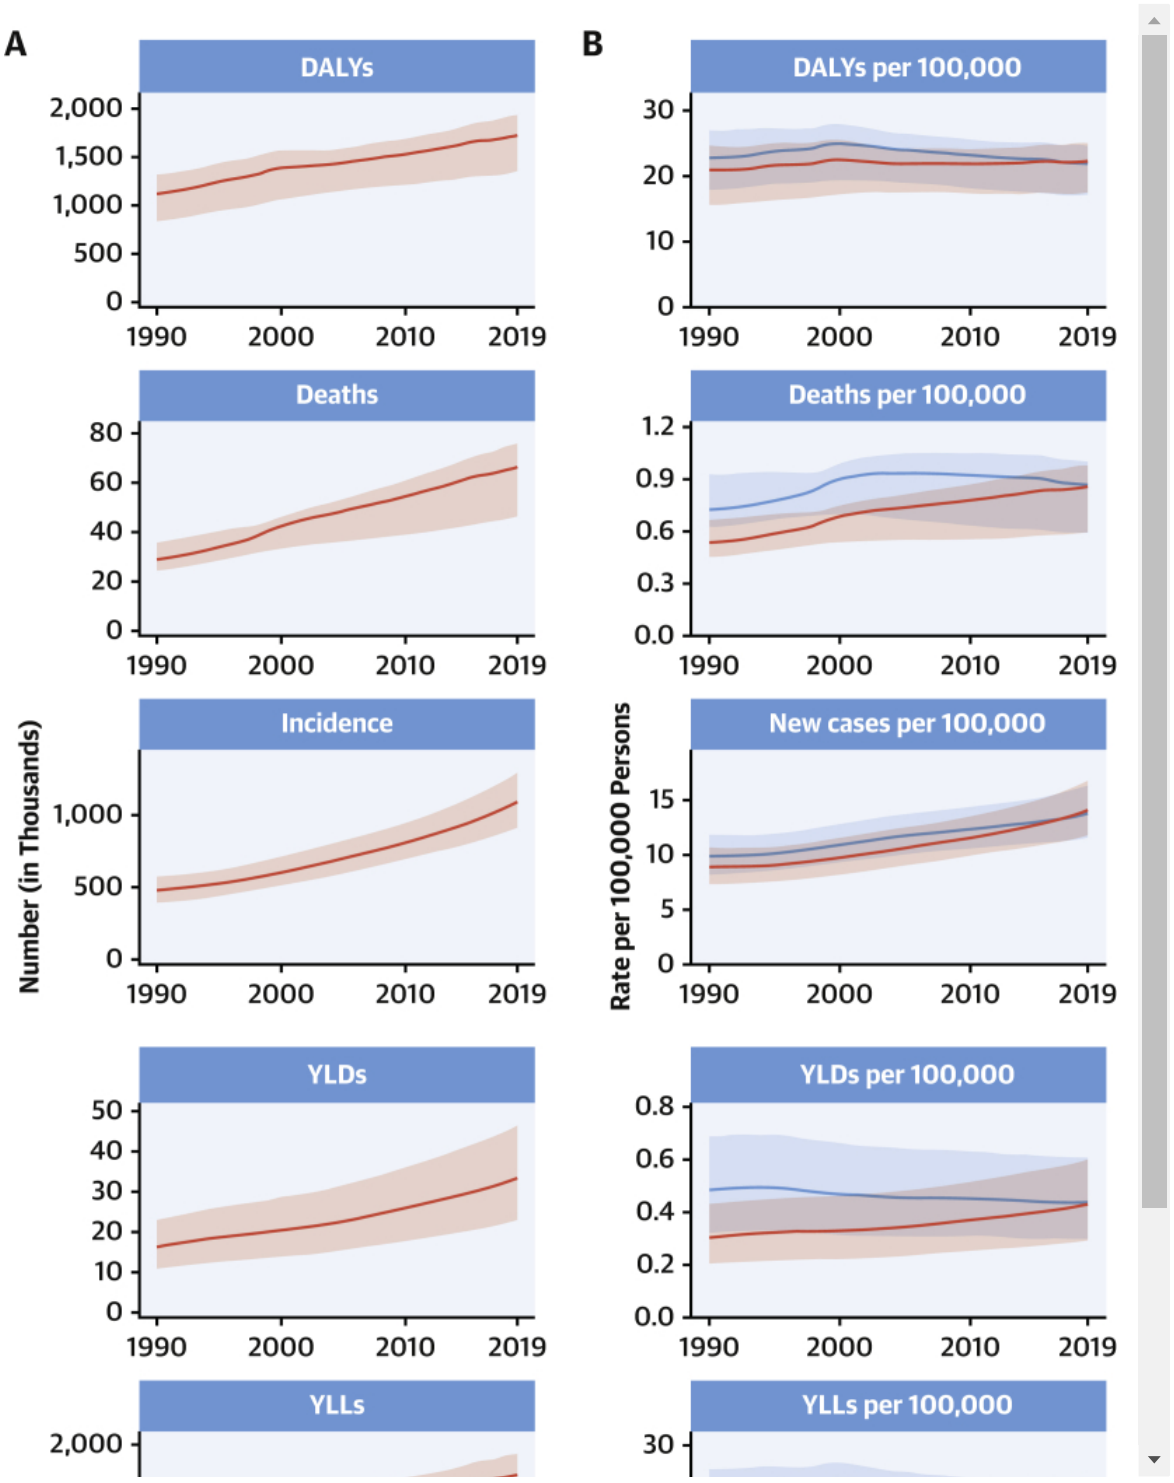
DALYs Due to Nonrheumatic Degenerative Mitral Valve Disease in 2019 by Age



Number of DALYs due to nonrheumatic degenerative mitral valve disease by age and sex with 95% uncertainty intervals, 2019. Ages younger than 15 years were removed from the figure because they are not modeled for this cause. DALYs = disability-adjusted life years.

Age-standardized DALYs due to MV disease were highest for both men and women in Central Europe; specifically, high rates were seen in Serbia, Bosnia and Herzegovina, and Hungary, with the lowest levels seen in Southeast Asia, East Asia, and Andean Latin America (Supplemental Figure 29). Women had higher DALYs than men in most regions except Central Asia, Eastern Europe, Australasia, the Caribbean, and Western sub-Saharan Africa (Supplemental Figure 30).

Degenerative MV disease continues to be a major threat to public health, and the overall burden in terms of number of DALYs, deaths, and prevalent cases is increasing globally. Prevention of MV disease through reduction in risk factors remains a key public health issue. In addition, given an aging population in many regions, health systems should focus on improving access to diagnostic imaging (i.e., echocardiography) and subspecialty care for close follow-up. Improved access to surgical and percutaneous interventions is also needed to decrease mortality and long-term sequelae and improve quality of life for those with MV disease (33).

Endocarditis

The total number of DALYs due to endocarditis has risen steadily since 1990, reaching 1.72 million (95% UI: 1.36 to 1.94 million) DALYs and 66,300 deaths (95% UI: 46,200 to 75,900 deaths) in 2019 (Figure 13A). GBD 2019 estimated 1.09 million (95% UI: 0.913 to 1.30 million) incident cases of endocarditis in 2019.

(A) Total number of DALYs, deaths, incident cases, YLDs, and YLLs due to endocarditis, 1990 to 2019. **Shaded regions** represent 95% uncertainty intervals. **(B)** Age-standardized and all-ages DALY, death, incidence, YLD, and YLL rates of endocarditis, 1990 to 2019. **Shaded regions** represent 95% uncertainty intervals. Abbreviations as in Figure 1.

Age-standardized rates show an increase in incidence, from 9.9 per 100,000 (95% UI: 8.2 to 11.8 per 100,000) to 13.8 per 100,000 (95% UI: 11.6 to 16.3 per 100,000), as well as deaths, from 0.7 per 100,000 (95% UI: 0.6 to 0.9 per 100,000) to 0.9 per 100,000 (95% UI: 0.6 to 1.0 per 100,000) (Figure 13B). Although there has been a slight increase in the DALYs, YLLs, and YLDs caused by endocarditis across all ages, once standardized for age structure and growth, these metrics are largely static between 1990 and 2019. The increase in death may be explained by an increasing proportion of endocarditis caused by virulent organisms such as staphylococci or complex infection in patients not fit for surgical intervention.

At the global level, more total DALYs due to endocarditis were experienced by men than women in 2019 (973,000 DALYs [95% UI: 736,000 to 1,120,000 DALYs] versus 751,000 DALYs [95% UI: 537,000 to 871,000 DALYs]). DALYs from endocarditis rose rapidly for both sexes from birth and reached a peak at age 55 to 59 years for men and age 65 to 69 years for women (Supplemental Figure 31). Women ages 75 years and older had more DALYs due to endocarditis than men in the same age group.

There is wide variation in the regional age-standardized DALY rate due to endocarditis (Supplemental Figures 32 and 33). In 2019, the highest rates were seen in Oceania, with 44.9 DALYs per 100,000 (95% UI: 30.7 to 60.7 DALYs per 100,000) (across men and women), followed by Southern Latin America (40.1 DALYs per 100,000 [95% UI: 32.7 to 49.6 DALYs per 100,000]) and Southeast Asia (38.6 DALYs per 100,000 [95% UI: 31.6 to 53.8 DALYs per 100,000]). There were also high rates in Eastern Europe (especially in men), the Caribbean, Tropical Latin America, and Africa. The lowest DALYs for endocarditis were seen in Central and East Asia. In large part, areas with high age-standardized DALY rates for endocarditis mirror those areas with a high prevalence of RHD, for example, in Oceania, Southeast Asia, and sub-Saharan Africa.

The epidemiology of endocarditis, including predisposing conditions, is heterogeneous. Therefore, it is not surprising that the endocarditis-associated YLDs and DALYs vary considerably by location. Both the endocarditis-associated YLDs and DALYs increased in 76.2% and 52.4% of locations, respectively. *Staphylococcus aureus* has become the predominant endocarditis pathogen in many areas of the world and is extremely virulent and a well-recognized marker of worse outcomes (34). As a result, mounting human and health care burdens mandate that an individualized approach be developed for each location to better understand the unique epidemiology of endocarditis so that efforts can be focused on management and prevention of this life-threatening condition.

Peripheral artery disease

The global numbers of prevalent cases and deaths due to PAD have risen consistently each year since 1990, resulting in a 2-fold increase to 113 million cases (95% UI: 99.2 to 128 million cases) and 74,100 deaths (95% UI: 41,200 to 128,000 deaths) in 2019 (Supplemental Figure 34A). Comparable trends in DALYs, YLLs, and YLDs have resulted in 1.54 million (95% UI: 1.01 to 2.37 million), 1.04 million (95% UI: 0.604 to 1.78 million), and 501,000 (95% UI: 235,000 to 898,000) respectively in 2019.

In keeping with the increase in numbers of prevalent cases, deaths, DALYS, YLLs, and YLDs, rates per 100,000 persons of all ages increased between 1990 and 2019 (Supplemental Figure 34B). The trends in age-standardized rates of deaths and YLLs were flat from 1990 to 2019, and prevalence, YLDs, and DALYs declined slightly. Overall, the PAD prevalence increase reflects population growth rather than a major change in age-specific incidence. In both 1990 and 2019, cross-sectional analyses show that the numbers of prevalent cases increased with age in both men and women up to 70 years of

age and prevalence rates increased throughout the whole age spectrum. Numbers and rates of cases were higher in women than men at all ages. Deaths and DALYs showed increases with age comparable to prevalence except that deaths and DALYs were higher in men than women up to very old age.

The numbers of prevalent cases increased in both men and women at all ages by up to 2-fold since 1990, but age-standardized prevalence rates were slightly lower in 2019 than in 1990. Numbers of deaths and DALYs were higher in 2019 compared to 1990 in both men and women at all ages, but over the same period, age-standardized death rates remained much the same, and DALY rates fell slightly.

Age-standardized DALY rates varied by world region in 2019 (Figure 14). Higher rates (>25 per 100,000 persons) were found in both men and women in Europe (western, central, and eastern), North America, Australasia, the Caribbean, and sub-Saharan Africa (central, eastern, and southern) (Supplemental Figure 35). Especially high rates occurred in men in Eastern Europe and areas of sub-Saharan Africa. Lowest DALY rates were found in Asia, Andean countries, West and North Africa and the Middle East. The pattern was similar in men and women, with most regions showing higher rates in men, but in regions with low overall rates, the sex differences were small. The burden of PAD is increasing not only in developed HICs but also in LMICs, where concomitant risk factors such as diabetes and obesity are increasing.

Open in a separate window

Figure 14

Map of Age-Standardized DALYs Due to Peripheral Artery Disease in 2019

DALYs = disability-adjusted life years.

Despite decreases in PAD age-standardized prevalence, deaths, DALYs, YLDs, and YLLs, overall rates have increased because of worldwide increases in life expectancy. High DALY rates of PAD in Eastern Europe and parts of Africa, particularly in men, require investigation. PAD is highly prevalent and is both underrecognized and inadequately studied.

Modifiable Risk Factors

High systolic blood pressure

With aging of the population and population growth, the number of adults worldwide affected by high systolic blood pressure (SBP) increased from 2.18 billion (95% UI: 95% UI: 2.11 to 2.26 billion) to 4.06 billion (95% UI: 3.96 to 4.15 billion) from 1990 to 2019 (Supplemental Table 1). High SBP is defined by GBD 2019 according to a theoretical minimum risk exposure level (TMREL) of ≥110 to 115 mm Hg, which is the level of exposure that minimizes risk at the population level. In 2019, there were 828 million (95% UI: 768 to 888 million) adults with SBP >140 mm Hg, a common threshold for treatment with pharmacotherapies. The prevalence of adults worldwide with high SBP increased from 84,481.1 per 100,000 persons (95% UI: 81,641.5 to 87,579.2 per 100,000 persons) in 1990 to 88,971.1 per 100,000 persons (95% UI: 86,950.0 to 91,028.8 per 100,000 persons) in 2019.

From 1990 to 2019, the total number of DALYs due to high SBP increased from 154 million (95% UI: 139 to 169 million) to 235 million (95% UI: 211 to 261 million) (Supplemental Figure 36A). Additionally, between 1990 and 2019, the number of deaths (6.79 million [95% UI: 6.07 to 7.50 million] to 10.8 million [95% UI: 9.51 to 12.1 million]), YLDs (10.1 million [95% UI: 7.30 to 13.1 million] to 21.2 million [95% UI: 15.2 to 27.2 million]), and YLLs (144 million [95% UI: 129 to 158 million] to 214 million [95% UI: 191 to 237 million]) attributed to high SBP increased. The age-standardized rates of DALYs, deaths, and YLLs attributed to high SBP declined from 1990 to 2019, whereas the age-standardized rate of YLDs did not change substantially over this time period (Supplemental Figure 36B). These data indicate that the increases in total number of disease events can be attributed to population growth and aging. However, in some regions—for example, Oceania—the age-standardized rates of DALYs, deaths, YLDs, and YLLs increased between 1990 and 2019.

Globally, DALYs due to high SBP in 2019 were higher among men compared with women from ages 15 to 19 through 70 to 74 years, but higher among women compared to men in those 80 to 84 years or older (Figure 15). Age-standardized DALYs were higher among men compared with women in all regions of the world (Supplemental Figure 37).

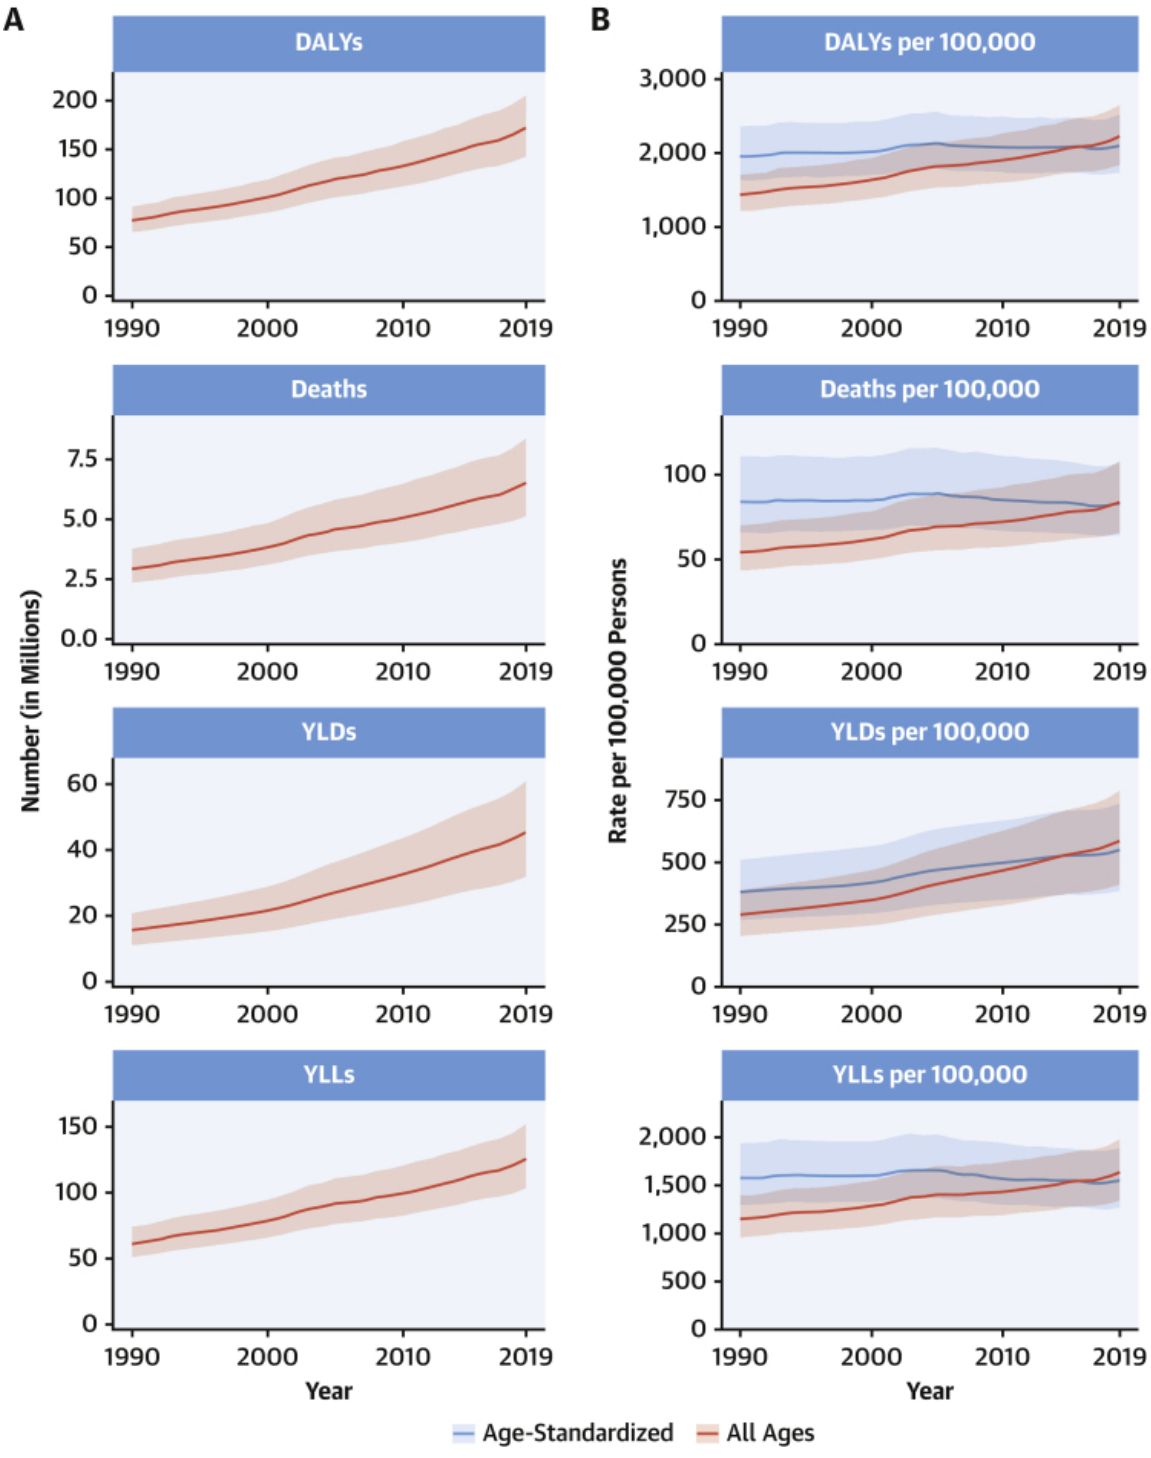
Open in a separate window

Figure 15

DALYs Due to High Systolic Blood Pressure in 2019 by Age

Number of DALYs due to high systolic blood pressure by age and sex with 95% uncertainty intervals, 2019. Ages younger than 15 years were removed from the figure because they are not modeled for this risk.

DALYs = disability-adjusted life years.



In 2019, there was an approximately 8-fold variation across regions in age-standardized DALYs attributed to high SBP (Supplemental Figure 38). Rates of DALYs were lowest for both women and men in the high-income Asia Pacific region and highest in Central Asia. Marked variation was also noted for rates of death, YLLs, and YLDs. The highest age-standardized rates of death and YLLs were noted in Central Asia and Eastern Europe among men and in Central Asia, North Africa and the Middle East, and Central sub-Saharan Africa among women. The highest rate of YLDs was noted in Central Asia, Central Europe, and Southeast Asia for men and in North Africa and the Middle East, East Asia, and Southeast Asia for women.

High SBP is a major public health challenge, affecting approximately 9 of 10 adults worldwide, and is associated with high rates of DALYs, death, YLDs, and YLLs. High SBP and its adverse health consequences can be prevented by eating a heart-healthy diet that includes <1 teaspoon of salt per day and adequate potassium from fruits and vegetables, maintaining a normal weight, increasing physical activity, and avoiding unhealthy alcohol intake (35).

High fasting plasma glucose

There are large differences between and within countries in the burden of high fasting plasma glucose, defined as above the TMREL of 4.8 to 5.4 mmol/l. The findings showed little improvement in age-standardized mortality rates from high fasting plasma glucose and significant increases in age-standardized YLDs between 1990 and 2019. Age-standardized mortality due to high fasting plasma glucose actually increased from 1990 to 2005, with a downward trend thereafter.

Between 1990 and 2019, a total of 134 million (95% UI: 107 to 171 million) deaths due to high fasting plasma glucose were recorded globally. The number of deaths increased from 2.91 million (95% UI: 2.34 to 3.75 million) in 1990 to 6.50 million (95% UI: 5.11 to 8.36 million) in 2019 (Figure 16A). The age-standardized mortality rate due to high fasting plasma glucose increased between 1990 and 2005 from 84.2 per 100,000 deaths (95% UI: 65.9 to 111.1 per 100,000 deaths) to 89.2 per 100,000 deaths (95% UI: 70.2 to 115.9 per 100,000 deaths) then declined to 83.0 per 100,000 deaths (95% UI: 64.5 to 107.1 per 100,000 deaths) in 2019 (Figure 16B). Age-standardized DALYs followed the same patterns with a peak in 2005 and then a decline until 2019. In contrast, age-standardized DALY rates were higher in 2019 at 2,104.3 per 100,000 (95% UI: 1,740.7 to 2,520.7 per 100,000) than in 1990 at 1,959.6 per 100,000 (95% UI: 1,638.7 to 2,362.4 per 100,000). Of course, this is the result of a sharp increase in age-standardized YLDs from 1990 to 2019. Men had higher DALY burden than women throughout the study period until the age of 80 years, after which women had a higher number of DALYs (Supplemental Figure 39). DALYs due to high fasting plasma glucose increased with age, peaked at 70 years, and then declined.

Open in a separate window

Figure 16

Total Numbers and Rates of High Fasting Plasma Glucose

(A) Total number of DALYs, deaths, YLDs, and YLLs due to high fasting plasma glucose, 1990 to 2019. **Shaded regions** represent 95% uncertainty intervals. **(B)** Age-standardized and all-ages DALY, death, YLD, and YLL rates of high fasting plasma glucose, 1990 to 2019. **Shaded regions** represent 95% uncertainty intervals. Abbreviations as in Figure 1.

Age-standardized DALYs due to high fasting plasma glucose were higher in Oceania, followed by Central Asia (Supplemental Figure 40). There were large variations between countries in high fasting plasma glucose DALY burden, with notably high rates in Uzbekistan, Afghanistan, Papua New Guinea, Egypt, and Oman (Supplemental Figure 41). The highest age-standardized DALYs in 2019 were observed in Kiribati at 12,255.2 per 100,000 (95% UI: 9,799.7 to 15,073.0 per 100,000), and the highest age-standardized death rates were also observed in Kiribati at 435.4 per 100,000 (95% UI: 347.0 to 540.5 per 100,000). Large variations were also observed within countries. For example, the age-standardized DALY rate varied in Brazil from 1,571.8 per 100,000 (95% UI: 1,293.6 to 1,909.1 per 100,000) in Minas Gerais to 3,286.5 per 100,000 (95% UI: 2,735.5 to 3,907.3 per 100,000) in Alagoas, a 70.6% difference in the country.

These population-based estimates of plasma glucose level help track the global rise in diabetes. GBD 2019 showed low rates of physical activity (LPA) and poor diet in many countries. Both are major risk factors for high fasting plasma glucose and have led to caloric imbalance and higher rates of obesity, which has rapidly increased globally since 1990 and affects most geographic areas. There is a need to develop and implement both public health policies and clinical programs to reduce health disparities and disease burden due to diabetes.

High low-density lipoprotein cholesterol

The total number of DALYs due to high low-density lipoprotein (LDL) cholesterol, defined by a TMREL of 0.7 to 1.3 mmol/l, has risen steadily since 1990, reaching 98.6 million (95% UI: 80.3 to 119 million) DALYs and 4.40 million (95% UI: 3.30 to 5.65 million) deaths in 2019 (Supplemental Figure 42A). Over the same period, the YLDs and YLLs rose to 5.71 million (95% UI: 3.68 to 8.27 million) and 92.9 million (95% UI: 75.6 to 111 million), respectively. This indicates that the direction of the global trend for high LDL is increasing.

Over the study period, the global all-age rates for DALYs, deaths, and YLLs remained relatively static and increased for YLDs (Supplemental Figure 42B). During this time, the age-standardized rates for the same measures all declined. This difference between all-age rates and age-standardized rates suggests that although the global burden of LDL-related disease remains unacceptably high, on average, the observed increases in the burden of DALYs in locations like China and India have been driven primarily by population growth and aging. This trend is important for global health because it implies that there has been at least modest progress in reducing the burden of LDL-related disease globally. Age-standardized DALY rates attributable to elevated LDL cholesterol, however, are estimated to be increasing in some locations, including Pakistan and Saudi Arabia.

At the global level, significantly more total DALYs from elevated LDL were experienced by men than women. LDL-related DALYs increased rapidly for men beginning at age 30 years (Supplemental Figure 43). Men ages 40 to 44 years had as many DALYs due to LDL as women ages 60 to 64 and 80 to 84 years and more than women in all other age groups. In aging post-menopausal women, the LDL cholesterol levels are comparable to those of men of similar age. The difference in DALYs by sex and age suggests that the burden of premature LDL-related disease in men younger than 65 years may need focused public health attention.

Age-standardized DALYs due to high LDL cholesterol were highest in Eastern Europe, North Africa and the Middle East, Oceania, and Central Asia (Supplemental Figure 44). The lowest levels are present in high-income Asia Pacific, Australasia, Western Europe, and Andean Latin America and, by

country, in the Republic of Korea, Japan, Rwanda, France, Israel, and Spain (Figure 17). Potential explanations for these differences in regional patterns include the correspondingly LPA, increased high body mass index (BMI), dietary patterns, and increased tobacco use in the same regions and countries.

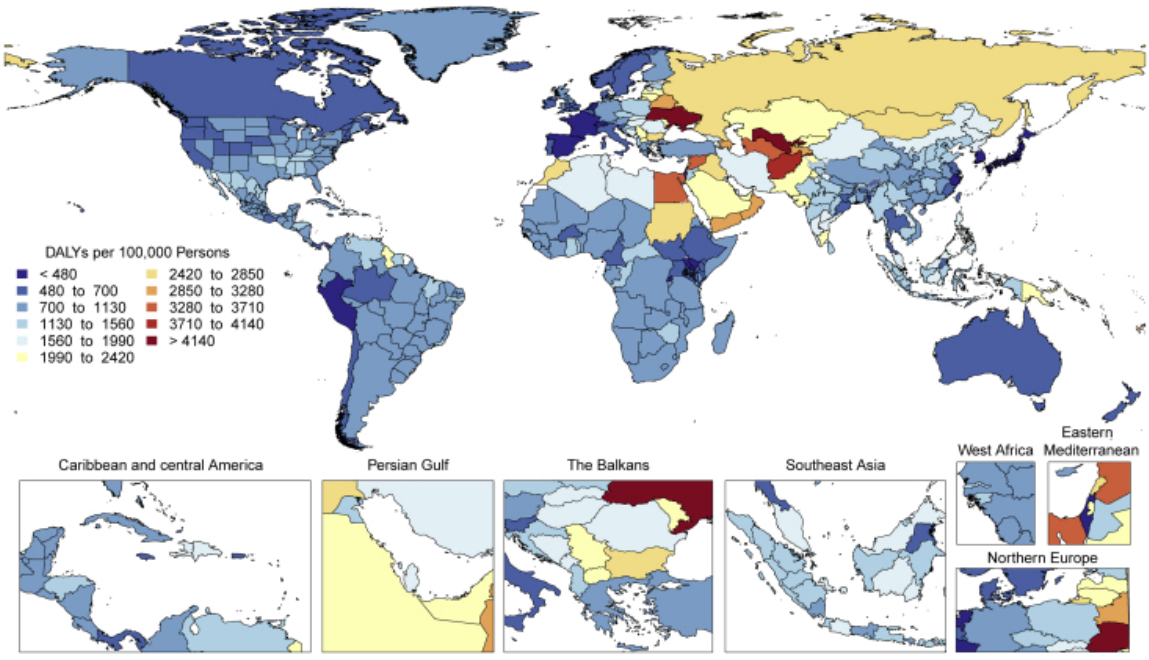


Figure 17

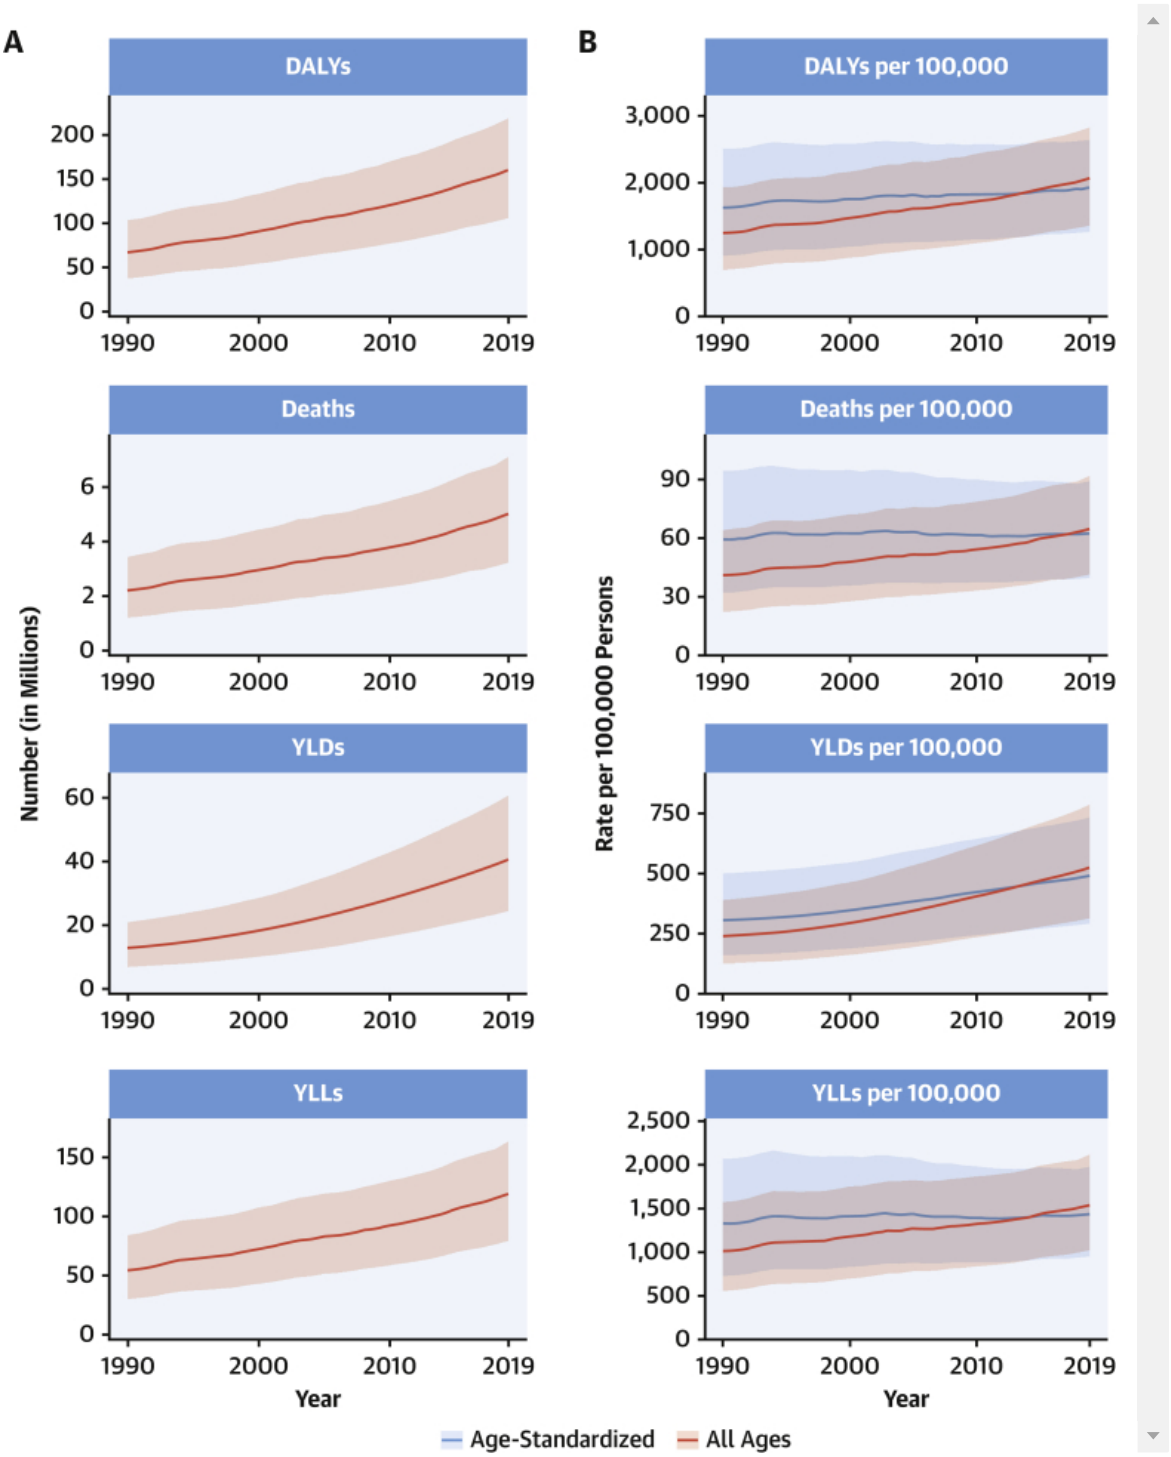
Map of Age-Standardized DALYs Due to High LDL Cholesterol in 2019

DALYs = disability-adjusted life years; LDL = low-density lipoprotein.



High LDL cholesterol remains a major threat to public health, and the overall burden in terms of number of DALYs, deaths, YLDs, and YLLs is increasing globally. In some locations, the risk associated with high LDL cholesterol is especially high and deserves immediate public health attention. Health systems and countries may need to focus on new approaches that can reverse these trends. These might include improved government policies on diet and tobacco, school physical activity programs, and, when needed, the use of lipid-lowering therapy in keeping with contemporary guidelines in which statins are the first choice. More global investment in research to address LDL cholesterol–related knowledge and therapeutic gaps is needed to address this persistent global health threat.

High BMI

Obesity, defined by elevated BMI (≥30 kg/m^2), has reached epidemic levels worldwide. Elevated BMI worsens most of the CVD risk factors, including adverse effects on blood pressure, blood sugar, lipids, and inflammation and has adverse effects on cardiac structure and function. Not surprisingly, hypertension, coronary heart disease, heart failure, and AF are increased with obesity (36).

Globally, 5.02 million (95% UI: 3.22 to 7.11 million) deaths and 160 million (95% UI: 106 to 219 million) DALYs were attributed to high BMI in 2019 (Figure 18A). High BMI, defined as above a TMREL of 20 to 25 kg/m^2 for adults and above normal weight for children, contributed to more YLLs

(119 million [95% UI: 79.6 to 164 million]) than YLDs (40.9 million [95% UI: 24.5 to 60.9 million]) in 2019. Globally, between 1990 and 2019, the absolute numbers of deaths attributable to high BMI increased (2.20 million [95% UI: 1.21 to 3.43 million] to 5.02 million [95% UI: 3.22 to 7.11 million]), as did DALYs (67.3 million [95% UI: 38.0 to 104 million] to 160 million [95% UI: 106 to 219 million]), YLDs (12.9 million [95% UI: 6.9 to 21.0 million] to 40.9 million [95% UI: 24.5 to 60.9 million]), and YLLs (54.4 million [95% UI: 30.2 to 84.4 million] to 119 million [95% UI: 79.6 to 164 million]).

Open in a separate window

Figure 18

Total Numbers and Rates of High Body Mass Index

(A) Total number of DALYs, deaths, YLDs, and YLLs due to high body mass index, 1990 to 2019. **Shaded regions** represent 95% uncertainty intervals. **(B)** Age-standardized and all-ages DALY, death, YLD, and YLL rates of high body mass index, 1990 to 2019. **Shaded regions** represent 95% uncertainty intervals. Abbreviations as in Figure 1.

After standardization for population growth and aging, rates of deaths attributable to high BMI have increased only modestly from 1990 to 2019 (4.9% increase [95% UI: –7.3% to 24.6%]), DALYs (18.0% [95% UI: 2.2% to 42.3%]), and YLLs (8.3% [95% UI: –6.6% to 31.2%]), suggesting that population growth and aging of the population have contributed substantially to the global trends in obesity-associated burden of disease (Figure 18B). YLDs have increased more sharply (60.2% [95% UI: 41.3% to 90.2%]) from 1990 to 2019. Since population growth and aging from 1990 account for much of the absolute increases attributable to high BMI, the focus may need to be on strategies targeting prevention of weight gain at younger ages to decrease the burden of all measures, including YLDs.

Global DALYs attributable to high BMI are highest between ages 45 and 75 years and are slightly higher for men at younger and middle ages and for women at older ages (Supplemental Figure 45).

Age-standardized DALY rates due to high BMI are highest in Oceania, Central Asia, North Africa and the Middle East, Southern sub-Saharan Africa, Eastern Europe, Central Latin America, the Caribbean, and Central Europe (Supplemental Figure 46). Among countries, Japan has the lowest and Kiribati the highest age-standardized DALYs in the world (Supplemental Figure 47). The global findings are generally similar between men and women in most regions, but age-standardized DALYs are notably higher for men in Central Asia and Central and Eastern Europe.

Great efforts are needed to promote the prevention of obesity and its progression to more severe forms (36). A multifactorial approach is required to promote improving dietary quality, especially reductions in simple sugars, complex carbohydrates, and total calories. Community prevention programs, like the Diabetes Prevention Program, duplicated in many programs (37), are needed (36). Optimizing efforts to promote physical activity and exercise training are needed, as well as reductions in sedentary behavior and making neighborhoods, communities, and workplaces more suitable to allow for these healthier lifestyle behaviors. Potential governmental involvement, such as mandating caloric/nutrition menu labeling and regulation of food ingredients, as well as controlling advertisements and certain forms of beverage and food item taxation, etc., could be instituted. Governmental intervention was very successful decades ago in the North Karelia Project in Finland (36,38), and potentially, similar efforts could be successful for obesity intervention worldwide. Research is needed to identify effective methods of health promotion that will reduce obesity and align all allied health professions toward this important goal (36).

Impaired kidney function

GBD 2019 estimates use the term chronic kidney disease (CKD) to refer to the morbidity and mortality that can be directly attributed to all stages of CKD and the term impaired kidney function (IKF) to capture the additional risk of CKD from other associated conditions such as CVD and gout. The DALYs due to IKF nearly doubled from 1990 to 2019, reaching 76.5 million (95% UI: 67.8 to 86.3 million) DALYs and 3.16 million (95% UI: 2.72 to 3.62 million) deaths globally in 2019 (Supplemental Figure 48A). The estimated global prevalence of CKD is 9,011.9 per 100,000 (95% UI: 8,401.3 to 9,577.8 per 100,000) (697 million [95% UI: 650 to 741 million] people), 41.1% (95% UI: 38.9% to 43.4%) higher than in 1990 due to aging (Supplemental Figures 49A and 49B).

Age-standardized DALYs due to IKF declined slightly from 1,024.1 DALYs per 100,000 people (95% UI: 898.4 to 1,154.8 DALYs per 100,000 people) to 945.3 DALYs per 100,000 people (95% UI: 836.3 to 1,066.8 DALYs per 100,000 people) from 1990 to 2019 (Supplemental Figure 48B). This 7.7% (95% UI: –12.9% to –2.4%) decline in DALYs lags behind the 39.3% (95% UI: –43.5% to –34.9%) decline in DALYs for all risk factors combined. The age-standardized rate per 100,000 people for

YLDs from IKF increased from 115.9 (95% UI: 84.7 to 150.5) to 139.4 (95% UI: 101.8 to 181.8) from 1990 to 2019. Growth and aging of the global population resulted in an increase in all unadjusted disease burden measures for IKF.

CKD and its consequences generally rise markedly with age and are higher among men than women, but trends over time were similar across age and sex groups (Supplemental Figures 50 and 51).

Geographically, the highest age-standardized rates of DALYs due to IKF are now seen in Central Latin America, Central Asia, the Caribbean, North Africa and the Middle East, Oceania, and Southeast Asia (Figure 19). Men in Central Latin America have among the highest age-standardized DALYs at 2,091.2 per 100,000 people (95% UI: 1,791.6 to 2,424.8 per 100,000 people), double the global rate and 60% higher than in 1990 (Supplemental Figure 52), which represents an epidemic of CKD of unknown origin that appears to be common in coastal lowlands, with repeated heat stress, pesticide, and heavy metal exposure implicated as potential causes (39).

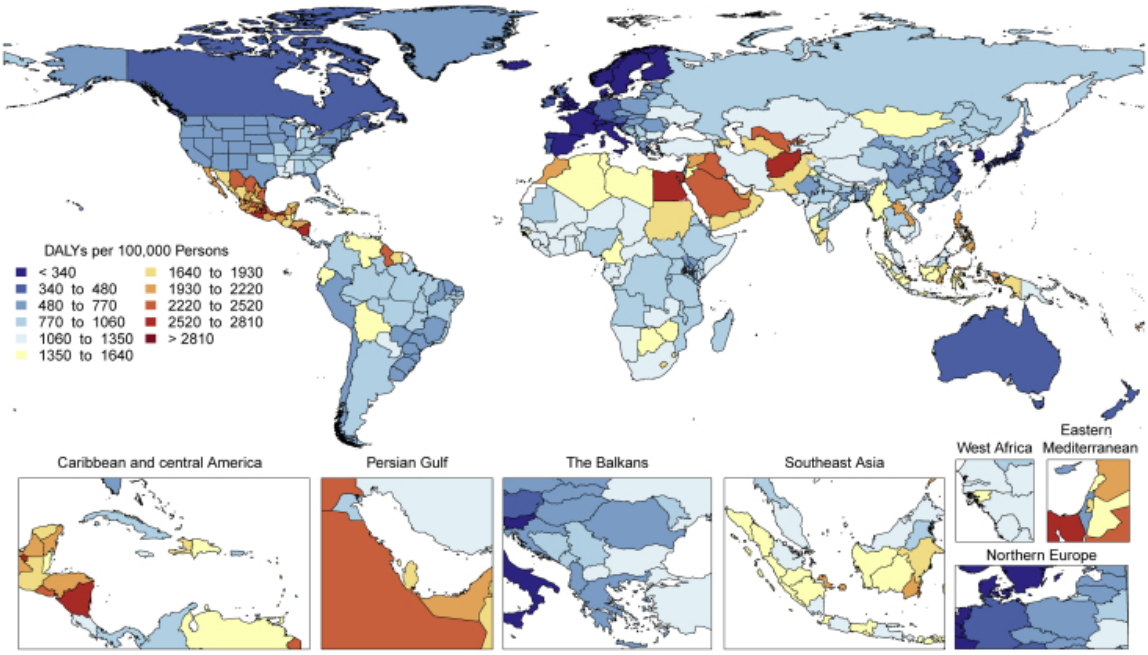


Figure 19

Map of Age-Standardized DALYs Due to Impaired Kidney Function in 2019

DALYs = disability-adjusted life years.

CKD is emerging as a growing global problem, with marked growth related to the aging population. Age-standardized DALYs for IKF have declined by only 7.7%, compared to 39.3% for all risk factors, and they increased in Central and Andean Latin America, the Caribbean, Central and Southeast Asia, Oceania, and Southern sub-Saharan Africa. Much of CKD remains undiagnosed and undertreated. Governments, health systems, physicians, and patient attention are needed to improve the diagnosis of CKD by measuring proteinuria and estimated glomerular filtration rate. There is also a need for earlier markers of kidney injury. Diabetes and hypertension are leading factors for CKD, its progression, and associated risk. Improving their prevention and control will reduce the burden of CKD. Therapeutic options for CKD are increasing with the proven benefits of renin-angiotensin system blockade in

proteinuria and possibly sodium-glucose cotransporter-2 inhibitors and mineralocorticoid receptor antagonists. Trials are underway to test prevention of kidney events in patients with CKD without diabetes. A combination of population-based public health measures for increased CKD recognition and awareness and improved therapies to reduce risk is needed to reduce the burden of CKD.

Ambient and household air pollution

Air pollution is the leading environmental risk factor for global health and the fourth largest risk factor for global mortality. Two main forms of air pollution quantified in GBD 2019 contribute substantially to the burden of CVD: ambient particulate matter with an aerodynamic diameter smaller than 2.5 μm ($PM_{2.5}$) and household air pollution (HAP) from the use of solid fuels for cooking. In 2019, CVD accounted for 51.5% and 30.5% of the total DALYS attributable to $PM_{2.5}$ and HAP, respectively.

Despite substantial reductions in ambient $PM_{2.5}$ concentrations in North America and Europe, levels remain high throughout most of the world (40). Global annual average population-weighted $PM_{2.5}$ levels increased slightly from 40.8 $\mu g/m^3$ in 1990 to 42.6 $\mu g/m^3$ in 2019. However, the global disease burden attributable to ambient $PM_{2.5}$ increased from 70.5 million (95% UI: 47.3 to 98.9 million) DALYs and 2.05 million (95% UI: 1.45 to 2.74 million) deaths in 1990 to 118 million (95% UI: 95.9 to 138 million) DALYs and 4.14 million (95% UI: 3.45 to 4.80 million) deaths, respectively, in 2019 (Supplemental Figure 53A). Age-standardized rates for DALYs and deaths attributable to $PM_{2.5}$ have remained relatively constant between 1990 and 2019, indicating that, on average, global increases in attributable disease have been due to population growth and aging, especially in locations with high exposures (Supplemental Figure 53B). Age-standardized DALYs attributable to $PM_{2.5}$ were higher than the global mean in East, Central, and South Asia; North Africa and the Middle East; and Southern and Western sub-Saharan Africa (Figure 20).

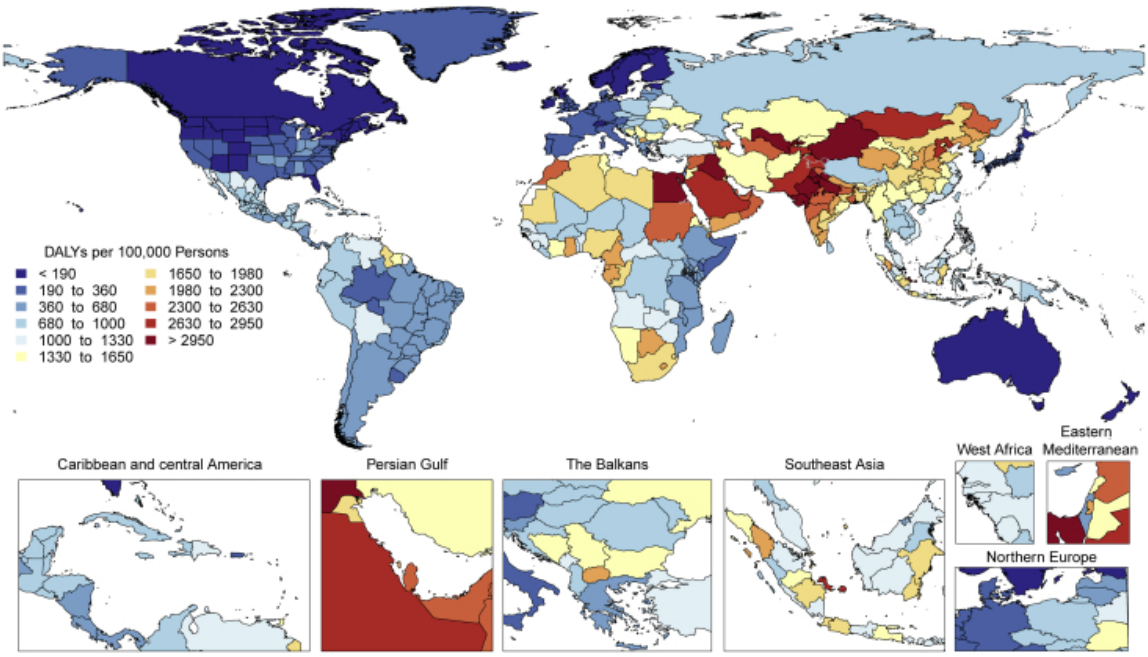

Figure 20

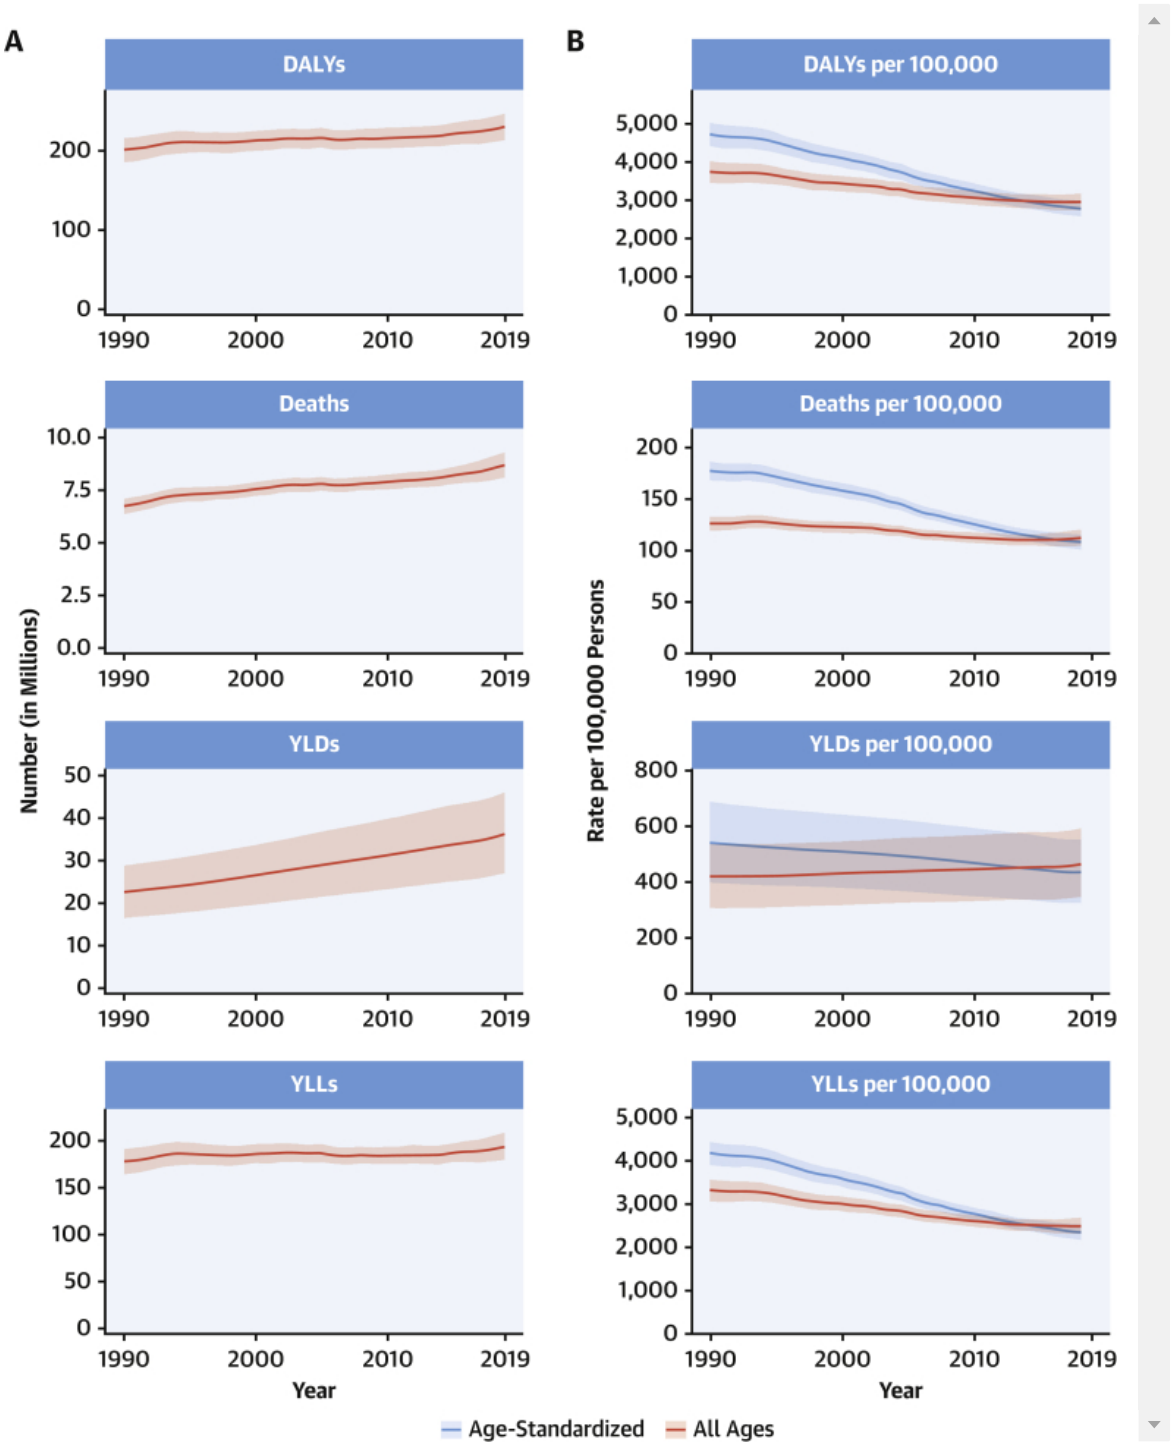
Map of Age-Standardized DALYs Due to Ambient Particulate Matter Pollution in 2019

DALYs = disability-adjusted life years.

In contrast to ambient $PM_{2.5}$, the burden attributable to HAP decreased sharply from 208 million (95% UI: 162 to 259 million) DALYs and 4.36 million (95% UI: 3.33 to 5.40 million) deaths in 1990 to 91.5 million (95% UI: 67.0 to 119 million) DALYs and 2.31 million (95% UI: 1.63 to 3.12 million) deaths in 2019 (Supplemental Figure 54A). Trends for both all-age and age-standardized DALYs and death rates attributable to HAP have also declined sharply, indicating the impact of exposure reduction (Supplemental Figure 54B). However, age-standardized rates of DALYs attributable to HAP remain high throughout much of sub-Saharan Africa, which has yet to experience the benefits of improved access to clean household energy sources seen in India, China, and much of Southeast Asia (Supplemental Figure 55). The highest rates of DALYs for HAP were in Oceania; Eastern, Western and Central sub-Saharan Africa; and South Asia, driven by differences in exposure.



DALYs attributable to $PM_{2.5}$ and HAP were higher in men, driven by sex differences in rates of the diseases affected by air pollution (Supplemental Figures 56 and 57). These sex differences were less pronounced for HAP given that women tend to be more highly exposed. DALYs attributable to HAP had the largest impacts in infancy and early childhood, whereas for $PM_{2.5}$, it was between ages 30 and 90 years.

Increased attention to air pollution as a CVD risk factor is warranted and will require concerted action and collaboration between government health and environmental agencies. This is especially relevant given high levels of exposure in many parts of the world and links between $PM_{2.5}$ and health risks at levels substantially below those of current regulatory levels (41). As demonstrated in North America and Western Europe, air quality management, coupled with regulation and enforcement, is effective at reducing ambient air pollution and its disease burden (42). Similar approaches applied elsewhere, in combination with actions to reduce emissions of climate-forcing agents will be necessary. In the

interim, personal-level interventions, such as the use of portable air cleaners, may be effective (43). Continued reductions in HAP exposure through programs to improve access to clean energy sources will lead to both health and climate benefits (44).

Tobacco

Tobacco, including primary smoking, secondhand smoke, and use of chewing tobacco, accounted for 8.71 million (95% UI: 8.12 to 9.31 million) deaths and 230 million (95% UI: 213 to 246 million) DALYs in 2019 (Figure 21A). Of tobacco-attributable deaths, 36.7% were due to CVD. The number of YLLs attributable to tobacco (194 million [95% UI: 180 to 209 million]) far exceeded the number of attributable YLDs (36.1 million [95% UI: 27.0 to 46.0 million]), highlighting the outsized effect of tobacco on premature mortality.

Figure 21

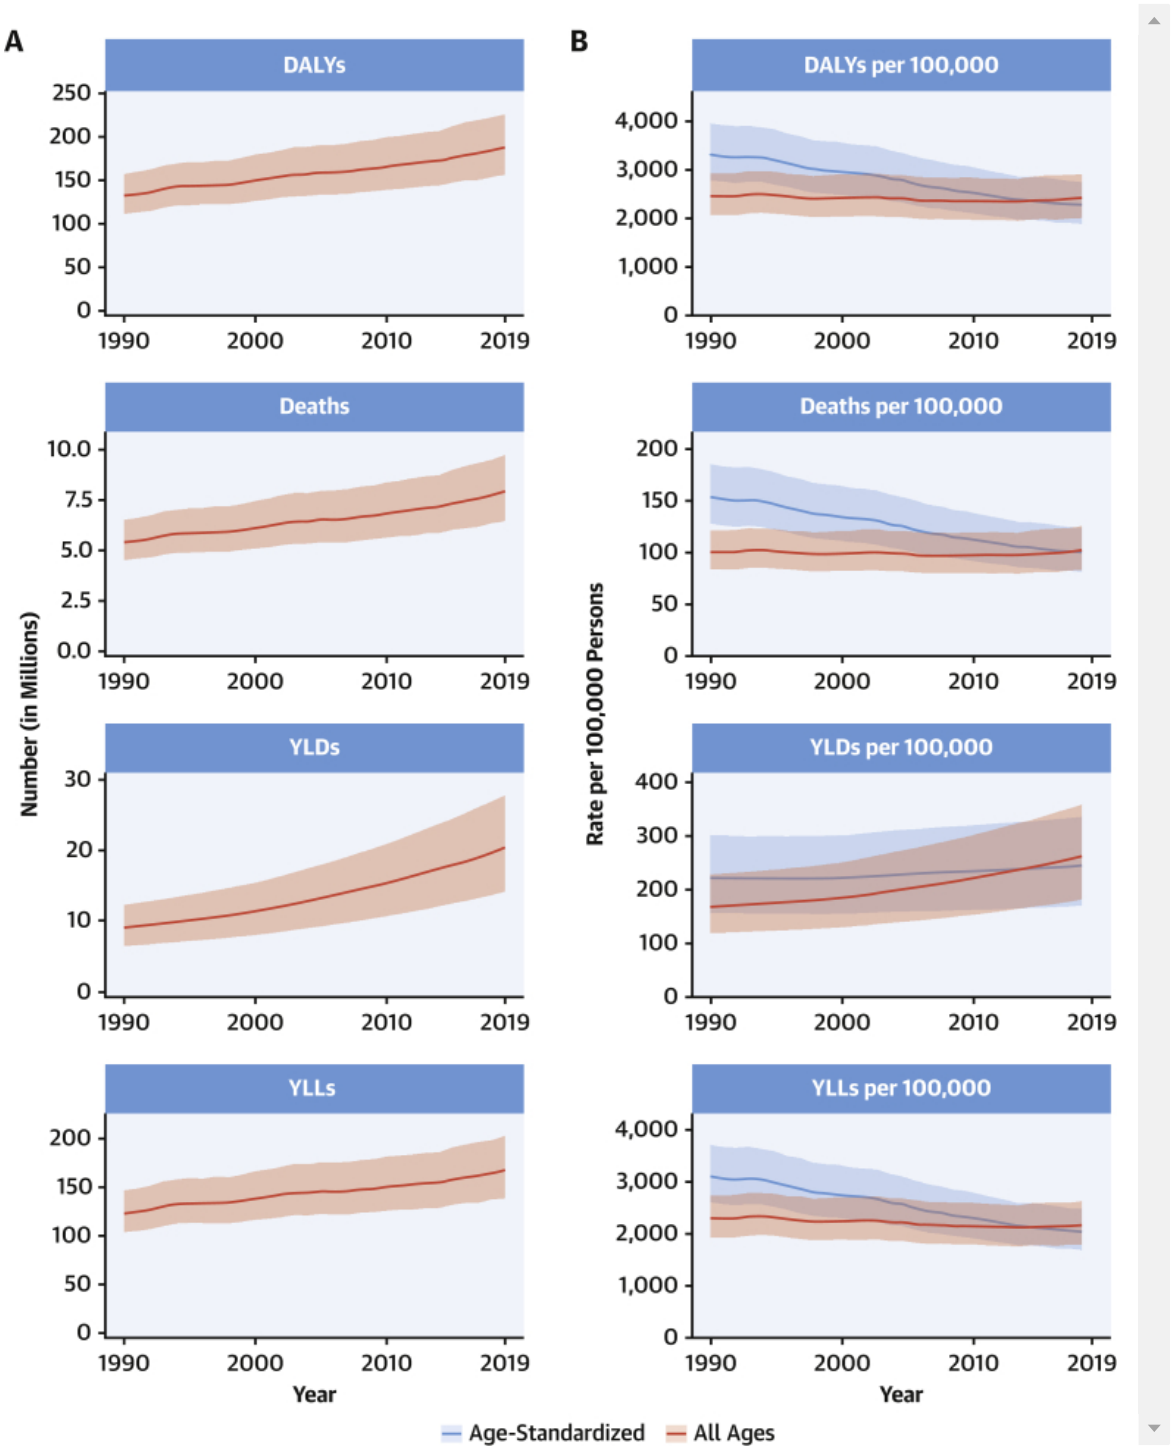
Total Numbers and Rates of Tobacco

(A) Total number of DALYs, deaths, YLDs, and YLLs due to tobacco, 1990 to 2019. **Shaded regions** represent 95% uncertainty intervals. **(B)** Age-standardized and all-ages DALY, death, YLD, and YLL rates of tobacco, 1990 to 2019. **Shaded regions** represent 95% uncertainty intervals. Abbreviations as in Figure 1.

Progress in reducing tobacco use and exposure has not kept pace with competing demographic forces, namely, population growth and population aging. Population growth, particularly in countries with a large population of tobacco users, has resulted in an increasing number of tobacco-attributable deaths and DALYs since 1990. When controlling for population growth, decreases in both death and DALY rates are observed. However, population aging has resulted in smaller decreases in all-age rates compared to age-standardized rates (Figure 21B). With approximately 80% of current smokers living in LMICs, these demographic forces will continue to counter progress in tobacco control for years to come.

In 2019, global smoking prevalence among men was 33.5% (95% UI: 33.1% to 33.9%), and smoking prevalence among women was 6.8% (95% UI: 6.6% to 7.0%). As a result of this difference, 75.4% of smoking attributable deaths occurred among men. The age pattern of tobacco use and exposure, combined with the age distribution of associated health outcomes, results in age-specific DALYs peaking among men ages 60 to 64 years and among women ages 65 to 69 years (Supplemental Figure 58).

The highest age-standardized tobacco-attributable DALY rates among men were observed in Eastern Europe, Central Asia, and Oceania (Supplemental Figure 59). Among women, the highest rates were observed in Oceania, high-income North America, and Central Europe. Thirty percent of all current smokers live in China, and nearly one-third of tobacco-attributable deaths occurred in China in 2019.



With more than 1 billion active tobacco users, the tobacco epidemic remains a central challenge to global health. The global disease burden of tobacco use continues to increase, attributable in large part to population growth and falling most heavily on LMICs, where the large majority of tobacco users live. Effective tobacco control measures available to governments and private sector institutions include policies that increase taxes on tobacco, fund mass media education campaigns, ban tobacco marketing and sponsorship, require prominent warning labels on tobacco products, require environments to be smoke-free, and ensure access to and delivery of tobacco cessation treatments in health care systems. The evidence-based measures are included in the World Health Organization's Framework Convention on Tobacco Control, a public health treaty that took effect in 2005 and has been ratified by 182 countries. Despite this global commitment, adoption of the Framework Convention on Tobacco Control measures has varied widely across countries. Increasing adoption and effective implementation of evidence-based tobacco control policies is a key worldwide public health priority. Looking ahead toward non-communicable disease targets set in the Sustainable Development Goals, accelerated progress in implementing proven policies and interventions is necessary to substantially reduce tobacco-attributable burden.

Dietary risks

In GBD 2019, dietary risks comprise the sum of adverse effects of diets in which 15 food types are either underconsumed (fruits, vegetables, legumes, whole grains, nuts and seeds, milk, fiber, calcium, omega-3 fatty acids from seafood, and polyunsaturated fatty acids) or overconsumed (red meat, processed meat, sugar-sweetened beverages, *trans*-fatty acids, and sodium).

CVDs are the primary consequence of these dietary risks, with 7.94 million (95% UI: 6.47 to 9.76 million) annual deaths and 188 million (95% UI: 156 to 225 million) annual DALYs attributed to dietary risks (Figure 22A). Worldwide, the absolute disease burden caused by dietary risks has risen for 30 years, regardless of how measured. Over the same period, age-standardized rates have fallen for

most measures, indicating the central role of population growth and population aging on the observed increases (Figure 22B). The exception is age-standardized rates of YLDs caused by dietary risks, which have grown in both absolute and proportional terms.

Open in a separate window

Figure 22

Total Numbers and Rates of Dietary Risks

(A) Total number of DALYs, deaths, YLDs, and YLLs due to dietary risks, 1990 to 2019. **Shaded regions** represent 95% uncertainty intervals. **(B)** Age-standardized and all-ages DALY, death, YLD, and YLL rates of dietary risks, 1990 to 2019. **Shaded regions** represent 95% uncertainty intervals. Abbreviations as in Figure 1.

Worldwide, the number of DALYs caused by dietary risks peaks between 55 and 70 years of age for both men and women, with a large excess of DALYs among men compared to women in every age group to 80 years old (Supplemental Figure 60). Age-standardized rates of DALYs caused by dietary risks are highest in Central Asia, Oceania, and Eastern Europe and lowest in Australasia, HICs of the Asia Pacific, and Western Europe (Supplemental Figures 61 and 62). Differences in age-standardized DALY rates among populations reflect a complex interplay between variations in diet quality, levels of exposure to different dietary risks, and access to interventions targeting the downstream clinical effects of CVDs.

The detailed effects of many dietary risks are poorly understood because assessments are hampered by the challenges of accurately quantifying exposures and separating the effects of each risk from those of important covariates. However, the effects of dietary risks on CVD remain large whether assessed as individual dietary factors or measures of overall diet quality, and there is little doubt about the importance of dietary risks as a cause of global disease burden.

Strong commercial interests driving the sales of unhealthy foods have made it challenging to persuade policy makers, clinicians, or community members to act decisively on diet quality. Easy access to healthy fruits, vegetables, and whole grains remains limited for much of the world. Many countries have adopted policies to limit consumption of added sugar, sodium, and harmful fats, but implementation has mostly been weak, and the impact on global health has been limited. Exceptions are regulatory and fiscal interventions such as soda taxes and beverage reformulation programs that have led to lower intakes of added sugars, proving the feasibility of determined intervention. Likewise, the removal of artificial *trans*-fat from the food supply in the United States has improved diet quality, although the amount of *trans*-fat in the global food supply remains high. Reliance on drug therapies targeting downstream metabolic risk factors caused by obesity may be inadequate. Ill health caused by dietary risks is anticipated to rise rapidly in LMICs over the coming years, and behavioral and policy interventions suited for implementation at scale in diverse settings around the world are urgently required.

Low Physical Activity

LPA is an important risk factor for IHD, stroke, diabetes, breast and colon cancers, and other noncommunicable diseases. The combination of increased risk for important causes of mortality and significant levels of LPA in most countries has led to physical inactivity being characterized as a pandemic. LPA is an important contributor of premature mortality, morbidity, and DALYs for adults in most of the world.

Globally, the total number of DALYs due to LPA, defined as <3,000 to 4,500 metabolic equivalent minutes per week, continuously increased from 8.61 million (95% UI: 4.28 to 15.9 million) in 1990 to 15.7 million (95% UI: 8.52 to 28.6 million) in 2019 (Supplemental Figure 63A). A linear trend was observed in the numbers of deaths due to LPA, reaching 832,000 premature deaths (95% UI: 427,000 to 1,470,000 premature deaths) in 2019. During the same time period, the estimated YLLs grew steadily from 7.51 million (95% UI: 3.62 to 14.4 million) in 1990 to 12.7 million (95% UI: 6.58 to 23.8 million) YLLs in 2019.

Over time, the all-ages rate of DALYs, deaths, and YLLs due to LPA has increased, and the age-standardized rate has decreased (Supplemental Figure 63B). This pattern reflects increased burden due to growth and aging of the population, an effect that is removed by age standardization.

Total global DALYs due to LPA were similar for men and women until the 65- to 69-year age group, with men consistently higher (Supplemental Figure 64). This pattern reversed in the 70- to 74-year age group as DALYs for women surpassed those for men. At all ages beyond 75 years, women had more DALYs than men, presumably driven by greater survival among women. LPA DALYs rose steadily for both men and women beginning at age 25 years, peaking for both sexes in the 80- to 84-year age group and declining thereafter.

Age-standardized DALYs due to LPA were highly variable by both region and sex. The highest rates were seen for both men and women in North Africa and the Middle East, Oceania, tropical Latin America, and the Caribbean (Figure 23), with high rates for men also observed in Central Asia (Supplemental Figure 65). The lowest age-standardized DALYs for LPA were seen for both men and women in high-income Asia Pacific, Southern Latin America, and Eastern sub−Saharan Africa; for men in high-income North America; and for women in Andean Latin America.

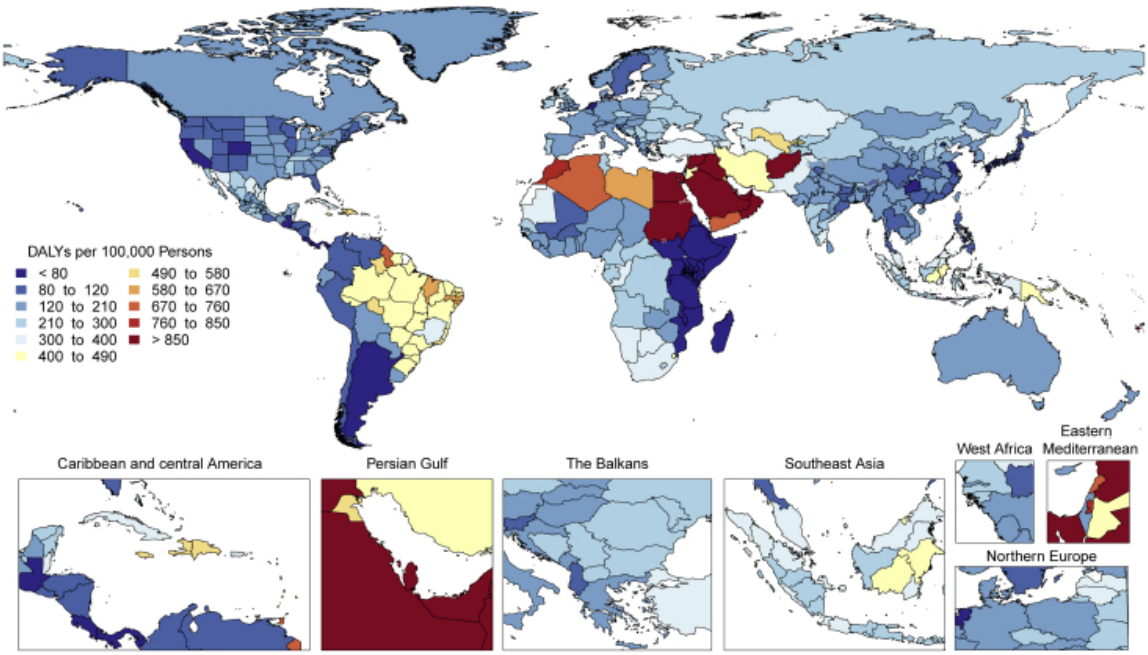


Figure 23

Map of Age-Standardized DALYs Due to Low Physical Activity in 2019

DALYs = disability-adjusted life years.

LPA remains a major threat to public health, and the overall burden is increasing globally even as age-standardized rates are declining. Although few health systems have historically focused on LPA, there is increased awareness and attention being paid to LPA as exemplified by the 2018 World Health Organization Global Action Plan for Physical Activity. However, the factors that influence population physical activity largely reside outside of the health sector. Increasing physical activity will depend on effective partnerships and collaboration between health and sectors such as transportation, education, urban planning, workplace health strategies, and environmental protection.

Subnational Disease Burden

GBD 2019 estimates disease burden within countries as well as between countries. Figure 24 shows the age-standardized rate of YLLs due to CVD for all countries, with Brazil, China, India, Indonesia, Japan, Kenya, Mexico, the United States, and the United Kingdom shown at the first subnational administrative level and Stockholm County shown separately from the rest of Sweden. Subnational disease estimation is made possible through collaboration with these governments. Subnational data reveal wide differences in DALYs within countries. For example, in Kenya in 2019, IHD DALYs were estimated to vary from 342.7 per 100,000 (95% UI: 212.4 to 531.7 per 100,000) in Turkana to 1,215.4 per 100,000 (95% UI: 856.8 to 1,612.4 per 100,000) in Nyeri, a 112.0% difference within Kenya. IHD DALYs in India ranged from 506.6 per 100,000 (95% UI: 379.6 to 819.0 per 100,000) in Mizoram to 5,413.2 per 100,000 (95% UI: 4,316.9 to 6,389.9 per 100,000) in Punjab, a 165.8% difference within the country. In Brazil, IHD DALYs varied from 771.2 per 100,000 (95% UI: 679.4 to 866.3 per 100,000) in Amazonas to 2,416.2 per 100,000 (95% UI: 2,176.7 to 2,686.2 per 100,000) in the Rio de Janeiro state, a 103.2% difference within the country. Within the United States, there was a 99.6% difference in IHD DALYs, ranging from 1,438.3 per 100,000 (95% UI: 1,210.7 to 1,699.0 per 100,000) in Utah to 4,293.1 per 100,000 (95% UI: 3,636.0 to 5,033.0 per 100,000) in West Virginia. In Mexico, they ranged from 890.5 per 100,000 (95% UI: 752.2 to 1,073.3 per 100,000) in Quintana Roo to 2,315.1 per 100,000 (95% UI: 1,932.1 to 2,716.3 per 100,000) in Chihuahua, an 88.9% difference within Mexico. Disease burden attributable to elevated levels of metabolic risk factors also varies significantly within countries.

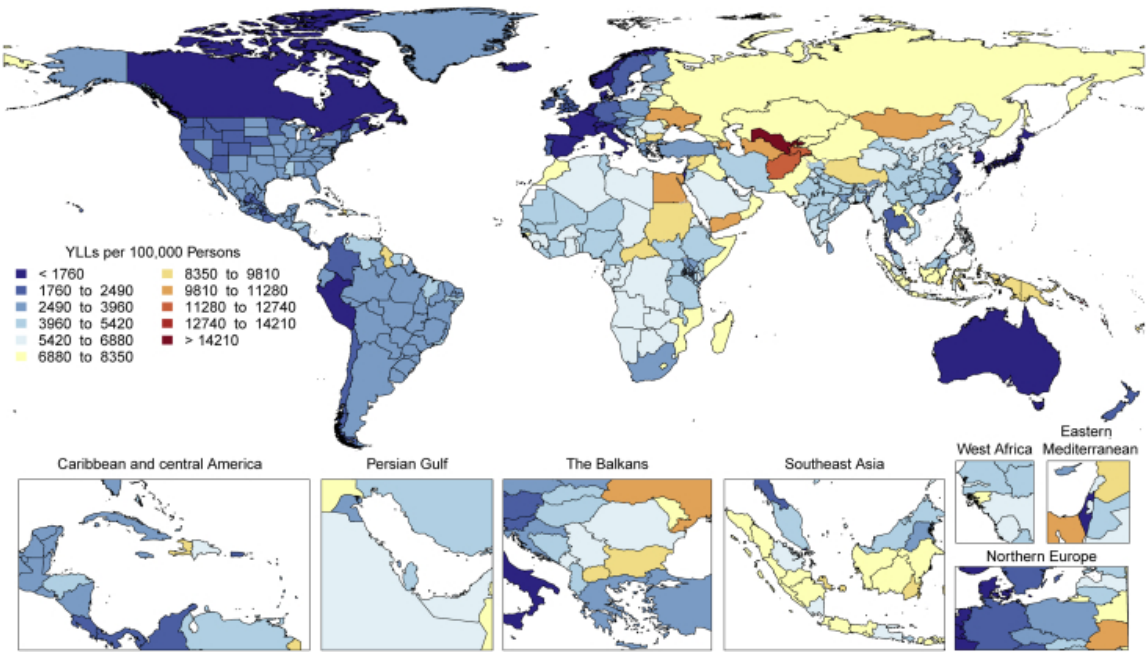

Figure 24

Map of Age-Standardized YLLs Due to Cardiovascular Diseases in 2019

YLLs = years of life lost.

Further analysis of the variation of CVD burden within countries will be vital to implementing health policies that reduce burden but also decrease disparities. The strategies to deal with these inequalities include: 1) targeting reduction in key modifiable risks including diet, tobacco, alcohol, physical

activity, and obesity; 2) improved access and quality of health care; and 3) a renewed focus on the social determinants of health. Addressing risk factors may prove to be an important initial opportunity to reduce disparities in parallel with broader efforts targeting social determinants, with potential indirect benefits for improving those social determinants, such as reduced financial hardship due to fewer acute cardiac events among working-age adults.

Several risks are increasing globally and warrant increased policy and health system attention, including high BMI, blood pressure, unhealthy cholesterol, and poor diet. Targeting subnational locations where metabolic risks are rising rapidly may be an important approach for testing new interventions and delivering resources where they will have the biggest impact. There is often a gap between the identification of a problem, the location of a solution, and the translation of that solution to an entire population. We currently lack a systematic, scalable process for determining which interventions are most likely to succeed in a given location, and research funding should be directed at addressing this gap.

Study limitations

Estimates from GBD 2019 should be interpreted in light of several limitations. Death certificates, although an essential source of data for public health, may be misclassified given the difficulty of identifying an underlying cause of death. GBD 2019 applies statistical methods to improve the comparability of health information coded using the ICD system and continuously evaluates, improves on, and reports the details of these methods. The use of different subnational population-based studies may lead to compositional bias of national estimates, although GBD 2019 adjusts variance and weighting to reflect this possibility. ICD system codes from administrative health facility data may represent a group of patients that differs from the standard case definition for a disease, although GBD 2019 applies adjustments to these data to account for differential access to health care and alternate case definitions. Access to CVD diagnostic technologies is likely to influence estimates of some conditions, with lower access resulting in lower observed prevalence. Some commonly used diagnostic tools—for example, electrocardiogram for AF—will underestimate true disease prevalence. Estimates are reported with an uncertainty interval that should always be carefully considered, given that it represents both data sparsity and differences in sample size across data sources and study locations. However, uncertainty may be underestimated in locations where no data on CVD of any kind are available. Limited data on CVD and resulting wider uncertainty intervals for parts of sub-Saharan Africa, Oceania, and Asia may restrict our ability to interpret trends in burden over time. An important use of GBD results is therefore to identify gaps in CVD health data and guide investments in future disease surveillance. In particular, better data are needed on the incidence of coronary events, cardiac arrest, and the severity and associated disability of chronic heart and vascular diseases. Comorbidity of CVD and the joint effects of multiple risk factors remains a topic where further investigation is also needed.

Conclusions and Recommendations

CVDs remain the leading cause of disease burden in the world. CVD continues its decades-long rise for almost all countries outside the high-income world and, alarmingly, age-standardized CVD rates have begun to rise in many locations where they were previously declining. There remains a large gap between identifying CVD as a problem, identifying the best package of solutions, and delivering them to the entire population.

GBD 2019 continues to be a platform that allows tracking and benchmarking of progress in the reduction of CVD burden. However, large investments are still needed to improve disease surveillance, including the expansion of robust vital registration systems, reliable electronic health records, and health surveys to all countries.

High rates of excess mortality are currently being observed because of the global severe acute respiratory syndrome coronavirus 2 pandemic, and much of this additional disease burden may be CVD due to the effects of both viral infection but also the unintended consequence of social distancing behaviors, such as changes in the delivery of health care (45,46). Further research in this area is urgently needed.

CVD was the cause of 6.2 million deaths occurring between the ages of 30 and 70 years in 2019. There is a pressing need to focus on implementing existing cost-effective interventions and health policies if the world is to meet the targets for Sustainable Development Goal 3 and achieve at least a 30% reduction in premature mortality due to noncommunicable disease by 2030. In the face of a global viral pandemic, we still must emphasize global commitments to reduce the suffering and premature death caused by CVD, which limits healthy and sustainable development for every country in the world.

Author Disclosures

This study was funded by the Bill and Melinda Gates Foundation. Dr. Benjamin has received funding from the National Institutes of Health (NIH)/National Heart, Lung, and Blood Institute (NHLBI) (R01HL092577, 1R01HL128914) and American Heart Association (18SFRN34110082). Dr. Brauer has received a grant from the Bill and Melinda Gates Foundation. Dr. Catapano has received support from Fondazione Cariplo 2015-0524 and 2015-0564, H2020 REPROGRAM PHC-03-2015/667837-2, ERA NET ER-2017-2364981, GR-2011-02346974, Ministry of Health - Ricerca Corrente Multimedica; has received research grant/support from Sanofi, Sanofi Regeneron, Amgen, Mylan, Menarini, and Eli Lilly; has served on the speakers bureau for Akcea, Amgen, Sanofi, Esperion, Kowa, Novartis, Ionis Pharmaceuticals, Mylan, Menarini, Merck, Recordati, Regeneron, Daiichi-Sankyo, AstraZeneca, Aegerion, Amryt, and Sandoz; has received honoraria from Akcea, Amgen, Sanofi, Esperion, Kowa, Novartis, Ionis Pharmaceuticals, Mylan, Menarini, Merck, Recordati, Regeneron Daiichi-Sankyo, AstraZeneca, Aegerion, Amryt, and Sandoz; and has served as a consultant/on the Advisory Board for Akcea, Amgen, Sanofi, Esperion, Kowa, Novartis, Ionis Pharmaceuticals, Mylan, Menarini, Merck, Recordati, Regeneron Daiichi-Sankyo, Genzyme, Aegerion, and Sandoz. Dr. Coresh has received funding from the NIH and National Kidney Foundation; and has served as an advisor to Healthy.io. Dr. Fowkes has served on the Advisory Board for AstraZeneca. Dr. Muntner has received grants and personal fees from Amgen Inc. Dr. Ribeiro has received partial support by CNPq (310679/2016-8 and 465518/2014-1) and by FAPEMIG (PPM-00428-17). Dr. Zuhlke has received funding by the UK Medical Research Council (MRC) and the UK Department for International Development (DFID) under the MRC/DFID Concordat agreement and the National Research Foundation of South Africa. Dr. Rigotti has served as a consultant to Achieve Life Sciences; and has received royalties from UpToDate, Inc. Dr. Rodgers is employed by The George Institute for Global Health (TGI) and seconded part time to George Medicines Pty Ltd (GM); TGI has submitted patent applications with respect to low-fixed-dose combination products for the treatment of cardiovascular or cardiometabolic disease and is listed as one of the inventors; George Health Enterprises Pty. Ltd. (GHE) and its subsidiary, GM, have received investment funds to develop fixed-dose combination products, including combinations of blood pressure-lowering drugs; GHE is the social enterprise arm of TGI (Dr. Rodgers does not have a direct financial interest in these patent applications or investments). Dr. Sundström holds ownership in companies providing services to Itrim, Amgen,

Janssen, Novo Nordisk, Eli Lilly, Boehringer Ingelheim, Bayer, Pfizer, and AstraZeneca, outside the submitted work. All other authors have reported that they have no relationships relevant to the contents of this paper to disclose.

Indian Journal of Public Health Research & Development

EXECUTIVE EDITOR

Prof Vidya Surwade
Prof Dept of Community Medicine SIMS, Hapur

INTERNATIONAL EDITORIAL ADVISORY BOARD

1. **Dr. Abdul Rashid Khan** B. Md Jagar Din, *(Associate Professor)*
Department of Public Health Medicine, Penang Medical College, Penang, Malaysia
2. **Dr. V Kumar** *(Consulting Physician)*
Mount View Hospital, Las Vegas, USA
3. **Basheer A. Al-Sum,**
Botany and Microbiology Deptt, College of Science, King Saud University, Riyadh, Saudi Arabia
4. **Dr. Ch Vijay Kumar** *(Associate Professor)*
Public Health and Community Medicine, University of Buraimi, Oman
5. **Dr. VMC Ramaswamy** *(Senior Lecturer)*
Department of Pathology, International Medical University, Bukit Jalil, Kuala Lumpur
6. **Kartavya J. Vyas** *(Clinical Researcher)*
Department of Deployment Health Research, Naval Health Research Center, San Diego, CA (USA)
7. **Prof. PK Pokharel** *(Community Medicine)*
BP Koirala Institute of Health Sciences, Nepal

NATIONAL SCIENTIFIC COMMITTEE

1. **Dr. Anju Ade** *(Associate Professor)*
Navodaya Medical College, Raichur,Karnataka
2. **Dr. E. Venkata Rao** *(Associate Professor)* Community Medicine, Institute of Medical Sciences & SUM Hospital, Bhubaneswar, Orissa.
3. **Dr. Amit K. Singh** *(Associate Professor)* Community Medicine, VCSG Govt. Medical College, Srinagar – Garhwal, Uttarakhand
4. **Dr. R G Viveki** *(Associate Professor)* Community Medicine, Belgaum Institute of Medical Sciences, Belgaum, Karnataka
5. **Dr. Santosh Kumar Mulage** *(Assistant Professor)*
Anatomy, Raichur Institute of Medical Sciences Raichur(RIMS), Karnataka
6. **Dr. Gouri Ku. Padhy** *(Associate Professor)* Community and Family Medicine, AII India Institute of Medical Sciences, Raipur
7. **Dr. Ritu Goyal** *(Associate Professor)*
Anaesthesia, Sarswathi Institute of Medical Sciences, Panchsheel Nagar
8. **Dr. Anand Kalaskar** *(Associate Professor)*
Microbiology, Prathima Institute of Medical Sciences, AP
9. **Dr. Md. Amirul Hassan** *(Associate Professor)*
Community Medicine, Government Medical College, Ambedkar Nagar, UP
10. **Dr. N. Girish** *(Associate Professor)* Microbiology, VIMS&RC, Bangalore
11. **Dr. BR Hungund** *(Associate Professor)* Pathology, JNMC, Belgaum.
12. **Dr. Sartaj Ahmad** (Assistant Professor),
Medical Sociology, Department of Community Medicine, Swami Vivekananda Subharti University, Meerut,Uttar Pradesh, India
13. **Dr Sumeeta Soni** *(*Associate Professor)
Microbiology Department, B.J. Medical College, Ahmedabad, Gujarat,India

NATIONAL EDITORIAL ADVISORY BOARD

1. **Prof. Sushanta Kumar Mishra** (Community Medicine)
GSL Medical College – Rajahmundry, Karnataka
2. **Prof. D.K. Srivastava** *(Medical Biochemistry)*
Jamia Hamdard Medical College, New Delhi
3. **Prof. M Sriharibabu** *(General Medicine)* GSL Medical College, Rajahmundry, Andhra Pradesh
4. **Prof. Pankaj Datta** *(Principal & Prosthodentist)*
Indraprastha Dental College, Ghaziabad

NATIONAL EDITORIAL ADVISORY BOARD

5. **Prof. Samarendra Mahapatro** *(Pediatrician)*
Hi-Tech Medical College, Bhubaneswar, Orissa
6. **Dr. Abhiruchi Galhotra** *(Additional Professor)* Community and Family Medicine, AII India Institute of Medical Sciences, Raipur
7. **Prof. Deepti Pruthvi** *(Pathologist)* SS Institute of Medical Sciences & Research Center, Davangere, Karnataka
8. **Prof. G S Meena** *(Director Professor)*
Maulana Azad Medical College, New Delhi
9. **Prof. Pradeep Khanna** *(Community Medicine)*
Post Graduate Institute of Medical Sciences, Rohtak, Haryana
10. **Dr. Sunil Mehra** *(Paediatrician & Executive Director)*
MAMTA Health Institute of Mother & Child, New Delhi
11. **Dr Shailendra Handu,** *Associate Professor,* Phrma, DM (Pharma, PGI Chandigarh)
12. **Dr. A.C. Dhariwal:** *Directorate* of National Vector Borne Disease Control Programme, Dte. DGHS, Ministry of Health Services, Govt. of India, Delhi

Print-ISSN: 0976-0245-Electronic-ISSN: 0976-5506, Frequency: Quarterly (Four issues per volume)

Indian Journal of Public Health Research & Development is a double blind peer reviewed international journal. It deals with all aspects of Public Health including Community Medicine, Public Health, Epidemiology, Occupational Health, Environmental Hazards, Clinical Research, and Public Health Laws and covers all medical specialties concerned with research and development for the masses. The journal strongly encourages reports of research carried out within Indian continent and South East Asia.

The journal has been assigned International Standards Serial Number (ISSN) and is indexed with Index Copernicus (Poland). It is also brought to notice that the journal is being covered by many international databases. The journal is covered by EBSCO (USA), Embase, EMCare & Scopus database. The journal is now part of DST, CSIR, and UGC consortia.

Correlation between Type of Diet and Periodontal Parameters

Harshit Atul Kumar[1], Neetha J Shetty[2]

[1]Former Student, Manipal College of Dental Sciences, Mangalore, Manipal Academy of Higher Education,
[2]Associate Professor, Department of Periodontology, Manipal College of Dental Sciences, Mangalore, Manipal Academy of Higher Education

ABSTRACT

Introduction: Investigations about the Correlation between type of diet and periodontal parameters are very few and with less sample size. The main objective of this study was to establish the possible co-relation between type of diet and Wear patterns (erosion, abrasion, attrition) periodontal status (gingival index, periodontal pocket depth), plaque index and oral health parameters along with the help of questionnaire survey.

Materials and Method: Sample sizes of 260 healthy male and female subjects within the age group of 18-50 years were equally distributed into vegetarians and non-vegetarian groups. Clinical checkup will include examination of all the parameters. A questionnaire has been prepared for the participants for assessing the oral habits, dietary habits and the knowledge of oral health care. Statistical analysis of the data was conducted using pearson chi-square tests

Results: Periodontal findings comparing both the groups were not statistically significant. In the questionnaire survey, it was found that halitosis was greater in non-vegetarians when compared to vegetarians which were statistically significant. The remaining findings were not statistically significant.

Conclusion: Type of diet does not really affect the periodontal status of an individual. Both vegetarians and non-vegetarians show almost same level of gingival index, plaque index and periodontal pocket depths with dental education slightly lower in non-vegetarians than vegetarians with equal amount of regular dental visits. However, with proper oral hygiene procedures such as vertical brushing, brushing twice daily, using interdental aids and regular dental visits alone one can maintain good periodontal health regardless of diet being followed.

Keywords: *Vegetarian, Non-vegetarian, Periodontal parameters, full mouth examination, questionnaire, wasting diseases*

INTRODUCTION

Relation between diet and oral health is the most basic and often controversial subject and also there are increasing number of individuals complaining about oral health. Eating habits in developed and developing countries have changed in recent years. Various food stuffs have been introduced into diet that previously did not form a part of nutritional choices. This has resulted in an enrichment of daily diet, with the opportunity to vary foodstuffs more often and moreover this has led to the assumption, at least apparently, of wider spectrum of nutrients required for the wellbeing of the body.[1]Considering the relevance of effects of diet and food habits on oral health care, recent research reports have showed an actual co-relation between diet with that of parameters such as erosion ,attrition ,abrasion

,gingivitis, periodontal status, amount of plaque etc. To understand this relation and promote better oral health ,better knowledge of diet is very important.

However, there is a lack of established facts and knowledge with regard to the concerned co-relation of diet and oral health parameters[2]. The purpose of this clinical study was mainly to understand and establish a better pathway to improve oral hygiene among the people in society with different food habits.

MATERIALS AND METHOD

Sample size of 260 healthy male and female subjects within the age group of 18-50 years, equally distributed in both the groups (vegetarians and non-vegetarians) respectively have participated in this study. Taking into consideration the possible risk factors affecting the parameters taken for the study, the exclusion criteria were: subjects with medical disorders, undergoing antibiotic or other anti-microbial therapy.

The inclusion criteria were subjects who were smokers and alcoholics. The subjects received verbal and written information about the study.

This study was a randomized controlled clinical study which included 260 participants, divided into two groups. Clinical checkup included examination of the following parameters: wearing of teeth, plaque index, periodontal status apart from which also the other parameters like color of gingiva, depth of periodontal pockets if present, gingival inflammation, bleeding on probing, number of decayed, missing teeth ; that is a full mouth assesment[2].A questionnaire was prepared for the participants for assessing the habits and the knowledge of oral health care among them. This was also done to sub categorize participants under the major study groups to narrow down the results obtained to a more accurate conclusion.

Baseline data on the medical history and previous hospital visits of the participants was recorded to minimize the factors affecting the results of the study and maintain the exclusion criteria. The participants were asked to answer the questionnaire.

Following this, clinical check-up was done on subjects for all the parameters included in the study using mouth mirror, an explorer and a periodontal probe[2]. The subjects were examined mainly for plaque to calculate plaque index, periodontal status, wearing of teeth which included abrasion, attrition and erosion and also for other parameters such as gingival inflammation, bleeding on probing and depth of gingival pocket.

Based on the clinical check-up the participants were asked to undergo dental treatment if needed or advised to take necessary oral prophylactic measures.

Clinical assessment of plaque index and gingival index was performed on four sites (buccal, lingual, mesial, distal) of the six key teeth (FDI tooth number 16,12,24,36,32,44) according to Loe H & Silness J. [3-6]. Each of the sites was given a score from 0-3 depending on the severity of the gingival condition.

Periodontal pocket depth and clinical attachment loss was recorded using William's graduated periodontal probe

STATISTICAL ANALYSIS

The calculation of the sample size was carried out using nQuery Advisor 6.0 (Statistical Solutions, Saugas, MA, USA). The analysis showed that a sample size of 160 in each group had a power of 80%. The recorded data were documented and analysed by the data procession program SPSS 17.0 for Windows (SPSS, Chicago, IL, USA).

RESULTS

In this study, 130 healthy male and female subjects aged 18-50 years for both the groups were included as participants. The prevalence of smoking and alcohol consumption was statistically similar in both the groups, with the non-vegetarian group being slightly greater.

Mean and range values of periodontal parameters are presented in table-1. There was greater probing depth in the vegetarian group compared to the non-vegetarian group, which was statistically not significant. While comparing the plaque index, it was higher in the vegetarian group and was statistically non-significant. But, even though statistically non-significant, the gingival index was seen to be a little greater in the non-vegetarian group when compared to the vegetarian group.

Table-1: Results of T-test for plaque index, gingival index and probing pocket depth among vegetarians and non-vegetarians

	1. DIET	N	Mean	Std. Deviation	t	df	P VALUE
PI	VEGETARIAN	129	1.22062	0.473661	1.299	258	0.195
	NON VEGETARIAN	131	1.14313	0.487665			
GI	VEGETARIAN	129	1.02744	0.560884	-0.173	258	0.863
	NON VEGETARIAN	131	1.03977	0.588518			
PPD	VEGETARIAN	129	2.7669	0.677827	0.506	238.97	0.614
	NON VEGETARIAN	131	2.71626	0.920669			

The wear pattern was not same among both the groups. Vegetarians had greater amount of attrition as compared to non-vegetarian group out of which occurrence of generalized attrition was found more in non-vegetarians. The cervical abrasion was more in non-vegetarian group as compared to vegetarians. This was also associated with the increased horizontal technique of brushing seen in non-vegetarian group.

Analysis of questionnaire showed that vegetarians and non-vegetarians had similar frequency of oral hygiene maintaining practices. It revealed that both the groups had similar number of dental visits. The brushing technique among the non-vegetarian group was more of horizontal technique when compared to the vertical technique used by vegetarian which was statistically significant. Also another statistically significant finding in the questionnaire was that halitosis was a more common complaint among the non-vegetarian group when compared to the vegetarian group. Level of dental education was about the same in both the groups apart from the type of brushing.

DISCUSSION

The effects of a vegetarian diet on systemic diseases like cancer, type 2 diabetes and coronary heart diseases have been studied by various authors and revealed predominantly less systemic diseases in vegetarians.[8,9]. Studies investigating correlations between vegetarianism and oral health are rare. Most authors assessed dental parameters or performed a saliva test.[10-14] In this study, emphasis on effect of diet on periodontal parameters is given. A very few studies have shown effect of diet on periodontal parameters as most of them compare oral health care among vegetarians and nonvegetarians.[15-18] Also, the studies done earlier have a comparatively smaller sample size (20-60), whereas this study has a significant sample size (n=130).

In addition, this study along with investigation of plaque score, gingival status, wear pattern have also gathered data regarding brushing technique, oral habits (smoking, alcoholism), oral hygiene practices, level of dental education and oral health problems via a multiple choice based questionnaire.

Our data indicates plaque index is slightly higher in vegetarian compared to non-vegetarian but it is not statistically significant. In our study the gingival index among non-vegetarians is slightly greater than vegetarians, yet statistically not significant. Since both the interrelated indices are inconsistent in both the groups and are almost similar, we believe that type of diet does not affect the periodontium in further causing gingivitis or periodontitis. In contrast a recent study by I Staufenbiel et al [2] in 2013 showed that gingival inflammation was significantly lesser in vegetarians. In addition, a study by Linkosalo et al.[16] revealed less bleeding on probing in vegetarians.

There are several pathways, which may lead to less inflammatory signs. Generally, vegetarians show more physical activity and a lower BMI. Hence, the prevalence of obesity, which may cause an increased local inflammatory response is lower. [19] Additionally, vegetarians consume a higher amount of antioxidants, which improves immune response, [20] and may lead to less inflammation.

Second, according to our study the average periodontal pocket depth in vegetarians was slightly higher than non-vegetarians. This is explained by the gingival score for vegetarians which was found slightly higher suggesting the presence of plaque causing slight loss of attachment, increasing the pocket depth. This may suggest chance of developing periodontal destruction irrespective of the type of diet and both vegetarians and non-vegetarians are equally susceptible to periodontal destruction. This is in contrast to the importance of an adequate nutrition for a healthy periodontium which was documented by Jenzschet al.[21]They demonstrated that solely a dietary change from non-vegetarian to vegetarian, according to the recommendations of Korber et al.[22]leads to better periodontal conditions. Jenzsch et al.[21] showed that 1 year after a dietary change without affecting dental hygiene and without dental therapy, patients had lower PPDs, less inflammatory signs and lower concentrations of interleukin-1β and interleukin-6 in the gingival crevicular fluid.

Third, the wear pattern observed among both the groups revealed that generalized attrition was more prevalent in non-vegetarians compared to vegetarians, but attrition of selected teeth was more common in vegetarian group. However, prevalence of cervical abrasion was notably greater in non-vegetarians than vegetarians. The potential etiological factors for such non-carious cavities are not very clear but it can be attributed to improper horizontal brushing technique. Interestingly, increased use of horizontal brushing technique in non-vegetarians was seen which was statistically significant.

This is in contrast to the recent study report given by Herman et al in 2011[1, 15], stating that vegetarians are more susceptible to non-carious cavity. He reported horizontal brushing technique is more in vegetarians than in non-vegetarians to his conclusion. In contrast, other authors could not find a different prevalence of erosion between vegetarians and non-vegetarians. Herman et al. [23] evaluated the prevalence of erosion and the consumption of acidic products in vegetarians and non-vegetarians. Regarding the prevalence of erosion, they could not show significant differences between the groups, although a significantly more frequent consumption of acidic products was observed among vegetarians.

Questionnaire analysis revealed equal level of dental education among both the groups and also similar frequency of regular dental visits. In contrary to this, various authors have showed higher level of dental education in vegetarians [24, 25] and also several studies have reported a lower use of prescription medications and health services by vegetarians.[25]. Statistically significant finding obtained from questionnaire reveals greater horizontal brushing in non-vegetarian group, this can be co-related to the increased amount of cervical abrasion seen in non-vegetarian group than in vegetarian group. This gives us quite a clear picture of how dental education is related to brushing technique which if faulty may cause cervical abrasion as seen in the non-vegetarian group.

Another statistically significant result from the questionnaire tells us halitosis was more common in non-vegetarians, which could probably arise because of the basic biochemical degradation of major component which constitutes an individual's diet. Meat being rich in protein undergoes putrefaction unlike carbohydrate that undergoes decomposition. Vegetarians usually tend to have high carbohydrate and low protein diet. When the results of smoking and alcoholism were matched in between vegetarians and non-vegetarians, both the group had similar distribution of smokers and alcoholics. This is in contrary to a study which states that Vegetarians consume less tobacco and alcohol, are physically more active and have a lower BMI compared with nonvegetarians.[21, 22]

CONCLUSION

Type of diet does not really affect the periodontal status of an individual. Both vegetarians and non-vegetarians show almost same level of gingival index, plaque index and periodontal pocket depths with dental education slightly lower in non-vegetarians than vegetarians with equal amount of regular dental visits. However, with proper oral hygiene procedures such as vertical brushing, brushing twice daily, using interdental aids and regular dental visits alone one can maintain good periodontal health regardless of diet being followed.

The Effect of Kitchen Table Exercise Program on Strength, Balance and Functional Mobility in Elderly Population

Kiran K Kamble[1], Smita B Kanase[2], Khushboo Bathia[2]

[1]Physiotherapist, Faculty of Physiotherapy, KIMS 'Deemed to be' University, Karad, Maharashtra, India,
[2]Assistant Professor, Department of Musculoskeletal Sciences, Krishna College of Physiotherapy, KIMS 'Deemed to be' university, Karad, Maharashtra, India

ABSTRACT

Background: The elderly population is the population of 60 years old and above and they are considered as a targeted population. This targeted population is more prone for risk of falls due to strength and balance dysfunction. So this study is conducted to improve this dysfunction with Kitchen table exercise program.

Objective: To find the effect of Kitchen Table Exercise Program on strength, balance and functional mobility in elderly population.

Materials and Method: 60 Subjects with 60 years of age and above included in the study. Subjects were divided into the two groups 30 in each group. Group A received the Kitchen table exercise program and Group B received conventional exercises. Both groups received 12 weeks of exercise program. In pre interventional assessment strength was taken by 1 RM; Balance was taken by Berg Balance scale and Functional mobility by Elderly mobility scale. Post interventional assessment was taken by the same outcome measures after 6th and 12th weeks of intervention.

Result: Both the groups showed improvement in the strength, balance and functional mobility. But the group A is improved in comparison with group B ($P<0.0001$)

Conclusion: The kitchen table exercise program can improve strength, balance and functional mobility in elder population.

Keywords: *Kitchen Table Exercise Program, Strength, Balance, Functional mobility, elderly population.*

INTRODUCTION

India has acquired label of an ageing nation with 7.7% of its population being more than 60 years old. The population of 60 years old and over are considered as elder people.[1-2] As the age advances the risk of fall increases[3-5]. Around 25%- 35% of older population are prone to fall i.e., one or more falls every year[4-7]. Strength of muscle decreases as the age advances and in older individual's activities become much harder (lifting a bag of groceries) or may not be able to perform activity without assistance. Impairment of muscle strength leads to falls (impairment in balance) and functional inability.[8] The muscle mass decrease by 50% between the age group of 20-90 years. This results in decline in strength which correlates with increased risk of fall[9]. Factors contributing to loss of balance are intrinsic and extrinsic factors. Intrinsic factor includes change in muscular strength.[10, 11]. Important parameter of balance performance includes range of motion, muscle strength, somatosensory function and the size and the quality of the base of support.[12-14] Rehabilitation of balance can work on static or dynamic balance. Dynamic balance is the ability to maintain balance while body is in motion and it keeps the centre of gravity over the base of support[15].

Mobility is nothing but the physical ability to move. The first signs of decreasing mobility are mostly observed for more demanding mobility tasks, such as walking longer distances.[16] Environmental barriers and reduction in physical activities shows increased in level of mobility decline. Environmental barriers directly relates with fear of falling and moving outside which produces avoidance of outside activities[17]

Regular exercise has been shown to improve and maintain muscle strength and to improve mobility and balance in elderly individuals.[18] The rehabilitation of this targeted population should include a simple and understandable exercise program.

The current study is conducted with the same objectives to solve the above age related problems and make the older individuals independent in their functional activities. The kitchen table exercise program is designed to address the components of strength, balance and functional abilities. The Kitchen table exercise program is the simple exercise program.

But the effectiveness of this exercise program is still not studied in older population. So this study is conducted with an aim to find the effectiveness of KTE program on targeted population of community.

MATERIALS AND METHODOLOGY AND PROCEDURE

The study was conducted at Krishna Institute of Medical Sciences, Physiotherapy OPD, Karad. The Ethical clearance was taken from Institutional Ethical committee prior to the start of treatment. The subjects were taken as per the inclusion and exclusion criteria. The inclusion criteria was both male and female of 60 years of age and above having Berg balance scale score less than 45 and who were willing to participate was taken. Subjects with cardiac diseases, who have undergone recent surgeries and traumatic conditions, were excluded. An informed consent was taken from the subjects selected for the study.

The random sample of 60 subjects was studied in this experimental study. These subjects were divided into 2 groups with simple random sampling method. Group A was experimental group with the mean age of 69.86±6.42 years while the group B was an control group with a mean age of 71.9±6.68. Group A had a Kitchen table exercise program i.e., Sit to stand, Plantarflexion and Dorsiflexion, Weight bearing exercises, Standing with feet apart, Weight shifting exercises and Clock exercises.The group B was a control group.They were given conventional treatment of free exercises, Reach out exercises, Balance board exercises, Walking and Resisted exercises.

The pre treatment and post treatment assessment was done by outcome measures like 1 RM, Berg Balance Scale and Elderly mobility Scale.

Data analysis -The statistical analysis of 1 RM, Berg Balance Scale and Elderly mobility Scale was done by repeated measure anova test.

1) 1 Repetition Maximum:

Table 1: Comparison of pre and post 1 RM score within the group

	PRE	POST 6thWeek	**POST 12thWeek**	**P VALUE**	**F VALUE**	**INFERENCE**
GROUP A	28.73± 4.54	32.6±4.64	36.66±4.69	<0.0001	1011.7	Extremely significant
GROUP B	29.3 ±3.33	30.6±3.28	32.13±3.17	<0.0001	119.8	Extremely significant

In the Group A, the P value by repeated measure anova test was found to be <0.0001 which was extremely significant. In Group B, the P value by repeated measure anova test found to be <0.0001 which was extremely significant.

2) BERG BALANCE SCALE:

Table No.2: Comparison of pre and post Berg balance score within the group

	PRE	POST 6TH WEEK	POST 12THWEEK	P VALUE	F VALUE	INFERENCE
GROUP A	41.36±1.77	45.43±1.94	50.13±1.87	<0.0001	654.38	Extremely significant
GROUP B	41.7±2.20	43.56±1.97	45.2±2.09	<0.0001	296.85	Extremely significant

In the Group A The P value by repeated measure anova test was found to be <0.0001 which was extremely significant. In Group B, the P value by repeated measure anova test was found to be <0.0001 and which was extremely significant.

3) ELDERLY MOBILITY SCALE

Table No. 3:Comparison of Pre and Post ELDERLY MOBILITY SCALE score within the group

	PRE INTERVENTION	POST INTERVENTION 6TH WEEK	POST INTERVENTION 12TH WEEK	P VALUE	F VALUE	INFERENCE
GROUP A	10.56±1.16	13.76±1.07	17.03±0.92	P <0.0001	1046.8	Extremely significant
GROUP B	10.23±0.89	11.73±0.82	13.2±1.09	P < 0.0001	338.49	Extremely significant

In Group A, the P value by repeated measure anova test was found to be <0.0001 which was extremely significant. In Group B, the P value by repeated measure anova test found to be <0.0001 which is extremely significant.

RESULT

The Kitchen table exercise program i.e., Group A showed extremely significant improvement than the Group B which was controlled group.

DISCUSSION

This study was conducted in the elderly population of 60 years of age and above to determine the effect of kitchen table exercise program on strength, balance and function mobility. In this study, 60 subjects had participated who were screened as per the inclusion and exclusion criteria and analysed as per the pre test outcome measures out of which 35 were male subjects and 25 were female subjects. The mean age of subjects included in Group A was 69.86 and in Group B was 71.9 out of 60 subjects, this was statistically not significant. Subjects were analysed and were divided into two groups according to random sampling method. 30 subjects were included in Group A and were received Kitchen table exercise program. The treatment protocol was continued for 12 weeks. Similarly, 30 subjects were included in Group B and were received conventional exercises for strength, balance and functional mobility and the treatment protocol was continued for 12 weeks.

Pre and post treatment outcome measures for strength, balance and functional mobility was done with 1 Repetition maximum, Berg balance scale and elderly mobility scale. The specific treatment protocol was followed for 12 weeks.

Kitchen Table Exercise program is designed to be a self directed exercise program. The program consists of six levels and each level contains six exercises. The exercises are specifically designed to address components of strength, balance and functional mobility. The purpose of present study was to find out effect of Kitchen Table Exercise program on strength, balance and functional mobility in elderly people.These exercise program consists of various closed kinematic chain exercises, weight bearing exercises.

According to various studies it was analysed that closed kinematic exercises may help in improving quality of life of elder population. This study aims to improve quality of life of oldersubjects. In this study treatment protocol was given for twelve weeks. As this program consists of six levels each level of exercises were given for two weeks.

I ntra group comparison (within group) was analysed by repeated measure anova test for 1 Repetition Maximun, Berg Balance Scale and Elderly mobility Scale. This showed that there was extremely significant difference of Group A 1 RM score with (P<0.0001). Berg Balanve Scale scores was also extremely significant with (P<0.0001). Elderly Mobility Scale score shows extremely significant difference with (P<0.0001).

Similarly, In Group B, there was extremely significant difference of 1 RM with (P<0.0001) respectively. Berg Balance Scale score was also extremely significant with (P<0.0001). Elderly Mobility Scale score was also extremely significant with (P<0.0001).

In this study, an attempt was made to improve strength, balance and functional mobility. Improvement of subject on 12th week i.e. after the treatment program gets over.

The subject could perform exercise without support.

There could be improvement in balance in subject.

There was reduction in symptoms in both the groups but the reduction of symptoms was more in group A then group B.

The muscle strength increases consistently through gradual resistance exercises.[19,20]The body reacts to new positions based on the changes in the base of support.[12,13] Hence, various exercises such as open chain and closed kinematic exercises are used to improve balance.[21,22,23] Regular resistance exercise improve muscle function. Increases strength after damage and it prevents decline in muscle strength despite aging.[24,25]

In conclusion, the result of current study shows that Kitchen table exercise program ismore significant than routine exercise program for strength, balance and functional mobility in elderly people. Further studies can be done for longer duration of treatment protocol in order to determine the long term effect of this program.

CONCLUSION

Different approaches are used for improvement of the strength, balance and functional mobility in elderly people but this study concluded that the Kitchen Table Exercise program was more effective than the conventional routine exercises in improvement of the strength, balance and functional mobility and improving quality of life.

Hence, It is proved that Kitchen Table Exercise Program has significant effect in elderly population.

Ethical Clearance: Ethical clearance was taken from institutional ethical committee of KIMSDU, Karad

Is Dietary Management is Essential for Gallbladder Diseases? A Review based on Available Literature

Sahil George Lal[1], K. Chithra[2], Nageshwar V[3]

[1]M.Sc. Nursing 2nd Year Student, [2]Associate Professor, [3]Assistant Professor,
Teerthanker Mahaveer College of Nursing, TMU, Moradabad, U.P

ABSTRACT

BACKGROUND: In biliary system, Gall bladder diseases (GBD) are the most common disorder, and most of the cases are asymptomatic. It is also one of the most common diseases affecting 10-15 % of Caucasian adults (racial group having light-colored skin; white) in developed countries have GBD.

OBJECTIVE: To explore the evidence on patients' knowledge on common gallbladder diseases, as well as their practice regarding dietary management of GBD.

METHOD: Pub Med and EBSCO were searched for reviews on knowledge and practice regarding dietary management among patients affected with GBD.

RESULTS: The accessible literature refines to get 7 qualitative studies. In this narrative review, 6 research studies supported that dietary management is helpful in gallbladder diseases and may provide proper health, if it is followed. 1 research study shows that there is no remarkable result of low-fat diet in the prevention of gastrointestinal symptoms and specially gallstones.

CONCLUSION: Gallbladder diseases can not only be treated with medicines, but it actually requires dietary management so that it can be treated with diet.

KEYWORDS: *knowledge, practice, dietary management, patients, gallbladder diseases.*

INTRODUCTION

A gallbladder disease is one of the highest common gastrointestinal disorders, which result from a complex synergy of genetic and environmental factors. At present, it assumed as a big cause of abdominal morbidity, which greatly increase hospital admissions in the developing countries. In developed population of North India, its degree is 7.4%.where as in cadavers, it was only 6.3%. In some studies, the incidence of GBD in the Iranian men and women is quite low between the age group of 31-40 years. It increases sharply in men older than 60 years and women older than 50 years to more than ten-fold (12.5 and 24.6% in males and females 71-80 years respectively).

NEED FOR THE STUDY

GBD is a common medical condition, one among which is Cholelithiasis (formation of stone in the gallbladder), Cholecystitis (infection and inflammation of gallbladder) and Choledocholithiasis (formation of stone in the common bile duct). Regarding diet as an vital environmental agent, mounting cue in nutritional epidemiology commends that pattern assay is the most realistic approach to assess the associations between overall diet and health or disease. **Stinton and Shaffer, (2012)**, in their study showed that up to 80 % of cases are asymptomatic. **Amaral and Thompson, (1985); Erlinger,** state that diet is the most common risk factors for gallbladder disease specially high intake of energy leads to obesity where as high fat will increase the risk for GBD.

Gall bladder diseases are genuine and their vogue increases greatly with age; it is also decided by gender, body weight, and race. Gall bladder disease does not account serious notes such as colic and jaundice. Generally, gall bladder diseases are extensively cured by

cholecystectomy, and most of the cases are executed by laparoscopy.

https://www.ncbi.nlm.nih.gov/pmc/articles/PMC1116086/

AIM OF THE STUDY

To identify the knowledge of the patients affected with gallbladder disease regarding the dietary management.

OBJECTIVE: To explore the evidence on patients' knowledge on common gallbladder diseases, as well as their practice regarding dietary management of GBD.

METHODOLOGY

Search strategy methods-

An electronic search of articles published in various journals has been done. Search was restricted to only English language.

The database search was PubMed and EBSCO.

Types of Studies- Cohort study, Case-control study, Phenomenological approach, Prospective analytical single center study, Randomized clinical trial, Descriptive study.

Types of Participants- Patients suffering from GBD.

Settings- Government and private hospitals.

For this narrative review, articles were searched on Pub Med and EBSCO, using keywords such as knowledge, practice, dietary management, patients, and gallbladder diseases. During initial search **13447** titles were retrieved andnumber of records screened after duplication were**12660** and rest **787** records were excluded. **35** records screened and records excludedwere **12625,** full text articles assessed for eligibility were**14.** Full text articles excluded due to irrelevant content and subscription were **21** and finally**7** studies included in qualitative synthesis.

Outcome: The outcomes from these studies clearly focus to the understanding about the knowledge and practice of gallbladder disease patients regarding their dietary management and up to which extent it is essential. Knowledge and practice of dietary management plays an important role in gallbladder disease patients.

DISCUSSION

According to **Gonzalez et.al, 2014,** the finding showed that abdominal adiposity**,** insulin resistance, obesity and nutritional factors such as higher intake of total energy, fats, sugar and long fasting periods are the cause of gallstone formation while satisfactory fiber intake in diet is a protective factor.[1]

According to **Menezes et.al, 2013**, it was observed that there was permanence, appearance or disappearance of symptoms postoperatively.[2]

As per the study of **Kim E and Lee Y, 2012**, it shows that there is a little association that dietary habits are related with cholesterol gallstone formation.[3]

According to **Johansson et.al, 2014**, the study suggested that Gall stones can be treated in the primary care, at home which are less serious for the patient as well as cheap for the society.[4]

As per the study conducted by **Jyi Tsai et.al, 2014**, the results suggested that high intake of vegetable protein can decrease the complication of cholecystectomy in women.[5]

According to **Bansal A et.al, 2014**, 43.56 years is the average of the clients with the ratio of 0.52:1 for male and female respectively In this study, fused type of regime, and multiple gallbladder calculi was observed.[6]

According to **Jessri and Rashidkhani, 2015**, dietary pattern system gives data related to the disease and dietary.[7]

Ethical Consideration:

This manuscript is ethically considered by the panel of Teerthanker Mahaveer College of Nursing, Teerthanker Mahaveer University after discussing with each and every point of this manuscript

Summary of Findings:

Out of 7 articles, 6 research studies supported that dietary management is helpful in gallbladder diseases and may provide proper health if it follow in appropriate manner.

Importance in Education:

Education is an important part for every individual not only to learn the facts about different aspects but

also to apply the facts in our life and more over that to follow them in daily routine in order to get a better life. Like the same way this review suggests that having a good dietary knowledge as well as practice during the gallbladder diseases is an essential part to follow in order to maintain a healthy lifestyle. Appropriate knowledge leads to better health which comes only with the education.

Future Significance:

It's always easier to prevent a problem rather than treat it, and this is especially true when it comes to the gallbladder problems.

Limitations:

- Computerized data bases were limited.
- Limited to only in pregnant women.

Strength:

- Article search was carried out on a significant problem
- Review could find out the gap in knowledge and practice on dietary management of patients affected with gallbladder diseases.

Weakness:

- Articles mainly focus on only knowledge and practice regarding dietary management.
- Only 7 qualitative articles were included for data synthesis due to limitations.

CONCLUSION

A healthy regime deals with a converse coalition with gallbladder disease. As a result, these data need to be acknowledged in future prospective studies for etiological purposes in both men and women to draw more deciding events. High intake of vegetable protein can reduce the effect of cholecystectomy in females.

Community Satisfaction Index as an Evaluation of Health Services Quality

Panjumi Khorida[1], Imas Sayyidati Hadidah[1], Nyoman Anita Damayanti[2]

[1]Student of Health Policy Administration Program Study, Faculty of Public Health, Airlangga University, Indonesia, [2]Lecturer of Health Policy Administration Program Study, Faculty of Public Health, Airlangga University, Indonesia

ABSTRACT

Quality control of service is the most important part in health service, so that the measurement of patient satisfaction level is absolute in effort to improve health service quality. Through these measurements, it can be known to what extent the dimensions of health services quality that have been held to meet patient expectations. This research aims to find out the result of community satisfaction index as an evaluation of health service quality in Brondong Primary Health Care of Lamongan Regency, using 9 elements taken from Permenpan Number 16 year 2014. The data were taken by observation with cross sectional study design using questionnaires analyzed descriptively. Samples were taken using Slovin formula, so that the respondent obtained 394. The measurement result shows that in general the quality of Brondong Primary Health Care of Lamongan Regency service is included in good category with CSI value of 3,050. However, when each element be viewed, there are still three elements with the lowest of community satisfaction index value indicating that there are still people who feel less satisfied with the service in Brondong Primary Health Care of Lamongan Regency. The three elements that have the lowest of community satisfaction index value are the element of service time, the service announcement, and the handling of complaints, suggestions, and inputs of the community. Therefore, this research suggests in Brondong Primary Health Care of Lamongan Regency needs to improve the quality, especially on the three elements with the lowest of community satisfaction index value.

Keywords: *community satisfaction index, health service quality.*

INTRODUCTION

The role and function of Primary Health Care in the implementation of Community Health Efforts and Individual Health Efforts should always pay attention to the needs of the community as a service user. In addition, it is necessary also the input and evaluation of the performance of Primary Health Care for use in efforts to improve and improve the service quality. Therefore, a system is required to get an analysis of community needs and expectations and feedback on Primary Health Care performance.

Patient satisfaction is a level of patient feeling that arises as a result of the health service performance it receives after the patient compares it to what they expect. The new patient will feel satisfied if the performance of health services obtained equal or exceeded the expectations and on the contrary, dissatisfaction will arise or the patient's disappointment will occur if the performance of health services obtained was not as expected[1].

To measure the level of patient satisfaction is not easy, because the effort to obtain the necessary information to measure the level of satisfaction of the patient will be faced with a cultural constraint, so that, there is a tendency of people who are reluctant or unwilling to express criticism, especially to government health service facilities. Service user satisfaction determines the next option, willing to keep using the service or move to another health facility.

Quality is a service that can meet customer expectations and understand customer needs in the future[2]. The quality of health services is the application

of medical science and technology to maximize health benefits without an increased risk[3]. Furthermore, the good quality of health services when patients are served with appropriate services, both in terms of competent way of serving, good communication, decision making together and cultural sensitivity[4]. Quality has an abstract concept[5]. The concept of abstract quality leads to the definition of quality depending on the perspective of each individual[4].

Previous research conducted by Analysis of the Effect of Patient Perception about Quality of Doctor Service on Patient Loyalty in Public Policlinic of Outpatient Care Installation of Panti Wilasa Citarum, Semarang Hospital in 2008, the result of the research shows there is a significant influence between medical technical skill, attitude, the delivery of information, the timeliness of service, and the availability of the doctor's consultation time on patient loyalty[6].

Brondong Primary Health Care as a public service provider is also responsible for carrying out the mandate from Permenpan and RB Number 16 Year 2014 on Guidelines for the Implementation of Public Satisfaction Survey of Public Service to obtain a Public Satisfaction Index nationally.

There are 9 elements or indicators to assess the satisfaction of society according as follows: The first element (E1) is a requirement to get service. In this element how society assess their easiness in fulfilling technical and administrative requirement to get service at government institution. Second element (E2) is the service procedures, in this element society assess the service unit of government institution based on society ease in comprehending service or procedure in the unit. The Third element (E3) is the service time, the duration in completing the service that has been determined by the service provider facilities and the accuracy of the schedule that has been determined. The fourth element (U4) is the cost/service tariff, here how the community assess the fairness and affordability of the service fee. The fifth element (E5) is a type of health service, where the community assesses the type of health services in health facilities is in accordance with the needs of the community. The sixth element (E6) is the competence / skill of the officer, where the aspect seen by the community is the skill and skill of the officer in providing the service. The seventh element (E7) is the behavior / attitude of the officers, hospitality and courteous of service providers in providing services to the community is an important point assessed by the community. The eighth element (E8) of the services ministry, which assessed is the ability of PHC officers to serve according to the standards. The ninth element (E9) is a tool for complaints of suggestions and input from the community as well as follow-up[7].

This study aims to determine the community satisfaction index as an evaluation of health services quality of Brondong Primary Health Care of Lamongan Regency in year 2017.

MATERIAL AND METHOD

The method of this research was an observational study with cross sectional study design used questionnaires analyzed descriptively. Data was collected in 2017 at Brondong Primary Health Center, while the population in this study was all patients who visited Brondong Primary Health Center for 1 year. Sampling in this study has been used Slovin formula with a fault tolerance of 5%, so that obtained 394 respondents.

Respondents were interviewed with questionnaires. The questionnaire contains questions about the level of patient satisfaction based on the elements of community satisfaction on Guidelines for the Implementation of Public Satisfaction Survey of Public Service.

The data that have been obtained, was processed in the way has been adopted from Kepmenpan Number Kep / 25 / M.PAN / 2 / 2004, on General Guidelines for Preparation of Public Satisfaction Index of Government Services Unit. Stages of data processing are as follows: First, Determine the value of weighted mean with the following formula:

$$\textbf{Weighted mean value} = \frac{The\ Sum\ of\ Weight}{The\ Sum\ of\ Elements} = \frac{1}{9} = 0{,}111$$

Second, determine the mean value per service element by:

The value per service element be summed up then divided by the number of respondents

Third, determine the weighted mean value of each element service by:

The mean value per service element is multiplied by the weighted mean value

Fourth, Calculation of Community Satisfaction Index of Service Unit, by adding 9 (nine) elements of weighted mean value

Table 1. Perception values based on The Calculation fo Community Satisfaction Index[8]

Perception Value	CSI Interval Value	CSI Conversion Interval Value	Quality of Services	Criteria of Performance
Dissatisfied (1)	1,00 – 1,75	25,00 – 43,75	D	Not Good
Less Satisfied (2)	1,76 – 2,50	43,76 – 62,50	C	Less Good
Satisfied (3)	2,51 – 3,25	62,51 – 81,25	B	Good
Very Satisfied (4)	3,26 – 4,00	81,26–100,00	A	Very Good

RESULTS AND DISCUSSION

Based on interviews with the help of questionnaires to 394 respondents who were patients who visited Brondong Primary Health Care, the result of Community Satisfaction Index based on the calculation that has been adopted from Kepmenpan Number Kep / 25 / M.PAN / 2 / 2004 can be seen in table 2 below.

Table 2. Calculationf of Community Satisfaction Index in Brondong Primary Health Care in 2017

Element	1	2	3	4	Amount	Weight per elements	Mean Value per elements	Weighted Mean per elements
E1	2	25	316	51	1204	0.111	3.056	0.340
E2	0	27	318	49	1204	0.111	3.056	0.340
E3	1	36	324	33	1177	0.111	2.987*	0.332*
E4	0	23	331	40	1199	0.111	3.043	0.338
E5	1	24	320	49	1205	0.111	3.058	0.340
E6	0	24	316	54	1212	0.111	3.076	0.342
E7	0	24	306	64	1222	0.111	3.102	0.345
E8	1	24	331	38	1194	0.111	3.030*	0.337*
E9	0	27	324	43	1198	0.111	3.041*	0.338*
CSI value								3.050

NOTE - * The lowest value element

The Table 2. above Indicts that the patient satisfaction index with the quality of health service in Brondong Primary Health Care in Lamongan Regency is 3.050. If that refers to the quality of service category from Kepmenpan Number Kep / 25 / M.PAN / 2/2004, so that the health service quality of Brondong Primary Health Care of Lamongan Regency is included in category B, which means that health service quality of Brondong Primary Health Care was good.

Elements that have the highest satisfaction value is the seventh element that is the behavior / attitude of the officer with the value of Community Satisfaction Indeks (CSI) of 3.102 are included in the good category. Friendliness and courteous service providers in providing services to the community is an important point assessed by the community.

Elements that have the second highest value is the sixth element that is the competence or skill of the officer with the value of CSI of 3,076 are included in the category elements above is a potential owned by

Brondong Primary Health Care, where qualified human resources are able to provide maximum performance in an organization.

Element that has the third highest value is the fourth element that is about the type of health services with the value of CSI of 3.058 are included in either category. It is seen that the clarity of the types of services available, listed on the announcement board, banner, brochures and leaflet in Brondong Primary Health Care, and the type of health services available is the result of the survey of the needs and expectations of the community about the types of services available at the Brondong Health Center[9].

The element that gets the first lowest value is the third element that is about the time of service with the value of CSI amounted to 2.987. Although it is still included in the good category but needs to get attention for improvement. It is seen that many patients are queuing up and the target of waiting time service has not been achieved due to less supportive systems such as slow internet access and search for old medical records. The long waited queue will cause a negative perception on the customer about the production, the quality of service and satisfaction[10].

Element that got the second lowest value is the eighth element of the service information with the value of CSI 3.030. It is still seen some employees who have not implemented commitments that have been agreed together as there are still employees who arrived late and not in accordance with the specified working hours or still seen some employees are less friendly so that it can provide a negative assessment by the community.

The third lowest element is the ninth element of complaint handling, suggestion and community input with the value of CSI of 3,041. This is still an obstacle for Brondong Primary Health Care if the complaints, suggestions and inputs of society in the form of facilities and infrastructure, such as lack of seating, lack of loudspeakers, and lack of air conditioning. Comfortable environment is one of expected service by customer, while a service can be said to be qualified if it can meet customer expectations[2]. In this context, the Primary Health Care is only able to make submission of the completeness of the higher level of infrastructure facilities, where the realization takes a long time. So that condition causes perception of dissatisfying society to health service at Brondong Primary Health Care of Lamongan Regency.

Previous research reveal on the Analysis of Influence of Patient Perception about Quality of Doctor Service on Patient Loyalty in Public Policlinic of Outpatient Care Installation of Panti Wilasa Citarum Semarang Hospital in 2008, the result of the research shows that there is a significant influence between medical skill, attitudes, delivery of information, timeliness of service, and availability of time doctor consultation on patient loyalty[6]. Another study, entitled "Analysis of the Effect of Patient Perception about Quality of Obstetric and Gynecology Specialist Doctor With Interest of Patient Re-visit in Outpatient Care Installation of RSI Sultan Agung Semarang in 2006" showed the result of perception about the accuracy of the officers and medical technical skills affect the interest of re-visit[11].

The above description shows that the need to improve the quality of Brondong Primary Health Care of Lamongan Regency service to be able to increase the satisfaction of the community of health service users.

Health care user satisfaction is often used as an indicator of the quality of health services. This is because health facilities have orientation to the user (customer orientated) in ordering their services, so health facilities need to evaluate the quality of service based on the perspective of the service user. Service user satisfaction is the user's perception and evaluation of the services they receive[12].

CONCLUSIONS

The quality of health services at Brondong Primary Health Care of Lamongan Regency based on the measurement of 9 elements or indicators adopted from Permenpan and RB Number 16 year 2014, is generally considered good by the community of Health-Care users. However, when every element have been viewed, there are still three elements with the lowest CSI value indicating that there are still people who feel less satisfied with the service Brondong Primary Health Care of Lamongan Regency. The three elements that have the lowest CSI value are the elements of service time, the service announcement, as well as the handling of complaints, suggestions and community input. Therefore, this study has been suggested that Brondong Primary Health Care of Lamongan Regency still needs to improve the quality of service, especially on the

three elements with the lowest CSI value based on the element or indicator from Permenpan Number 16 year 2014, because the satisfaction of users of health services is often used as an indicator of the quality of health services.

ABSTRACT

Aims: Determine the realization of women realizing for importance of optimizing health prior to pregnancy. **Background :**The idea of preconception care (care before pregnancy), has came into in recent years, as a vital element , not only for improving young adult and women's health during pregnancy birth, but for future health. Preconception care is a positive new approach to upgrade the health of future children through primary intervention. Although most women have no positive attitude towards preconception care as they found that it would harm their health and will not acquire the healthy pregnancy due the certain domestic reasons or their cultural belief. **Methods:** Pub Med-Medline, EBSCO were searched for research articles in awareness on preconception care among women of reproductive age and found little awareness regarding preconception care. **Results:** Out of 9 articles, 6 research studies supported that awareness regarding preconception care revealed that variation in the level of awareness **Conclusion:** The review concludes that awareness on preconception care reveals very low level of awareness. **Clinical significance**: Preconception care is to reduce the risk of unfavorable health effect for the women and unborn baby by optimizing the women health awareness before planning and conceiving pregnancy.

Keywords: *Awareness, Preconception care, and Reproductive age women.*

INTRODUCTION

Preconception care (PCC) aims to promote the health of women of reproductive age before conception, while preventing pregnancy-related outcomes such as low birth weight, premature birth, and infant mortality.

The beginning of Preconception care was started to prevent low birth weight. Then later it came with slogan "Caring for Our Future," Preconception care first developed in developed countries like London, Britain etc. Preconception care is a set of planning that aim to analyze and reshape the biomedical, behavioral, and social risks to a woman's health or pregnancy outcome through prevention and management.

Preconception health care is a protection given to a woman before pregnancy to manage conditions and behaviors which could be a risk to women and baby. It targets those particular women who are never been pregnant as well as the women who could be pregnant in the near future. The key for encouraging the preconception health is to meet the effective medical care, healthy behavior, strong support and safe environment at home and at work.

It is targeting the existing risk before pregnancy where by using the beneficial resources for enhancing the improvement of reproductive health and optimizing the knowledge before conception and it provides the chance to intervene prior for to optimize health of the potential mothers and prevent from affecting the fetus.

Preconception care is a very strenuous task for

engaging the public for the awareness as it is a form of patient care or an intervention provided to the women of an reproductive age, or the women who enters in child bearing age or having the desires of before pregnancy to improve the health outcomes and prevent from any deleterious effect over the health of the mother and fetus.

Worldwide in 2010, 287000 women died, 3.1 millions newborn babies died in their first month of life while 14.9 million were born prematurely and 2.7 million were stillborn. These statistics represents that due to the following risk factors are associated to change the health of the mother and child or severely it effected the entire process of healthy outcome behavior which results death. Hence need of preconception care is necessary for further reduction in the risk of fetal and maternal deaths and the planning of intervening services are more in range so as to reduce the problems.

In India very less number of Women received Preconception Care. National Family Health Survey (NFHS) found that 37 percent of all pregnant women not received the preconception care during their pregnancies where 13% of literate women received the preconception care as compared to half of illiterate who have not received care and this survey analyses the various additional services are engaging a women in preconception care so as to improve the healthy behavior and indented the most of pregnancies result in good maternal and fetal outcomes , some pregnancies may result in adverse health effect for the women and fetus and some of these outcome cannot be prevented.

Optimizing a women health so there is a need to identify the barrier to preconception care and introducing the risk reduction intervention and screening methods to a women of child bearing age and may contribute in the reduction of maternal and infant mortality rates.

METHODOLOGY

Search strategy methods-

An electronic search of articles published in various journals has been done. Search was restricted to only English language.

Types of studies: descriptive Cross -sectional studies, qualitative, mixed longitudinal descriptive and survey study

Type of participants: Community women, health care workers, health professional workers.

Setting: Maternal and health care centers and community areas.

The systematic search was conducted by framing the terms separately and in combination with the different variables with different search terms .In addition to this, a manual Pub Med search and EBSCO was undertaken by using the keywords and search synonyms and found the relating articles, in addition where 9 articles were found. Initial search retrieved 1382 articles over which 116 articles were selected manually. Duplicates were removed and 40 articles were reviewed for eligibility. 76 articles were excluded because they don't match with the study criteria. 21 more studies were excluded due to subscription and ten articles due to irrelevant content. Finally nine articles were selected where six were quantitative and two were qualitative and one was mixed longitudinal descriptive studies. These articles are supporting the used study.

DISCUSSION

The quantitative studies conducted on knowledge regarding preconception care among the women were reviewed. Most of the studies were conducted in foreign countries including North west Ethiopia , Malaysia, Nigeria, Australia, Jordan, England, London and concluded that women were having less knowledge on preconception care .

According to **Adeoye Tokunbo O et al, 2017**, it concluded that there is high level of awareness among health workers especially in doctors about 83.3%. Introduction of various in training services in professional education will ultimately improve the knowledge and awareness of preconception care services [1]

According to **Yitayal Ayalew et.al, 2016**, finding showed that overall 27.5% of women are aware of preconception care indicated very low level of awareness and suggesting that there is a need to give importance for delivery of health education about preconception care to a woman in order to increase their knowledge [2]

According to **Prashana Gautam et.al, 2016**, Overall 57.3% belongs to the highest level of knowledge in the area of reproductive health risk factors and the lowest in an area of health promotion and suggested that initiation of education programme on different aspects of preconception care will improve the health risk and

obtain the healthy future outcomes [3]

According **Roshanani Bkasim et.al 2016,** majority of participants had good knowledge, attitude and practice towards preconception care was about 98%, 45.2% and 51.9%. Pre-pregnancy care information can be integrated into educational programmes especially in secondary schools and this information should also be provided to all women who attend antenatal clinics [4]

According to **N.A.AL-Akour et.al, 2015** revealed that nearly 50% of the participants were awarded about preconception care associated factor. Majority of women and men are aware of the changes that should be made prior to conception [5]

According to **Judith Stephenson et.al, 2016,** revealed that 20 professionals expressed the low level of awareness regarding preconception health situations and ignorance about responsibility for delivery of preconception care and declares linkage between the health professionals input and healthy behavior before the pregnancy will improve the awareness and brings wider benefits for public health [6]

According to **S. Braspenningx et.al, 2013**, a systematic review on awareness, current situation and recommendation of future aspects of preconception care, Forty-six articles were identified for review and it shown that preconception care that might be result in excellence pregnancy outcomes, including e.g. a reduction of congenital abnormalities. Health care workers are in favor of the implementation of preconception care, but claim that they don't have enough knowledge to do so. In results the general population shows interest in receiving the preconception care and wanted to increases the awareness of preconception care and this should be implemented in terms of checklist and health education[7]

According to **Helena Toumainen et.al, 2013,** the results suggested that Women had modest or poor awareness of preconception health issues and the study concluded that raising preconception health will improves the pregnancy outcomes [8]

According to **Eric AP Steegers et.al, 2012,** Women expressed a positive attitude towards preconception care. Due to some aspects or subjective norms around the process of becoming pregnant may falling out with the current practice of preconception care. There is a Need for enhancing the awareness by adopting the following interventions and education programme among the women [9]

According to **Keith A. Frey et.al, 2006,** Majority of women understand the importance of optimizing their health prior to preconception and there is a need to forming the focused group so that entire women will be involved to improve the deficiencies over the health of the mother and fetus [10]

Ethical Consideration: This manuscript is ethically considered by the panel of Teerthanker Mahaveer College of Nursing, Teerthanker Mahaveer University after discussing with each and every point of this manuscript

SUMMARY FINDINGS

The available literature is refined to get six quantitative, two qualitative and one mixed approach.

Out of Nine articles, six research studies findings are showing the awareness on preconception care of a woman and categorized the level of awareness as low, poor, average and good. Under these categories the awareness was seen and found that majority of women have poor awareness regarding various aspects of preconception care.

Most of the studies were refined and concluded that recommendation is necessary to cover all reproductive age women under the boundaries of preconception programmes and services so as to reduce the harmful impact over the health of the mother and child. Five articles show the majority of women have the modest or poor awareness of preconception heath issues. They perceived that it can be reduced by addressing the preconception care in different areas of perspectives and as found that challenges faced by women is critical to achieve preconception care due to the following factors like unawareness of family planning, health lifestyle, smoking/alcohol, folic acid supplementation etc.

FUTURE SIGNIFICANCE

Based on this review the finding reveals that majority of women have lack of knowledge on preconception care which is greatly playing an undesirable effect over the health of mother and fetus. To overcome the problems there is a need to improve the preconception care health and pregnancy outcomes and this will protect the mother and fetus from various associated factors

affecting the health. It will lead to improve maternal nutrition, tackle obesity, related issues, under nutrition and micronutrients deficiencies. In order to decrease the mortality and morbidity rate. Various maternal services and programmes will be performed so that every individuals will be saved and acquire healthy pregnancy in a future

Nearly half of the pregnancies in United State are unplanned. Therefore the challenges of preconception care are more progressed. It is not only addressing the pregnancy planning but also address the women who are seeking for the medical consultation and care to secure their health but they failed to approach due to the cultural and educational barriers. The introduction of various educational programmes and screening programme for the women of child bearing age on an ongoing basis will analyse the prospective of maternal-fetal risk and hazard before and between the pregnancies.

Several national and international medical organization and advocacy group have focused on the promotion of health before conception, resulting in development of clinical recommendation and education materials and clinician will encourage the women to formulate the reproductive health plan so it will promote the healthy pregnancy outcomes.

CONCLUSION

Majority of studies highlights that education is needed to improve the level of knowledge on different aspects of preconception care among reproductive age women. Initiating the offer of preconception health intervention at this point is needed. First, and for most step is to give importance for those who belongs to deprived backgrounds, so that it will increases the potential to engage them in health educational programmes of preconception care and improves the knowledge regarding preconception care.

ABSTRACT

Background: India is undergoing a rapid epidemiological and nutritional transition characterized by persistent nutritional deficiencies, as evidenced by the prevalence of children suffering from stunting, anemia, and iron and zinc deficiencies. Subsequently, there is a steep rise in the prevalence of childhood obesity, diabetes, cardiovascular disease etc. The impact of obesity or underweight upon a child's mental health, immediate and future social life is as important as the impact on physical health. So, the need of the hour is to address child's weight-related problems of being obese or underweight at an early stage of life in connection with their primary care and primary care giver/parents.

Aim: To assess the impact of parental stress on body mass index of children within Indian school setting.

Method: A sample of 250 students and their parents were contacted personally to obtain information on parental stress scale and body mass index of children. Students with the age range of 10-14 years (grade IV -IX) from three different schools of Jaipur city.

Result: The findings of the present study found to be statically significant that there is a difference in parental stress level associated with children's BMI.

Conclusion: Present study paves the way for future studies examine the relationships of parental stress with body mass index of children, as well as BMI on academic performance. The findings suggest that higher level of parental stress leads to higher level of BMI in children which could possibly lead to poor academic performances within a period of middle school aged students.

BACKGROUND

Childhood obesity is one of the major public health challenges of the 21st century. The problem is encompassing globally and is rapidly affecting many underdeveloped and developed countries, particularly in urban settings[1]. Globally in 2016, the number of overweight infants and children is estimated to be over 42 million and about 35 million of these are living in developing countries[1].

India is undergoing a rapid epidemiological and nutritional transition characterized by persistent nutritional deficiencies, as evidenced by the prevalence of children suffering from stunting, anemia, and iron and zinc deficiencies[2,3]. Subsequently, there is a steep rise in the prevalence of childhood obesity, diabetes, cardiovascular disease etc. Studies from different regions of India within last decade are also evident of similar trend [2,3]. This trend has been challenging over recent years and can be presently considerd as different forms of the National malnutrition problem.

The most surprising aspect of all the attention is beign paid to the prevelance with numbers and figures and physical consequences of childhood obesity without going in depth of the problem and its global perspective. But, this alone can not slove the severity of the problem. The impact of obesity upon a child's mental health,

immediate and future social life is as important as the impact on physical health [4]. So, the need of the hour is to address the wider issues of child's weight-related problems of being obese or underweight at an early stage of life in connection with their early care and primary care givers/parents (for e.g. Can parental stress lead to abnormalities related to BMI (underweight/overweight) .The parent becomes a model for the their child. The child observes how the parents and other people around them respond to the child's needs. The child learns to adapt their behaviour to suit their environment therefore, children often repeat their parent's behaviours, which may then be carried into their adulthood [4,5]. Some previous studies found a relationship between stressful events or situations (stressors) resulting in negative physiologic or psychological responses (stress) in parents of obese and underweight children [5,6]. There are several mechanisms for how parent stressors can influence child obesity development [7]. Parents experiencing multiple stressors or who perceive that they are under stress may spend less time with their children, use less effective parenting approaches, or both [8]. This can yield less supervision for children, who may make unhealthy food and activity choices resulting in overweight or underweight. Similarly, stressed parents may be less likely to model and encourage their children to engage in physical activity as thi may be a sign of risk towards obesity [8,9].

Parent stressors that have been associated with childhood obesity and underweight include poor physical and mental health, financial strain, and single-family households [8-10]. Although, multiple stressors of parents can elicit a "stressor pile-up" causing adverse physical health consequences in children [10] and a number of studies have examined associations between dietary and psycho-social factors and prevalence of underweight, overweight, and obesity at the International level (i.e. American states,[11,12] Arab states[13]) little research has examined similar associations in India.

Therefore, the primary aim of the present study is to assess the impact of parental stress on body mass index of children within Indian school setting.

MATERIALS AND METHOD

Study design:

A school-based ex-post facto study with contrast group comparison was conducted in three private schools from different parts of Jaipur city of Rajasthan state after obtaining permission from the school administration, parents and children. The study was conducted over a short period of three months from August to October 2017 to avoid the examination related stress issues with children, parents and school administration to interfere with the results of the present study. This is not an intervention based research and no clinical trials on samples were conducted. The synopsis of this study has gone through stringent evaluation by Students Research Degree Committee with an external member in it.

Participants:

Present study included 250 students, with equal number of males and females in the age range of 10 to 14 years (enrolled in class V to IX) attending regular school and their parents. Studens School Principals, Class Teachers and Parental consents were obtained through a circular explaining the purpose and procedure of the study. Those present at the time of study and consented to participate were included in the study.

The socio-demographic characteristics of the sample included their religion (Hindu/non-Hindu), diet pattern (vegetarian/non-vegetarian), academic records, and number of siblings. The sample selected was from three different private schools of Jaipur city with comparable fee structure and parental education, justifying the similar socio-economic status of these children.

The justification for choosing the sample for this age group was:

1.There is a steep rise of obesity among school going children and the age of onset is declining [4]. To nib at bud this psychosomatic disorder, we need to identify its correlates at an early age to evolve preventive and curative measures.

2. The age group of 10-14 years fall in pre-adolescence where usually the body starts taking shape with pubertal changes [4,14].Adolescents of 10-14 years of age constitute a homogeneous group who have characteristics similar [14], have knowledge about health promoting and health hindering life style to some extent. They start taking independent decisions about themselves and their lifestyle and food choices. Younger children are more dependent on their parents in their lifestyle (selection, amount and frequency of food, screen time and sleep patterns). Moreover, relationship

with parents develop and impact health gradually and it seems the right time to study these health dynamics in relation to parental stress.

3. Students of grade V to IX are not hassled by board exams, competitions, and future career issues compounding to adaptive behaviors like over or under eating.

Exclusion criteria

Those students/ parents did not give the written consent to participate in the study.

Those who were taking treatment for certain alignments.

Procedure:

Parental stress scale developed by Berry and Jones (1995) based on 5 point scale with satisfactory levels of internal reliability (.83), and test-retest reliability (.81) and satisfactory convergent validity with various measures of emotions, role satisfaction, perceived stress, marital satisfaction, job satisfaction and social support.

Body mass index of children was measured by BMI machine (Model-Omeron HBF-121). Criteria for measuring BMI - Underweight - a percentile range of less than 5, Normal weight –a percentile range of 5 to less than 85, Overweight - a percentile range of 85 to less than 95 and Obese - a percentile range equal to or greater than 95 [15,16].

Statistical Package for Social Sciences, Version 22 for Windows (SPSS 22) was used to analyze the quantitative data. One way ANOVA was computed and .05 level of confidence was used to interpretate the results of the present study.

FINDINGS

Table. 1 Mean, standard deviation of parental stress on body mass index of children

Body Mass Index	Mean	Std. Deviation
Normal	37.95	4.379
Underweight	49.72	7.393
Obese	74.50	8.069
Total	54.92	17.869

Table.1.2. F value of parental stress and body mass index in children

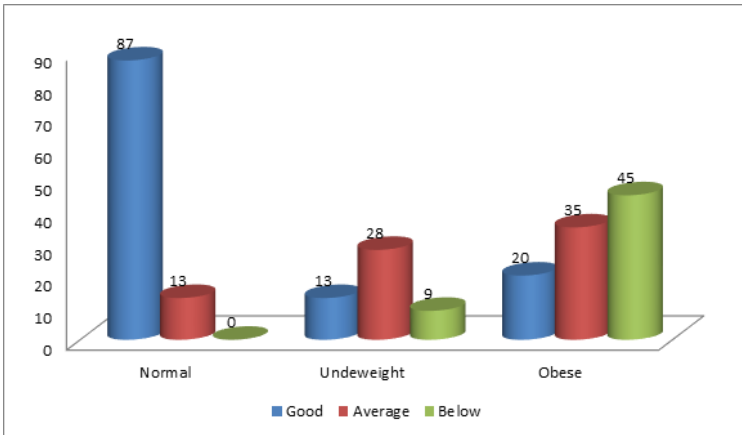

Figure 1. Body mass index and academic performance of children

DISCUSSION

The findings of the study are very promising and conclusive showing a clear trend of how parental stresss relates with BMI . The F ratio of parental stress and BMI of their children of the present study found to be statistically significant (*F = 767.407 , df=2 ,p=.00;table1 and 1.2)*. The results clearly show that the parental stress of children with body mass index labelling them as obese or overweight was significantly high. Moreover, the mean of parental stress of children with different BMI provides a clear difference (mean of obese/overweight children found to be *74.50* and mean of normal and underweight children *37.95, and 49.72* respectively). The findings support studies indicating positive relationship between parental stress with overweight and obesity in children [4-10]. The probable reasons could be that stress in parents leads to poor family functioning and poor communication which involves the disturbed emotional, physical and psychological activities between family members and has been found to be strongly associated with childhood obesity [17,18].Moreover, parental stress have also been associated with poor parenting style such children who experience authoritarian and neglectful parenting have higher risk of being overweight/obese [19]. Parental Stress also influences their attachment style with their children [19,20]. When children relate and interact with high stressed parents , they develop insecure attachment style (avoidant or anxious attachment style) which is associated with disturbed weight regulation in children [20]. House and professional demands (i.e. family environment, interpersonal relation, their education or socio-economic status combined with host of other variables) act as the major reason for stress among parents, which could be associated with higher/lower metabolic syndrome in children [21-22]. Many chronically stressed parents become chain smokers and consume excessive alcohol or drugs and become habitual drinkers/ addicts. Such pathological behaviours of parents can directly affected the child mental and physical health responsible for child obesity or underweight [23].The present evidences shows that parental stress can be a strong predictor of higher or lower than normal BMI levels in children.

Although the academic performance of children was unaffected by the stress of parents, but it is noteworthy that the body mass index of children was found to be stastically significant with academic performance of children *(x2=121.747,df=4,p=.00 ; table 2; figure 1)* in the present study. Significantly greater numbers of children having obese/overweight or underweight scored average or poor performance and children with normal BMI were found to be good in their academic performance. Some previous studies support these findings by reporting the association of cognitive abilities, poor nutrition and BMI, stating that cognitive ability is influenced by obesity and the likelihood of being obese is influenced by the quality of nutrition, so poor nutrition is associated with obesity leading to poor academic performance of child [24,25,26]. However, not all available studies have found a positive association between BMI and academic performance [27,28]. Such observations suggest that obesity is a complex problem there are so many factors which could be responsible for increase and decrease of body mass index of children.

FUTURE DIRECTION AND CONCLUSION

Since, this study was conducted only in three modern high schools of the Jaipur (Rajasthan) with a small sample of 250, a similar study of larger population from diverse locations and demographic specifications could be planned for greater generalizability of the study and results could be treated with more cross sectional and longitudinal researches. Separate stress responses of father and mother along with an account of stress level of children with different BMI could be taken and evaluated for better understanding of these complex demograpic and psycho social health issues.

In order to address the problem associated with BMI of school children we need to address the problem of stress of their parents. Interventions to reduce parental stress, household stress, environmental stress for the parents are required to help them to cope with stress might help to reduce obesity and underweight in children [22]. Interventions to alter and create healthy home environment has to be stressed. Educational support to children and counselling facilities for their stressed parents might help in providing healthy life style including diet and exercise behaviours in children to foster healthy habits and optimum growth in children.

Present study paves the way for future studies with more robust and comprehensive research designs and examine the relationships of parental stress mental health with body mass index of children as well as their academic performance.

Utilisation of Janani Suraksha Yojana among Women in Urban and Rural Areas of Western Uttar Pradesh

Shalki Mattas[1], Bhawana Pant[2], Saurabh Sharma[3], Arvind Shukla[4]

[1]Postgraduate Resident, [2]Professor, [3]Assistant Professor, [4]Assistant Professor, Department of Community Medicine, Subharti Medical College, Meerut

ABSTRACT

Background: In April 2005, under the National Rural Health Mission, the Government of India launched a scheme known as Janani Suraksha Yojana (JSY). It aims to promote institutional deliveries among pregnant women living below poverty line in all the states and Union Territories of the country with special focus on low performing states. **Aims & Objectives:** To find out the extent of utilisation of the JSY scheme by rural and urban women in the community. **Material & Method :** The present study was done in the catchment area of rural and urban health and training centre of Subharti Medical College. The sample size was 150 each in urban and rural area. **Findings:** Complete antenatal care was received by only 19.2% of the beneficiaries. 24% of the beneficiaries in urban area and 17% of the beneficiaries in rural area received complete antenatal care. Among the women who registered under JSY, 71% of the women received money after delivery in rural area and 82% of the women received money in urban area.

Keywords : *Janani Suraksha Yojana; Utilisation; Urban; Rural; Western Uttar Pradesh.*

INTRODUCTION

Mother and child constitute a priority group in a community. They comprise of approximately 57.5% of the total population and constitute a vulnerable group.[1]

In April 2005, under the umbrella of National Rural Health Mission (NRHM) in response to the slow and varied progress in improvement of maternal and neonatal health, the Government of India launched a scheme known as Janani Suraksha Yojana (JSY).[2]

The scheme aims to promote institutional deliveries among pregnant women living below poverty line in all the states and Union Territories (UTs) of the country with special focus on low performing states (LPS). In Uttar Pradesh, about 2.33 million beneficiaries have been benefited under JSY in 2014-15.

METHOD

The present study was conducted in Khajoori area (RHTC) and Multan Nagar area (UHTC) of the department. The sample size was calculated using prevalence of institutional delivery taken from National Family Health 2005-06 Survey (NFHS-3) India-Uttar Pradesh which was 22%[3] and was rounded off to 300, 150 each from rural and urban area, respectively. Fourteen colonies are covered under UHTC, there were 3300 families residing there, out of which 488 families had married females above 19 years who had delivered in the past one year and seven villages are covered by RHTC, there were a total of 4436 families with 627 families having married females above 19 years who had delivered in the past one year. Number of families to be included in the study from each selected colony was calculated by proportion method using a simple proportion formula.[4]

$$n_i = nN_i/N$$

Where, n_i= sample size in i^{th} stratum.

n= Total sample size.

N_i= Total number of units in i^{th} stratum.

N= Total number of units in all the strata.

The calculated number of families in each colony were selected by Simple Random Sampling technique using online random number generator. Data was analysed using appropriate statistical tests by Statistical Package for Social Sciences (SPSS) software version 19.0 and Microsoft excel 2013. Ethical clearance was obtained from ethical committee of Swami Vivekanand Subharti University, Meerut. Informed written consent was obtained from each participant after explaining them about the purpose of the study.

FINDINGS

Table 1 shows that out of the total 182 beneficiaries who were aware about JSY, 164 (90%) beneficiaries got registered under JSY, 113 of which belonged to rural area and 51 were from urban area. 83.5% of the beneficiaries went for at least 3 antenatal checkups, 91.2% got the appropriate doses of Tetanus Toxoid and only 28.6% consumed 100 tablets of Iron and Folic Acid (IFA). Only 10.2% of the women in rural area and 7.3% of beneficiaries in urban area were given postnatal care under JSY. BCG and Zero polio were given to approximately 94% of the babies of the beneficiaries and all the beneficiaries were given advice on breastfeeding. The difference in the number of beneficiaries who had minimum three antenatal checkups in rural and urban areas was seen to be statistically significant.

Complete Antenatal care (ANC) includes beneficiaries who went for 3 or more ANC visits, 2 doses of TT or booster dose and received 100 IFA tablets. Table 2 shows that overall, Complete ANC was received by only 19.2% of the beneficiaries. 24% of the beneficiaries in urban area and 17% of the beneficiaries in rural area received complete antenatal care.

In the present study, 38.3% beneficiaries had to travel <5km to the place of delivery, 41.8% travelled 5-10km, 17.7% travelled 11-20km and 2.1% travelled >20km to their place of delivery. The distance of place of delivery from residency varied in rural and urban areas and this was seen to be statistically significant. It was observed that many of the beneficiaries went to district and tertiary care hospital at their own will or referral from peripheral hospital (PHCs/CHCs) due to lack of Basic Emergency obstetric care services. 61% of beneficiaries used hired vehicle to reach the place of delivery, 39% had personally owned vehicle. Amount incurred on transportation was reimbursed in just 1.4% cases.

70% of the deliveries in the rural area and 60% of the deliveries in the urban area were conducted in an institution. Government facilities were the most common institution for delivery in both rural and urban areas with 84% and 58% of the institutional deliveries, respectively. Accredited Private facility accounted for only 1% of the institutional deliveries in rural area and for about 14% institutional deliveries in urban area. 15% and 28% of the institutional deliveries in rural and urban areas, respectively were conducted in other private facilities. This distribution was seen to be statistically significant.

Table 3 shows that 100% of the beneficiaries in rural area and only 29% of the beneficiaries in urban area were contacted/ advised for institutional delivery during pregnancy and this variation was seen to be statistically significant. Grassroot level workers (65%) followed by Others (22%) were the most common people to advise for institutional delivery in rural area while Other sources (51%) followed by Doctor (36%) were the most common sources in urban areas and this distribution was statistically significant. Place of delivery was identified in advance in 69.8% of the beneficiaries who were aware about JSY. In rural area, Doctors conducted the delivery in 69% of the beneficiaries aware about JSY while in urban, 78% of the deliveries were conducted by doctors.

Table 4 shows that among the women who were registered under JSY, 71% of the women received money after delivery in rural area and 82% of the women received money in urban area. More than three fourth of the beneficiaries received money within a week after discharge in both rural and urban area. 90% of the rural beneficiaries and 93% of the urban beneficiaries received the appropriate amount of money for their respective areas.

DISCUSSION

Majority of women (90%) got registered during pregnancy. The results are consistent with the findings of Kumari V., et al (2009)[5] and Banerjee B., et al(2009).[6]

The study found that 83.5% had more than three antenatal checkups and it was higher (92.7%) in urban than in rural areas (79.5%). Similar findings were seen in studies conducted Dolma Y, et al (2015)[7] and Panja T.K., et al (2012)[8].

In our study, 91.2% beneficiaries got the appropriate doses of Tetanus Toxoid and only 28.6% consumed 100

tablets of IFA. In Annual Health Survey (AHS) 2012-2013,[9] it was found that mothers who received at least one Tetanus Toxoid (TT) injection were 83.2% in rural UP, 88% in urban UP and 84.1% in total and 82.9% in rural Meerut, 86.5% in urban Meerut and 84.3% in total. Mothers who consumed IFA for 100 days or more were 8.3% in rural UP, 16% in urban UP and 9.7% in total and 12.3% in rural Meerut, 16.4% in urban Meerut and 14% in total. NFHS IV (2015-16)[10] data shows that in Uttar Pradesh, 86% mothers in rural and 88.5% mothers in urban UP received protection against neonatal tetanus in their last birth. Only 10.9 % mothers in rural UP and 20.2% mothers in urban UP consumed IFA tablets for 100 days or more. The indicators in Meerut were in general found better than those of Uttar Pradesh. Mothers whose last births was protected against neonatal tetanus were 91.1% in rural Meerut and 86.1% in urban Meerut. Similar results have been shown as per the report of DLHS (2002-2004).[11]

Complete Antenatal care was received by 19.2% of the beneficiaries in our study with 17% and 24% beneficiaries in rural and urban areas, respectively, receiving complete antenatal care. Similar results were observed by Kumari V,[5] et al where Complete ANC was availed by 25.5% of the women.[12] According to NFHS IV[10] data, in rural India, only 16.7% mothers had full antenatal care while it was 31.1% in urban India. Complete antenatal care was received by 3.8% mothers and 13.5% mothers in rural and urban UP, respectively.

In the present study, 70% and 60% deliveries in rural and urban area, respectively were conducted in an institution. According to NFHS IV,[10] 78.9% deliveries in India occur in an institution and 75.1% and 88.7% in rural and urban areas, respectively. Similar results were also found in the studies done by Vora SK., et al(2009).[12]

Findings of the present study reflect the role of ASHA in motivating women for institutional delivery. Of all the women who were aware about JSY, 100% beneficiaries in rural area and only 29% beneficiaries in urban area were contacted/advised for institutional delivery during the course of pregnancy. Similar pattern was seen in the study by Dolma Y, et al[7] where ASHA were the source of motivation in 58.1% followed by doctor in 20% cases and ANM (16.3%) while 3.7% cases got motivated through other channels like TV, Radio, friends, relative and 2% of women were motivated by AWW.

CONCLUSION

Out of the total 182 beneficiaries who were aware about JSY, 164 (90%) beneficiaries got registered under JSY, 113 of which belonged to rural area and 51 were from urban area. Complete antenatal care was received by only 19.2% of the beneficiaries of which 24% of the beneficiaries belong to urban area and 17% of the beneficiaries were from rural area. 70% of the deliveries in the rural area and 60% of the deliveries in the urban area were conducted in an institution. Amount incurred on transportation was reimbursed in just 1.4% cases. Among the women who were registered under JSY, 71% of the women received money after delivery in rural area and 82% of the women received money in urban area.

Comparison of Microleakage in Repairing Furcal Perforations in Biodentine with Cyanoacrylate and Biodenine Alone: An Invitro Study

Aditya Shetty[1] , Anuj Varshney[2], Lakshmi Nidhi Rao[3], Mithra N Hegde[4], Tony Mathew[3], Chitharanjan Shetty[3]

[1]Additional Professor, [2]Post Graduate Student, [3]Lecturer, [4]Head of the Department, Abshetty Memorial Institute of Dental Sciences Derlakatte, Mangalore

ABSTRACT

Perforations in the furcation region are one of the major complications leading to **failure** of **endodontic treatment** and causes significant impact on the long term prognosis of the tooth. It is estimated that furcation perforation is the **second major cause** of failure in endodontics.Biodentine is a calcium silicate-based bioactive material. It is a powder liquid system, powder composed of Tri-calcium silicate, Di-calcium silicate, Calcium carbonate and oxide, Iron oxide, Zirconium oxide. Liquid consist of Calcium chloride, Hydro soluble polymer.It is easy to handle owing to its **ease of manipulation** and a **short setting time** approximately 12 minutes, has **high alkaline pH** and is a **biocompatible material** makes it a favourable material for perforation repair,whereas cyanoacrylate has been shown to be an excellent **tissue adhesive** and **hemostatic agent** which is well tolerated by the tissues of the oral cavity, promotes healing of the tissues. Hence,this study would compare the microleakage of mineral trioxide aggregate and cyanoacrylate cement , in repairing furcal perforations using 2% methylene blue dye solution , conc. Nitric acid, ELISA plates for detecting the maximum dye leakage.

Keywords: *Perforations, bioactive material, short setting time, tissue adhesive, hemostatic agent,microleakage*

INTRODUCTION

In endodontic practice procedural accidents are encountered that will affect the prognosis of root canal space therapy. [1]

One of these accidents is **endodontic perforation**; which can often result in the loss of tooth. [1]

The root perforation can be repaired **surgically**, but a furcation perforation is surgically **inaccessible**.[1]

Therefore, furcal perforations have a more **unfavorable prognosis** than the perforations occurring in the middle and apical root thirds.[1]

Corresponding author:
Dr. Anuj Varshney
Post Graduate Student, Abshetty Memorial Institute of Dental Sciences Derlakatte, Mangalore

Repairing a perforation plays a vital role in preventing bacterial contamination of the furcal area. Hence a material which is used for sealing should provide an **adequate seal, be biocompatible, and should be bactericidal.**

Amalgam, Cavit, Super-EBA, glass ionomer cements and resins are materials used for sealing furcal perforations.[2]

Biodentine is a **high-purity calcium silicate**–based dental material composed of tricalcium silicate, calcium carbonate, zirconium oxide, and a water-based liquid containing calcium chloride as the setting accelerator and water-reducing agent.[1]

It is recommended for use as a **dentin substitute** under resin composite restorations and an endodontic repair material because of its **good sealing ability,** high compressive strengths, **short setting time (10minutes)**, biocompatibility, bioactivity, and biomineralization

properties. [1]

Tissue adhesives, such as **cyanoacrylates**, have been used in dentistry and in medicine because of their adhesive potential to the human tissue, even in the presence of **moisture**, their biological compatibility, surface isolation, hemostatic properties and bacteriostatic features.[3]

In endodontics, Cyanoacrylate has been used to **seal** the **remaining dentin** of endodontically treated teeth as it was found to control **micro-leakage** of oral fluid at the tooth / filling interface. [3]

No studies have been documented to evaluate the sealing ability of biodentine with cyanoacrylate for perforation repair.

Materials and methods

SOURCE OF THE DATA

The study was conducted in the Department of Conservative Dentistry, A.B.Shetty Memorial Institute of Dental sciences on 20 extracted human mandibular molars collected from the Department of Oral and Maxillofacial surgery, A.B.Shetty Memorial Institute of Dental Sciences, Deralakatte, Mangalore.

Method of collection of data

Selection of Teeth:

Inclusion Criteria : Intact Mandibular molars with minimal caries and restoration.

Exclusion criteria: Teeth with extensive caries

Procedure

Twenty extracted mandibular molar teeth were used.

The molars were amputated **3 mm** below the furcation area by using a **diamond disk** followed by preparation of Endodontic access cavity .

A perforation was made **between the orifices** to the furcation area by using a high speed long shank carbide **round bur** (2 mm in diameter).

Every molar were then covered completely including cavity walls and pulpal floor with two successive layers of **varnish**.

Study design:

20 extracted mandibular molars with 5 molars in each group

Groups divided as follows

Group 1: Biodentine (bioactive dentin substitute)

Group 2 : Cyanoacrylate and biodentine (bioactive dentin substitute)

Group 3: Positive control (Unsealed molars)

Group 4: Negative control (Non perforated molars)

Experimental groups : Group 1 and Group 2

Furcation perforation sealed with biodentine (bioactive dentin substitute)

Furcation perforation sealed with biodentine, cyanoacrylate

Control groups: Group 3 and Group 4

EVALUATION OF EXPERIMENTAL GROUPS

To avoid dye penetration through other areas, all experimental teeth were coated homogeneously with two coats of **varnish** for 1 to 2mm around the perforation.

After 24 hours of drying, all teeth were immersed in at **2% methylene blue solution** for 48 hours.

After removal from the dye, the teeth were rinsed with water and **dried** at **room temperature** for 24 hours.

The teeth were placed in vials containing **1ml** of **concentrated** (65 wt%) **nitric acid** until complete dissolution.

Vials were centrifuged at **9000 rpm** for 7 minutes.

Two hundred microliters of the supernatant from each sample was transferred to a 96 well plate.

Sample absorbance were read by an **automatic spectrophotometer** at **550 nm** using concentrated nitric acid as a blank.

SAMPLE ANALYSIS

ANOVA test was used to compare the mean of the different groups. Post hoc Tukeys test was used in the procedure of pair-wise comparisons between the group when ANOVA test is significant. The level of significance were set at p value < 0.05.Statistical analysis was

performed with SPSS 16.0 software(Statistical Package for Scientific Studies).

FINDINGS

TABLE1: Sample absorbance values obtained from each sample measured using a spectrophotometer at 550nm.

Biodentine	Biodentine with cyanoacrylate	Positive control	Negative control
0.138	0.081	0.314	0.024
0.092	0.039	0.412	0.040
0.076	0.044	**0.98**	0.032
0.112	**0.033**	0.518	0.016
0.082	0.062	0.756	0.010

Table 2: Oneway ANOVA Test depicting the mean, standard deviation and ANOVA results of the various groups

Descriptives				
	No. of samples	**Mean**	**Standard Deviation**	**P value**
Bioactive dentine substitute	5	.10000	.025259	<0.001
Bioactive dentine substitute and cyanoacrylate	5	**.05180**	.019588	
Positive control	5	**.59600**	.270426	
Negative control	5	.02440	.012033	
Total	20	.19305	.270895	

- According to the results the positive control showed the highest mean absorbance (0.596)i.e. maximum dye leakage/ dye extraction.
- Bioactive dentine substitute(0.1) showed next mean dye absorbance value.
- Bioactive dentine substitute with Cyanoacrylate (0.051) showed lesser dye absorbance i.e. lesser dye leakage/ dye extraction than biodentine.
- The ANOVA test depicted overall significant differences between the groups in dye absorbance so a Post Hoc TUKEY test for pair wise comparison between the mean of the groups was performed.

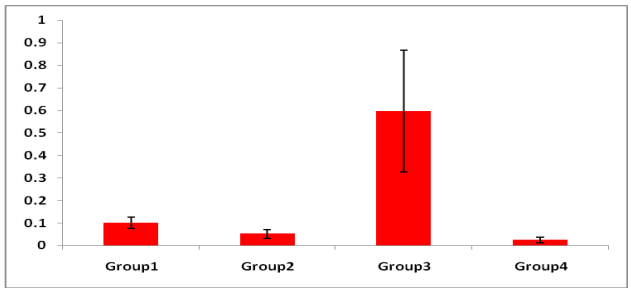

Table 3: Post Hoc Tests depicting pair wise comparison between the groups

(I) grp	(J) grp	Mean Difference (I-J)	P value
Bioactive dentine substitute	Bioactive dentine substitute and cyanoacrylate	.048200	.943
	Positive control	-.496000*	.001
	Negative control	.075600	.817
Bioactive dentine substitute and cyanoacrylate	Bioactive dentine substitute	-.048200	.943
	Positive group	-.544200*	.001
	Negative control	.027400	.988
Positive control	Bioactive dentine substitute	.496000*	.001
	Bioactive dentine substitute and cyanoacrylate	.544200*	.001
	Negative control	.571600*	.001
Negative control	Bioactive dentine substitute	-.075600	.817
	Bioactive dentine substitute and cyanoacrylate	-.027400	.988
	Positive group	-.571600*	.001

- Amongst all the groups Bioactive dentine substitute alone , Bioactive dentine substitute with cyanoacrylate had significantly lesser absorbance than positive control. ($p < 0.05$)
- Bioactive dentine substitute alone (0.1) and Bioactive dentine substitute with cyanoacrylate(0.051) showed a significant difference with positive control group when

compared with each other.

- Positive control group(0.596) showed highly significant difference with Bioactive dentine substitute and Bioactive dentine substitute with cyanoacrylate.

- The mean difference is significant at the 0.05 level.

Graph 1: BAR DIAGRAM REPRESENTING THE SAMPLE ABSORBANCE (DYE EXTRACTION) OF THE VARIOUS MATERIALS USED

- The important factors that are considered in sealing furcation perforations are sealing ability of the repair materials and their extrusion into furcation areas. In this study perforation sealing ability of Bioactive dentine substitute and Bioactive dentine substitute with CYANOACRYLATE was evaluated.
- This study uses the **dye extraction** method by Camp and Pashley (2003) to study the sealing ability of the materials. This method is a **more reliable technique** than dye penetration as it considers all the **dye absorbed** by the samples used. [4]
- A study comparing the efficacy of dye penetration to dye extraction method concluded that, dye extraction method may be preferred because of its **simplified procedure** and its ability to **simulate oral conditions**.[4]
- A spectrophotometer reader is used here to measure the **fraction of incident light** transmitted through a solution. [5]
- It can be used to determine concentration of compounds in solutions because concentration of the absorbing compound can be determined by the amount of light absorbed by the sample as it is directly proportional to it.[5]
- In this study **negative control**, showed **lowest dye absorbance** (0.024) and had absorbance values were near blank HN03 (0) and **positive controls** had the **highest dye absorbance** (0.596).
- In this study results showed that sample absorbance of the bioactive dentine substitute was more than that of bioactive dentine substitute with cyanoacrylate,which suggest **better sealing ability of bioactive dentine substitute with cyanoacrylate as a repair material in furcal perforations .**
- CYANOACRYLATE alone was not used in the study because of the chances of the **adhesive seepage due to the greater flow of the material** whereas is was used in combination with bioactive dentine substitute to enhance the **seal** of the furcal perforation region since its acts as a **water proof dressing**.
- Further studies are required before bioactive dentine substitute(Biodentine) with cyanoacrylate could be used a furcal repair material in clinical use.

CONCLUSION

- From this present study we could infer that the sample absorbance of BIODENTINE alone was more than that of BIODENTINE WITH CYANOACRYLATE.
- Statistically sealability of BIODENTINE and BIODENTINE WITH
- CYNOACRYLATE had a significant difference suggesting that the
- BIODENTINE WITH CYANOACRYLATE had a better sealing ability compared to BIODENTINE alone.

Mental Health among High and Higher Secondary School Students

Nangaiyarkarasi S

Vels Institute of Science, Technology & Advanced Studies, Chennai

ABSTRACT

The objective of the present study was to examine the relationship between mental health and academic achievement among high and higher secondary students. The sample consists of 511 (boys 288 and girls 233) high and higher secondary students were randomly selected from Chennai and Kancheepuram district schools in Tamil Nadu. Correlation and independent t-test, ANOVA were used for analyzing the data. The result shows that there is significant difference between mental health and sample sub groups. More over the result reveals that the positive correlation between mental health and academic achievement of high and higher secondary students. Early detection for indications of mental health problems and understanding factors contributing to stress among students would promote better understanding of mental health in future.

Keywords : *Mental health , Academic achievement*

INTRODUCTION

Mental Health of the learner is very important for efficient learning and proper development of personality. Mental Health which today is recognized as an important aspect of one's total health status is a basic factor that contributes to the maintenance of physical health as well as social effectiveness. Mental Health may be defined as the adjustment of the individuals to themselves and the world at large with a maximum of effectiveness, satisfaction, cheerfulness and socially considerate behavior and the ability of facing and accepting the realities of life, with minimum friction and tension. Hadfield (1952) defined "Mental Health is the full and harmonious functioning of the whole personality.[1] According to statistics from the World Health Organization (2003b), 12% of global diseases (121 million people suffer from depression, 70 million from alcoholism, 24 million from schizophrenia and 37 experiences dementia) were a result of mental health problems.[2] By 2020 as indicated by the World Health Organization (2003b) the burden will be increased by nearly 15%.[3] This will result in the loss of disability-adjusted life-years to illness and young adults in developing countries seem to be the most prone. Hill and Wigfield (1984) states that test anxiety is one of the most important aspects of negative motivation and has direct debilitating effects on school performance.[4] Students' Academic, Behavioral, Cognitive, Affective factors also influenced their mental health. Students poor academic performance and inconsistent of attendance are leads to their mental health problems.[5] (DeSocio & Hootman, 2004)

OBJECTIVES OF THE STUDY

To find out the impact of mental health of high and higher secondary school students.

To find out the influence of mental health on academic achievement of high and higher secondary school students.

HYPOTHESES

H.1) There is no significant difference between mental health of high and higher secondary students and the subgroup of the sample.

H.2.1	Sex
H.2.2	Parent education
H.2.3	Standard
H.2.4	Family income
H.2.5	Recreational activities
H.2.6	Study time

H.2). There is no significant relationship between mental health and academic achievement

H.1.1 Behavior problem and conduct

H.1.2 General positive affective

H.1.3 Hyper active

H.1.4 Emotional

H.1.5 Pro social

H.1.6 Depression

H.1.7 Anxiety

METHOD

The sample consists of 511 high and higher secondary school students, of whom 288 were boys and 223 are girls from chennai and kancheepuram district school in TamilNadu. Stratified random sampling technique used in the present study under this process, the entire universe or population is divided into a number of homogenous or types of classes. On the present study high and higher secondary students can be divided into number of sex (Boys, Girls) Parent Education (Non graduate, Graduate), Standard (High school level, Higher secondary level) Family Income (Above 12,000, Below 12,000), Recreational activities (Involved and Uninvolved), Study Times (Morning, Evening, Both).

Instruments and Techniques applied

Mental health scale

Mental health of individual was measured by mental health inventory which was developed by Veit & Ware (1983) in RAND Corporation. To measure the mental health among high and higher secondary students, the student form was prepared and which was consisted of 78 statements with four responses like always, often, sometimes and never. Mental health inventory (MHI) have are seven dimensions of mental health inventory are behavioral problem conduct , general positive affective , hyperactivity, emotional, pro social , depression , and anxiety are helpful to measure the student's mental health status.

Analysis

Descriptive analysis was done using the statistical package SPSS to stratify the subgroups of the sample by the method of finding our averages, deviation and t test. Correlation was dome in order to find out the relationship between Mental Health and Academic Achievement.

Purpose and nature of the test

This study intends to find out the level of mental health and the various psychological issues which the students are being faced and the influence of this issues may cause of their slow learning. Administration of the tool was conducted individually to ensure accuracy.

ANALYTICAL DISCUSSION

Table 1 and 2 represents the mean and standard deviation of the mental health scores based on the subgroups of the sample.

Table 1 : Mean and S.D of the Mental Health score based on the subgroups of the sample

	Sub group	*N*	Mean	*S.D*	*t*- value	Level of significance
Sex	Boys	288	187.57	35.88	3.893	<0.01**
	Girls	223	199.31	31.60		
Parent education	Non graduate	280	186.48	34.75	4.560	<0.01**
	Graduate	231	200.22	32.82		
standard	High school level	257	195.82	30.56	2.070	0.14*
	Higher secondary level	254	189.52	37.94		
Family income	Above 12,000	253	189.56	36.50	2.037	0.04*
	Below 12,000	258	195.76	32.82		
Recreational activities	Involved	441	196.30	31.47	6.137	<0.01**
	Uninvolved	70	169.96	43.52		

Note . *p<0.05, **p<0.01

Table 2: ANOVA for significant difference in Mental Health and its Factors among students with respect to Study Time

	Study Time			*F* value	*P* value
Mental Health	**Morning**	**Evening**	**Both**		
	184.71[a] (41.48)	189.49[a] (30.96)	198.51[b] (32.45)	7.18	< .001**

Note: The value within bracket refers to SD

Different alphabet among Educational Qualifications denotes significant at 5% Level using Duncan Multiple Range Test (DMRT)

***p*<0.05, ***p*<0.01**

Table 1 represents the mean and standard deviation of the mental health scores based on the subgroups of the sample. There was a significant effect of sex $t = 3.893$, parent education $t=4.560$, recreational activities $t=6.137$ and $p = 0.001$. Since the p value of mental health and its dimensions less than the 0.001. It reveals that there is significant difference between mental health and sample sub group. So hypothesis H.2 is rejected.

Moreover result indicated that in sex, girls mean score are high than boys. The above result with the respect to the gender is in concordance with the study done by Nanda, A.K.(2001), Female students had better mental health than male students[6] and Peterson et al (1991) found that adolescent girls generally experienced more challenging and stressful events than boys.[7] In parent education, graduate level parents' children are having good mental health. Students who are involved in recreational activities, are having good mental health than uninvolved students. It further shows that significant effect at $p = 0.005$ level in students standard $t = 2.070$ and family income $t= 2.034$. It revealed that those who are studying high school level having good mental health than higher secondary level students and if the family income below 12,000/- those students having good mental health than other.

Table 2 emphasized that in DHRT analysis of $F = 7.18$, $p = 0.001$. So students study time also significant effect of their mental health. It reveals that the students those who are preferred to study both morning as well as evening, they have good mental health. The students spending the amount of time is correlated with their academic achievement [8](Gettinger & Walter, 2012). It may be observed from table 1 and 2 that there exists significant difference with almost all the chosen sub groups of the sample and hypothesis H.1 is rejected.

Table 3: Correlation between Mental health and Academic Achievement

Variables	Sub – variables	*r*- value	Level of significance
Mental health	Behviour Problem and Conduct	0.401	**<0.01****
	General Positive Affective	0.473	<0.01**
	Hyper Active	0.459	<0.01**
	Emotional	0.434	<0.01**
	Pro social	0.458	<0.01**
	Depression	0.446	<0.01**
	Anxiety	0.476	<0.01**
	Overall Mental Health	0.549	<0.01**

Note . *p<0.05, **p<0.01

Table 3 shows that the correlation value of Behaviour problem and conduct r = 0.401, general positive affective $r = 0.473$, hyper active $r = 0.459$, emotional $r = 0.434$, pro social $r = 0.458$, depression $r = 0.446$, anxiety $r = 0.476$ and over all mental health $r = 0.549$. Since the p value of mental health and its dimensions less than the 0.001. It reveals that there is significant positive correlation between mental health and academic achievement. So the hypothesis H.2 is rejected at 1% level. If the students have good mental health, they can study well and their academic performance also good. This result corroborating with the study of Anita Chawla (2012) indicated that High academic achievement corresponds to high mental health[9] and similar findings like maintaining emotional

balance among students through a psychologist by using auto counselling increased their academic performance[10] Panchanatham (1999). To be precise, The result of the above table reveal that mental health plays a vital role in determining the academic achievement of the high and higher secondary students.

CONCLUSION AND SUGGESTIONS

The study also reveals that there are gender difference in the level of mental health, Therefore, it understands that both boys and girls are having similar in their innate capacities, girls seems to process higher level of mental health. In the area of gender-role conflicted men has suggested that these men are not only more likely to experience psychological distress, but also less likely to use available services.[11] Marks (2001) & Wood (1995)

It can perceived that the students those who are having the habit of studying at morning as well as evening , those students are higher mental health and involvement of recreational activities also helps to develop the good mental health

The study clearly reflects that there is a positive relationship between mental health, and academic achievement among high and higher secondary level students. Students, who are having good mental health, are reflecting better in academic achievement also. Whereas poor mental health result is, poor in academic achievement.

Gender Gap in Literate Life Expectancy –A District-Wise Study in India

Barnali Thakuria

Research Scholar, Department of Statistics, Gauhati University, Guwahati, Assam, India

ABSTRACT

Inadequate literacy describe as a strong barrier to access healthcare services .So, in the present study, the innovative indicator literate life expectancy (LLE) has been implemented to highlight the social differences existing in different parts of the country. Wolfgang Lutz (1995) was the first to develop LLE which gives an expected number of years a person lives in a literate state i.e., able to read and write under current mortality and literacy conditions. The obtained results showed that compared to men, women experienced less number of years in the literate state in almost all the districts of the selected states. It is believed that findings of the result in this study will help the policy makers and the government to focus more on literacy and programs relating to elementary education at the district level for the welfare and well being of the society.

Keywords: literate-life expectancy, education, gender-gap, India, district.

INTRODUCTION

Literacy is one of the important factors in the life of an individual. Lack of literacy directly affects the health of an individual, so the importance of education on physical health is fundamental. Inadequate literacy will also describe as a strong barrier to access healthcare services. So, in this perspective we tried to implement the literate life expectancy indicator to bring out the scenario of the people residing in different parts of the country .The concept of literate life expectancy (LLE) was first developed by Wolfgang Lutz in 1995 as an indicator of social development and quality of life. It is interpreted as an expected number of years a person lives in a literate state i.e., able to read and write under current mortality and literacy conditions [1]. The indicator is innovative and simple which accounts only two essential elements of social development namely literacy and life expectancy[2].It is based on age-specific mortality rates and age-specific literate proportions and computed by means of life table method [3]. The aim of this indicator is to look at person-years of life but in a literate state [2].

Lutz (1995)[4] mentioned that this indicator has numerous advantages over other indicators of social and educational development like literacy rate by sex and age-standardized literacy rate. It is not an abstract index on a relative scale and can be expressed in terms of individual years of life [1]. Moreover, LLE is the only social development indicator which can be projected into the future on the basis of other already accepted forecasts and thus illustrates both the path dependence and realistic prospects of development [5]. This indicator does not reflect any measure of economic income rather it is based purely on individual characteristics like literacy and mortality [6]. In addition to this, LLE can also be readily calculated for both the sexes separately that makes it very suitable for gender-specific analysis. It can also be evaluated for any subgroups of the population. The indicator not only shows the current level of social development but it also portrays the nation's possibility for future development [2]. LLE is an absolute number of social development which does not depend on any assumption.

Numerous studies in the literature showed that LLE has been widely used by various researchers for measuring the social development of a country which includes Khan and Asaduzzaman (2007) in Bangladesh[6], Medina (1996) in Mexico[2] and Huang and Nanjo(1998) in China[7], Chattopadhyay (2010) in India[5]. But the study on LLE at the district level is very limited. The LLE for females at the district level of India based on 2001 census data has been studied by Choudhury et.al (2013)[1] for the first time in the literature. Since then no study has been undertaken at the district level of India

with regards to LLE. The district is the basic territorial unit of administration in India and also the keystone of the whole administrative structure. It is believed that social development of any country is not possible if the equity conditions which are reflected at the micro level are not considered. So, the analysis of LLE at the micro level is essential to get a socio-development scenario in the administrative units. Out of 640 districts as per 2011 census of India, 190 districts from the selected states are included in the present analysis.

OBJECTIVE

With this backdrop, the objectives of the present study are:

1.To calculate the literate life expectancy (LLE) at the district level of some selected states representing various zones of India namely Assam from the North-East, Gujarat from the West, Kerala from the South, Rajasthan from the North, Uttar Pradesh from the Central and West Bengal from the East respectively for both the sexes based on 2011 census.

2. To assess the gender gap in terms of LLE at birth for the districts of the selected states mentioned above to capture the existing heterogeneity in the country.

DATA AND METHODOLOGY

The required data for the analysis are ordinary life tables and age-specific proportions of literate at the district level. The district-wise life tables for both the sexes have been constructed in a similar manner as the method developed by Choudhury and Sarma (2011)[8]. The one parameter model life tables for the major states and their corresponding districts were generated by Choudhury and Sarma (2011)[8] where the life expectancy at birth was the only input. As the life expectancy at birth at the district level is not readily available, so it has been estimated by the method of regression approach. Hence, the life tables at the sub-state level are constructed from the estimated expectation of life at birth. Secondly, information on literacy data was taken from the C8 table of the Census of India based on 2011 which is labelled by "*Educational Level By Age and Sex Population Age 7 and above"*. Data on literacy in the census table are structured in single, five and seven year age groups namely 0-6, 7, 8, ... 19, 20-24,25-29,...,70-74,75-79,80+ by sex and place of residence. The age group 0-6 were divided into single year ages by applying Karup-King Interpolation formula. Then all the single year ages are converted into following year age groups viz.,0-1, 1-4, 5-9, 10-14, 15-19,…,60-65,65-70,70+ respectively. Also, the corresponding population data were obtained to calculate the literacy rate.

The LLE estimation follows the ordinary life table method which is used to compute mortality based life expectancy, with the only addition being that the number of person-years at each age is weighted by the age-specific proportion literate. If P_x is the age-specific proportions in age x then the literate person-years lived in the age x (L_x) is given by the following equation:

$$L_x \times P_x = L_x$$

where L_x denotes the total number of person-years living in age x.

Then the LLE (e_x^0) is obtained by dividing the cumulative literate person-years (T_x) with the number of survivors (l_x) i.e.

$$e_x^0 = \frac{T_x}{l_x}$$

where $T_x = \sum L_x$

RESULTS AND DISCUSSION

The 2011 Census of India reports that the total literacy rate of the country stood at 74.04 %. Due to the limitation of the space, only the highest and lowest values of LLE at birth for the districts of the selected states are presented in the following table (Table 1). Table 2 displays the number and percentages of districts in each of the selected states having a literate life expectancy at birth below 20 years, 20-40 years, 40-60 years and above 60 years for both the sexes respectively. Table 3 presents the district-wise gender differential in LLE at birth.

Table 1: **Maximum and minimum values of LLE at birth at the district level of Assam and Some of its Selected States for the period 2011**.

States	Number of Districts	Districts with (male)		Districts with (female)	
		Maximum LLE at birth	Minimum LLE at birth	Maximum LLE at birth	Minimum LLE at birth
Assam	27	Kamrup Metropolitan (49.80)	Dhubri (29.79)	Kamrup Metropolitan (49.62)	Dhubri (22.68)
Gujarat	26	Ahmedabad (51.55)	Dohad (32.93)	Navsari (46.61)	Dohad (19.61)
Kerala	14	Pathanamthitta (66.02)	Wayanad (56.14)	Pathanamthitta (69.78)	Kasaragod (52.43)
Rajasthan	33	Jaipur (50.37)	Banswara (29.06)	Kota (37.16)	Jalor (15.83)
Uttar Pradesh	71	Gautam Buddha Nagar (47.40)	Shrawasti (26.58)	Kanpur Nagar (40.71)	Shrawasti (12.85)
West Bengal	19	Purba Medinipur (55.99)	Uttar Dinajpur (34.68)	Kolkata (47.55)	Uttar Dinajpur (23.75)
Total	190	Pathanamthitta (66.02)	Shrawasti (26.58)	Pathanamthitta (69.78)	Shrawasti (12.85)

The above table (Table 1) depicts that out of the total of 27 districts of Assam, the highest LLE at birth for males prevailed in the Kamrup Metropolitan district with 49.80 years. This means that a person in this district on an average will survive for 49.80 years in a literate state. Lowest male LLE at birth prevails in the Dhubri district with 29.79 years. Similar districts also performed the highest and lowest score in case of females. The corresponding figures for LLE at birth ranges from 22.68 years (lowest) to 49.62 years (highest).

In Gujarat amongst the 26 districts, Ahmadabad occupied the highest position while Dohad stood the lowest position in terms of male LLE at birth with 51.55 years and 32.93 years respectively while in case of females, Dohad remains the lowest position with 19.61 years and Navsari district is the highest with 46.61 years. Among the 14 districts of Kerala, the highest male LLE at birth is indicated in the Pathanamthitta district with 66.02 years and lowest is recorded in the Wayanad district with 56.14 years. For females, Pathanamthitta district remained the highest position in 69.78 years while in Kasaragod district, females had only 52.43 years as the lowest value.

In Rajasthan out of 33 districts, Jaipur district registered the highest LLE at birth (50.37 years) among the males while lowest male LLE at birth is recorded in Banswara district with 29.06 years. Kota recorded the highest position (37.16) years in terms of female LLE at birth and the lowest is found in Jalor district with 15.83 years.

Among 70 districts of Uttar Pradesh, a higher value of LLE at birth is noticed in Gautam Buddha Nagar district and lowest is found in the Shrawasti district for males. The corresponding figures stood at 47.40 years and 26.58 years respectively. Highest female LLE at birth is found in Kanpur Nagar with 40.71 years and lowest is seen again in Shrawasti district with 12.85 years respectively. The situation of females in the Shrawasti

district in terms of literacy performed poorly as males are spending more than the double number of years in a literate state as compared to the female counterparts. Also for the same state, the value of LLE score varies widely within the districts amongst the females as the highest figure for female LLE at birth is more than three times the lowest figure of female LLE at birth. Possibly due to economic backwardness and enlightenment towards education are the major causes of the very low level of female literacy in this district[9].

Finally, out of a total of 19 districts of West Bengal, the highest male LLE at birth is found in the Purba Medinipur district with 55.99 years and Uttar Dinajpur district stood the lowest position in terms of LLE at birth (34.68 years). In case of females, LLE at birth is highest in Kolkata district with 47.55 years and lowest is seen in Uttar Dinajpur with 23.75 years. The district Uttar Dinajpur is characterized by low-health care and livelihood access and widespread rural poverty. This district is a largely agricultural district, rapid population escalation restricts the absorption of the new rural workforce into farm-based employment, while the low level of urbanization restrains the growth of the non-farm sector[10] .These are the reasons that had made the level of literacy not up to the mark as compared to other districts. The table reveals that the people of the backward districts are having less years of education in comparison to the people of the advanced districts. Possibly people of the backward districts are unaware about the value of education and the government schemes that were related to literacy. It is also noticed from the Table 1 that the level of education among the districts of Uttar Pradesh is very poor for both the sexes. One interesting feature which is found that the female LLE at birth in the Pathanamthitta district has surpassed the male LLE by 3.76 points.

Table 2: Difference between male and female LLE at birth among the districts of the selected states.

States	Number of districts	Districts with	
		Highest Difference	Lowest Difference
Assam	27	Dhemaji (11.09)	Kamrup Metropolitan (0.18)
Gujarat	26	Banas Kantha (14.11)	Navsari (1.16)
Kerala	14	Kasaragod (5.41)	Ernakulam (0.05)
Rajasthan	33	Karauli (20.44)	Ganganagar (10.56)
Uttar Pradesh	71	Sant Ravidas Nagar (17.62)	Kanpur Nagar (3.89)
West Bengal	19	Puruliya (18.46)	Kolkata (3.69)
Total	**190**	**Karauli (20.34)**	**Ernakulam (0.05)**

The existence of gender gap is also reflected in the above table (Table 2). In Assam, the highest male-female difference in terms of LLE at birth is found in Dhemaji with 11.09 years while the lowest is seen in Kamrup Metropolitan with 0.18 years. Amongst the 26 districts of Gujarat, the highest gender differential in terms of LLE at birth occurred in Banas Kantha district with 14.11 years and the lowest is reflected in Navsari by 1.16 years. In Kerala, the highest male-female difference with regards to LLE at birth is found in Kasaragod with 5.41 years and the lowest is observed in Ernakulam with 0.05 years. In Rajasthan, the male-female gap in association to LLE at birth is noticed in Karauli (20.44 years) and the lowest prevailed in Ganganagar with 10.56 years. Similarly, out of 71 districts in Uttar Pradesh, the gender gap in terms of LLE at birth ranges from 3.89 years to 17.62 years. Finally, in West Bengal among the 19 districts, the highest gender difference in terms of LLE at birth is seen in Puriliya district with 18.46 years and the lowest revealed in Kolkata with 3.69 years. The possible reason for the huge gender discrimination might be due to the fact that school dropout rate among the girls is the highest since due to poverty in some families where parents cannot afford to send all the children to school, boys get the opportunity to attend the school as they give more priority to educate the boys.

Conclusion: The innovative indicator LLE has been implemented to highlight the social differences existing in different parts of the country. Compared to men, women experienced less number of years in the literate state in almost all the districts of the selected states. It is believed that findings of the result in the present paper will help the policy makers and the government to focus more on literacy and programs relating to elementary education at the district level for the welfare and well being of the society. Attention should be highly focused

on increasing the educational level, particularly among the females as literacy is the crucial parameter for the empowerment of women in the society.

Ethical Clearance: Not applicable as the paper is based on secondary data from the published source.

Evaluation of a Community Orientation Program for First Year Medical Undergraduate Students

Suvetha Kanappan[1], Subhashini Ganesan[2], Sivan YS[1], Darshan Manoj[3]

[1]Associate Professor, [2]Assistant Professor, [3]P G, Department of Community Medicine, PSG Institute of Medical Sciences & Research, Peelamedu, Coimbatore

ABSTRACT

Background: Against the backdrop of the new changes effected in the curriculum by the affiliating university a short-term community orientation programme was designed for the medical undergraduate (MBBS) students. This study aims at evaluating the one-week community orientation program based on students' feedback, their performance in the assessment test and to understand the correlation between feedback evaluation scores and the student assessment scores.

Method: Feedback was obtained by an anonymized self administered questionnaire which assessed their improvement in understanding through likert scale and understanding the factors which facilitated or hindered learning through open ended questions. Student assessment was conducted in the form a 20-item MCQ test. Spearman's correlation was done to find out the association between program feedback scores and student assessment scores.

Results: 61.5% said that the program had greatly improved their understanding of the topics. Field visits (72.6%) and intra-session activities (71.6%) had helped in improving their understanding greatly and lecture mode of teaching (68%) was perceived by majority of students as a session that had slight or no change in the understanding of the subject. Students scored highest on topics that used activities in intra-session activities (95.3 %), field visits and group discussions (93.5% each) followed by role plays (91.6%).

Conclusion: Active teaching methods are greatly accepted by students and help them attain their learning objectives and feedback serves as an effective evaluation tool for assessing teaching programs.

INTRODUCTION

Medical education is the basis on which high quality health care is built. So it becomes imperative to train medical students to become competent doctors of tomorrow. The medical curriculum should train doctors to respond to the health needs of the community.[1] Medical Schools shares responsibility for a comprehensive set of health services to a defined population in a given geographical area, consistent with values of quality, equity, relevance, and efficiency for developing and assessing innovative models integrating population and individual health activities, for learning and for conducting health research, and so it is important to orient the students to work as community physicians. [2]

The focus of medical education has changed from individual hospital centred to promotion of health of the community. [3] The ROME program by WHO emphasised on community oriented medical education to produce doctors who are socially responsible and who possess the technical, scientific and management competence which

will enable them to play a useful role in the development of comprehensive health systems based on primary health care.[4] A curriculum which gives consideration for and emphasises on community oriented teaching alone would help achieve the goal of developing primary care physicians. To keep up with the changing needs of the society the University to which this institute is affiliated has revised the Graduate medical curriculum.

Hence against the backdrop of the new changes effected in the curriculum by the affiliating university of our medical school, we designed a short-term community orientation programme for the medical undergraduate (MBBS) students under the aegis of the Department of Community Medicine of the medical school. It is also a well established fact that individuals have diverse learning styles and therefore for any teaching program to be successful different teaching strategies addressing the varying and diversified learning preferences of students have to be employed. [5] By encouraging active learning in students, their performances also improves in examinations.[6] Further, student feedback is an effective tool for evaluating the teaching-learning methods and contributing towards the success of the learning program. [7,8] It gives rich information which helps to improve the program and teaching methods.

Thus keeping in mind the diverse learning preferences of the students and the short term and long term goals of the graduate medical curriculum a learning program was designed. This study aims at evaluating the one-week community orientation program based on students' feedback, to assess the knowledge gained by students based on their performance in the assessment test and to understand the correlation between feedback evaluation scores and the student assessment scores

METHOD

This is a cross sectional study using retrospective data obtained from feedback evaluation and assessment scores of community orientation program for 1st year undergraduate medical students. The week long program in community medicine is the first exposure for the students to the subject. A total of 150 students underwent the orientation program.

Study setting:

The Tamil Nadu Dr. M.G.R. Medical University (to which our medical school is affiliated) introduced a curriculum in community medicine for I year medical undergraduate (MBBS) students, [9] according to which the students must have knowledge about:

- the evolution of community medicine
- definition of health and factors affecting it
- health care delivery system
- demographic pattern of the country
- the roles of the individual, family, community and socio-cultural milieu in health and disease
- social factors related to health
- disease and disability in the context of urban and rural societies
- the impact of urbanization on health and disease

Therefore a community orientation program was designed, which spread over 60 hours and focussed on the various objectives that the program had planned to attain. The program was also constructed in a way that it incorporated the various teaching styles addressing the diversified learning preferences of students. Table 1 shows the schedule planned for the one week orientation program comprising all the topics to be covered as per the new university curriculum.

Table 1: The schedule designed for the orientation program based on areas stressed by the university curriculum

Session / Areas / Topics / Concepts	Program Objectives	Teaching / Learning Method	Duration (minutes)
Introduction to the Department of Community Medicine	To understand as to why they are posted to community medicine: its importance vis-a-vis community health	Lecture	60
History of public health, changing concepts of health	To understand the evolution of community medicine To define health and factors affecting it	Lectures using story line	60

Cont... **Table 1: The schedule designed for the orientation program based on areas stressed by the university curriculum**

Principles of Primary Health Care	Enunciate the principles and elements of primary health care	Interactive lecture, Question & Answer sessions	60
Health Care Delivery System (Principles, Services available and utilization of health care services)	Describe the health care delivery system	Interactive lecture, Question & Answer sessions	60
Group work & Discussion: Health Care Delivery System: PHC Health Care Delivery System: Taluk Hospital Health Care Delivery System: Tertiary Hospital	Describe the organization and functions of the health care team at Primary Health Centre, Community Health Centre and District levels.	Lecture Group work & Discussion Pre-visit briefing Visit to health centres/ hospital	120 for group discussion
Demographic trends, cycle	Understand the demographic pattern of the country and fertility	Lecture	60
Fertility and factors affecting it		Interactive lectures	60
Family welfare and population control		Interactive lectures	60
Hospital sociology, doctor patient relationship, ethics	The principles of practice of medicine in hospital and community Setting including medical ethics	Role play	120
Social factors influencing health- Socio economic status, cultural factors	Social determinants of health, disease and disability in the context of urban and rural societies	Lecture, Question & Answer session, MCQs	60
Urbanization and its impact on health	Appreciate the impact of urbanization on health and disease	Lecture	60
Beyond hospital- reaching out to the community	Understand the principles of practice of medicine in hospital and community Setting including Medical ethics Develop rapport with the community using various participatory tools	Interactive lectures	60
Health communication	Describe the principles and practice of health education and to apply appropriate communication skills to bring about behavioural change in the community.	Intra session activities	90
Field visit and Presentations on visit to the Community	Observe and interpret the dynamics of community behaviour	Health education in the field by students	240

The orientation program incorporated various teaching methods to address the diverse needs of students. Some of the sessions had lecture classes. Story lines comprising the various historic changes in the public health field were used to teach the changing concepts of public health. Interactive lectures comprised of theory lectures and question and answer sessions in between and using probe questions to elicit answers of already known facts from students. Small group discussions were done before field visits on the various levels of health care to ensure that they had sufficient knowledge of the services available, thus enabling them to have a better understanding of the different health care systems during the visits. Through role play students were able to understand doctor patient relationship and medical ethics. Intra session activities

included giving students an information and asking them to communicate among their peers involving different methods of communication and encouraging them to come out with the challenges and barriers they had come across in doing the activity.

Students conducted supervised health education sessions in the community using various audio- visual aids like flip charts and posters.

Student's feedback and assessment was done at the end of the posting. Feedback was obtained using self-administered questionnaire which assessed their understanding of the subject using likert scale (greatly improved, slightly improved, no change) and understanding the factors which facilitated or hindered learning using open ended questions. Student assessment was conducted by administering a 20-item MCQ test which was aligned with the objectives.

The data are presented as frequencies and proportions. Spearman's correlation was done to find out the association between program feedback scores and student assessment scores.

106 students (includes males and females) who completed the feedback and the assessment test were included in the study. Sampling method was universe.

RESULTS

Of the total 150 students, 106 students completed program evaluation questionnaire.

Table 2 Shows the various teaching techniques used and the understanding of the sessions based on student's feedback

	Teaching-learning methods	Understanding about the topic/concept (n=106)		
		Improved greatly (%)	Improved Slightly (%)	No change (%)
1	Field Visits	79.3	19.5	1.2
2	Intra-session activities	73.7	24.4	1.9
3	Student Presentations	66.4	31.7	1.9
4	Used story line	61.9	32.4	5.7
5	Role plays	60.6	35.6	3.8
6	Group discussions	63.9	30.9	5.2
7	Interactive lectures	56.6	36.8	6.6
8	Lectures	32.1	50	17.9

Table 2 shows that 61.5% of students said that the program had greatly improved their understanding of the topics; 32.8% said that their understanding improved slightly and 5.7% said that the program made no change in their understanding of the subject.

Individual sessions feedback was analyzed based on the mode of teaching-learning used. The result showed that field visits (79.3%) and intra-session activities (73.7%) had helped in improving their understanding greatly and lecture mode of teaching (68%) was perceived by majority of students as a session that had slight or no change in the understanding of the subject.

Table 3 shows based on the assessment students scored highest on topics that used activities in intra-session activities (95.3 %), field visits and group discussions (93.5% each) followed by role plays (91.6%).

Table 3 Shows the comparison between student's feedback and the Assessment scores obtained (n=106)

	Teaching-learning methods	Improved greatly (% of students who responded that their knowledge improved greatly)	Assessment scores (% of students who gave correct answer)	Correlation between Program evaluation and Assessment Score (significance)
1	Field Visits	79.3	93.5	**0.778***
2	Intra-session activities	73.7	95.3	
3	Student Presentations	66.4	77.6	
4	Used story line	61.9	86.0	
5	Role plays	60.6	91.6	
6	Group discussions	63.9	93.5	
7	Interactive lectures	56.6	75.7	
8	Lectures	32.1	49.5	

* - significant (p<o.o5)

There was a significant correlation (r=0.778) between the student's feedback and assessment scores as shown in table.3

Table 4: Leading factors that were mentioned in feedback regarding facilitating and hindering factors of the orientation program

Facilitating	Hindering
Field visits Interaction with the community Teaching with videos	Lecture classes Lengthy duration of theory classes

DISCUSSION

Our study shows that based on student feedback, active forms of learning like field visits which provided opportunities for experiential learning, intra-session activities and student's presentation had greatly improved students understanding of the concepts. It also showed that lectures had played a minimal role in improving their understanding of the subject. This shows that students prefer to be active in their learning process. Active learning processes are desirable for many students as it helps them attain the learning outcomes. [10] Studies among undergraduate medical students have showed that interactive teaching styles are more popular than didactic lectures; and that the least preferred teaching method was didactic lectures.[11,12] Our study results are in agreement with the findings from these studies.

Our study also showed that teaching techniques rated as 'greatly improved' their understanding based on student's feedback had also scored well in the assessment test. But techniques which were rated as 'not greatly improved' their understanding based on student's feedback had actually scored high in the assessment test scores. Role play and group discussions which were rated by 40% of the students as 'not improved' their understanding greatly had actually resulted in more than 90% of them scoring well in those topics. A probable explanation would be that the task of preparing for class outside class hours and stage fear as mentioned by students in the feedback would have given a subjective feeling of rating them as not so good an option but had actually led to improvement in knowledge.

Similar studies have shown that techniques which involve greater effort from the student's side had led to attainment of learning objectives. However for these methods students lack the enthusiasm because of the comfort from lectures. [13] Also studies show that when student's presentation or participation is there, the anxiety is more among students.[14] So these would have been probable causes for students not giving a very positive feedback on methods like role-play but had actually made them attain their learning objectives.

Our study also showed that feedback on 'factors that facilitated their learning', most of the students have

quoted that field visits greatly improved their learning, and factors like lectures and long theory sessions have hindered their learning process.

The study also shows a significant positive correlation between student's feedback and the assessment scores. This brought out the fact that student's feedback is not only an effective evaluation tool to assess the teaching program; if properly designed it can be used effectively as an assessment test for evaluating student's understanding of the subject.

Overall, the findings of this study suggest that for community orientation program in undergraduates, active teaching methods or opportunities for active learning are greatly accepted by students and had helped them attain their learning objectives. Students learn best by field visits, and activities in between theory sessions have helped students be active in their learning process. It also reiterates the fact that anonymized student's feedback is an effective way of evaluating teaching sessions.

Though role plays and group discussions have not been perceived by students to improve their understanding it actually had resulted in attaining their learning objectives. Lack of enthusiasm and additional efforts needed from students could be a reason; further research is needed to understand why students haven't perceived those methods to improve their understanding though it actually had.

Our study used student's feedback which was subjective and the feedback though anonymous was collected by the department faculty which could have influenced the results.

Effectiveness of an 'Abridged Course in Medical Education Technology' based on Students' Evaluation of the Teachers' Performance

Alexander John[1], Teena Mary Joy[2], Nimitha Paul[3], Sumithra Unni[4], Suja Gopalakrishnan[4], Anusha G[4]

[1]Professor, Dept. of Community Medicine and Co-ordinator, Medical Education Department, [2]Assistant Professor, [3] Lecturer in Bio Statistics, Dept. of Community Medicine, [4]Assistant Professor, Medical Education Department, Amrita Institute of Medical Sciences, Amrita Vishwa Vidyapeetam, Kochi, Kerala

ABSTRACT

Background: To sustain the standards of quality medical education, the faculty needs to be well trained in the medical education technologies, both traditional and innovative. Students are the real beneficiaries of all training programmes conducted for faculty development and they appreciate good teaching. Their involvement in all possible aspects of teaching and learning will go a long way in achieving the best outcomes.

Objective: To assess the effectiveness of an 'Abridged course in Medical Education Technology', for entry level teachers, based on the students' evaluation of the (teaching) performance of the teachers.

Materials and Method: An experimental study in which an educational intervention was done and the effectiveness of the 'Abridged course' was assessed. Teaching by the teacher trained through the 'Abridged course' formed the 'intervention' in the study. 'Evaluation of the teaching performance' by the students was the outcome studied.

Results: The performance of teacher as assessed by the students had a higher mean score (61.28, SD 9.8) for residents who underwent training in medical education technology, as compared to other residents (56.81, SD 9.2) with a p-value of <0.001.

Conclusion: This study highlights that an abridged course in teaching methodology for entry level medical teachers improves the quality of their teaching.

Keywords: *Medical Education Technology, Abridged course, Effectiveness, Teachers' performance, Evaluation.*

INTRODUCTION

Faculty members of medical colleges play an important role in the training and instruction of future doctors and are expected to address a wide variety of educational goals. Due to the complexity of effective teaching, medical teachers need to be able to deploy many teaching skills. There is a growing consensus now on the fact that, to sustain the standards of quality medical education, the faculty needs to be well trained in the Medical Education Technologies.

Pre- service teachers' training routinely takes place in the general education sector in many countries. However this is not widely practiced in the field of medical education. World over, efforts are made to make teachers more efficient in their assignments by giving them various forms of training.[1] To improve the

Co-ordinator, Medical Education Department,
Amrita Institute of Medical Sciences Amrita Vishwa Vidyapeetam, Kochi, Kerala.
Email id: teenatixon@gmail.com

quality of teaching, faculty development programmes exist in most educational institutions. More emphasis is now given to faculty development programs which include planned activities to enhance faculty members' teaching and education- research skills. The Minimum Requirements laid down by the Medical Council of India (MCI) mandates every medical college in the country to have a Medical Education Unit (MEU) for faculty development and curriculum improvement.[2]

We have developed an eight hour 'Abridged course in Medical Education Technology' adapted from the curriculum of the Basic Course of the Medical Council of India, and customized it to meet our requirements, with an intention to impart to the entry level teachers the knowledge, attitudes and skills that they require to carry-out their routine teaching assignments. In an earlier study, we evaluated the programme in a faculty group and found that it was effective in improving their knowledge, motivation to teach and practice.[3] Another important aspect of any educational program design is assessing program effectiveness. There are only a few published researches that demonstrate the effectiveness of such educational interventions.[6-13] Most studies have relied on indirect measures such as learner- satisfaction surveys or self-assessment by participants. Actual effectiveness of the training can be assessed only through studies on implementation of the learned concepts by the faculty and the impact of the same as gauged by students' learning. It is to be appreciated that students are the real beneficiaries of all training programmes conducted for faculty development. The current study made an attempt to assess the effectiveness of our 'Abridged course in Medical education Technology', for entry level teachers, based on the students' evaluation of the (teaching) performance of their teachers.

OBJECTIVE

To assess the effectiveness of an Abridged course in Medical education Technology, for entry level teachers, based on the undergraduate students' evaluation of the (teaching) performance of the teachers.

MATERIALS AND METHOD

Study setting: A private Medical college in Kerala which has undergraduate, post graduate and super specialty training with an annual intake of 100 MBBS students, 95 junior residents [those who join for their post graduate training (MD, MS)] and 35 Senior residents [those who enroll for super specialty training (DM, MCH)].

Study design – an experimental study in which an educational intervention was done to assess the effectiveness of an abridged course. Teaching by the teacher trained through the abridged course formed the 'intervention' in the study. 'Evaluation of the teaching performance' by the students was the 'outcome' studied.

Sample size and sampling technique: Six junior residents of community medicine were stratified according to their year of joining and were randomized into two groups. One group received an educational intervention and the other group served as control.

Intervention:

Step-1 - A curriculum for an abridged course in Medical Education Technology was designed to impart to the residents the knowledge, attitudes and skills they require to carry-out their routine teaching assignments. The entire course duration was eight hours. The course content included Systems approach to medical education, Teaching-Learning process, Principles of Adult learning, Self- Regulated and Self-Directed learning, Taxonomy and domains of learning, writing Specific Learning Objectives, Microteaching, Curriculum, Interactive and Innovative teaching methods and teaching aids, Clinical teaching including bedside teaching etc. Three out of the six residents, received the training based on this curriculum.

Step-2 – The residents who were trained undertook 234 student hours and the residents who were not trained 213 student hours of teaching respectively. The teaching sessions were of similar topics from the usually prescribed schedule of classes for undergraduate students of the department of Community Medicine in our institute.

Thus the trained residents' classes constituted the intervention-limb of the experiment.

Evaluation: The impact of the course on teaching abilities was assessed using outcome levels defined by Kirkpatrick which included reaction, learning, behaviors and results.[14] To evaluate the first level (K1) participants' responses regarding the impact of the training on them was evaluated using a researcher-administered feedback which captured qualitative descriptions of their reactions

to the course. In the second level (K2), the learning of the participants' was evaluated. A pre- evaluation was done using a self –administered questionnaire including closed and open-ended questions to assess the cognitive, affective and psycho-motor components of the Teaching-Learning process in medical education technology. A post- evaluation was done using the same questionnaire after one week of the completion of the training. The questionnaire was concurrently administered to both groups of residents and the results of this evaluation were compared.

In the third level (K3), the participants' behavioral changes (with reference to teaching) were measured. This was the objective of the present study. For this the "trained" and the "untrained" residents were given teaching assignments on similar topics to teach the same batch of MBBS students. The topics were allotted to residents by lottery method. Thereafter, students, who were blind on the intervention, were asked to evaluate the teaching of the individual residents, using a structured evaluation format at the end of each session. This format drew ideas from the standardized format used in micro-teaching exercises used by the Medical Council of India's Regional centres and others. (This format was discussed with the faculty of our centre and accepted and consisted of 14 points which the student needed to rate on a Likert scale of 1-5).Thus the participants' teaching behaviour as evaluated by the under graduate students were compared with the control group residents.

The fourth level (K4) involves evaluation of the program's long-term impact on the learners' learning outcomes which will be the reflection of the results of the training. This evaluation was not one of our listed objectives (because data collection would be complex, time-consuming and costly). However a pre and post test (maximum 10 marks, multiple choice questions) to assess knowledge gain among students was conducted for each session, to study student's cognitive gain after the session. This took care of possible ethical issues also.

Analysis: Data were entered into Excel sheet and analysed using Statistical Package for Social Sciences software for Microsoft Windows version 20**.** Pre and post test scores of residents were described using mean and standard deviation. Scores were calculated for teaching merits of residents based on the responses from students and were compared using independent sample t-test. The students' pre and post-test scores were analysed to look for differences if any using paired sample t- test.

Ethical Consideration: Ethical clearance was obtained from the Institutional Ethics Committee.

RESULTS

The K1 level evaluation was based on the participant feedback. The feedback given by the trained residents was very encouraging and positive. Participants who underwent the course were "impressed with the workshop" and expressed their "willingness to introduce and implement these methodologies in their day to day teaching/learning exercises."

The comparison between the pre and post scores of the trained residents helped in assessing the K2 level. The mean knowledge score in teaching methods among junior residents prior to and after intervention was 2.33 (SD 0.57) and 8.67 (SD 4.16) in the intervention group while the figures were 2 (SD 1) and 1.67 (SD 0.57) for the control group respectively.

The evaluation of K3 level was the objective of the current study. The performance of teacher as assessed by the students had a higher mean score (61.28, SD 9.8) for residents who underwent training in medical education technology, as compared to other residents (56.81, SD 9.2) with a p-value of <0.001. (The result is shown in Table 1.)

The pre and post-test scores obtained by students were compared using paired t test. There was statistically significant improvement in knowledge among students taught by both 'trained' and 'untrained' residents. The mean score difference in the pre and post test scores being 4.1 in the trained residents' classes and 3.76 in the untrained residents' sessions with a p- value of <0.001 in both the groups. (Table 2)

TABLE 1: Performance of Teachers as Assessed by the Students

	Total number of responses from the students who attended the class	Mean scores	Standard Deviation	p value
Trained residents	234	61.28	9.8	<0.001
Untrained residents	213	56.81	9.2	

TABLE 2: Pre and Post Test Scores of Students

	Number of students attended the class	Mean scores	Standard Deviation	p value
Sessions by Trained residents Pre Post	234	5.13 9.03	1.4 1.1	<0.001
Sessions by untrained residents Pre Post	213	3.19 7.35	1.5 1.8	<0.001

DISCUSSION

Our study supports the evidence that abridged courses in Medical education technology for faculty development enhances their teaching skills. Many previous studies that were reviewed report similar outcomes as gains in knowledge, changes in attitudes, satisfaction with the program, and self-report of changes in behavior. However, many of these published studies lacked a control group.[6-13] Our findings are important because we have included a comparison group, and have evaluated the intervention from students' perspectives which will increase the validity and reliability of our findings.

The results of a systematic review of 53 faculty development programs found that such programs resulted in high levels of satisfaction and changes in attitudes, knowledge, skills, and teacher behaviours.[15] The review also highlighted the fact that participants consistently found such programs acceptable, useful and relevant to their objectives. Participants who underwent our course also were "impressed with the workshop" and expressed their "willingness to introduce and implement these methodologies in their day to day teaching/learning exercises."

In the K2 dimension, the pretest and posttest results showed that there were significant increases in participants' knowledge and noticeable differences between study and control group. These findings are also consistent with the findings of the systematic review.[15] The elevated post-test marks among the entry level teachers signify the immediate effectiveness or usefulness of the training with regard to their learning.

In the K3 dimension, we obtained students' evaluations of the trained teachers, and compared it with teachers who were not trained using the Abridged course in Medical Education Technology. The results were positive and showed statistically significant improvements in formers' teaching skills, but no significant improvements in the latter's, as judged by the students. This result is evidence of the positive impact of the program on teacher- effectiveness as a result of changes in their teaching behavior/ performance. Positive changes observed by students in the intervention group is a major impetus to have a pre-induction faculty training program in medical colleges/ schools. Teachers who receive some form of systematic training definitely perform better and this is appreciated by the students. This can also catalyze changes that make them better learners.

The improvement in teaching skills alone may not necessarily bring about immediate changes to student learning. While it is rational to believe that improving the pedagogic skills of (entry level and other) teachers promotes learning by medical students, there is only limited evidence suggesting that the effectiveness of teaching perceived by students can positively affect their performance and learning outcomes. Our study has shown an increase in knowledge gained by both group of students taught by 'trained' as well as the 'untrained' teachers. Many perceive medical students as persons with capacity to adapt and self-motivate, likely to possess the ability to achieve assessed learning outcomes, regardless of the teaching they receive**.** However we contend that organized training in medical education technology will make the teachers' roles more effective.

According to all the dimensions that we evaluated, the program had a positive impact on teaching abilities. Effect of randomization was uncertain due to the small

numbers. Potential confounding factors need to be considered which could be intrinsic to student participants or extrinsic related to the resident teachers. Despite these limitations, the study findings are highly relevant. This study highlights that an abridged course in teaching methodology for entry level medical teachers improves the quality of their teaching. The changes in teaching behaviour have been appreciated by the students also. This in turn should help the student/ learner in achieving short and long-term goals. Directions for future research should include an understanding of how to accurately and reliably evaluate the result of the training as regards improved student learning i.e., the desired final outcome. We conclude that faculty development programmes will promote high quality of teaching and must be an essential activity of every medical school. Therefore designing formal approaches to achieve the goals in this area is recommended.

An Economic Analysis of Small Scale Industries in Pudukkottai District (Tamil Nadu)

S Sureshand[1], S Jasirani[1]

[1]Associate Professor in Economics, Department of Economics,Vels University, Chennai

ABSTRACT

The important role-played by Small Scale Enterprises in promoting the economic development of India in recent decades especially in providing more jobs for rural people and bringing about a more equitable distribution of national income has been well recognizedWhile the majority of small enterprises depend on retained profit and informal source of credit for expansion, with growth in size, the need increases rapidly for external finance for working and fixed capital. In recent years, following the successful example of Japan, the Republic of Koria and India, in mobilizing and channeling finance to SSI,many schemes are experimented with a wide array of new financial institutions, instruments and innovations. The significant role that this sector plays in the development strategy of India's economy is not only based on the fact of its being, labour-intensive and capital saving in character but also in 3 areas namely Production, Employment and Export.

Keyword: *Economic Development, Working Capital, Production, Employment and Export.*

INTRODUCTION

Generally a dry and hot climate prevails in the district(Pudukkottai District) which is not favorable for agricultural sector.So agricultural sector is inadequate to provide livelihood to the entire working force. On the other hand, the establishment of large- scale-industries cannot solve the problem of seasonable unemployment found in India,which is solved by SSI sector only. More-over the growth of capitalist enterprises and concentration of the means of production in few hands have led to the emergence of inequalities of income and wealth. So SSI units are ideal instruments for decentralization of industrial production is achieved especially in Pudukkottai District.

PudukkottaiDistrict, formed in January 14, 1974 out of certain pockets of the then Trichy and ThanjavurDistricts, has on area of 4663 Sqkm with a coastal line of 39 Kms. The District lies between 78.25 and 79.15 of the eastern longitude and between 9.50 and 10.40 of the northern latitude. It is bounded by Trichy District in the north and west, Sivagangai District in the south and Bay of Bengal in the east. Pudukkottai District is economically, industrially and educationally a backward district. Both the Central and State Government have declared it as an economically backward district. In order to promote the industrial scene in such backward areas both the Government of India and the Government of Tamil Nadu provide so many concessions and incentives to SSI units through District Industries Centre, which is located in Collector Office,TrichyRoad[1].

OBJECTIVES OF THE STUDY

The potential role of small-scale industries in Pudukkottai District during the period 1995-2000 is examined here. The present study is an analytical and descriptive one, based on a survey of One Hundred Small Scale Industrial Entrepreneurs.One Hundred Entrepreneurs were selected out of (5441) Five Thousand Four Hundred and Forty One units on the basis of random method of sampling. A preliminary sketch of the growth of Small-Scale Industries in India and Tamil Nadu in general and Pudukkottai District in particular is presented. The SSI units Pudukkottai District have classified into three categories.

1. **Agro-based processing units**-Food, Rice Mill,Wood,Oil and Rubber, Coir Units(Total 30 units).

2. Industry- based production units-Gem Cutting,

Paper, Aluminium,Metal Products, EngineeringGoods, ElectricalUnits (Total 40 Units)

3.Business based units – Beverages, Pan (Beeda), Xerox, PrintingPress (Total 30 units),Gross Total 100.

Among the sample units selected at random, Industries manufacturing Aluminium,Paper,Plastic,Rubber,Chemical,Coir,Metal Products are found in large numbers in this study area of the One Hundred sample units, Fifty Two units are run by sole proprietorship and Forty Eight units are run by Partnership concerns. Sole Proprietorship is preferred more in Pudukkottai District[2].

(A) MAJOR OBJECTIVES

1.To find out the Capital Labour ratio of small-scale units.

2.To know the degree of capital output ratio of SSI units in Pudukkottai District.

3.To access the extent of capacity utilization of SSI units in the study region.

4.To analyses the structure and performance of small-scale industries.

5.To study the problems faced by various small-scale industrial units.

6.To identify the factors retarding the growth of small-scale industrial units in the study area and

7.To understand the sickness of Small Scale Industries in the study area.

HYPOTHESIS

The following hypotheses were formed.

1.The Credit given for the operations on development purpose is more useful than loans given on a general basis.

2.There is a relationship between the traditional background of the owners and entrepreneurs and the growth of small-scale industrial units.

3.The borrowings from commercial banks have paved the way for the growth of SSI units

4.The financial assistance to SSI from Central and State Government is inadequate.

5.The growth of productivity is positively associated with growth in input.

6.The manufacturing sector is not experiencing technological change.

7.The factor productivity and capital intensity are inter-related.

METHODOLOGY

Researchers collected both secondary 1990-95 period and primary 1995-2000 periods of data's:

The primary data were collected through questionnaire from the entrepreneurspersonally, particulars required to fulfill the objective of the study were asked in the questionnaire.

The District Industry Centre and the Commercial Banks given the Secondary Data. For further informations,books,journals,magazines and other relevant material were referred too. The data collected from various sources were transcribed in to a master table to facilitate easy tabulation;percentages and ratios were worked out.Tools like the Granger test,Sims test and modified Sims test were also used to analyse the data.

The study covers the SSI Units registers with the District Industry Centre,Pudukkottai District during 1995-2000.Among the total units of 5441, 2290 SSI Units are sick and some are closed.The remaining 3150 units have been found to be healthy units and are efficiently operating during the period 1995-2000.Researchers had taken 100 units at random and have found that 42units are sick in Pudukkottai District.

The researchers had also used secondary data through the Reports of Finance, Government of India,National Planning Commission, Reports of Ministry of Finance, State Planning Commission of Tamil Nadu,IOB Annual Credit Plan Reports,Articles of journals,Research papers.The published data of SIDCO, TIIC have been used and have been referred to[3].

CHAPTERISATION OF THE STUDY

The study is presented in seven chapters.

First chapter deals with introduction.In the Second chapter early studies are reviewed many studies on this subject undertaken by researchers have brought

to light,the innumerable difficulties that the Small-Scale entrepreneurs have had to face in running their enterprises in India

The Third chapter deals with objectives, hypothesis,methodology and there is a discussion on the profile of the sample units in Pudukkottai District. Chapter Four discusses land factors for SSI.Chapter five deals with problems of SSI units and strategy for resolvingsuch problems. In Sixth chapter, there is a discussion and proof with statistical models.In chapter Seven findings,suggestions and conclusion are presented.

The study shows how much capital invested in every SSI units,working capital,value of production,reason for low production,estimates of cost of production,number of workers employed in each SSI units,mode of employment of workers. Marketing conditions,they too are experiencing many constraints,such as shortage of working capital and raw material,poor infrastructure facilities and irregular power supply.

LIMITATIONS OF THE STUDY

1. The study does not cover the institutional assistance for sick units of SSI.

2. Further this study does not cover the performance of some Central Government Institutions because of the scarcity of data.

3. Researchers could not receive Secondary Data sources from PudukkottaiTamiI Nadu Industry Investment Corporation Office directly;only data gathered through Annual Credit Plan Report published annually by IOB (Lead Bank)Pudukkottai District, is available.

4. The Researchers were not able to collect more as well as correct information from the respondents.Their ignorance and inexperience are stumbling blocks for the data collection.

5. The study is related to private SSI units only.No public sector units were considered in the process.

ANALYSIS OF THE CHAPTER.

The total population of the district as per 1991census is Thirteen Lakhs,Twenty Seven Thousand and One Hundred Forty Eight (13, 27,148) of which males and females are almost equally divided.The total population of the district as per 2001 census is 14, 52,269 of which male's population was 7, 20,847,Female population was 7,31,422. According to 2001 census, Female population was more than Male population in Pudukkottai District.

The study is confirmed to pudukkottai district,which is an industrially backward area in Tamil Nadu and it is now slowly developing into industrialized district of the state.This district has got 5441 registered SSI units (99-00), medium large-scale industries-34, Handicrafts units-2328 and Pudukkottal district is having 9 Taluks and 13 blocks. There is on SIPCOT industrial complex in the district 6km from head quarters with an area of 412acres and 76 plots are available here which is located Trichy road,the extension of Cauvery water for the industrial units in the estate is planned[4].

The Tamil Nadu forest plantation corporation had also drawn up a detailed scheme for replacing the old fielding cashew plantations in the district with high yielding varieties. The TNFPC has brought over 1000 hectares of land eucalyptus and many of land under and many private farmers were also keen on taking up eucalyptus plantations.So that related industries could come up.

Out of the 18 institutions 3 banks have shown excellent performance by achieving 100/- target PNB-174% achievements,Bank of India 136% achievement,ICICI – 125% achievements.

REVIEW OF BANK PERFORMANCE -1995-2000

Target-144.29 Crores93%

Achievements-134.83 Crores

Of the One hundred units selected for this study fifty three percent are located in Pudukkottai and seventeen percent in Mathur and MandiyurnearbyTrichy. Out of the one hundred SSI industries collected through random sampling method during the period of 1995-2000. Pudukottai proper town having 53 units of SSI units Alangudi 6 units, Aranthangi 6 units, Ponamarravathy 1 unit, Mathur, Mandiyur 17 SSI units, Keeranur 5 units,Viralimalai 2 units,Kottaipatinam 2 units, Athanakootai 1 unit, Tirumayam 2 units, Kandarvakottai 1 unit,Annavasal 4 units. Total 100 units were collected by researchers through proper questionnaire.

The location of the majority of the sample units in Pudukkottai town and Mathur block must be attributed to the pioneering role played by these blocks in the Industrial Development of the District and the availability of infrastructural facilities in these two centers.

RESULTSTHEORETICAL PROVED

1.The credit given for specific operations on development purpose is more useful than loans given on general basis.

One of the striking findings of the present study is the fact that the Credit for specific operations is 95 of the entrepreneurs have taken to SSI as a since of profitability, lessrisk, priorexperience, self employment,5 units have been started with the only aim of profitability earned from SSI units. Earning more profit is more useful and it is specific operation than other purposes that is less risk,prior experience,and self employment-as a general basis.

2. There is a relationship between the traditional backwardness and social background of the owners and the growth of SSI.

People in the age group between40-60 are continuing (i.e.) 56 units in Pudukkottai District) the work of their ancestors professions. This hypothesis is proved. Backward Caste people have some political influence through which they are dominating SSI units and Scheduled Caste people did not shine inSmall Scale Industrial units due to poverty,ignorance and the apathy shown by officials too. This hypothesis is also well proved[5].

3. The borrowing from commercial banks and the growth of SSI units.

In Pudukkottai District,commercial banks were established for improvement of SSI sectors particularly 72% of loans given to SSI units during the period of 1995-2000 by commercial banks,especially(IOB, SBI BANKS) had been well proved the financial strength of commercial banks than other sources of finances.This hypothesis is proved.

4. The State Government financial assistance to SSI units is very poor.

Only 8% of the loans were given to SSI units by the State Government.This hypothesis is also proved.

5. Statistical Proved

The growth of productivity is positively associatedwith growth in input:-Emerging input likecapital structure from this study according to SSI development in this district has also been worked out.It is presumed that greater the K/O ratio of output, the greater will be need for fixed capital and the sizes of output are highly correlated.For different industries in Pudukkottai District,it is that input that is investment and output are highly correlated.It is found that capital investment and output are highly correlated,as rank correlation is 0.70 where as capital investment and output at different levels are found 0.72.It means that at district level size of total capital employed plays important role for generation of income through value of output proceeds due to location choice of SSI units in Pudukkottai District[6].

6. The manufacturing sector is not experiencing technological change – it is proved.

Capital productivity in PDKT District - 1.082%

Capital Intensity - 3.296%

Raw Material Productivity- 1%

But Labour Productivity - 4.487% (per year)

7. Capital intensity and the factor productivity are inter-related

This hypothesis is disproved

Rs.26, 000/- will be required to employ one labourer annually in 1981.This ratio is higher than the other states. Rs.18, 418 will be required to one labourer in other states in the same year. Recently between 1995 and 2000 O/K,ratios shows productivity of capital. It shows how much output is produced by a unit of capital. Sample units of PDKT Districtshows O/K ratio is 0.84 i.e. Rs.84, 000/- will be required to a unit of output which is higher than All India level ratio of 0.15 i.e. Rs.15, 000/- will be required to a unit of output or registered manufacturing sector.

FINDINGS AND SUGGESTIONS

1.Government Liberalization, Globalization, Privatization policies are not favorable to SSI Units in PDKT District.

2. TNEB levied heavy power rate for SSI,which is very heavy to bear.

3. Most of the units in SIPCOT complex are very sick due to low power supply mismanagement,lack of working capital, power shortage, and marketing problems.

4. Lakshmi Shanmuga Spinning Mill,NamanaSamuthram which arelocated in Pudukkottai district is sick due to rise in raw material prices, heavy interest rates levied by banks according to Board of Industrial Financial Re-construction. Only remedy is government must take over all the important,SSI units with strict Government order.

5. Central exercise duty exemption should be granted to SSI and tiny sectors[7].

CONCLUSION

No doubt if the SSI meets challenges with determination,innovation and hard work they can even compete with foreign products also which are chapter even after levy of duties. The lowering of interest rates-on their (SSI Units) borrowings to 5 or 6%, by a sympathetic attitude on the part of nationalized banks to those sick units in particular and by greater co-ordination among Government banks and other financial institutions and the entrepreneurs and the researchers portrays many invaluable ideas to develop the economically backward district.

Role of Microfinance and Women Empowerment in Madurai District, Tamil Nadu

S Thangamayan[1], S Suresh[2], B Chithirairajan[3]

[1]Assistant Professor, [2]Associate Professor, [3]Assistant Professor, Department of Economics, VISTAS

ABSTRACT

The key elements in empowerment are enabling and providing power and they reinforce each other. Women's empowerment is a multifaceted concept that extends to the economic, social, cultural, political and psychological aspects of women's life. The major objectives of the study are to study the socio economic impact of women SHGs on group members and to know the role of SHGs in providing rural credit. Total 50 women were interviewed. 10 SHGs of were selected by simple random sampling method. As far as the selection of group members is concerned, five members were deliberately selected from each group. The study is purely descriptive. In order to achieve the objective of poverty eradication, every poor person should have easy access to credit for starting small economic activities based on local resources. However by 1970, the limitations and the critique of the welfare approach became obvious and resulted in the development of a number of alternative approaches based on equity, poverty alleviation, efficiency, and empowerment. Microfinance is not merely a financial business, but is a strategy or tool for empowerment of women particularly the poor. The microfinance concept when coordinated with the SHG lending system, those people who have been deprived of credit, could have their fair share of credit.

Keywords*: Self Help Groups (SHGs), Micro Finance, Women Empowerment, Credit, Poverty Eradication, Economic development.*

INTRODUCTION

The Concept of women empowerment is defined as the process by which women take control and ownership of their choices. The core elements of empowerment here have been defined as agency (the ability to define one's goals and act upon them), awareness of gendered power structures, self-esteem and self-confidence. Empowerment can take place at a hierarchy of different levels individual, household, community and societal and it is facilitative by providing encouraging factors (e.g. lack of resources and skills)[1]. In this connection micro finance with self-help groups play an effective role for promoting women empowerment. Indian women have to be made as an integral part of the socio economic structure of the society. The social values, norms, which influence social expectations regarding the behavior of women, will determine a role and her position in society to a great extent in the process of changing era. Changes have been taken place in the position of Indian women as a part of the process of transformation of the traditional society[3]. The situation of women actually has changed completely in the last thirty years. In the beginning of 1970s; women were behind in the field of development. There were no changes for the empowerment of women. In the Third World both rural and urban women were playing a significant role in the activities of managerial decision making. Self-help groups have been instrumental in the empowerment of women by enabling women to work together as a collective agency[5]. Women command few economics resources and frequently rely on family or male members. However, self-help groups, when combined with savings and credit, have enabled women to benefit economically by monetizing their contribution and in the process have empowered them to become agents of change. Another related aspect is that self-help groups have facilitated the formation of social capital where people learn to work together for a common purpose in a group or organization. Women learn to work for a common purpose in a group or organization. They learn to work for a common purpose in self-help groups leading to the formation of social capital. Although women form nearly half of the human capital, they are still the most deprived and neglected segments of the

society despite the constitutional guarantee, and for equal rights and privileges for men and women. Women constitute to be the victims of a process of economic, social, cultural and political marginalization[2]. While a large part of the world countries look at women's issues in terms of paternalism and well-being, the concept of women's empowerment in the social, political, and economic order as a pre-requisite of human development is hardly given the priority that it deserves.

THE CONCEPT OF MICROFINANCE AND SELF-HELP GROUPS

The concept of SHG which has been gaining significance especially in area of micro-finance is mainly the off-shoot of the success of group based approach to savings and credit for the rural poor followed by the Grameen Bank of Bangladesh. The group based approach not only enables the poor to accumulate capital by way of small savings but also, and more importantly, helps them to have easy access to formal credit facilities[7]. These groups by way of joint liability enable the poor to overcome the problem of collateral, which is a major hurdle in gaining access to institutional credit. The joint liability not only improves group member's accessibility to credit but also creates conditions or mechanisms like peer monitoring, leading to better loan recoveries. Formation of Self-Help Groups is the prime-mover as well as integral part of microfinance based credit delivery system and involves the following three basic steps:

- Group formation (formation, development and strengthening of the groups to evolve into self-managed people's organizations at grassroots level);
- Capital formation through the Revolving Fund, skill development (management skills for management of their organizations as well the activity); and
- Taking up economic activity (micro-enterprises) for income generation.

Microfinance refers to the supply of loans, savings and other basic financial services to the poor. It envisages mobilizing thrift and supplementing it with loan from the financial institutions. By providing access to financial services, microfinance plays an important role in the fight against the many aspects of poverty. Main objectives of microfinance are:

1. Poverty alleviation
2. Empowerment of women
3. Financial sustainability
4. Increased outreach and impact

OBJECTIVES OF THE STUDY

1. To study the socio economic impact of women SHGs on group members.
2. To know the role of SHGs in providing rural credit.
3. To study on status and impact of Micro finance in India.

METHODOLOGY

The present study focused on Madurai District and selected village in this District SHGs are functioning in the very success manner. The primary data were collected during the period January 2014 with the help of interview schedule. The schedule included related to general information about the SHGs members, socio demographic profile, income, expenditure, savings and loan schemes available to SHGs members.Total 50 women were interviewed.10 SHGs of was selected by simple random sampling method. As far as the selection of group members is concerned, five members were deliberately selected from each group. The study is purely descriptive. The researcher has undertaken every possible effort to fill up the gaps of information by conducting individual interviews.

SOCIO ECONOMIC IMPACT OF SHGS

Women self-help groups have been proving their significance in entrepreneurship development, marketing and active participation in social welfare campaigns, fighting against alcoholism, child marriages, dowry and superstitions. Saving is the principal activity of self-help groups. It was observed that after joining SHGs, the women members had become habitual of savings and depositing a certain amount regularly with their respective groups.

Table 1: Monthly Savings, Loan Purpose and Credit Facility availed by Responds

1) Monthly Savings	No. of the respondents	Percentage
Up to 25	13	26
26 – 50	24	48
51 – 100	7	14
101 – 250	4	8
151 and above	2	4
2) Loan Purpose	No. of the Respondents	Percentage
Business activity	12	24
Household needs	15	30
Festivals	4	8
House construction and Repair	7	14
Education	5	10
Repayment of loan	3	6
Other Purposes	4	8
3) Loan Amount (in Rs.)	No. of the Respondents	Percentage
Up to Rs. 500	2	4
501 – 1000	13	26
1001 - 2500	16	32
2501 – 5000	12	24
5001 – 10000	5	10
10001 and above	2	4
4) Loan Repayment	No. of the Respondents	Percentage
Regular	42	84
Irregular	8	16

Source: Field Survey, 2014.

As far as repayment of loan was concerned, 84 percent women members were regular at repayment of loan whereas 16 percent respondents were irregular. The major reasons of irregular repayment were use of loan amount for unproductive purpose, uncertain and inadequate income of the respondents.

The major aim of the SHGs is to promote savings and to credit for the productive purposes. This is true because many people in the study area join the SHGs for getting loan and promote their personal savings, in addition to get social status Table-1.The highest number of the respondents 30 percent had used loan amount for meeting household needs, such as, purchasing food grains, clothes etc. whereas repayment of loan was the main purpose in case of 6 percent women respondents.

RURAL CREDIT AND SHGS

One of the reasons for joining SHGs is to avail credit which is true in the present study area. The second objective of the present study is to know the rural credit by SHGs. The credit organizations like nationalized banks, Cooperative Societies and so on, follow many formalities to provide credit to the rural people. At the same time village money lenders change very high rate of interest. In this situation SHGs are the boon to the rural people, because instead of approaching banks individually, SHGs can easily approach the banks and other institutions to get loan. The SHGs get loan from credit institutions refinance (share) to the members in the SHGs. In the study the prevailing interest rate is 1 percent to 4 percent. Therefore members are repaid the loan in time.

Table 2: Types of Loans in the SHGs

Sl. No.	Types of the Loan	Maximum amount Rs.
1	Business Loan	20000 to 25000
2	Marriage Loan	Up to 20000
3	Repay the old Loan	10000 to 15000
4	Medical Loan	10000 to 15000
5	House repairing Loan	Up to 5000
6	Cattle Loan	5000 to 7500

Source: Field Survey, 2014.

Most of the respondents are received business loan and repay the old loan. Cattle loan are received by agricultural labour and famers. Marginalized people are received by house repairing loan in study area. All the SHGs are having a procedure to upper limit of loan. Table – 3 gives to maximum limit of loan amount in SHGs in study area.

Table 3: Amount of Loan Availed by the members through SHGs

Sl. No.	Amount of Loan	No. of respondents	Percentage
1	Less than 5000	8	16
2	5000 to 10000	10	20
3	10000 – 15000	12	24
4	15000 – 20000	13	26
5	Above 20000	7	14
	Total	**50**	**100**

Source: Field Survey, 2014.

Table 4: Repayment of Loan by SHGs members

Sl. No.	Amount of Loan	No. of respondents	Percentage
1	Repayment in time	31	62
2	Repayment in advance	11	22
3	Repayment not in time	8	16
	Total	**50**	**100**

Source: Field Survey.2014.

Moreover banks instruct the members to save minimum Rs.200 per month. So repayment is very easy to SHGs. The loans can be used by individual group members for their personal needs, sometime the group may invest on any economic activities. Nowadays many SHGs are starting small business, cottage industries, food processing units etc. The SHGs in the study are granting the loan to their member for various purposes. The maximum loan amount per members is decided by the personal by the general body meeting (Table 4). Almost the all members in the study areas are availing the loan facilitates SHGs.

STATUS OF MICROFINANCE IN INDIA

The microfinance initiatives of NABARD yielded remarkable success and the SHG bank linkage programme has emerged as the largest microfinance programme in the world. The pilot project started in 1992 has turned into a national movement leading to the socio-economic empowerment of women.

Table No. 5: SHG – Bank Linkage Programme 2013-14 : Physical

(As on 31 March 2010)

Total number of SHGs savings linked with banks	:	69.53 lakh
Out of total, [of which] exclusive Women SHGs	:	53.10 lakh
Out of total, [of which] -SGSY SHGs	:	16.94 lakh
Total number of SHGs credit linked during 2009-10	:	15.87 lakh
Out of total [of which] exclusive Women SHGs credit linked	:	12.94 lakh
Out of total ,[of which]- SGSY SHGs credit linked	:	2.67 lakh
Total number of SHGs having loans outstanding as on 31 March 2010	:	48.51 lakh
Of which exclusive Women SHGs	:	38.98 lakh
Of which-SGSY SHGs	:	12.45 lakh
Estimated number of families covered up to 31 March 2010	:	97 million

Source: NABARD, Annual Report 2013 - 2014

IMPACT OF MICROFINANCE

The micro-enterprises run by the SHG members through the microfinance provided improve their economic condition as follows;

- It enables the poor to take advantage of existing opportunities
- It builds up their assets
- It generates self-employment
- It develops micro enterprises
- It raises their income
- It builds up their self-confidence and self-esteem
- In enhances overall economic growth
- In enhances domestic savings and improves financial market
- It provides escape route from poverty

The benefits are not merely economic; they have also helped the women gain qualities of leadership; attain self-confidence, economic self-sufficiency, self-respect and concentrates on capacity building among women. The women undergo training programmes and discuss various issues that concern them and their village. They have become very articulate and enterprising. Microfinance will also give an access to support network thus enabling them to advance their individual and collective interests at local and macro level. Sustainable microfinance services lead to women's individual economic empowerment by stimulating women's micro-enterprise development and leading to increased income under women's control[10]. Women's control over these resources will then lead to increased well-being (health, nutrition, literacy, and housing) and reduced mortality rates for women and their children. Microfinance has the effect of increasing the political empowerment of individuals in a society. Microfinance can primarily strengthen political empowerment through two mechanisms. First, if microfinance improves the economic and the social conditions of the poor, the poor's political empowerment will consequently rise due to an increase in their self-efficacy. Second, in addition to increased self-efficacy, microfinance can also increase the social capital in a society, which then improves individual's access to political information and capacity to participate in politics.

RECOMMENDATIONS OF THIS STUDY

The following recommendations are made on a pragmatic basis and with a view to provide a new base-line of action.

1. There is a need for providing social security schemes like provident fund, medical benefits, pension etc., to the members of SHGs.
2. The government, bank and educational institutions should regularly arrange training programmes for the SHGs members for improvement of their managerial and behavioral competency.
3. The banks should relax their terms and conditions while giving loans to the SHGs. Bank should not impose any minimum limit for the savings.
4. There is a need for enacting separate act to provide legal framework for the functioning of SHGs in the country.
5. Encouraging the media with the help SHGs organizations to project positive images of women and girl child, change the mind-set of the people and thus promote balanced portrayals of women and men.
6. The government department should make budgetary allocation for training components for the Self Help Group members.

CONCLUSION

Microfinance is not merely a financial business, but is a strategy or tool for empowerment of women particularly the poor. The microfinance concept when coordinated with the SHG lending system, those people who have been deprived of credit, could have their fair share of credit. Considering the vast number of poor, discriminated and underprivileged women and the need of financial services, there is tremendous scope for micro financing through SHGs in India. The NBFCs, Banks and Voluntary Organizations play a crucial role in the micro finance market. In order to achieve the objective of poverty eradication, every poor person should have easy access to credit for starting small economic activities based on local resources. Women self-help groups can play a very positive role in socio economic empowerment of poor women. Micro finance can play

a crucial role in achieving Millennium Development Goals and reducing world's poverty by 50 percent by the end of 2015. Poverty reduction is possible by providing easy access to credit for small entrepreneurial activities. Empowerment of women can be promoted through socio economic activities at grass root level. Confidence build up by SHGs helps women members to fight against injustice and secure their rights.

An Empirical Study on Retail Demand for Store Brand Pickles in Tirunelveli, Tamil Nadu

Varadarajan Rangarjan[1], K Thulasi Krishna[1]

Department of Management Studies, MITS, Madanapalle, Chitoor District AP

ABSTRACT

Retail business hasexpanded quickly within a short period in India and has raised critical concerns such as management of service level while meeting consumer needs. That impact the performance of the retailers and their cost-effectiveness. The paper probesthe estimation of demand for a store brand household item, namely Pickle, and demonstrates the benefits of multinomial logistic regression as a useful tool for handling categorical demographic variablesvery frequently used as predictors. Retailers can benefit immensely, by the methodology for other similar products. Moreover, they can enhance space optimization and achieve greaterprofitability per unit retail space and improve customer satisfaction. The research finds that the probability of buying the store brand pickle increases with age of customer and evinces a clear gender bias in the inclination to buy store brand Pickle.

Keywords: *inventory management, assortment planning, multinomial logistic regression, R environment*

INTRODUCTION

Economic policies changes, growth of middle class population, and higher in per capita income hasspurred economic growth in India,leading to prosperi*ty* retail sectoras a resultnow the retail sector represents 10% of India's GDP and a 8% share of employment. Additionally, food inflation is exerting pressure on the retailers to reduceoperating cost to sustainbusiness and profitability. Food price inflation has strained consumer budgets leading them to reduce frequency of visits to the stores and also their purchase volumes. Though it is well known that inflation is due to dynamics of global economic environment, and uncertain rainfall, it has certainly broughtoperations efficiency to retailer's attention.

The competition in the retail in industry in India has been dynamicdue tothe emergence of retail chains and modern retail stores. The critical issues in retailing is the decision about the variety of items a retailer decides to carry for satisfying the consumer. While a wide product assortment meetsevery consumer's needs, it increases inventory. Additionally, it leads to shelf space allocations problems. The problems acquire intensity since retail space is expensive and limited. In view of such constraints, retailers need to use efficient assortment strategies. This means that the retailers would strive to find an optimal mix of products to minimize cost of operations without affecting service levels. This pivots on estimating demand for products. Regression, moving average, and exponential smoothing are frequently used to estimate aggregate demand. At SKU level, logistic regression has been suggested by literature for demand estimation.Logistic regression helps in establishes link between demographics and consumer choice of products. Demographics have been found to be good predictors for retail demand.Demographic variables are categorical in nature and simple regression is not suitable. Logistic regression and multinomial logistic regression are best options. This research uses multinomial logistics regression to determine the probability of purchase as a function of demographic variables age, gender.

Pickles are an integral part of food in Indian households and are traditionally prepared at home using several spices in various combinations leading to different tastes and health benefits. The combination of spices and methodology determines the shelf life of the pickles. It pertinent to point out that homemade pickles do not use preservatives but are prepared in such a manner that they remain good for long durations (2 to 3 years). More over pickles are known to be used only after a period of maturation, that is generally

not less than 6 months. In recent times due to lack of expertise and time families have started to purchase pickles made commercially, which are known to use preservatives and other artificial ingredients. The older generation still believes that pickles made at home are better tasting, hygienic, and good for health as they are devoid of artificial chemicals. While brand owners claim that their products are equivalent to homemade pickles, consumers' trust seems to be latent. Our study does not explicitly dwell into the hygiene aspect of the off the shelf pickles, but it seems that hygiene is an intrinsic part of the consumer choice and purchase intentions. Since we have not explicitly studied the hygienic aspects of the pickle as commercial products, the research does not make any comments on that aspect

Abundant literature on studies on various aspects of supply chain management for FMCG goods including food and grocery items is available. In this study how,inventory can be smartly managed in retail outlets is presented. The retail outlets are the first point contact for consumers and they relay the consumer requirements up the supply chain to the manufacturers. Variables such as floor space, shelf space, display methodology etc. have been identified as the measures that determine selling efficiency.

LITERATURE REVIEW

Retailer's assortment of products is dependent on the target customers, shelf space availability, brand perception, financial strength, and the competitive profile. Even though many retailers claim to offer a one stop shopping experience, providing the whole range of product a random customer would want to buy is next to impossible. Moreover,there is empirical evidencethat on an average customer visit at least three shops before fulfilling all their requirements. The number of consumers served by a retail outlet is so large that satisfying each customer in the target set would be difficult[1] and consumers first-choice preference changes from time to time [2,3]. Consumer preferences are directed by factors such as fulfilment of global and local utility, estimated search cost, and availability of substitutes etc. Such changes can occur due to satiation, need for a change due to changing objectives, social position[4], or to know[5,6] about other items. Such changes lead customers to seek variety. Findings of the above papers means that high levels of heterogeneity in consumer preferences are ubiquitous and a retailer may have to stock an extensive variety of products and SKUs. Stocking of inventory is limited by availability of resources. In addition, studies have evinced that offering too many choices negatively affects consumer perception about the store[7,8] because consumers are beset with the amount of choice and find it difficult arrive at a purchasing decision and the customers may not come back to the store[9]. Moreover, apparent variety has an influence on consumers' buying decision and a mismatch between actual variety and perceived variety can potentially negatively impact buying experience and may lead to lost sales or the consumer [10,11,12]. Perceived variety is dependent on method of display and the symmetry of the assortment [13]. Further retailers may lose sales (lost sales to extent of 4% occurs due to OOS[14] due to out of stock situations in which the consumer can either buy a substitute or buy the preferred product from a competing store. The following table shows reactions to stock out situations:

Multinomial Logit model (MNL)

Theory of utility is the basis for the MNL model. Each customer relates a utility for the purchase or no-purchase of a particular category/SKU. The no-purchase decision is coded in the model as product 0, i.e.when a customer chooses product 0 it is considered a no purchase decision. The consumer's utility related to choose of a product j from S U {0} the Union of set of products carried by the retailer and product 0 is represented as U_j. The utility U_j is considered to be sum of a deterministic part and a random part

$$U_j = u_j + \varepsilon_j$$

The random portion is modeled as a double exponential random variable with the following distribution:

$$\Pr \{X < \varepsilon\} = \text{Exp} (-\text{Exp} – (\varepsilon/\mu + \gamma))$$

Where γ is Euler's constant (0.57722). Its mean is zero, and variance is $\mu^2\pi^2/6$. As the degree of heterogeneity among the customers increases μ also increases. The ε_j are independent across consumers. Hence the product wise general utility for each consumer is same; the actual realized utility may be different based on the level of heterogeneity of the customer population. Additionally, unobservable factors determining the utility of the product to the individual may also be a cause. An individual maximizes utility when choosing a product from the available set. Hence, the probability

that an individual chooses product j from S U {0} can be represented as

$$p_j(s) = \Pr\{Uj = \max_{k \in sU\{0\}} (U_k)\}$$

The double exponential distribution being closed under maximization we can write the probability that a random customer chooses product j from S U {0} as (For proof refer Anderson et al (1992)19.

$$pj(s) = e^{\mu j/\mu} / \sum_{k \in sU\{0\}} e^{\mu k/\mu}$$

Guadagni and Little (1983)[15], show how MNL model can be used for estimating demand for a group of products.

The major criticism for the MNL model is due to Independence of Irrelevant Alternatives (IIA) property. This property is true when ratio of choice probabilities for any two alternatives is independent of ratios for other such alternatives. When we compare two brands within a category, choices within one brand will only lead to cannibalization under high brand loyalty and this property would not be true. Such situations are not rare. One way of overcoming this is to use a Nested Logit Model that is the customer first makes a choice of the brand and follows it up with choosing the SKU. Probability of choosing within a brand follows an exponential distribution and hence the choice probability between two brands also follows an exponential distribution and we can write the total probability as

In which the first term on the right hand side refers to the choice between brands and the second term refers to the choice within a brand. One difficulty in using this nested logit model is that we need know the product attributes the customer uses in the choice process and how the customer prioritizes them. The MNL is also deficient in capturing intricate issues with substitution behavior. The model cannot differentiate between products that have same penetration rate but different substitution rates.

METHODOLOGY

A retail store frequented many consumers located in a residential area was chosen for the study. The name of store and Picklebrand is being kept confidential for commercial reason at the request of the store owner. Mall encounter method of sampling was used to find out purchase intention of store the brand pickle.Ashort demographic profile consisting only of gender and age was also collected as only these two demographic variables are used in this analysis. In total details from 133 customers was collected and analyzed. The analysis was carried out using "nnet" package in the R environment. Chi square test function available in the generic R environment was used to perform chi square test prior to performing the multinomial regression.

RESULTS AND DISCUSSION

The sample profileis as in table 1

Table 1: Sample Profile

Total number of respondents	133
Gender ratio	62% male and 38 % female
Age group	
Group I 20-25 years	39%
Group II 26 -30 years	30%
Group III 31 -35 years	31%

As a firststep the data was put through a chi square test to see if there are significant differences between the groups based on gender, age and education. The Routput for chi square test is given in table 2:

Table 2: Pearson's Chi-squared test with Yates' continuity correction for gender Vs purchase intention

data: product purchase		
Chi Square	Df	P – Value
12.032	1	0.005228

The null hypothesis that there is no gender-based difference in purchase intentions is rejected at alpha of 5%. Which indicates that there is significant difference men and women about choice of Pickel brands.A similar chi square test on age and purchase preference yielded the following results:

Table 3: Pearson's Chi-squared test for Age group vS Purchase intension

data: purchase of product		
Chi Square	Df	P – Value
10.036	2	0.006619

Which clearly shows that the purchase preference of different age groups is different and highly significant at an alpha of 5%.

The output of the multinomial logistic regression using "multinom" function in nnet package is given below in table 4

Table 4:; Multinomial Regression: logit z associated with purchase intention and independent variables Age and Gender

Coefficients:	Values	Std. Err.	P values
Intercept	3.50769445	1.225891	0.0042185035
Age	-0.09448192	0.041458	0.0226683025
Gender	-1.46494357	0.397377	0.0002273296

Residual Deviance: 165.2999

AIC: 171.2999

From the table it is clear that all the coefficients are significant at an $\alpha = 0.05$. The following regression equation (* is used as multiplication sign) can be constructed from the above

(logit) Z = 3.5077 – 0.0945*Age – 1.465*Gender (1)

The probabilities can be calculated using equation 2

(2)

From the regression equation it can be inferred that the variables age and gender have negative effect on the probability of purchase, i.e. as we move from group I to Group II in the age category the probability of purchase diminishes by a factor of 0.0945 and between men and women the change in probability is to the extent of 1.46. This is clear from the predicted probabilities for the sample.

The predicted probabilities are given in table 5

Table 5: Predicted probabilities

Age	Gender	Logit(Z)	Exp(Z)	Predicted probabilities
34	1	-1.1696	0.31	0.24
30	1	-0.7917	0.453	0.31
33	1	-1.0752	0.341	0.25
31	0	0.57875	1.784	0.64
28	1	-0.6027	0.547	0.35
30	0	0.67324	1.961	0.66
30	1	-0.7917	0.453	0.31

Cont... **Table 5: Predicted probabilities**

22	0	1.42909	4.175	0.81
24	1	-0.2248	0.799	0.44
29	1	-0.6972	0.498	0.33
20	1	0.15311	1.165	0.54
30	0	0.67324	1.961	0.66
31	1	-0.8862	0.412	0.29
21	1	0.05863	1.06	0.51
30	1	-0.7917	0.453	0.31
32	0	0.48427	1.623	0.62
31	1	-0.8862	0.412	0.29
27	1	-0.5083	0.602	0.38
27	1	-0.5083	0.602	0.38
20	0	1.61806	5.043	0.83
22	1	-0.0359	0.965	0.49
20	0	1.61806	5.043	0.83
25	1	-0.3193	0.727	0.42
23	1	-0.1303	0.878	0.47
31	0	0.57875	1.784	0.64
24	1	-0.2248	0.799	0.44
33	1	-1.0752	0.341	0.25

Gender is coded as Male = 1 and Female = 0

Summary analysis of the predicted probabilities based on gender and age group is presented in table 6. From the table it can inferred that women of all age groups have greater preference for the store brand Pickle whereas younger men prefer the store brand Pickle than older men.

Table 6: Average Predicted Probabilities

Age group 20 - 25	
W	M
0.79	0.48
Age group 25-30	
W	M
0.68	0.35
Age group 31-35	
W	M
0.61	0.25

CONCLUSION

It has been established, how demographic data can be used to estimate demand for packaged food item such as Pickle. Additional demographic details could be used to get further clarity about the purchase intent of customers but the investigation becomes tedious and statistical significance may not be realized, thereby making the results not useful for realistic demand estimation. Additionally, the study provides direction for future research with more detailed demographic profile of customers to enable the retailers to manage their inventory and shelf space well and reduce cost of operations. Further simulation can be used to produce greater clarity into the buying behavior of consumer. Moreover, the analysis presented here can also be used by manufacturers to develop marketing plans for their merchandises. The preference for the store brand is gender as well as age dependent. Older age customers have greater preference for the store brand pickle when compared to younger customers. Women have greater preference for the store brand pickle across all age groups but men of younger age have greater preference for the store brand pickle than older age men.

Nutritional and Sensory Evaluation of Moringa Oleifera Cookies

K Manivel

Assistant Professor, Hotel and Catering Management, Vels Institute of Science Technology and Advanced Studies (VISTAS), Pallavaram, Chennai

ABSTRACT

Cookies are a favorite American sweet, made from dough of cereal flour and brown sugar that contains a relatively high ratio of fat, such as butter, vegetable shortening, or margarine. The increasing popularity of cookies especially among children is growing and has become commercialized. This study is an alternative approach to biscuit manufacturing, in order to develop healthy cookies, as it would supplement the essential nutrients needed for all age groups. The different blends of cereal flour (Millet, corn meal and rye flour) with wheat flour and Moringa oleifera leaf powder were processed into cookies in the following ratios 50:30:20 (wheat flour, millet flour, Moringa) (WMM), 40:30:30 (wheat flour, rye flour, Moringa) WRM, 30:30:40 (Wheat flour, corn meal flour, Moringa) (WCM). The sensory evaluation of the cookies samples from the blends was performed using a 9-point hedonic scale. The highest mean score of the cookie was analyzed further for its nutrient content. The results of the sensory evaluation are to show that there were significant differences in the diverse attributes that were determined such as in color, texture, taste, flavor and general acceptance. It was analyzed further for its nutrient content. Incorporating moringa leaf in cookies or any other baked foods may be claimed as a means of boosting nutrition and can be served as an alternative approach to the manufacture of healthy cookies.

Keywords: *Moringa oleifera, nutri cookies, Malnutrition herbal cookies, Healthy cookies.*

INTRODUCTION

Cookie making ingredients are flour, eggs, sugar, butter and flavoring agent. It may comprise other ingredients such as raisins, corn flakes, chocolates, coconut powder and various nuts as per the flavor required. Cookie dough is basically made with flour, fat, moistening agent, raising agent and flavoring agent in various ratios and methods of preparation. Moringa Oleifera is used as a source of Malnutrition relief. Moringa trees have been used to resist malnutrition, especially among infants and nursing mothers. Since Moringa flourishes in arid and semiarid environments, it may provide a versatile, nutritious food source all over the year. There are lots of nutritional benefits in the whole Moringa Oleifera tree[1]. I have researched cookies with the leaves of Moringa Oleifera (Drumstick leaves) with regular cookie ingredients. Drumstick tree is called the powerhouse of minerals and is the most common tree in India. Its leaves, fruits, flowers, bark and seeds are all edible. They all have medicinal values and are used as ingredients in most dishes. The leaves are especially beneficial in the treatment of many ailments due to their various medicinal properties as they are rich in iron content[2].

NEED FOR THE STUDY

Cookies are served at high tea or as snacks across the world. The increasing popularity of cookies especially among children is growing and has become commercialized. This study is an alternative approach to biscuit manufacturers in order to develop healthy cookies, as it would supplement the essential nutrients needed for all age groups. This study is mainly targeted to reduce the malnutrition rate, which can be achieved by the consumption of Moringa oleífera. The cookie, which is made by incorporating Moringa leaves, has all the vital nutrients, which will help in bringing down the malnutrition rate to a great extent[3]. Moringa Oleifera itself has various health benefits such as stabilizing the blood pressure, controlling glucose level in case

of diabetes, used in treating diarrhea and bronchitis. The main aim of the study is to develop and perform the sensory evaluation of Moringa oleifera cookies.

METHODOLOGY

The present study was undertaken to study the "sensory evaluation". Data collected, comprised of the following:

MATERIALS AND METHOD

DEFINING THE PROBLEM

Malnutrition describes a state of imbalance between the dietary needs of the body and the type of diet provided to the body. It impacts brain development, behavioral development, cognitive development and perhaps most visibly growth development. More specifically, the numbers of underweight (low weight-for-age), stunted (low height-for- age) and wasted (low weight-for height) children are common measures for the number of malnourished children in a particular country[4]. Children are more at risk for serious complications due to nutritional deficiencies than adults. Kids require different amounts of Iron at various ages and stages. Infants who are breastfed tend to get enough iron from their mothers only until 4-6 months of age. Iron is the major nutrient, which is used to treat malnutrition. After 12 months of age, toddlers are at risk for Iron deficiency because they are no longer entitled to breast-feeding. Thus, they are forced to Consume Iron rich food in some other forms. Iron is found in foods such as dark leafy greens, red meat, and egg yolks. Moringa Oleifera is rich in Iron Content[5]. A dosage of just two or three spoonsful of Moringa leaves Powder provides a substantial amount of Iron. Moringa Olefera when Consumed in raw form is bitter in taste which makes it very hard for kids to consume them. Thus, when it is incorporated in cookies, it becomes edible and much tastier.

SELECTION OF INGREDIENTS

Whole Wheat Flour

The three parts of the wheat kernels are the germ, bran and the endosperm. Refined wheat flour is made up almost entirely of the endosperm which is a compound of starches and proteins. These proteins and starches allow a baker to create a dough with a lot of strength that is able to trap the gas produced by the yeast and this in turn gives the dough volume[7]. Absence of endosperm in the dough would restrict rise or not possess a shape. This is a reason baking with a white flour is so considerable. As it has more percentage of flour protein than any other grains it can be used as an essential ingredient in cookie making. The demerits of baking with only the endosperm let's go off all the vitamins, minerals, fats and fiber that are contained in the germ and bran during the milling process[8]. These areas are where all the health benefits of wheat reside. It is essentially the entire kernel of wheat milled up into flour form which contains nutrition and flavor.

Shaping:

Due to the weakened state of dough prepared with whole-wheat flour it is significant to handle the dough gently. When shaping, the dough will have a tendency to tear much easier than when using only Refined wheat flour and it will not get the dough as stiff or Shape it firmly.

Selection of Secondary Flour:

The following flours were used as Secondary flours in the cookies:

Rye flour:

Whole grain rye flour contains, as a percentage of dry matter, 56—70% starch, 8—1 3% proteins, 2—3% lipids, 2% ash and 1 5—2 1 % total dietary fiber. In addition, it is rich in minerals, vitamins, especially B-vitamins, and phytochemicals.

Corn-Meal flour:

Corn meal is flour made by grinding dried corn. It can be ground into a variety of consistencies and is also known as corn flour when it is finely ground. Corn meal flour contains nutrients like vitamin B6, Carbohydrates, dietary fiber, Protein and Calories.

Millet flour:

Millet is a rich source of magnesium, a mineral that acts as a co-factor for more than 300 enzymes, including enzymes involved in the body's use of glucose and insulin secretion. Millet is gluten-free and non-allergenic. In Western countries, dried leaves are sold as dietary supplements, in either powder or capsule form.

STANDARDIZATION OF MORINGA OLEIFERA COOKIES

Standardized recipes are used every day in child nutrition operations as a guide to preparing the foods served to customers. A standardized recipe is a recipe that has been carefully adapted and tested to ensure that it will produce a consistent product every time it is used[9]. The recipes of three cookies with various flour the incorporation of moringa oleifera were developed with specific ingredients.

Table 1: Standardized Sample I, II & III — moringa oleifera and Rye, Corn-meal and Millet flour incorporated Cookies One Portion is Four Cookies (4Ogms)

Ingredients for Sample I	Ingredients for Sample II	Ingredients for Sample III	Methodology
Whole wheat flour (80gm)	Whole wheat flour (60gm)	Whole wheat flour (100gm)	Moringa oleifera was de- stalked, sundried and powdered.
Moringa oleifera powder (60gm)	Moringa oleifera powder (80gm)	Moringa oleifera powder (40gm)	Cream together all the ingredients till soft in texture.
Rye flour (60gm)	Corn-meal flour (60gm)	Millet flour (60gm)	The dough was refrigerated for 15mins.
Clarified Butter (90gm)	Clarified Butter (90gm)	Clarified Butter (90gm)	Rolled out the dough and shaped them with cookie cutter.
Honey (10ml)	Honey (10ml)	Honey (10ml)	baked at 170*c for 12-15 minutes.
Palm Sugar (30gm)	Palm Sugar (30gm)	Palm Sugar (30gm)	Cooled at room temperature
Milk powder (2gm)	Milk powder (2gm)	Milk powder (2gm)	Stored in air tight container

The recipe standardization process of the three-nutri cookies was done for recipe verification, product evaluation, and quantity adjustment. Reviewing the recipe in detail, preparing it, verifying its yield, performed recipe verification and recording changes. Product evaluation was focused in determining the acceptability of the product produced from the recipe[10]. Changing the recipe yield and ingredient amounts was done in the quantity adjustment phase. A recipe went through all these phases several times before becoming standardized at the necessary quantity for an operation. Faculty and students of School of Hotel and catering Management worked together on the recipe standardization process. Input from students and other panel members were critical during the evaluation phase.

SELECTION OF METHOD AND TOOL FOR THE STUDY

Sensory method is an experimental study for the newly developed products of three different cookies in order to test, evaluate and get feedback on Sample I, Sample II and Sample III. Thirty (30) panelists were selected to conduct sensory characteristics of cookies which were assessed for sensory acceptability level of the panel members[11]. The sensory profile was taken on appearance, odor, texture, taste, flavor and acceptance.

PREPAR&TION OF HEDONIC SCORECARD

The sensory acceptability tests for moringa oleifera cookies was determined by using 9 point hedonic scale ranging from 1 indicating Dislike Extremely to 9 suggesting Like Extremely with a neutral category of 5 indicating neither like nor dislike for parameters like appearance, aroma, texture, taste, over all acceptance using questionnaire as tool.

CONDUCT OF THE STUDY

Sensory tests were carried out in a sensory light and good ventilation, and away from the preparation room. evaluation room. All the samples were prepared with

utmost care. Texture was maintained and carried out for the same in all samples. The volume of all the samples were equal. Samples were labeled as Sample I (moringa oleifere and Rye) Sample II (moringa oleifere and Corn-meal) and Sample III (moringa Oleifere and millet) to avoid bias.

DETERMINATION OF PROXIMATE NUTRIENT ANALYSIS

The highest mean score of the product, Sample II was analyzed further for its nutrient content which includes energy, carbohydrate, fat, dietary fiber, calcium, iron and sugar[12]. The energy was calculated by FAO method. The proximate nutrients composition such as protein, dietary fiber, total sugar and iron of sample II was performed according to AOAC method Carbohydrates were determined by different method.

RESULTS AND DISCUSSION

The purpose of the study is to Eradicate Malnutrition. The analysis of the data results is presented in this chapter.

The results of three different samples have shown that the texture of the cookies is same in all samples and varied slightly only in Sample III. In Sample II the taste has a mean score of 8, which is greater than the other two samples. The mean scores of Aroma and Appearance in all the three samples didn't have much of an impact. The Acceptance mean score did not have a vast difference between Sample I and Sample III but in Sample II it is 8.32 which was liked, compared to the other samples of the cookies. The results indicate that functional and adding Moringa Oleifera to many bakery products could develop health products with improved sensory quality. To make the Moringa Oleifera cookies more palatable a higher proportion of fine Moringa leaves may be incorporated.

RESULTS

Table 2- Mean Scores of Sensory Evaluation of Moringa Oleifera cookies

SENSORY EVALUATION	SAMPLE I MEAN SCORES	SAMPLE II MEAN SCORES	SAMPLE III MEAN SCORES
APPEARANCE	7.28	7.68	7.04
TEXTURE	7.36	7.60	7.04
TASTE	6.96	8.08	7.28
ODOUR	7.44	7.88	7.52
ACCEPTANCE	7.16	8.32	7.44
OVERALL AVERAGE	**7.24**	**7.91**	**7.26**

Sensory Evaluation of Products

Prepared cookies were subjected to sensory analysis based on 9-point hedonic rating scale for taste, texture, appearance, aroma and after-taste Using a panel of 30 untrained members. Trained members were chefs and academicians, bakery and Culinary preparations. Panel members were advised to use sensory evaluation sheet, mark and convert them into scores. The scores were based on the following criteria: Like extremely: 9; Like very much: 8; Like moderately: 5. , 7; like slightly: 6; Neither like nor dislike extremely: 1.

NUTR1TIVE VALUE OF MORINGA OLEIFERA COOKIES:

(SAMPLE II MORINGA OLEIFERA AND CORN MEAL)

The proximate nutrient analysis of Sample [I tisane was determined. The results expressed on l00 grams of

weight basis, are presented in table 3.

Table 3: Proximate Nutrient Analyses **Per**: l00 grams

S.NO	Parameters	Methods	Result
1.	Energy (By Calculation)	FAO Method	498.48 kcal
2.	Carbohydrate (By Difference)	CTL/SOP/FOOD/262-2014	65.96gm
3.	Total Fat	AOAC 19th Edn.2012,920.39g	23.58gm
4.	Protein (N*6.25)	DGHS Manual 3,2005	5.61gm
5.	Dietary Fiber	AOAC 19th Edn.2012,985.29	5.79gm
6.	Total sugar	AOAC 19th Edn.2012, 925.05	16.15gm
7.	Iron as Fe	AOAC 19th Edn.2012, 99.11	2.40mg

DISCUSSION

The study is based on the implementation of Moringa oliefera in cookies using various combinations of flours. The goal of this study is mainly to reduce the rate of malnutrition by adding Moringa in the cookies as the core ingredient to make Moringa tasty. when Moringa is consumed barely it is bitter in taste. This Cookies helps in improving nutrition value. The medicinal values present in the Moringa oliefera is also present in the cookies therefore there are various health benefits in the cookies. Moringa has been advocated as a natural nutrition for the tropics and is being used to combat malnutrition due to its high protein and fiber content. The developed product of this cookies for this study may be served as an alternative approach to the manufacture of healthy cookies.

CONCLUSION

There are various types of cookies prepared by using different ingredients. A Moringa Oleifera cookie aims at increasing the nutritional value and eradicating malnutrition. Nowadays throughout the world people are consuming Herbal Cookies, Non-Processed foods, organic vegetables, etc. For a disease-Free and healthy life consuming the Moringa Oleifera in the form of cookies makes it more edible and tasty. Usually Herbal items though it has lots of medicinal, it cannot be eaten without processing. These leaves are incorporated in various medicines since olden days. In Ayurveda this is the most important ingredient, thus incorporating it in cookies makes it healthy and edible. Incorporating Moringa leaf in cookies or any other baked food may be claimed as a means of boosting nutrition in India where Malnutrition is prevalent. The developed product of Moringa Oleifera cookies for this study may be served as an alternative. In the manufacturing of cookies. It is high time that we kick-start our life with our undiscovered leaves. Limitations of the study are, Eliminating the raw smell from the cookies was a little tough job, the leaves are to be cleaned carefully as it has lots of stalk in it, Preserving the Moringa oleifera leaves were hard, The moisture in the leaves had to be shallow fried in clarified butter to enhance the flavor for cookies and it had to be dried properly before it was added as an ingredient.

Occupational Health Hazards among IT Sector Women Employees in Tamil Nadu

B Chithirai Rajan[1], M Prabhakar Christopher David[2]

[1]Assistant Professor, Department of Economics, Vels Institute of Science, Technology and Advanced Studies – VISTAS (Deemed to be University), [2]Assistant Professor, Department of Business Administration, Vels Institute of Science, Technology and Advanced Studies – VISTAS (Deemed to be University)

ABSTRACT

In view of this healthcare importance, the real economic growth rate depends on the quality of human life especially in improving the women's standard of living around the world. At present, a large number of women are working in all sectors viz., primary sector, secondary sector and service sector in both the rural and urban areas. Further, they are actively participating in each and every job and express their knowledge and capacity to the society. However, most of the women are dominated by men and are affected psychologically and are under pressure in their work places. The term occupational hazards refer to a risk accepted as a consequence of a particular occupation. Regarding the occupational problems, the women employees in IT sector are facing health hazards like eye fatigue, headache, thyroid problem and others. It could be seen that over a past decade, a large number of women employees in IT sector suffer from heart related diseases. Moreover, the Poor health creates huge strain on physical and mental pressure in working places. At present, the large numbers of women employees also face many social, cultural and economic challenges. Hence, this study is an attempt to identify and analyse the reasons that affects the health of IT sector women employee respondents and give suitable measures to reduce the work related stress in IT sector among women employee respondents. Further, this study focused on primary data and the tools of analyses with using statistical techniques like percentages, t-test and rank value method. As a result found that, the urban area women respondents are highly affected as compared to that of rural area women respondents among the IT sector field. By and large, the study suggested that spiritual meditation is a way to help the reducing stress in psychologically and work related stress reduced through improving communication and technical skill.

Keywords: Women empowerment, health, IT sector, stress, economic development, communication skill, spiritual meditation

INTRODUCTION AND STATEMENT OF THE PROBLEM

In view of this healthcare importance, the real economic growth rate is based on to develop the quality of human life and especially to improve the women's standard of living around the world. The human development report (1995) stated that the basic capability for human development are living a long and healthy life, being educated and better standard of living in a society[1]. At present, a large number of women are working in all sectors like primary sector, secondary sector and service sector in which both rural and urban areas. Further, they are actively participating in each and every job and exposure their knowledge and capacity to the society. However, most of them women are conquered by men and they are affected in both psychology and mental pressure in working places[2]. The term occupational hazards refers to the stress related to the works require to be addressed without any delay. Regarding the occupational problems, the software women employees are facing continuously like eye fatigue, headache, thyroid problem and others. It could be seen that over a past decade, a huge number of software women employees are suffered due to heart diseases. Moreover, the Poor health creates huge strain on physical and mental pressure in working places[5]. At present, the large numbers of women employees are facing many problems from different directions like social problems, cultural problems, and economic problems. More specifically,

women are not only facing problems in working places and from her homes also. But some of them are actively participated in domestic work like cooking, washing, drawing water, preparing food and so on. Additionally, the physical health was majorly suffered due to that insufficient sleep as regularly[7]. Meantime, without yoga activity may be disturbed their psychological feelings also. The adverse impact of health is one of the major problems to makes gender equities in the society. In view of these all problems, maintaining health nutrition, and yoga and exercises, proper training and improving knowledge, good sleeping, and air conditioner facilities are the major solution to reduce their stress in software industries. Hence, the present study makes an attempt to analyze the health hazards among IT sector women employees in Tamil Nadu.

OBJECTIVES

To analyse the reasons for health affect in IT sector women employee respondents in selected region.

To suggest the suitable measures to prevent the work related stress in IT sector.

HYPOTHESIS

Rural area women employees are majorly affected as compared to urban area women employees in IT sector.

METHODOLOGY

Drawn from the present study has been focused on primary data and it involves a multi-stage sampling method. Further, the present study is covered four stages and the accurate information is derived from the field of inquiry in IT sector, Chennai city, Tamil Nadu: (i) Selection of Chennai district in Tamil Nadu, (ii) Selection of major towns' viz., Ambattur, Thiyagarayanagar, Kodambakkam and Nungambakkam in Chennai district (iii) Selection of few software industries in selected areas, (iv) Selection of rural area and urban area women employee respondents according to Tamil Nadu state and Other States in software sector. Among these four stages of investigation, 115 sample respondents are selected for the present study. In which, 63 respondents are collected from Tamil Nadu state and the remaining 52 respondents are collected from other states viz., Kerala, Bangalore, Sikkim, etc. Out of these 63 women respondents in Tamil Nadu, 27 respondents belonging to rural areas and the remaining 36 respondents are belonging to urban areas. On the other hand, out of 52 respondents in other states women respondents, 23 respondents are belonging to rural areas and the remaining 29 respondents are belonging to urban areas. In whole, 50 respondents are from rural area respondents and the remaining 65 respondents are from urban area respondents. Moreover, the present study is used by the convenient sampling method and the period covers from 2017 - 2018.

TOOLS FOR DATA ANALYSIS

To analyse the reasons for health affect in IT sector women employee respondents, rank analysis and t-test analysis have been applied.

To identify the major factors to prevent the work related stress in IT sector, the percentage analysis has been employed.

RESULTS AND DISCUSSIONS

TABLE 1: CAUSES OF WORK RELATED STRESS

Dimension on job stresses	Rural Area (Mean Value)	Rank	Urban Area (Mean Value)	Rank
Age Discrimination	7.23	7	6.80	10
Wage Discrimination	6.92	10	6.94	8
Heavy Workload	7.64	6	7.23	6
Gender Discrimination	7.70	5	6.89	9
Unable to achieve their Target	5.78	12	7.20	7
Family Problems	7.98	4	8.90	2

Cont... **TABLE 1: CAUSES OF WORK RELATED STRESS**

Health Issues	8.98	1	9.94	1
Problem with Co-workers	8.23	3	8.89	3
Could not provide maternity Leave	7.18	8	6.78	11
Poor working place	8.30	2	7.80	5
Sexual Harassment	6.99	9	6.21	12
Nightshift Work	6.78	11	8.01	4

Source: Computed

Table 1 analyzes the causes of work related stress with the help of utilizing the rank analysis method. Among the ranking method and estimating the mean value in rural area, most of the respondents are highly suffered by health issues under working in software sector which constitute the mean value at 8.98, followed by poor working places (8.30), problems with co-workers (8.23), family issues (7.98), gender discrimination (7.70), Heavy workload (7.64), age discrimination (7.23), could not provide maternity leave (7.18), sexual harassment (6.99), wage discrimination (6.92), working in night shift (6.78), and the remaining unable to achieve their target (5.78). In the case of urban area by using the mean value with the help of ranking method, the mean value is highly recorded in health issues (9.94), followed by the family issues (8.90), problem with co-workers (8.89), working in night shift (8.01), poor working places (7.80), heavy workload pressure (7.23), unable to achieve their target (7.20), wage discrimination (6.94), gender discrimination (6.89), age discrimination (6.80), could not provide maternity leave (6.78) and the remaining sexual harassment (6.21). As a result found that both rural and urban areas women respondents, health issues and health problems are mainly dominated the job related stress in the study area.

TABLE 2: CAUSES OF WORK RELATED STRESS WITH USING T- TEST METHOD

Dimension on job stresses	**Rural Area (Mean Value)**	**Urban Area (Mean Value)**	**t-value**	**p-value**
Age Discrimination	7.23	6.80	-2.019	.002*
Wage Discrimination	6.92	6.94	-1.090	.078(NS)
Heavy Workload	7.64	7.23	0.989	.049**
Gender Discrimination	7.70	6.89	-2.109	.067(NS)
Unable to achieve their Target	5.78	7.20	2.009	.093(NS)
Family Problems	7.98	8.90	-1.897	.003**
Health Issues	8.98	9.94	-3.478	.042**
Problem with Co-workers	8.23	8.89	-2.870	.021**
Could not provide maternity Leave	7.18	6.78	-3.092	.088(NS)
Poor working place	8.30	7.80	0.678	.097(NS)
Sexual Harassment	6.99	6.21	-0.110	.027**
Nightshift Work	6.78	8.01	1.201	.044**

Source: Computed, *1% level of significant, **5% level of significant, NS – Not significant

Table 2 examines the job related stress with testing of t-test analysis. The null hypothesis is based on "rural area women respondents are highly affected in work related stress with compared to urban area women respondents". The following results are mentioned the rural area respondents are highly suffered in job related stress with compared to urban area respondents. Age discrimination is found to statistically significant at 1% level, and the remaining factors are statistically significant at 5% level viz., heavy workload pressure, family issues, health problems, problem with co-worker, sexual harassment and working in night shift are found to be highly affected in rural area as compared to urban area respondents. Hence, accept the null hypothesis for the above mentioned factors. Rests of them, wage discrimination, gender discrimination, unable to achieve their target, could not provide maternity leave and the remaining poor working places are not significant. As a result found that, the urban area respondents are highly affected in these mentioned factors as compared to that of rural area women respondents. Hence, reject the null hypothesis for above the mentioned factors and accepted alternative hypothesis.

TABLE 3: IMPACT ON PERSONAL STRESS USING ANOVA

Factors	Groups Variable	Sum of Squares	df	Mean Square	F	Sig.
Child Care	Between Groups	.106	1	.106	.112	.739
	Within Groups	258.450	113	.954		
	Total	258.557	114			
Family Issues	Between Groups	.802	1	.802	1.014	.315
	Within Groups	214.260	113	.791		
	Total	215.062	114			
Personal Financial Burden	Between Groups	1.265	1	1.265	1.378	.241
	Within Groups	248.874	113	.918		
	Total	250.139	114			

Source: Computed

Table 3 interprets the impact on personal stress among IT sector women employees. It is seen that the rural area women respondents are highly affected due to the personal stress as compared to urban area respondents. The personal stress factors such as child care, family issues, and personal financial burden are statistically not significant at 5% or 1% level. Thus it leads to accept the alternative hypothesis i.e., urban area women respondents are highly affected in personal stress as compared to rural area respondents.

Table 4: Prevention of Work Related Stress

Parameters	YES	NO	Total
Group Discussion with Other Employees	96 (83.5)	19 (16.5)	**115 (100)**
Improve Communication and Technical Skill	82 (71.3)	33 (28.7)	**115 (100)**
Proper Training	78 (67.8)	37 (32.2)	**115 (100)**
Spiritual Meditation	99 (86.1)	16 (13.9)	**115 (100)**
Yoga and/or Exercises	83 (72.2)	32 (27.8)	**115 (100)**

Source: Computed; Figures in Parentheses denote percentages

Table 4 exhibits the factors attributing to prevent the work related stress among IT sector women employees in selected region. It is seen that more than three fourth of the respondents are stated that agree with spiritual meditation may reduce the work related stress which constitute 86.1 percent, followed by 83.5 percent of them where recorded group discussion with other employees, nearly three fourth of the respondents (72.2 %) are agree with yoga and/or exercises may reduce the work related stress, 71.3 percent of them recorded that improving communication and technical skills and the least recorded by the proper training method at 67.8 percent in selected region. It is noticed that on the table, spiritual meditation and group discussion may reduce the work related stress among IT sector women employees.

POLICY SUGGESTIONS

Protecting the women employees for the long hours of work in the software sector. Because the long hours of work due to increase the physical stresses and psychological stresses. Hence, all the software institutional should banned the long hours of work.

Improve the gender sensitive related and monitor progress about regulatory framework, software technologies and labour policies, and create infrastructural facilities are drawn it by the regulatory information as follow the ICT policies.

Improve the software mechanisms monitor the progress and to encourage gender development in IT field.

All the software institutions should strengthen their capacity through technical support, gender equality and ICT.

All the software institutions should provide the training facilities to the employees for improving the technical and communication skills and create more employment opportunities.

Government should promote software technologies, because it gives more taxation to the central and state Governments.

Government should collaborate with ICT sector. Because recently number of people depend on the software technologies. If the Government undertakes the ICT, it will helpful to increase the most employment opportunities.

ABSTRACT

Introduction: Sex ratio is defined as number of females per 1000 males. Decline in sex ratio leads to child marriage and poor status of women and it will affect us socially, economically and politically. The Government of India introduced the Preconception and Prenatal Diagnostic techniques act in 2003 to prevent the misuse of modern medical technologies for prenatal sex determination. This study was conducted among rural women of reproductive age group (20-35yrs) in a village of Trichy, southern India with the aim of studying gender preference and awareness about PCPNDT act.

Method: This cross sectional study was conducted using a questionnaire which comprised two sections including Socio demographic details and questions regarding gender preference, awareness about PCPNDT act.

Results: In our study, 120(60%) knew that prenatal sex determination was possible, 106(53%) participants had gender preference and Out of the participants preferring gender, 96(90.6%) of them preferred male babies. Mother-in-laws were the major persuaders. Relatives were the major source of information regarding prenatal sex determination tests. Only 29(14.5%) knew about the PCPNDT act.

Conclusion: Majority of the study population were aware of the possibility to do prenatal sex determination using Ultrasound techniques but not aware of the PCPNDT act and its provisions. Apart from legislative measures, people need to be educated about gender equality and PCPNDT Act.

Keywords: *PCPNDT act, prenatal sex determination, reproductive women, gender preference.*

INTRODUCTION

Sex ratio is defined as number of females per 1000 males. As per 2011 census, sex ratio in India is 940 females per 1000 males, which continues to be significantly adverse towards women[3]. Decline in sex ratio leads to child marriage and increasing number of child brides leads to poor status of women and it will affect us socially, economically and politically. There will be increased mother and child morbidity and mortality associated with early child birth. An associated phenomenon is the abduction and trafficking of girls. In this distorted social scenario marked by growing anti-social behaviour, crimes against women like rape, molestation, eve teasing, child marriages; forced polyandry etc. is also expected to rise. Adverse sex ratio also called female deficit syndrome female feticide, sex selective abortion is being the most common scenario in the present two child norm.

Child sex ratio indicates future sex ratio prediction. According to census 2011, child sex ratio for India is 919. Sex selective abortion has mainly two determinants- Gender preference and Sex determination. Former is influenced by beliefs in the Community and latter is influenced by Health Care providers and legislators.

Sex selective abortion is almost reported across every part of our nation irrespective of the socioeconomic status, religion and rural or urban background. Usage of appropriate modern technological advancement like ultrasound paves the way for prenatal identification of the sex and thereby declining sex ratio at birth. The main reason for female feticide is that female child are vulnerable to harassment and burden of dowry for the parents at their later stages while a male child earns and supports the family.

The government of India introduced the prenatal diagnostic techniques act in 1994 which was later amended in 2003 to the Preconception and Prenatal Diagnostic Techniques Act[1].The violation of this act can lead to a fine of Rs.10000 and three years imprisonment for first offence and further increase in punishment and fine for subsequent offences[1].The significance of this law is that it was necessitated to prevent the misuse of modern technology. It does not involve only change in social behaviour and practices; it demands ethical medical practice and the regulation of medical technologies that have the potential to be misused. This thus puts onus on the medical professionals and the general public as well .It is the responsibility to educate the people about the PCPNDT act and its significance. This study was conducted among reproductive age group women (20-35yrs) to study gender preference pattern and awareness regarding provisions of PCPNDT act.

OBJECTIVES

To determine the gender preference and awareness about PCPNDT act among women of reproductive age group (20-35 years of age) in villages of Trichy district.

MATERIALS AND METHOD

This study was conducted in a rural area (Sangenthi Village) in Trichy district, south India. The study population included women of reproductive age group (20-35 years of age). A total of 200 women participated in the study. After obtaining informed written consent and explaining the purpose of the study, data was collected using a pre-structured questionnaire which comprised a set of questions which included demographic details, socio economic status, gender preference and awareness. Participant's identity and collected information were kept confidential.

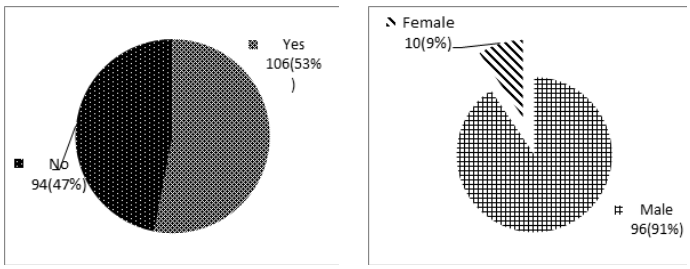
STATISTICAL ANALYSIS

Data were entered in MS EXCEL and statistical analysis done using EPIINFO software.

RESULTS

1. The results of our study are discussed in the following headings:
2. Socio-demographic details.
3. Gender preference.
4. Who persuade for prenatal sex determination?
5. Knowledge about possibility of prenatal sex determination and opinion about prenatal sex determination
6. Source of information for prenatal sex determination
7. Awareness about the provisions of PCPNDT act

1. Socio Demographic details:



A total of 200 reproductive women of age between 20-35 years were assessed for their knowledge, awareness and attitude regarding prenatal sex determination and PCPNDT act using a questionnaire. Results can be represented here using descriptive statistics which includes socio demographic details and key findings as represented in pie, bar and table separately. Age of the participants ranged between 20-35 years with mean age of 27 years, median of 27 and mode of 28, Standard deviation 3.515.

Majority of the study participants were housewives 81, (40.5%).Most of the participants completed middle school 69, (34.5%). About 11 participants were illiterate (5.5%).Among them, most study participants belonged to nuclear family 145, (72.5%).Among our study population, most of them belonged to middle and upper middle socio economic scale (According to modified BG Prasad scale, 2014). These demographic details are illustrated in table 1.

Table 1: Socio demographic details of the study population

Socio Demographic Factor		Frequency	Percent
Occupation	Agricultural labourer	39	19.5
	Daily wage labourer	29	14.5
	Housewife	80	40
	Teacher	19	9.5
	Tailor	8	4
	Others	25	12.5
Education	Illiterate	11	5.5
	Primary	21	10.5
	Middle	80	40
	Higher secondary	52	26
	UG	33	16.5
	PG	3	1.5
Family	Joint	43	21.5
	Nuclear	145	72.5
	Extended	7	3.5
	Three generation	5	2.5
Socioeconomic class (BG Prasad's Classification)	Upper	3	1.5
	Upper middle	97	48.5
	Middle	94	47
	Lower middle	6	3
	Lower	0	0

2. Gender preference:

Male babies were the most preferred gender even nowadays. Among our study participants, 106(53%) had gender preference and out of them 96 (48%) preferred male over female babies. (Figure 1)

Figure 1 Gender preference among study population

Who persuade for prenatal sex determination? :

On analysis, it was found out that mothers-in-law were the major persuaders towards prenatal sex determination tests (102, 51%) followed by husbands (28, 14%). (Figure 2)

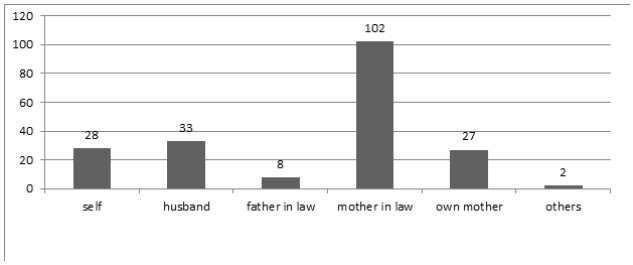


Figure 2 Who persuades for prenatal sex determination?

Knowledge about possibility of prenatal sex determination:

Among the study group, 120 (60%) of the study participants knew that prenatal sex determination was possible and 30 (15%) of them told it was not possible. (Figure 3)

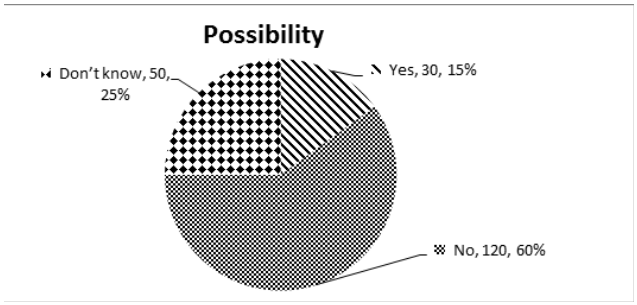

Figure 3 Knowledge about possibility of prenatal sex determination:

Source of information about prenatal sex determination:

According to our study, relatives were the major source of information regarding prenatal sex determination tests (106, 53%) followed by friends (58, 34%). (Figure 4)

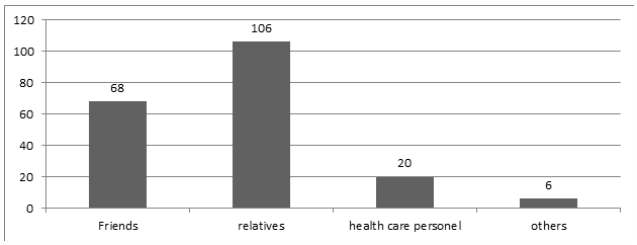

Figure 4 Source of information:

Awareness about PCPNDT act:

On observation of our study analysis, only 29 (14.5%) of the study participants knew the Government act against prenatal sex determination. (Figure 5)

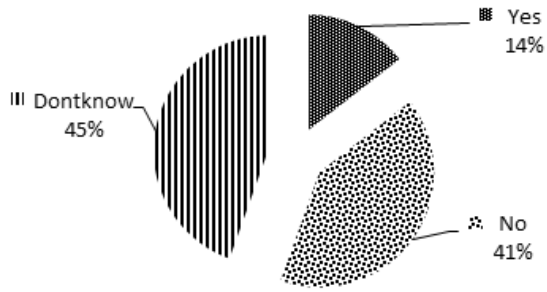

Figure 5 Awareness about PCPNDT act:

Irrespective of their knowledge on PCPNDT act, 40 (20%) of study participants knew that prenatal sex determination was punishable. Among the participants who knew prenatal sex determination is punishable, 26 (13%) knew that both doctors and people who seek for prenatal sex determination tests are punishable.

DISCUSSION

In India, first legal response to control the practice of sex determination and sex selective abortions came into effect in the year 1994 through the introduction of PNDT act which was amended later in 2004 as PCPNDT (Pre-Conception and Prenatal Diagnostic Techniques) act[6]. Though sex selective abortions have been reported all over India, registration and punishment rates have been less so far. Low registration and punishment rates may be due to improper implementation and lack of awareness of the act among public[6].In our study, 53% (106) of the participants had gender preference and among them, 96 of the participants need male babies. This indicates that gender preference is still prevalent.

In our study, mothers-in-law were the major persuaders towards prenatal sex determination. They can be educated regarding gender equality during antenatal visits of their daughters-in-law. About 60% (120) of the participants didn't know the possibility of prenatal sex determination, which is still an advantage for preventing sex selective abortion. Only 29 (14%) were aware of the PCPNDT act, which indicates that media, health care personnel, etc should take part in disseminating knowledge about gender equality and PCPNDT act. People should be educated that, those who seek for prenatal sex determination tests are also punishable by law, thus reducing the rate of prenatal sex determination.

In the present study, 60% of the participants knew

about possibility of sex determination which was lower than the study conducted at Puducherry (82.03%)[9], Mumbai[8], Maharashtra (73.5%) and Bareilly, Uttar Pradesh (80%)[7].In our study, only 21.5% were aware that USG is used for prenatal sex determination, which was lower than the study conducted in Puducherry (91.4%)[9], Hassan(73%)[10] and Mumbai (91.4%)[8].

Relatives (53%) were the main source of information in our study. Our observations were similar to the study conducted in Jammu[11] which was conducted in rural area among 400 people. In a study reported from Hassan (90%)[10], media was the main source of information.

In the present study, 14.5% of participants were aware of the government law against prenatal sex determination and 20% of the total participants knew that prenatal sex determination was punishable. These were lower than the study conducted in Puducherry (awareness of government law- 67.9%, punishable- 84.3%)[9], Hassan (punishable-53%)[10]and Mumbai (awareness of government law- 34.3%, punishable- 44.1%)[8] among which Puducherry(160 pregnant women)[9]and Mumbai(143 pregnant women)[8] were hospital based study while Hassan study included Teachers[10].

In our study, 1.5% said that only doctors should be punished , 4.5% said that only people who seek for sex determination should be punished and 13% were aware that both doctors and people who seek sex determination should be punished. This was lower than the study conducted in Puducherry (only doctors are punishable-3.9%, only people are punished-19.53%, both are punishable- 71.88%)[9].

CONCLUSION

More than half of our study population knew about the prenatal sex determination, still only one-tenth of them knew it was punishable. Nearly half of the study population preferred to know the sex of their unborn child and out of them 90% preferred male babies. Apart from legislative measures, people need to be educated about gender equality and PCPNDT Act.

Breast Feeding Literacy and Belief - A Community based Cross Sectional Study among Reproductive Age Group Women in Tamil Nadu

Neethu George[1], Meera George[2], Rock Britto D[1], Vinodhini[3], Varshitha Kutchre[3], Yogesh[3], S Elango[4]

[1]Assistant Professor, Department of Community Medicine, CMCH&RC, Trichy, Tamil Nadu, [2]Assistant Professor, Department of Community Medicine, Travancore Medical College, Kollam, Kerala, [3]CRRI, [4]Professor and Head, Department of Community Medicine, CMCH&RC, Trichy, Tamil Nadu

ABSTRACT

Background: Breast feeding have several benefits to both mother and infant; however despite strong evidences in support of breast feeding, its ignorance has remained high worldwide. **Objectives:** To assess the knowledge and attitude regarding breast feeding and its practices among reproductive age group women in rural area in Tamil Nadu. **Materials and Method:** A cross sectional community based study including 116 married reproductive age group women. A structured interview schedule consisting of questions about knowledge about breast feeding and Iowa Infant Feeding Attitudes Scale to assess attitude was administered to 116 reproductive age group women **Result:** Out of 116 subjects, 31.85% practiced exclusive breast feeding and only 61.2% of participants were aware of exclusive breast feeding, all the participants felt initial milk to be discarded, 8.6% are aware that breastfeeding protects against cancer; 23.2% felt that water is essential for baby along with breast milk; 25.8% were aware that lactation can be used as a contraceptive modality. Majority 103(88%) of mothers had neutral attitude towards breast feeding. **Conclusion:** The attitude and knowledge level towards breast feeding is still remaining low, which signifies the urgent need to address the issue. Like unmet needs for family planning "unmet adequacy of breast feeding" should be assessed and addressed.

Keywords: *Attitude, Belief, Breast feeding, Knowledge, Literacy, Reproductive age group women*

INTRODUCTION

Breastfeeding is one of the life saving nutrition for children and also improves future health for both mother and child .[1] More than 15% of 24 lakh death could be averted in India by optimal feeding practices.[2] Over the last couple of decades there has been an increase interest in the promotion of exclusive breast feeding as best feeding method for new borns.[3] Exclusive breast feeding is as infant feeding with human milk without addition of any other liquids or solids.[4] The WHO and UNICEF (1990) have recommended exclusive breast feeding for six months followed by introduction of complementary foods and continue breastfeeding for 24 months or more.[5]

For infants not being breast fed there is increased incidence of infectious morbidity like otitis media, gastroenteritis and pneumonia. There is also evidence of an increased incidence of breast cancer, ovarian cancer in mothers who neglect feeding. [6-9] The positive effects of breast feeding in the mortality pattern [10], intelligence [11] and long term consequences on their life[12] is well recorded.

For effective promotion of breast feeding active intervention should be promoted in the fields of health systems and services, home and family environment, community environment, work environment and policy environment or a combination of any of above.[13] In

recent years breast feeding has declined as a result of urbanization and maternal employment outside the home which eventually lead to formula feeding. In this study we aimed to assess the knowledge and attributes regarding breastfeeding and its practices among the reproductive age group of women in Tamil Nadu.

METHODOLOGY

This was a community based cross sectional study conducted among married reproductive age group women (18-49 years) who were selected consecutively for a period of 2 months (Dec 2017-Jan 2018). The study was conducted in Sangethi village (the rural field practice area of the institution) in Trichy district, Tamil Nadu.

The sample size was calculated using an estimated 50% prevalence of good knowledge about breast feeding. For 95% confidence limits and an absolute precision of 10%, calculated sample size was 96. Adding 10% non response rate, the minimum sample size came up to 106.

The predesigned structured questionnaire which included three parts

Part A: Socio-demographic data including age, education, income, religion, marital status.

Part B: Knowledge regarding breast feeding and practices (15 questions). Correct answer was awarded one point and wrong zero.

Part C: The Iowa Infant Feeding Attitudes Scale (IIFAS) [14] was used to assess mothers' attitudes toward breastfeeding. The scale included 17 attitude items to determine level of agreement to each question. A 5-point Likert scale from strongly disagrees to strongly agree was applied to all questions. Approximately half of the questions were negatively worded (i.e. 1, 2, 4, 6, 8, 10, 11, 14, and 17). Total IIFAS score ranged from 17 to 85 with higher scores reflecting more positive attitudes on breastfeeding. Total scores were grouped into three, (1) positive to breastfeeding (70-85), (2) neutral (49-69), and (3) positive to formula feeding or negative to breast feeding (17-48).

Written informed consent was obtained from the mothers who were willing to participate in the study. The data were analyzed using Epi info software. The relationship between Knowledge scores, IIFAS scores and socio-demographic variables was tested using appropriate tests

RESULTS

Socio-demographic details

The sample of reproductive age group married women (n=116) were of the age range from 19-45 years. The mean age (± SD) of the population was 29.91(±6.04) years. Maximum 45(38.8%) of the population belonged to more than 30 years. Majority 74(66.4%) of them had school education. More than half 64(534.3%) were homemakers and 61(52.6%) belonged to joint family. Majority 88(75.9%) of them were Hindu religion and had a mean (±SD) age at marriage of 21.84 (±2.81) years. Mean (±SD) years of marital life were 8.27(±6.62) years. The mean (±SD) age at marriage of the group was 21.84 (±2.81) years. Mean (±SD) years of marital life were 8.27(±6.62) years.

Mother's Knowledge about the breast feeding

The mean (±SD) knowledge score of the women was 9.39 (±1.55) which shows more than 50th percentile and range of the score lies between 6 and 14. (Table 1)

Table 1: Knowledge about breast feeding

		True(%)
1	Protection for baby	115(99.1%
2	Breast milk is the ideal food for the baby	40(34.4%)
3	Water is essential for baby along with breast milk	27(23.2%)
4	Prelacteal feeds are good to the baby	30(25.8%)
5	Initial milk – colostrums to be discarded	116(100%)
6	Promotes mother-baby relation	114(98.2%)
7	Frequent sucking increases breast milk production	60(51.7%)
8	Lactation helps lose weight gained during pregnancy	68(58.6%)
9	Lactation prevents next pregnancy	30(25.8%)
10	Protection against cancer	10(8.6%)
11	Breast feeding should be stopped after 6 months	96(82.7%)
12	Drugs can be excreted in breast milk	114(98.2%)
13	Smoking can affect breastfeeding	115(99.1%)
14	Alcohol can affect breastfeeding	83(71.5%)
15	Duration of exclusive breastfeeding is 6 months	71(61.2%)

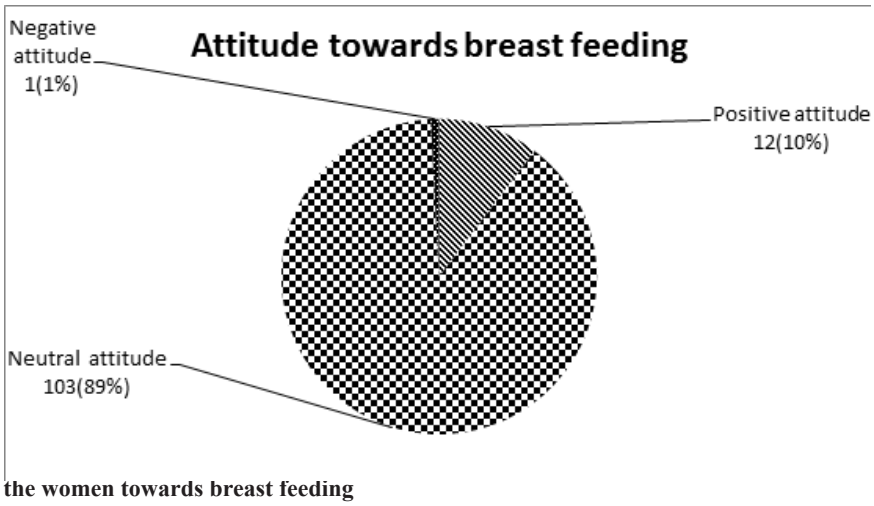

Figure 1: Attitude of the women towards breast feeding

In the study we found that majority of attitude questions scored a mean score of 3 or above indicating a neutral to positive attitude towards breast feeding. (Figure 2)

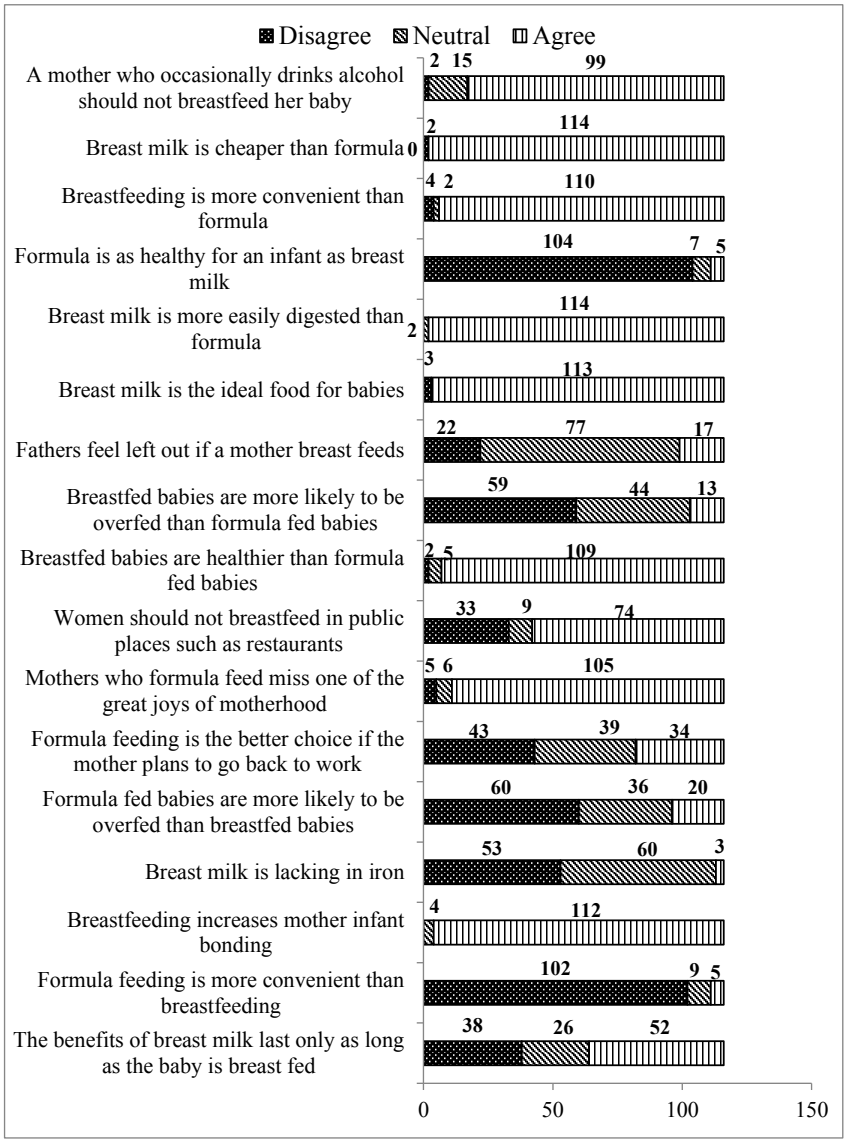

Figure 2: The Iowa Infant Feeding Attitudes Scale

In the study we did Kruskal Wallis test to find association between socio- demographic variables and knowledge score. Variables like family type, religion and act of giving prelacteal feeds were significantly associated with knowledge score. Other variables were not significantly associated with knowledge score.

Table 2: Multiple linear regression, factors associated with knowledge score

Variable	Regression coefficient	95% confidence interval	p value
Type of family	0.38	0.09 to 0.85	0.12
Religion	0.09	0.44 to 0.24	0.57
Prelacteal feeds given	0.83	0.24 to 1.42	0.006

*Significant p value <0.05

The table shows multiple linear regressions of knowledge score with the socio-demographic variables. Act of giving prelacteal feeds was found to be significant. Median knowledge score was 10 for those who didn't give prelacteal feeds compared to a score of 9 for those who gave. If one unit change happens in not giving prelacteal feeds knowledge score change by 0.83 and is statistically significant.

In the study we did one way Anova test to find association between socio- demographic variables and attitude score. Variables like family type, type of delivery, duration of exclusive breast feeding and act of giving prelacteal feeds were significantly associated with attitude score. Other variables were not significantly associated with attitude score.

Table 3: Multiple linear regression, factors associated with attitude score

Variable	Regression coefficient	95% confidence interval	p value
Type of family	0.73	-2.19 to 0.72	0.73
Type of delivery	1.53	-3.36 to 0.29	0.04*
Prelacteal feeds given	4.42	2.12 to 6.71	<0.001*
Exclusive breast feeding duration	0.81	-1.31 to -0.30	0.002*

*Significant p value <0.05

The table shows multiple linear regressions of attitude score with the socio-demographic variables. Type of delivery, duration of exclusive breast feeding and act of giving prelacteal feeds were significant. Mean attitude score for people who had normal delivery were more compared to those who had caesarean section. If one unit change happens in type of delivery attitude score change by 1.53 and is statistically significant.

Mean attitude score of people who didn't give prelacteal feed was 67.11 compare to score of 61.94 for those who gave. If one unit change happens in not giving prelacteal feeds attitude score change by 4.42 and is statistically significant.

Mean attitude score of people who exclusively breast feed for six months was less compare to those who did. If one unit change happens in decreased duration of exclusive breast feeding attitude score change by 0.8 and is statistically significant.

DISCUSSION

This study investigated knowledge and attitude of breast feeding among reproductive age group women. WHO recommends six months of exclusive breast feeding for infants, but in our study, 31.86% of participants practiced exclusive breast feeding. This finding is lower compared to that of NFHS 4 data of India (54.9%) and Tamil Nadu [15](48.3%).

In our study all the participants felt initial milk to be discarded, in contrary to other studies in India where the importance of colostrum was known to 56% of mothers[3] and 75-90% of mothers. [16] In our study, only 8.6% were aware that breastfeeding protects against cancer; 23.2% felt that water is essential for baby along with breast milk; 25.8% are aware that lactation can be used as a contraceptive modality..

Regarding the knowledge score mean score lies more than the 50th percentile denoting good knowledge about breast feeding which is consistent with other studies.[17,18] In our study women from joint and extended family, Muslim religion and who didn't give prelacteal feeds scored more in knowledge score. Women who live with multiple family members got influenced by family (particularly grandmother) in the decision and may result in increased knowledge. This finding is consistent with other studies.[19, 20]

Knowledge score was more among Muslim religion in this study can be due to decreased number of Muslim participants and also continued support from the part of the family for breast feeding which is similar to other studies.[21]

In the study we found that majority 103(88.8%) had neutral attitude towards breast feeding which is comparable to a study done in Bangalore.[18, 22, 23] Highest neutral attitude was in the questions "Fathers feel left out if a mother breast feeds" (66.38%), "Breast milk is lacking in iron" (51.7%) and" Breastfed babies are more likely to be overfed than formula fed babies" (37.93%). This result is similar to other studies.[21] In the present study 93.97% of the mothers believed that breastfeeding is healthier for babies. This result is higher than the results of other studies.[21, 24] Mothers' negative attitude toward breastfeeding could be due to lack of mothers' knowledge about breast milk contents and benefits and lack of facility to support mother's breastfeeding in workplace, feel uncomfortable to breastfeed in public places and negativity towards father's involvement in breastfeeding

This study showed attitude score was more for those from joint family, who had normal delivery, those who didn't give prelacteal feeds and those who exclusively breast fed less than 6 months. Again family influences the attitude as more support and supervision would be there in joint family with respect to a nuclear family. Also there will be a significant attitude change among working mothers and non working which is not significant in this study. Normal delivery may have made the women more comfortable in breast feeding due to the physical condition and immediate recovery than who had caesarean section. The finding that women who had exclusively breast fed less than 6 month having more favorable attitude than the other is in contrast to other studies[25, 26] which shows favorable attitude for those who exclusively breast fed for more than 6 months. The reason can be that women, who exclusively breast fed children for less than 6 months, may have suffered adverse events for infant or mother which was attributed to lack of breast feeding by health care practitioners.

The study lacked qualitative approach which prevented the researchers from delving deeper into other issues like cultural beliefs and deep rooted fads/myths regarding feeding practises. The study would have been more informative if more women were involved in different periods of their life like adolescent people, antenatal women, postnatal women and women in the late age groups. Also the knowledge and attitude of health care practitioners about breast feeding should have provided the present level of quality in health system.

CONCLUSION

This study reveals that knowledge and attitude of mothers towards breastfeeding is far from satisfactory. There is still a need for programmes which support and encourage breastfeeding focusing more on the benefits of breast milk. Training of health care deliverers in institutional setups on need for appropriate and timely intervention in certain breast feeding pattern like discarding initial milk should be executed. Also counseling of antenatal mothers on breastfeeding must be stressed.

A Study on Implementation of Powdered Cottonseed and Oil on Bread

K Manivel

Asst. Professor, School of Hotel and Catering Management, Vels University, Chennai, India

ABSTRACT

In general, bakers use refined flour for making various bread products. In this project we have made an attempt to add powdered cottonseed and oil as an adjunct. We have incorporated powdered cottonseed proportionate to whole wheat flour (i.e., 10: 90; 20:80; 30: 70) in making breads. During this attempt, it was found that these products tasted better than whole wheat breads. The tested products were found to have better taste, texture, aroma and overall appearance by the panelists using hedonic rating scale. As compared with bread from whole wheat, the tested products with powdered cottonseed have improved volume. The combination of whole wheat flour and powdered cottonseed has good hydration characteristics, creates high-fiber and/or reduced-calorie breads. Also, we believe the tested products using powdered cottonseed will help people to overcome certain nutritional deficiencies, specifically vitamin A, D and E.

Keywords: *Implementation, Powdered Cottonseed, Wheat, Cottonseed Bread*

INTRODUCTION

Cotton (*Gossypium hirsutum*) ranks next to corn and wheat in value in most of the western countries (Morrison, 1956), Cotton, the king of natural fibers is mainly cultivated for its lint which is the most sought-after textile fiber till date due to its inherent eco-friendly and comfort characteristics. It is also one of the important cash crops of many of the Afro-Asian countries like India, Iran, Egypt, Sudan, Uzbekistan, Tanzania, etc. and plays a major role in their economic development[1]. This research was aimed at the implementation of the powdered cottonseed and oil on bread products. We have used powdered cottonseed and cottonseed oil under various proportions in making bread products. We have made three samples of bread products with different proportions of powdered cottonseed and cottonseed oil in the recipes. We have incorporated powdered cottonseed proportionate to whole wheat flour (i.e., 10: 90; 20:80; 30: 70) in making breads. It contains a high amount of antioxidants which are essential for good health. It is also rich in Vitamin E, which like antioxidants, is important in fighting free-radicals. It is well known that as much as 60-70% of seed is available from seed cotton during ginning. Cottonseed oil is obtaining by extracted from the seeds of cotton plants of various species, mainly Gossypium hirsutum and Gossypium herbaceum, Cottonseed oil has traditionally been used in foods in ayurvedic cooking in Asian countries as shortening product. Cottonseed oil is a popular frying oil for the restaurant and snack-food manufacturing industries. In this research we have incorporated cottonseed oil as moistening agent for bread products. Cottonseed oil is low in cholesterol which makes it a great choice for those who want to lower their cholesterol levels[2]. It has a light, neutral taste that is accepted by people who do not like oils with concentrate flavors.

NEED FOR THE STUDY

The market for bread products has opened a gateway for enormous growth of Bakery. Anybody from any country loves bread products and has become a favorite one. It reflects the irony and latent humor that life often presents with and which we are often unable to appreciate. Certain bread products are good for health and at the same time satisfy taste buds has indulgent food option[3]. From the above factors it has become prominent the bread product has played a dominant role in the industry. This helps to generate awareness and also become a convenient food for all age group. This study is considered as an important one to analyze the pros and cons and health benefits of implementation of

powdered cottonseed in the bread products.

SCOPE OF THE STUDY

Use of same vegetable oil for repeated frying, common practice across the country in spite of health hazards Food safety and standards authority has noted that the repeated use of same oil making dough in bread products leads to changes in the physiochemical, nutritional and sensory properties of edible oil. Keeping this in view, the quality of the oil must be monitored to avoid the use of degraded oil for cooking purposes. Instance, Omega 3fatty acid is only found in mustard, rape seed, flax seed oil and soy-bean oil. In this study cotton oil was used as an alternate ingredient which provides supplementary benefits to the human body system[4]. Also, we believe the tested products using powdered cottonseed and their oil will help people to overcome certain nutritional deficiencies, specifically vitamin A, D and E.

OUTCOME OF THE STUDY

At the outset it has been found that the implemented cottonseed bread products are good in taste and nutritive values. It is also price reasonable so that volume of scale is also satisfactory. Marketing is facing a healthy competition in which Cottonseed has enormous fiber content[5]. The panelists prefer the most implementation of cottonseed product and its flavor. The product is generally having a warm welcome from the untrained panelists. This study analyses the implementation of cottonseed in the bread products and its nutritional benefits.

PILOT STUDY

The study which is done among the panelists helped in finding the overall quality of the cottonseed implemented bread products. The samples were given to the panelists and they were requested to evaluate the products using the hedonic scale method. The total sample of the target market segment is around 50 panelists.

MATERIALS AND METHODOLOGY

Collection of Materials:

Cottonseeds were procured from a local market. The main ingredients of the bread includes flour, yeast, sugar, salt, water cottonseed oil were also collected. The different quantities of ingredients taken for the sample A, B and C were given in the table below:

Table 1: Recipe formulation and standardization of three types of breads incorporated with cotton seed oil, cotton seed milk and cotton seed powder

S.No	Ingredients	Sample-A	Sample-B	Sample-C
1	Powdered Cottonseed	20 grams	40 grams	60 grams
2	Whole Wheat Flour	180 grams	160 grams	140 grams
3	Salt	5 grams	5 grams	5 grams
4	Sugar	30 grams	30 grams	30 grams
5	Yeast	10 grams	10 grams	10 grams
6	Cottonseed Milk	25 ml	50 ml	75 ml
7	Water	75 ml	50 ml	25 ml
8	Cottonseed Oil	2 tbsp	2 tbsp	2 tbsp

Bread Production incorporated with cottonseed powder:

The cottonseeds were allowed to dry in the sunlight and it was powdered without the cotton linter.

The cottonseeds were soaked overnight and the milk was extracted from the soaked cottonseeds. The cottonseed milk was ensured that it should doesn't has any impurities.

The dough were kneaded for 5-7 minutes

The cottonseed oil was applied on the dough and it was allowed for first fermentation upto 20 minutes.

After the dough is fermented, it was divided into 35-40 grams each.

The divided dough was then shaped and arranged in a greased tray.

Then it was allowed for second fermentation, upto 20 minutes

After the dough is fermented completely, it was baked in 220C for 15-20 minutes until it gave Golden Brown colour.

Once the dough was baked it was allowed to cool for some time. Then the breads were demounted from the tray[6].

STATISTICAL TOOLS USED

Analysis of data is the process by which data is converted into useful information. Raw data as collected from questionnaires cannot be used unless it is processed in some way to make it amenable to drawing conclusions. The various statistical tools used by the researcher for data analysis in this study are:

Percentage Analysis

$$\text{Percentage (\%)} = \frac{\text{Number of Respondents}}{\text{Total Respondents}} \times 100$$

t-Test

Graphs were used to represent the data for the better and accurate interpretation of results.

Percentage analysis:

Percentage method is used to make significant comparisons between various sets of data. Each items in the table is expressed as a percentage of the total in such way as to facilitate comparison of data and to describe the relationship between the variables under study[7]. The formula used here is given below.

t-Test

T-tests are used to compare two means to assess whether they are from the same population. T-tests presume that both groups are normally distributed and have relatively equal variances. The t-statistic is distributed on a curve that is based on the number of degrees of freedom (df). There are three kinds of t-tests: independent-samples, paired-samples, and one-sample.

Sensory Evaluation

These sensory evaluation methods are widely used both by the food industry and academics. Sensory analysis of food relies upon evaluation by our senses (odour, taste, colour, tactile, temperature, pain etc). Only by applying exact scientific testing methods can reproducible results be obtained and analyzed statistically[8]. In the present study the sensory evaluation was carried on between three various proportions of implemented cottonseed bread to find out the acceptance level of Sample A, B & C with 50 untrained panelists of School of Hotel and Catering Management Students and faculty from the Vels University, Tamil Nadu, India and completed the questionnaire. Sample infusions were coded A, B and C and served randomly to panelists. About 30 gm of each infusion was served in a full plate. Three samples were served at a time. The tests were carried out in ten minutes time. The sensory acceptance studied which includes taste, colour, aroma and temperature. Panel members scored their accepted level on a 9-point Hedonic scale. In this approach numbers from1 to 9 were assigned to the scale's and score 9 indicates 'like extremely', score 1 indicates 'dislike extremely' and score 5 indicates neither like or dislike.

Calculations of Nutritive Value

All three types of standardized bread incorporated with powdered cotton seed and cotton seed oil were calculated for its nutritional value using Calculation Nutritive values of Indian Foods by NIN[9].

Statistical Analysis

Sensory scores of three types of standardized bread incorporated with powdered cotton seed and cotton seed oil were dealt by usual statistical procedures. The mean and the difference between mean (t-test) was calculated. The mean scores obtained for code C was high and there was significant difference between the Code B and C.

RESULTS AND DISCUSSIONS

The present investigation was undertaken with the following major objectives.

To study about the implementation of powdered cottonseed in bread products.

To study about the use of cottonseed oil in bread products as a moisturizing agent

To study about the nutritional content of powdered cottonseed and cottonseed oil.

To study about the proportion in which the powdered cottonseed and its oil implemented in bread products.

To study about the drawback of implementation of powdered cottonseed in bread products.

This chapter furnishes the findings of the study entitled "A Study on Implementation of Powdered Cottonseed and Oil on Bread Products". The results are categorized and presented in this chapter under the following headings-

Sensory Analysis of Bread Samples incorporated with powdered cottonseed and cottonseed oil

Percentage was calculated for Sensory analysis of bread Samples incorporated with powdered cottonseed and cottonseed oil of three samples such as Sample A, Sample B and Sample C[10]. The Sample A implemented with 25% of powdered cottonseed and cottonseed oil, Sample B implemented with 50% of powdered cottonseed and cottonseed oil, Sample C were implemented with 75% powdered cottonseed and cottonseed oil.

Table 5: Significant score from the overall sensory evaluation for all the Sample -A, B, C

S. No	Sensory Attributes	Significant Score for Sample A	Significant Score for Sample B	Significant Score for Sample C
1	Taste	7(6.66)	8(7.54)	8
2	Texture	7(6.66)	7(7.40)	8(7.74)
3	Flavor	7(6.74)	7(7.40)	8(7.8)
4	Appearance	7(6.74)	7(7.42)	8(7.58)
5	Overall	7(6.72)	7(7.32)	8(7.66)

SUMMARY

The summary stated in this chapter gives a vital description about the procedure used for data collection and analysis undertaken for the study. Different aspects of rear in connection data is analyzed using various statistical tools and charts. The hedonic rating scale and assessed for its organoleptic qualities like taste, texture, flavor, appearance and overall acceptance of the bread products[11,12]. Bread products were served to untrained panelists. Panelists asked to access each coded sample, comparing it to the control (C), and to point the degree of difference using a 9-point scale where 0 = neither like nor dislike and 9 = extremely like. The significant sensory score of the Taste was 7(6.66), Texture was 7(6.66), Flavor was 7(6.74), Appearance was 7(6.74), Overall was 7(6.72) for the Sample-A. The significant score for the mean of the Taste was 8(7.54), texture was 7(7.40), Flavor was 7(7.40), Appearance was 7(7.42), Overall was 7(7.32) for the Sample-B. From the above findings of the sensory evaluation it is evident that the sample-C which has the highest proportion of powdered cottonseed and cottonseed milk has the highest significant score among the three samples.

CONCLUSION

Major consumers of bread are people from the lower middle class and economically weaker segments is blamed for wide spread poor health. Bread is the economical and basic instant food available for consumption. In India bread is still a secondary staple food when compared to chapati, puri or rice. It is important to realize that when bread ingredients especially refine flour is used vital nutrients are destroyed and also become unfit to consume. The tested bread products prepared with cottonseed were found to have better taste, texture, aroma and overall appearance by the panelists. As compared with bread from whole wheat, the tested products with powdered cottonseed have improved volume. The combination of whole wheat flour and powdered cottonseed has good hydration characteristics permits large percentage of the flour in bread to create high-fiber and/or reduced-calorie breads. In terms of bread when the nutritious part of the grain is removed it essentially becomes a form of sugar. The end result of excessive consumption of white bread and other processed form of grain products results in nutritional deficiencies in particular contribute to a wide range of illness. From this project it is suggested to shed excess fat and improve health is to moderate and

normalize the insulin response by limiting the intake of refined flour. Also, we believe the tested products using powdered cottonseed will help people to overcome certain nutritional deficiencies, specifically vitamin A, D and E. It also has enormous fiber content as the cotton by nature rich in fiber. It is recommended that the cottonseed bread can be a substitute for the whole wheat bread in the same economic price with reasonable nutritive content. This product can be successfully developed in the bakery industry in future.

Phacoemulsification in Patients with Fuchs Heterochromic Iridocyclitis

Mukesh Singh Rajpoot[1], Pritee Chouhan[2], Rahul Bhargava[3], Anuj Chauhan[4], Shiv K Sharma[5]

[1]Consultant, Laser Eye Clinic Noida, [2]Resident, Mahatama Gandhi Medical College, Indore, [3]Director, Laser Eye Clinic Noida, [4]Resident, Laser Eye Clinic, Noida, [5]Director Rotary Eye Hospital, Palampur

ABSTRACT

Purpose: To compare the safety and efficacy of phacoemulsification to treat cataract in patients with Fuchs heterochromic iridocyclitis (FHI).

Method: A Retrospective, multicenter study was done. Patients with cataract after FHI who had phacoemulsification were evaluated retrospectively. Complications (intraoperatively and postoperatively), operative time, visual acuities, and surgically induced astigmatism were evaluated.

Results: The mean follow-up period was 10.46 ± 2.56 months. The types of cataract included posterior sub-capsular cataract in 45 (86.5 %) eyes and milky cataract white in 7 (13.4 %) eyes. The mean preoperative vision was 0.8 ± 0.24. The mean day 1 post-operative vision was 0.28 ± 0.26 (Figure1). The mean final vision was 0.24 ± 0.10 (P <0.001). The BCVA remained less than 6/60 due to recurrent uveitis, glaucoma, vitreous opacities, healed posterior KP's and CME. However, pre-operative vitreous opacities (P =0.001) and posterior KP's (P = 0.006) had a significant effect on the final visual outcome.

Conclusions: Patients with a history of FHI and cataract having phacoemulsification with PC IOL implantation had excellent visual results with a relatively low complication rate.

***Keywords**: Phacoemulsification, Fuchs Heterochromic iridocyclitis, Cataract.*

INTRODUCTION

Fuchs heterochromic iridocyclitis (FHI) is an inflammatory eye disease of unknown cause. It is still a matter of debate, what triggers inflammation in FHI; the rubella virus, Toxoplasma gondii, and cytomegalovirus have been some of the probable causes.[1]

The prevalence of cataract in FHI is about 15% to 75%. [2] Cataract surgery in patients with uveitis is often done to visually rehabilitate the patients and better visualize the fundus to manage posterior segment pathology.[3] However, he most important step in the management of complicated cataracts is adequate preoperative control of inflammation; most authors consider the absence of cells in the anterior chamber to be synonymous with inflammatory control, as mild cellular reaction in the vitreous may persist even in inactive stages of FHI.[4]

The management, visual outcomes, and postoperative course in patients with uveitis may vary according to the type of uveitis as well as the technique of cataract surgery. Conventional extracapsular cataract extraction (ECCE) was associated with complications like bleeding from fragile vessels, posterior capsular rent with vitreous loss, secondary glaucoma, and retinal detachment. However, with modern small incision surgical techniques, introduction of acrylic intraocular lenses (IOLs), and more in-depth management of complications, there has been a great improvement in visual outcomes in patients with FHI. Phacoemulsification is now the preferred surgical modality of treating cataract in patients with uveitis. [5-6]

In the present study we retrospectively reviewed the outcomes of phacoemulsification in patients with FHI.

MATERIAL AND METHOD

Fifty-four eyes of 48 patients with FHI who had phacoemulsification with in-the-bag implantation of intraocular lens were evaluated retrospectively; and the primary and secondary outcome measures evaluated were the postoperative vision and complication rate.

The diagnosis was based on the criteria proposed by Kimura et al. [7]; the institutional review boards and the local ethics committees approved the trial. A written, informed consent for the study, based on Helsinki protocol was obtained from all the participating patients.

Exclusion criteria

Patients were excluded if their follow-up period was of less than six months and if they had posterior synechia, cystoid macular edema (CME) and a history of trauma and systemic diseases like diabetes mellitus. Patients with sulcus-to-sulcus and sulcus-to-bag implantation of the IOL were also excluded from the study.

The primary outcome measure was improvement in the post-operative visual acuity. The secondary outcome measure was the rate of postoperative complications.

The pre-operative protocol included routine investigations such as total and differential leucocyte counts, erythrocyte sedimentation rate and blood sugar levels, Mantoux test, chest X-ray, X-rays of the cervical spine and sacroiliac joints. Special investigations included rheumatoid factor, angiotensin converting enzyme assay, anti-nuclear factor, human leucocyte antigen typing and enzyme-linked immunosorbant assay (ELISA) for TORCH infections (Toxoplasmosis, Other agents, Rubella, Cytomegalovirus and Herpes), human immunodeficiency virus and tuberculosis.

B-scan ultrasonography was performed in cases where funduscopy was not possible due to a dense cataract. Gonioscopy was done in all patients with Sussman's four mirror, hand-held

gonioscope (Ocular Instruments, USA). Intraocular pressure was measured with applanation tonometry.

A minimum inflammation free period (defined as five or less than five cells per high power field in the anterior chamber) of a minimum of three months was a pre-requisite for eligibility for surgery. [8] Pre-operatively, topical antibiotic eye drops were prescribed to all patients. No patient received oral corticosteroids.

SURGICAL TECHNIQUE

Peribulbar anaesthesia was delivered. Asepsis was achieved; this included ciprofloxacin (0.3%) eye drops 6 to 8 times, 24 hours before the procedure; instillation of 5% povidone-iodine solution in the cul-de-sac before surgery; and ensuring patency of the nasolacrimal duct. In the preoperative holding area, periocular skin was cleansed with 10% povidone-iodine solution. On the operating table, periocular cleansing was repeated and a drop of 5% povidone-iodine solution instilled on the ocular surface.

Phacoemulsification was performed with peribulbar anaesthesia. Two side-port corneal incisions were created 180 degrees apart with a 20G microincision vitrectomy knife. Anterior chamber entry was fashioned with a 2.8-mm keratome. Anterior chamber was maintained with 2% hydroxypropyl methylcellulose. Trypan blue–assisted continuous curvilinear capsulorrhexis was done as described previously. Cortical cleavage hydrodissection was done just below the anterior capsule rim and the nucleus rotated in the bag. Phacoemulsification was performed with an Infinity vision system (Alcon, Inc) using the phaco-chop method. Bimanual irrigation/ aspiration technique removed cortical matter. IOL was implanted in the capsular bag. Paracentesis was hydrated. At the end of surgery, a subconjunctival injection of 20 mg gentamicin and 4 mg dexamethasone was given to all patients.

POSTOPERATIVE CARE

Patients were followed up on the first, third, and seventh postoperative days, then weekly for 2 weeks, monthly for 2 months, and every 3 months thereafter. The postoperative regimen included topical moxifloxacin every 4 hours for 7 days and topical betamethasone 0.1%, every 2 hours, tapered over 6 to 8 weeks depending on response. At each follow-up day, VA, AC reaction, and vitreous haze were evaluated. Goldman applanation tonometry was done on the first postoperative day, and if normal, repeated at monthly intervals for 3 months. Detailed fundus examination was done at 1 week, 1 month, and repeated at 3-month intervals.

STATISTICS

Vision was compared using the non-parametric Wilcoxon Test. The final vision and complication rate were compared with Mann Whitney test. The P value was calculated at 1 % and 5 % levels. A P value less than 0.001 at 1 % and less than 0.005 at 5% was considered statistically significant.

RESULTS

Two cases were excluded as their follow-up period was of less than six months. The number of valid cases was 52. The mean age was 36.41± 3.66 years. The types of cataract included posterior sub-capsular cataract in 45 (86.5 %) eyes and milky cataract white in 7 (13.4 %) eyes.

ELISA for TORCH infections was positive in one case. The mean follow-up period was 10.46 ± 2.56 months. Table 1 shows the baseline characteristics of the patients.

Snellen's visual acuity was converted to Log MAR units for comparison. The mean preoperative vision was 0.8 ± 0.24. The mean Day 1 post-operative vision was 0.28 ± 0.26 (Figure1). The mean final vision was 0.24 ± 0.10 (P <0.001) (Figure 2). Table 2 shows the percentage of patients at each level of corrected distance vision (CDVA). At the final follow-up, 88.6% of the patients had a vision of 0.5 or better (6/12).

The BCVA remained less than 6/60 due to recurrent uveitis, glaucoma, vitreous opacities, healed posterior KP's and CME (Table 4).

PREOPERATIVE SEQUELAE AND FINAL VISION

Pre-operative findings like heterochromia, iris atrophy or nodules, and vessels on the trabecular meshwork (TM) when present did not have a significant effect on the final visual acuity (Figure 1). However, pre-operative vitreous opacities (P =0.001) and posterior KP's (P = 0.006) had a significant effect on the final visual outcome (Table 2).

OCULAR INFLAMMATION

twenty eyes had a mild to moderate anterior chamber reaction on the first post-operative day.

At the end of the first post-operative month, six eyes had 2 + anterior chamber cells and four eyes had 1 + anterior chamber cells. Topical steroids were continued for eight weeks and resulted in the resolution of inflammation in most of these cases. However, five eyes had recurrent episodes of uveitis and developed PCO subsequently. Nd: YAG capsulotomy was offered after a quiet phase of three months. The eyes with recurrent uveitis had persistent vitreous haze at the final follow-up examination. (P = 0.001).

COMPLICATIONS

Intraoperative complications (Table 3) included hyphema in three eyes (5.7 %), which did not obscure visualization during surgery. Posterior capsule rent with a vitreous loss occurred in one case. A multi-piece PMMA IOL was implanted in the sulcus following anterior vitrectomy. The implanted IOLs were Acrylic in 17 eyes, PMMA in 34 eyes and silicone in 1 eyes. PMMA IOLs were implanted in those patients who could not afford foldable lenses.

The PCO was significantly more in the PMMA group (P = 0.001). There was no case of new onset postoperative glaucoma. However, the eyes of six patients had medically-controlled glaucoma prior to the surgery. At a mean postoperative duration of 1.86 ± 0.81 months, elevated IOP was seen in five eyes. A sustained rise of IOP, despite maximum topical therapy, developed in three eyes (P = 0.074). These patients were referred to the glaucoma clinic for further management. New-onset CME was clinically seen in sic (11.5 %) eyes. CME was detected within the second month in three eyes and within four months in the rest of the eyes.

Topical therapy with ketorolac four times a day for six weeks resulted in the resolution of the

CME in three eyes. However, two eyes with recurrent uveitis and one eye following Nd: YAG laser capsulotomy, had persistent CME on the final follow-up (P = 0.060). Posterior capsule opacification was a common cause (12/19 %) of postoperative reduction of vision (P < 0.001).

The mean duration of PCO after surgery was 3.42 ± 1.78 months. Pearl form of PCO was seen in eight (62.3 %) eyes and the fibrous form in four (33.3 %) eyes. All eyes with PCO except one achieved good vision after Nd: YAG laser capsulotomy; and CME was the cause of reduced vision in this one eye.

Table 1: Baseline Parameters

Age (years)	36.41±3.66
Sex n (%)	
Male	30 (57.7)
Female	22 (42.3)
Follow up (months)	10.46 ± 2.56
Preoperative VA (Log MAR)	0.8 ± 0.24
Postoperative VA (day 1)	0.28 ± 0.26
Postoperative VA(final)	0.24 ± 0.10

Table 2 Pre-operative finding and visual outcome

Pre-op finding	**N**	**%**	**P value (Mann Whitney test)**
Heterochromia	36	69.2	0.103
Iris atrophy	8	15.3	0.973
Iris nodules	0	0	NA
Vitritis	8	15.3	0.008
Raised IOP	5	9.6	0.079
Vessels on TM	4	7.6	0.074
Posterior KP's	10	19	0.006

Table 3 Complication and visual outcome

COMPLICATION	**n**	**%**	**P value**
Hyphema	3	5.7	0.079
IOL deposits	1	1.9	0.185
PCO	11	21.1	0.001
Vitreous opacities	4	7.6	0.002
Secondary glaucoma	3	5.7	0.597
Recurrent uveitis	4	7.6	0.002
Persistent CME	3	5.7	0.081

DISCUSSION

Cataract is a common complication of FHI. However, unlike age-related cataract, patients present at a relatively younger age (<40 years). In the present study, the mean age at presentation was 36.4 ± 3.66 years.

The treatment of cataract in patients with FHI has evolved from intracapsular cataract extraction and conventional ECCE to phacoemulsification and from implantation of AC IOLs to acrylic posterior chamber IOLs. Younger patient age and the posterior subcapsular location of most of these cataracts make phacoemulsification an easy procedure with fewer complications. In most countries and settings, phacoemulsification is now the preferred technique of cataract surgery. However, the outcomes of cataract surgery are sometimes difficult to assess as eyes with different types of uveitis respond differently to surgery.

In a RCT, Bhargava et al found that phacoemulsification is not always successful in fragmenting extremely dense nuclei with extensive posterior synechia; therefore, in general, authors routinely performed scleral tunnel incisions for phacoemulsification of uveitic cataracts, as it may be necessary to enlarge the incision to facilitate manual nuclear extraction. However, as synechia do not occur in FHI, scleral tunnel incisions were not done in the present study. 10

Intraocular lens implantation in an inflamed eye may cause concern because of exaggerated postoperative inflammation. However, FHI is not typically associated with severe uveitis in the postoperative period. In the present study, a mild to moderate reaction was seen in 15.3% of eyes. Recurrent uveitis with persistent vitreous haze at final follow-up examination was seen in 4.6% of eyes. Due to lack of posterior synechia in FHI and the fact that peripheral iridectomy was not performed in any case, postoperative inflammation was relatively mild. In a series of 103 eyes with complicated cataract after FHI and ECCE or phacoemulsification with posterior chamber IOL implantation, Tejwani et al did not find any case with severe postoperative inflammation, although 3 eyes had persistent vitreous haze at final follow-up.[6]

Most studies report excellent visual outcomes after cataract surgery in FHI. In the present study, 88.6% of patients achieved a CDVA of 20/63 or better at 6 months. Moreover, the mean SIA was significantly lower as compared to other studies in which small incision cataract surgery (SICS) was done in uveitic cataract ($P < 0.001$). Presumably, this was a result of the larger incision used by these authors for SICS. Our results were comparable to the studies by Budak et al and Gee and Tabbara. [11-12]

Posterior capsule opacification is a common complication in FHI, with an incidence of 20% to 40%. [13-14] The incidence of PCO in our study was 21%. The incidence of PCO is significantly higher with polymethyl metha acrylate IOLs as compared with acrylic IOLs, and PCO rates do not significantly differ between hydrophobic or hydrophilic acrylic IOLs at 6months' follow-up.[15-16] The higher incidence of PCO in the present study could be explained by the fact that a significant number of patients had PMMA implanted due to financial constraints.

Although there was no case of new onset postoperative glaucoma, the eyes of 8 patients had medically controlled glaucoma before surgery. Elevated IOP was seen in 3 eyes at a mean postoperative duration of 1.06 ± 0.4 months; 3 eyes developed a sustained rise in IOP despite maximum topical therapy with 2 drugs. These patients were referred to the glaucoma clinic for further management.

A shortcoming of the present study is that only 1 technique of phacoemulsification was studied. The results and complications like endothelial cell loss may vary slightly with the technique of nucleus delivery or chopping used.[17]

In conclusion, patients with a history of FHI and cataract having phacoemulsification with PC IOL implantation had excellent visual results with a relatively low complication rate.

Conflict of Interest: We do not have any conflict of interest.

Nutritional and Sensory Evaluation of Moringa Oleifera Cookies

K Manivel

Asst. Professor, School of Hotel and Catering Management, Vels University, Chennai, India

ABSTRACT

Cookies are a favorite American sweet, made from dough of cereal flour and brown sugar that contains a relatively high ratio of fat, such as butter, vegetable shortening, or margarine. The increasing popularity of cookies especially among children is growing and has become commercialized. This study is an alternative approach to biscuit manufacturing, in order to develop healthy cookies, as it would supplement the essential nutrients needed for all age groups. The different blends of cereal flour (Millet, corn meal and rye flour) with wheat flour and Moringa oleifera leaf powder were processed into cookies in the following ratios 50:30:20 (wheat flour, millet flour, Moringa) (WMM), 40:30:30 (wheat flour, rye flour, Moringa) WRM, 30:30:40 (Wheat flour, corn meal flour, Moringa) (WCM). The sensory evaluation of the cookies samples from the blends was performed using a 9-point hedonic scale. The highest mean score of the cookie was analyzed further for its nutrient content. The results of the sensory evaluation are to show that there were significant differences in the diverse attributes that were determined such as in color, texture, taste, flavor and general acceptance. It was analyzed further for its nutrient content. Incorporating moringa leaf in cookies or any other baked foods may be claimed as a means of boosting nutrition and can be served as an alternative approach to the manufacture of healthy cookies.

Keywords: *Moringa oleifera, nutri cookies, Malnutrition herbal cookies, Healthy cookies.*

INTRODUCTION

Cookie making ingredients are flour, eggs, sugar, butter and flavoring agent. It may comprise other ingredients such as raisins, corn flakes, chocolates, coconut powder and various nuts as per the flavor required. Cookie dough is basically made with flour, fat, moistening agent, raising agent and flavoring agent in various ratios and methods of preparation. Moringa Oleifera is used as a source of Malnutrition relief. Moringa trees have been used to resist malnutrition, especially among infants and nursing mothers. Since Moringa flourishes in arid and semiarid environments, it may provide a versatile, nutritious food source all over the year. There are lots of nutritional benefits in the whole Moringa Oleifera tree[1]. I have researched cookies with the leaves of Moringa Oleifera (Drumstick leaves) with regular cookie ingredients. Drumstick tree is called the powerhouse of minerals and is the most common tree in India. Its leaves, fruits, flowers, bark and seeds are all edible. They all have medicinal values and are used as ingredients in most dishes. The leaves are especially beneficial in the treatment of many ailments due to their various medicinal properties as they are rich in iron content[2].

NEED FOR THE STUDY

Cookies are served at high tea or as snacks across the world. The increasing popularity of cookies especially among children is growing and has become commercialized. This study is an alternative approach to biscuit manufacturers in order to develop healthy cookies, as it would supplement the essential nutrients needed for all age groups. This study is mainly targeted to reduce the malnutrition rate, which can be achieved by the consumption of Moringa oleífera. The cookie, which is made by incorporating Moringa leaves, has all the vital nutrients, which will help in bringing down the malnutrition rate to a great extent[3]. Moringa Oleifera itself has various health benefits such as stabilizing the blood pressure, controlling glucose level in case of diabetes, used in treating diarrhea and bronchitis. The main aim of the study is to develop and perform

the sensory evaluation of Moringa oleifera cookies.

METHODOLOGY

The present study was undertaken to study the "sensory evaluation". Data collected, comprised of the following:

MATERIALS AND METHODS:

DEFINING THE PROBLEM

Malnutrition describes a state of imbalance between the dietary needs of the body and the type of diet provided to the body. It impacts brain development, behavioral development, cognitive development and perhaps most visibly growth development. More specifically, the numbers of underweight (low weight-for-age), stunted (low height-for- age) and wasted (low weight-for height) children are common measures for the number of malnourished children in a particular country[4]. Children are more at risk for serious complications due to nutritional deficiencies than adults. Kids require different amounts of Iron at various ages and stages. Infants who are breastfed tend to get enough iron from their mothers only until 4-6 months of age. Iron is the major nutrient, which is used to treat malnutrition. After 12 months of age, toddlers are at risk for Iron deficiency because they are no longer entitled to breast-feeding. Thus, they are forced to Consume Iron rich food in some other forms. Iron is found in foods such as dark leafy greens, red meat, and egg yolks. Moringa Oleifera is rich in Iron Content[5]. A dosage of just two or three spoonsful of Moringa leaves Powder provides a substantial amount of Iron. Moringa Olefera when Consumed in raw form is bitter in taste which makes it very hard for kids to consume them. Thus, when it is incorporated in cookies, it becomes edible and much tastier.

SELECTION OF INGREDIENTS

Whole Wheat Flour

The three parts of the wheat kernels are the germ, bran and the endosperm. Refined wheat flour is made up almost entirely of the endosperm which is a compound of starches and proteins. These proteins and starches allow a baker to create a dough with a lot of strength that is able to trap the gas produced by the yeast and this in turn gives the dough volume[7]. Absence of endosperm in the dough would restrict rise or not possess a shape. This is a reason baking with a white flour is so considerable. As it has more percentage of flour protein than any other grains it can be used as an essential ingredient in cookie making. The demerits of baking with only the endosperm let's go off all the vitamins, minerals, fats and fiber that are contained in the germ and bran during the milling process[8]. These areas are where all the health benefits of wheat reside. It is essentially the entire kernel of wheat milled up into flour form which contains nutrition and flavor.

Shaping:

Due to the weakened state of dough prepared with whole-wheat flour it is significant to handle the dough gently. When shaping, the dough will have a tendency to tear much easier than when using only Refined wheat flour and it will not get the dough as stiff or Shape it firmly.

Selection of Secondary Flour:

The following flours were used as Secondary flours in the cookies:

Rye flour:

Whole grain rye flour contains, as a percentage of dry matter, 56—70% starch, 8—1 3% proteins, 2—3% lipids, 2% ash and 1 5—2 1 % total dietary fiber. In addition, it is rich in minerals, vitamins, especially B-vitamins, and phytochemicals.

Corn-Meal flour:

Corn meal is flour made by grinding dried corn. It can be ground into a variety of consistencies and is also known as corn flour when it is finely ground. Corn meal flour contains nutrients like vitamin B6, Carbohydrates, dietary fiber, Protein and Calories.

Millet flour:

Millet is a rich source of magnesium, a mineral that acts as a co-factor for more than 300 enzymes, including enzymes involved in the body's use of glucose and insulin secretion. Millet is gluten-free and non-allergenic. In Western countries, dried leaves are sold as dietary supplements, in either powder or capsule form.

STANDARDIZATION OF MORINGA OLEIFERA COOKIES

Standardized recipes are used every day in child nutrition operations as a guide to preparing the foods served to customers. A standardized recipe is a recipe that has been carefully adapted and tested to ensure that it will produce a consistent product every time it is used[9]. The recipes of three cookies with various flour the incorporation of moringa oleifera were developed with specific ingredients.

Table 1: Standardized Sample I, II & III — moringa oleifera and Rye, Corn-meal and Millet flour incorporated Cookies One Portion is Four Cookies (4Ogms)

Ingredients for Sample I	Ingredients for Sample II	Ingredients for Sample III	Methodology
Whole wheat flour (80gm)	Whole wheat flour (60gm)	Whole wheat flour (100gm)	Moringa oleifera was de-stalked, sundried and powdered.
Moringa oleifera powder (60gm)	Moringa oleifera powder (80gm)	Moringa oleifera powder (40gm)	Cream together all the ingredients till soft in texture.
Rye flour (60gm)	Corn-meal flour (60gm)	Millet flour (60gm)	The dough was refrigerated for 15mins.
Clarified Butter (90gm)	Clarified Butter (90gm)	Clarified Butter (90gm)	Rolled out the dough and shaped them with cookie cutter.
Honey (10ml)	Honey (10ml)	Honey (10ml)	baked at 170*c for 12-15 minutes.
Palm Sugar (30gm)	Palm Sugar (30gm)	Palm Sugar (30gm)	Cooled at room temperature
Milk powder (2gm)	Milk powder (2gm)	Milk powder (2gm)	Stored in air tight container

The recipe standardization process of the three-nutri cookies was done for recipe verification, product evaluation, and quantity adjustment. Reviewing the recipe in detail, preparing it, verifying its yield, performed recipe verification and recording changes. Product evaluation was focused in determining the acceptability of the product produced from the recipe[10]. Changing the recipe yield and ingredient amounts was done in the quantity adjustment phase. A recipe went through all these phases several times before becoming standardized at the necessary quantity for an operation. Faculty and students of School of Hotel and catering Management worked together on the recipe standardization process. Input from students and other panel members were critical during the evaluation phase.

SELECTION OF METHOD AND TOOL FOR THE STUDY

Sensory method is an experimental study for the newly developed products of three different cookies in order to test, evaluate and get feedback on Sample I, Sample II and Sample III. Thirty (30) panelists were selected to conduct sensory characteristics of cookies which were assessed for sensory acceptability level of the panel members[11]. The sensory profile was taken on appearance, odor, texture, taste, flavor and acceptance.

PREPAR&TION OF HEDONIC SCORECARD

The sensory acceptability tests for moringa oleifera cookies was determined by using 9 point hedonic scale ranging from 1 indicating Dislike Extremely to 9 suggesting Like Extremely with a neutral category of 5 indicating neither like nor dislike for parameters like appearance, aroma, texture, taste, over all acceptance using questionnaire as tool.

CONDUCT OF THE STUDY

Sensory tests were carried out in a sensory light and good ventilation, and away from the preparation room. evaluation room. All the samples were prepared with utmost care. Texture was maintained and carried out for the same in all samples. The volume of all the

samples were equal. Samples were labeled as Sample I (moringa oleifere and Rye) Sample II (moringa oleifere and Corn-meal) and Sample III (moringa Oleifere and millet) to avoid bias.

DETERMINATION OF PROXIMATE NUTRIENT ANALYSIS

The highest mean score of the product, Sample II was analyzed further for its nutrient content which includes energy, carbohydrate, fat, dietary fiber, calcium, iron and sugar[12]. The energy was calculated by FAO method. The proximate nutrients composition such as protein, dietary fiber, total sugar and iron of sample II was performed according to AOAC method Carbohydrates were determined by different method.

RESULTS AND DISCUSSION

The purpose of the study is to Eradicate Malnutrition. The analysis of the data results is presented in this chapter.

The results of three different samples have shown that the texture of the cookies is same in all samples and varied slightly only in Sample III. In Sample II the taste has a mean score of 8, which is greater than the other two samples. The mean scores of Aroma and Appearance in all the three samples didn't have much of an impact. The Acceptance mean score did not have a vast difference between Sample I and Sample III but in Sample II it is 8.32 which was liked, compared to the other samples of the cookies. The results indicate that functional and adding Moringa Oleifera to many bakery products could develop health products with improved sensory quality. To make the Moringa Oleifera cookies more palatable a higher proportion of fine Moringa leaves may be incorporated.

RESULTS

Table 2- Mean Scores of Sensory Evaluation of Moringa Oleifera cookies

SENSORY EVALUATION	SAMPLE I MEAN SCORES	SAMPLE II MEAN SCORES	SAMPLE III MEAN SCORES
APPEARANCE	7.28	7.68	7.04
TEXTURE	7.36	7.60	7.04
TASTE	6.96	8.08	7.28
ODOUR	7.44	7.88	7.52
ACCEPTANCE	7.16	8.32	7.44
OVERALL AVERAGE	**7.24**	**7.91**	**7.26**

Sensory Evaluation of Products

Prepared cookies were subjected to sensory analysis based on 9-point hedonic rating scale for taste, texture, appearance, aroma and after-taste Using a panel of 30 untrained members. Trained members were chefs and academicians, bakery and Culinary preparations. Panel members were advised to use sensory evaluation sheet, mark and convert them into scores. The scores were based on the following criteria: Like extremely: 9; Like very much: 8; Like moderately: 5. , 7; like slightly: 6; Neither like nor dislike extremely: 1.

NUTR1TIVE VALUE OF MORINGA OLEIFERA COOKIES:

(SAMPLE II MORINGA OLEIFERA AND CORN MEAL)

The proximate nutrient analysis of Sample [I tisane was determined. The results expressed on l00 grams of weight basis, are presented in table 3.

Table 3: Proximate Nutrient Analyses **Per**: l00 grams

S.NO	Parameters	Methods	Result
1.	Energy (By Calculation)	FAO Method	498.48 kcal
2.	Carbohydrate (By Difference)	CTL/SOP/FOOD/262-2014	65.96gm
3.	Total Fat	AOAC 19th Edn.2012,920.39g	23.58gm
4.	Protein (N*6.25)	DGHS Manual 3,2005	5.61gm
5.	Dietary Fiber	AOAC 19th Edn.2012,985.29	5.79gm
6.	Total sugar	AOAC 19th Edn.2012, 925.05	16.15gm
7.	Iron as Fe	AOAC 19th Edn.2012, 99.11	2.40mg

DISCUSSION

The study is based on the implementation of Moringa oliefera in cookies using various combinations of flours. The goal of this study is mainly to reduce the rate of malnutrition by adding Moringa in the cookies as the core ingredient to make Moringa tasty. when Moringa is consumed barely it is bitter in taste. This Cookies helps in improving nutrition value. The medicinal values present in the Moringa oliefera is also present in the cookies therefore there are various health benefits in the cookies. Moringa has been advocated as a natural nutrition for the tropics and is being used to combat malnutrition due to its high protein and fiber content. The developed product of this cookies for this study may be served as an alternative approach to the manufacture of healthy cookies.

CONCLUSION

There are various types of cookies prepared by using different ingredients. A Moringa Oleifera cookie aims at increasing the nutritional value and eradicating malnutrition. Nowadays throughout the world people are consuming Herbal Cookies, Non-Processed foods, organic vegetables, etc. For a disease-Free and healthy life consuming the Moringa Oleifera in the form of cookies makes it more edible and tasty. Usually Herbal items though it has lots of medicinal, it cannot be eaten without processing. These leaves are incorporated in various medicines since olden days. In Ayurveda this is the most important ingredient, thus incorporating it in cookies makes it healthy and edible. Incorporating Moringa leaf in cookies or any other baked food may be claimed as a means of boosting nutrition in India where Malnutrition is prevalent. The developed product of Moringa Oleifera cookies for this study may be served as an alternative. In the manufacturing of cookies. It is high time that we kick-start our life with our undiscovered leaves. Limitations of the study are, Eliminating the raw smell from the cookies was a little tough job, the leaves are to be cleaned carefully as it has lots of stalk in it, Preserving the Moringa oleifera leaves were hard, The moisture in the leaves had to be shallow fried in clarified butter to enhance the flavor for cookies and it had to be dried properly before it was added as an ingredient.

Emotional Impact of Diabetic Foot Ulcer

A Manjula[1], Prasannababy[2], S J Nalini[3] , R Ramya[4]

[1]Lecturer, Faculty of Nursing, [2]Former Principal, Faculty of Nursing, [3]Principal, Faculty of Nursing, [4] Professor, Dept of General Surgery, Sri Ramachandra Medical College and Research Institute, (Deemed to be University), Porur, Chennai, Tamilnadu, India

ABSTRACT

A descriptive design was used to assess the emotional impact. The sample consisted of 20 patients with diabetic foot ulcer satisfying the sample selection criteria. The setting was surgical OPD of Sri Ramachandra Hospital. The instrument consisted of two parts Part I-demographic variables, Part II-emotional domain of diabetic foot ulcer scale developed by Johnson& Johnson (2002). Emotional domain that measures the level of depression consisted of 17 items in 5 point likert scale. Data were collected on the day of selection on a one to one basis through interview method**.** The study findings revealed that 10(50 %) patients belonged to the age group of 66-75yrs. Regarding wound classification, 14(70%) patients had ulcer that penetrated to capsule or bone. The emotional impact among diabetic foot ulcer patients were, 12(60%) patients had moderate depression and 6(20%) had mild depression and 2(10%) had severe depression. There is no statistically significant association noted between emotional impact and background variables.

Keywords: *emotional impact; depression, diabetic foot ulcer.*

INTRODUCTION

Diabetic foot ulcer is one of the long term complications of diabetes mellitus. Diabetic foot ulcers are the sores which develop over the feet. It is one of the common cause of amputation.85% of amputation are due to diabetic foot ulcer among patients with type 2 diabetes mellitus[1] and 20% of hospital admission in people with diabetes are due to foot ulcers[2] and average stay at hospital is 9-10 days[3].

Advancement in health care facilities and treatment modalities have reduced mortality and extended the life expectancy of people. The long term treatment and deformity related to diabetic foot ulcer puts the individual in reduced social activities, increased family tension, limited employment, financial hardship[4] ultimately makes the patient emotionally weak and finds it difficult to cope up with the situation. The emotional impact of diabetic foot ulcer is often overlooked when medical care is given importance. In the present study, the investigators assessed the emotional impact among patients with foot ulcer

STATEMENT OF THE PROBLEM

A Study to assess the emotional impact of foot ulcer among patients with diabetic foot ulcer at Sri Ramachandra hospital, Chennai.

OBJECTIVES OF THE STUDY:

To identify the emotional impact of foot ulcer among patients with diabetic foot ulcer.

To associate the emotional impact of foot ulcer with selected background variables among patients with diabetic foot ulcer.

METHODOLOGY

A.Materials and Methods:

Research design : Descriptive design

Setting: Surgical Outpatient Department of SRH.

Population: Patients with Diabetic Foot Ulcer

Sample size: 20

Sampling technique: Convenience sampling technique

Sampling criteria:

1. Inclusion criteria

a. Patients with diabetic foot ulcer for 4weeks

b. Both male and female patients were included

2. Exclusion criteria

a. Patients not volunteering to participate

b. Patients with known depression

Description of the instrument

Part I - Background variables: Age, gender, residence, educational status, duration of diabetes mellitus, glycemic control and wound classification.

Part II - Emotional domain of diabetic foot ulcer scale developed by Johnson& Johnson (2002). Emotional domain that measures the level of depression consisted of 17 items in 5 point likert scale,1-not at all,2-slightly,3-moderately,4-quite a bit,5-extremely

Score interpretation is given as

<17 no depression

18-34 mild depression

35-51 moderate depression

52-68 severe depression

69-85 very severe depression

Data collection procedure

Ethical permission was obtained from Instituitional Ethics Committee Ref no.(IEC-NI/13/APR/33/24). All the subjects satisfied the criteria were selected. The researcher approached each selected patient and explained the purpose and nature of the study. The patient's consent was obtained individually and a one to one interview was conducted to obtain background information and identify emotional impact. 30min was spent for each patient to collect the data.

Statistical analysis

Descriptive (Frequency, Percentage distribution, mean and standard deviation) and inferential (chi square) statistics were used.

RESULTS

Table 1. Frequency and Percentage Distribution of Background Variables among patients with Diabetic foot ulcer (N=20).

SI. NO	DEMOGRAPHIC VARIABLES	FREQUENCY	PERCENTAGE
1.	**Age (in years)** (a) 36-45	-	-
	(b) 46-55	4	20
	(c) 56-65	6	30
	(d) 66-75	10	50
2.	**Gender** (a) Male	16	80
	(b) Female	4	20

Cont... **Table 1. Frequency and Percentage Distribution of Background Variables among patients with Diabetic foot ulcer (N=20).**

3.	**Residence** (a) Rural	8	40
	(b) Sub urban	6	30
	(c) Urban	6	30
4.	**Educational Status** (a) No formal education	3	15
	(b) Primary	8	40
	(c) High school	6	30
	(d) Higher secondary	3	15
	(e) Collegiate	-	-
5.	**Duration of diabetes mellitus** (a) <1 year	-	-
	(b) 1-5 years	-	-
	(c) 5-10 years	6	30
	(d) >10 years	14	70
6.	**Glycemic control** PPBS (mg/ dl) a) <250	4	20
	b) 251-350	12	60
	c) >351	4	20
7.	**Wound classification** (a) IA	3	15
	(b) IIA	3	15
	(c) IIIA	14	70

Table 1 represents the frequency and percentage distribution of background variables. Majority, 10(50%) of the patients were between 66-75 yrs of age. With respect to gender 16(80%) were male. Maximum 8(40%) are from rural area. Majority of the patients educational status was primary school 8(40%). Regarding duration of diabetes mellitus 14(70%) has diabetes for more than 10yrs

Table 2. Mean and standard deviation of Emotional Impact of diabetic foot ulcer among patients with diabetic foot ulcer (N=20).

Si.no	Variable	Mean	Standard Deviation
1.	Emotional impact	39.35	10.68

Table 2 shows the mean emotional impact score as 39.35 with the SD 10.68.

Table 3. Level of emotional impact of foot ulcer among patients with diabetic foot ulcer (N=20).

Si.no	Level of emotional impact	Frequency	Percentage
1.	Normal	-	-
2.	Mild depression	06	30
3.	Moderate depression	12	60
4.	Severe depression	02	10
5.	Very severe depression	-	-

Table 3 depicts the level of emotional impact, 12 (60%) patients have moderate depression and 2(10%) of patients have severe depression and 6 (30%) have mild depression.

DISCUSSION

Description of the study variables

Table1 represents the frequency and percentage distribution of background variables. Majority, 10(50%) of the patients were between 66-75 yrs of age. With respect to gender 16(80%) were male. Maximum 8(40%) are from rural area. Majority of the patients educational status was primary school 8(40%). Regarding duration of diabetes mellitus 14(70%) has diabetes for more than 10yrs. Pengzi Zhang (2016) in is study on Global prevalence of diabetic foot ulcer the ulcer was found to be more prevalent in males, Type 2 Diabetes mellitus, older people and longer duration of diabetes[5].

The first objective of the study was to assess the emotional impact of foot ulcer among patients with diabetic foot ulcer.

The emotional impact of diabetic foot ulcer was assessed by using the Diabetic Foot Scale (DFS) developed by Johnson& Johnson (2002). Emotional domain that measures the level of depression consisted of 17 items in 5 point likert scale.

(Table 3) shows analysis of level of emotional impact, 12 (60%) patients have moderate depression and 2(10%) of patients have severe depression. The study findings are consistent with the results of Maria Teresa de Jesus Pereira (2014) study were 50 patients with diabetic foot ulcer was studied for feelings of powerlessness using Powerlessness Assessment Tool for adults (PAT) with the mean total score 50.12. The results indicate that patients with diabetic foot ulcers had strong feelings of powerlessness[6].

(Table 2) shows the mean emotional impact score to be 39.35 with the SD 10.68.

The second objective of the study was to associate the level of emotional impact of foot ulcer with selected background variables among patients with diabetic foot ulcer.

There was no significant association found between the background variables.

CONCLUSION

Depression symptoms at various levels are present among most of the patients suffering from diabetic foot ulcer due to long term management, life style modification and recurrence of disease. Nurses need to play an important role in meeting the emotional needs of patients and help to lead a better quality of life.

Conflict of Interest: Conflict of interest declared none.

A Review of Epidemiology of Unintentional Injuries among Children in India

Alex Joseph[1], Dhasarathi Kumar[2], King David Edward[2]

[1]Assistant Professor, School of Public Health, [2]Research Assistant, School of Public Health, SRM Institute of Science and Technology, Chennai, Tamil Nadu.

ABSTRACT

Childhood injury is a major public health problem which requires immediate attention. According to the estimates of WHO, Injuries are of higher health concern in every country causing over 3.8 million deaths per year where Unintentional injuries account for almost 90% of these cases in Lower and middle income countries. Every year, approximately 875,000 children are killed and nonfatal injuries affect the lives of 10 to 30 million globally. In India, the mortality rate related to injuries among under-5 children is contributing to 5.9% of the total deaths. The objective of this study is to estimate the magnitude and prevalence of Unintentional injury distribution & pattern among children of 1-18 years of age in India. A thorough search was done using PUBMED, BMC PUBLIC HEALTH, IJPH, BMJ PAEDIATRICS and finally narrowing down to Pub Med where the articles published for the last ten years were extracted. The studies revealed that RTI, Burns, Falls, Drowning & Bites were the common causes and where meagre knowledge associated to the given injuries were significant influence to the pattern of Injury occurrence. Distribution & pattern of injury, including the health- seeking behaviour seemed to vary across both in Rural and Urban settings. Poor perception of injury was a common indicator of prevalence. Strategies on prevention and education still need improvisation. 90% of childhood injuries were both predictable and preventable. Unintentional injuries account for both the functional and financial healthcare burden on population under unintentional injury.

Keywords used: *Injury in India, Unintentional injuries in India, Childhood injury in India, Childhood and Injuries.*

INTRODUCTION

The perspective of some events never takes a better turn until there is more importance added to it by valuing that with something of historical origin. As we go on the same path we realize that Injury is not an unknown guest. This dates back more than a hundred years ago in England where a playful adventure of an 8-month-old turned to a tragic case of drowning.[1] Unintentional injuries are one of the leading causes of death and disability among children in most of the countries.[2] According to the baseline scenario of 2015, the deaths due to unintentional injuries are higher than the intentional injuries.[3] Indirect estimates of WHO says Injuries are of higher health concern in every country causing over 3.9 million deaths per year where Unintentional injuries account for almost 90% of these cases in Lower and middle income countries, which show an emerging trend towards the rise of unintentional childhood injuries especially among the 0-14 years of age children. The commonly seen unintentional injuries are Road traffic injuries, fall, Burn, Drowning, Poison related injuries which may be due to ingestion of medication and chemical fluids. Each has its own numbers on prevalence data. [4,5]

A growing child has little knowledge about its surrounding environment and this presents bigger chances of hazardous encounters. Each child is unique to every parent, whether they live in an undeveloped or the urban atmosphere. Child survival is important for the improvement of both national and international

child health.[6] While presently available data exhibit increased frequency of cases in the rural population (north or the southern part of India), the number of hospital episodes continues to increase among the rural community.[7] Where perceptions and treatment seeking behaviour are still a matter of high concern.[8,9] This can be a major indicator of under-reported information, therefore, presenting a necessity for further investigation. Moreover, the psychosocial torment the family of the injured child goes through is unquantifiable. Another important part of this scenario is the financial burden and healthcare need that it inflicts.[10,11] Disability adjusted life years (DALY) associated with unintentional injuries had indicated that there has been an increase in which proves to project greater chances of lifelong functional impairments and Disability. Studies affirm the facts that though hundreds of deaths occur due to injuries and/or violence, many millions suffer from non-fatal injuries according to injury prevention report of WHO. Distribution of the previously mentioned injuries is most prominent among males over female children.[12]

Rationale: Though most of the injuries are preventable and predictable, there is a lack of social and political will to make a radical change in the incidence rate. While some of the studies provide evidence to the prevailing scenario in the northern part of the country the evolving epidemiological trend is still to improve in the southern side in better understanding the burden of the present issue that could provide a better picture which can help discover feasible interventions.[13, 14]

MATERIALS AND METHOD

The review initiated by a self-addressed guideline which helped the researcher set clearly defined rules as to the screening of studies.

Eligibility criteria: The inclusion criteria for selecting the studies was

1) Study was done in India,

2) Studies were only related to injuries, and

3) The participants were <18 years. The articles extracted were full-text from the last 10 years.

There was heterogeneity of literature (including study designs and sample size) that was recorded in the review, so there were meagre reasons to perform any synthesis of quantitative information.

Exclusion criteria: Whereas violence-related injuries, International studies, Birth injuries, Studies that were addressing any birth defects or congenital abnormalities were rejected.

Information sources: The review began with a web-based search on Google, to get a clearer picture of the available studies. Further exploration of evidence was carried out using PUBMED DATABASE, BMC PUBLIC HEALTH, AJPH, and BMJ PAEDIATRICS and was later restricted to the PUBMED DATABASE to maintain the integrity of the search and because of the availability of full-text papers. The given MESH terms were used to gather additional literature (Table 1).

TABLE I: Mesh terms that were used to generate a search of articles

MESH Terms
Wounds AND Unintentional Injuries (INDIA)
"Unintentional" AND (Childhood Injuries) NOT Intentional
"Childhood injuries" AND India
Unintentional Childhood Injuries AND India NOT Disability
Wounds AND Injuries (Unintentional injuries in INDIA) NOT Elderly

Risk of bias detection: Review articles for Unintentional injuries were also checked for any details on reliable evidence on estimates under Indian scenario. Further, the articles were screened using strobes checklist for observational studies as well as the Cochrane Collaboration's tool also used for assessing risk of bias. Information regarding the quality of the papers was assessed exhibiting clarity in Inclusion/ Exclusion criteria, study design, operational definitions (if any), sampling strategies and also the duration of each study.

Every study was also screened for ethical clearance by an Institutional review board or ethical committee, Informed consent (especially for community-based studies) and also whether the informant was a parent or caregiver.

RESULTS

Study selection: After the exhaustive search, the studies were narrowed down to only studies done in India, out of which 8 studies were selected. Thereon the Mesh terms (Table 1) were customized for an effective search strategy. The keywords were initially used to acquire the current literature with any unintentional injury study with several study designs. Studies using randomized controlled designs and case-control study design were excluded. The search result of each search strategy was recorded. The recurrences of some articles were observed to be more than once is any of the employed strategies and therefore those articles was included. This additionally determined the quality of the studies selected.

Synthesis of results: The overall prevalence of Unintentional injury in the selected studies among the age group of 1-18 years was observed around 7% to 23%. The common cause of injury was fall, followed by RTA and Burns. The minimum study duration was two months and the maximum duration is one year. A Study was done by **Parameswaran** had clearly mentioned sampling methodology including the derivation method that contrasts between both rural and urban-based study. These studies provided a better foundation which followed a discrete structure of information using analysis. Community-based studies had well defined operational definitions, sampling strategies, and sampling interval. Majority of the studies were done in the rural part of India.[10]Some literature carried a rural community-based study covering households in villages and studies had defined operational definitions that addressed better clarity among each level of data collection. **WHO TEACH-VIP 2** Guidelines were adopted by community- based studies to develop questionnaires for a survey on injuries.[15] Certain studies have provided details regarding tools which were translated and back-translated and most of the study articles were cross-sectional designs. There was a lack of clarity of the statistical method used amongst substantial studies. Most of the literature contains analysis done using statistical package SPSS or EPI Info followed by STATA. Studies included used Chi-square analysis followed by other studies with only descriptive and frequencies. Most of the unintentional injuries seemed to occur during daytime.

A Study done by **Bhanderi** extracted basic information like demographic details alongside other information on injury by activity, severity and equipment-related injury and observed the difference in distribution of frequency of cases among male gender than females except for study done by **Bhuvaneshwari** which shows that females getting injured over males was significantly higher, the common injury being Falls.[14,16]Another study done by **Inbaraj** showed that 89.3% of the children with primary caregivers had a higher rate of injury as compared to mothers as caregivers. Further adding that most of the Unintentional injuries fall between 0 to 14 years.[9]The home was the most common place of injury especially in the summer and **Sivamani** highlighted an effective method of validation (Lincoln Peterson capture-recapture) that ensured complete coverage of household survey data. A meagre amount of households refused to give consent. The studies included had One year as recall period of any unintentional injury.[17]

DISCUSSION

Literature shows that the trend of unintentional injuries needs a significant attention and research especially from the caregiver point of view. In many situation the unintentional injuries goes unnoticeably.[18] There is still demand high quality study, because quality study will to help provide a wider picture and the true incidence of injuries.[19] The health-related quality of life is very poor, especially among children.[20,21] It could be an iceberg phenomenon that health research could assist within gathering evidence for more interventions, and these measures can create a need for longitudinal studies.[22,23] Present status has proven that surveillance has effective strategy to prevent child injury, the Haddon's Matrix model will help to understand prevention of unintentional injuries.[17] The current community-based studies show that there is an increase in cases and a decrease of case reporting in community, where case reporting is also importance. Institutional based studies are sometimes lacking in essential information, even if it's a minor injury and still, it requiring extra attention. The quality of community-based studies proves to be an actual picture of a current situation. The integration of child health programmes in prevention strategies would provide a sustainable result on reducing injuries.[24] Overall there are certain individual risk factors and other social and physical factors which may changes over time, resulting in the distribution of prevention strategies and risk

factors in low and middle- income countries (LMIC) due to globalization. The use of geospatial methods, like mapping, to understand the epidemiology is also help to estimating what is the present magnitude and pattern of occurrence of unintentional injuries in identifying priority areas. [25,26] These types of approaches may help to produce the validated research findings.

CONCLUSION

A safer home environment for a child should be available at every household. Most of the unintentional Injuries are preventable rather than accidental. It is still predictable and therefore preventable rather than inevitable. The community needs more awareness of the effects of unintentional injuries among children so that could help to make a better policy. Most of the evidence is either missing or they are lack of manpower to document any such epidemiological data, leading to undermining the quality of research.

Study of Socio-Demographic Factors Affecting Infant Feeding Practices in an Urban Area of Punjab

Amanpreet Kaur[1], Jagdeep Singh[2], Harpreet Kaur[3], Harpreet Kaur[4], Priyanka Devgun[5]

[1]Associate Professor, [2]Assistant Professor, Department of Medicine, SGRDIMSAR, Amritsar, [3]Professor, [4]Statistician cum Lecturer, [5]Professor & Head Department of Community Medicine, SGRDIMSAR, Amritsar

ABSRACT

Background: Optimal infant and young child feeding practices rank among the most effective interventions to improve child health.Breastfeeding is an unequalled way of providing ideal food for the healthy growth and development of infants; it is also an integral part of the reproductive process with important implications for the health of mothers.Many factors affect the feeding practices including education of mother, awareness about the benefits of breastfeeding. So this study was done to know the factors affecting the infant feeding practices.

Material and Method: A cross-sectional study was conducted in the urban field practice area of the Department of Community Medicine of SGRD Institute of Medical Sciences and Research, Amritsar. All the mothers of infants were included in the study. House to house survey was done to collect information about demographic profile, feeding practices and socio cultural factors affecting the feeding practices.

Results: It was observed that 53.7% mothers started breast feeding next day, 30.4% mothers started breast feeding the same day and 16% started breast feeding immediately.Pre lacteal feed was given by most of the mothers (89.5%). The common pre lacteal feed given was honey (67.3%). The colostrum was given by 59.1% of mothers. Weaning after 6 months was started by 53.3% mothers while 46.7% started after 4 months. Education had a significant association with age at weaning (p=0.018).

Conclusion: The present study revealed that various inappropriate feeding practices are prevalent in the community.Health and nutrition programmes should be concentrated on counselling of the mothers regarding breastfeeding especially exclusive breastfeeding.

Keywords*: Feeding, Infant, mother*

INTRODUCTION

Optimal infant and young child feeding practices rank among the most effective interventions to improve child health. In 2006 an estimated 9.5 million children died before their fifth birthday, and two thirds of these deaths occurred in the first year of life. Under-nutrition is associated with at least 35% of child deaths. It is also a major disabler preventing children who survive from reaching their full developmental potential.It is estimated that sub-optimal breastfeeding, especially non-exclusive breastfeeding in the first 6 months of life, results in 1.4 million deaths and 10% of the disease burden in children younger than 5 years.[1]

Adequate nutrition during infancy and early childhood is fundamental to the development ofeach child's full human potential. It is well recognized that the period from birth to two years ofage is a "critical window" for the promotion of optimal growth, health and behavioral development. Longitudinal studies have consistently shown that this is the peak age for growth faltering, deficiencies of certain micronutrients, and common childhood illnesses such as diarrhea.[2]

Efforts to promote modest nutritional improvements such as changes in feeding behaviour will have a beneficial impact on mortality rates over time. Feeding practices adopted by mothers depends on the knowledge, attitude, socio-cultural tradition they are exposed to.[3]

Breastfeeding is an unequalled way of providing ideal food for the healthy growth and development of infants; it is also an integral part of the reproductive process with important implications for the health of mothers. Review of evidence has shown that, on a population basis, exclusive breastfeeding for 6 months is the optimal way of feeding infants. Thereafter infants should receive complementary foods with continued breastfeeding up to 2 years of age or beyond.[4]

Despite the many benefits of EBF, sound breastfeeding practices are not the norm in many countries, and large differences exist in the EBF rates between regions and among countries. The promotion, support and protection of optimum breastfeeding take a different type of engagement from the health system, because breastfeeding is a social behaviour and not a medical practice. It is not a typical intervention, because there is no pharmaceutical product to be purchased or distributed and the practice is not dependent on a facility or health provider. These factors pose particular challenges, which have been addressed with varying degrees of success by breastfeeding programmes.[5]

According to DLHS 4 in Punjab, 56.4% of Children age 0-5 months are exclusively breastfed and 74.4% of Children age 6-9 months are receiving solid/semi-solid food and breast milk.[6]

Many factors affect the feeding practices including education of mother, awareness about the benefits of breastfeeding. So this study was done to know the factors affecting the infant feeding practices.

MATERIAL AND METHOD

A cross-sectional study was conducted in theurban field practice area of the Department of Community Medicine of SGRD Institute of Medical Sciences and Research from April to June 2014. The mothers of infants were included in the study. A pre-designed andpre tested questionnaire was used to collect theinformation. Verbal consent was taken from the mothers after explaining the purpose of the study. Out of 263 mothers 257 were willing to participate in the study.House to house survey was done to collect information about demographic profile, feeding practices and socio cultural factors affecting the feeding practices. Statistical analysis was done by using SPSS 20.0.

RESULTS

It was a cross-sectional study conducted in the field practice area of Community Medicine, SRDIMSAR, Amritsar. There were total 263 infants in the area.The mothers of these infants were contacted. Out of 263 mothers, 257 gave consent to participate in the study. Most of the mothers were in the age group of 25-30 years. 19.8% of mothers were illiterate and rest were literate up to different levels a shown in table. 87.9% were housewives. Education profile of the fathers revealed that 55.6% were educated up to matric, 26.8% up to middle school, 13.6% above matric and only 10 (3.9%) were illiterate. Majority of the fathers (61.9%) were semiskilled workers, 30.7% were skilled and 7.4% were unskilled workers (Table I).

There were 138 (53.7%) male and 119 (46.3%) female children. Out of total children, 56.4% belonged to joint family and 43.6% children were from nuclear family. Majority of the children (87.2%) were Sikh by religion and 12.8% were Hindus. It was observed that 45.9% mothers had one, 33.1% had two, 14.8% had three and 6.2% had four living children respectively. Immunization status of 87.2% children was complete till date.

While all the mothers started breast feeding their child after birth, 80.2% mothers were still practicing breast feeding at the time of study. It was observed that 53.7% mothers started breast feeding next day, 30.4% mothers started breast feeding the same day and 16% started breast feeding immediately. The most common reason for delay in breast feeding was due to no milk secretion (58.8%), followed by caesarean section (26.1%), traditional practice (10.9%), baby asleep (2.3%) and mother tired (1.9%) respectively.

Pre lacteal feed was given by most of the mothers (89.5%). The common pre lacteal feed given was honey (67.3%). The colostrum was given by 59.1% of mothers while 40.9% discarded the colostrum. The most common reason for not giving colostrums was ceasarian section in 45.7% of mothers, while in 38.09% of mothers it was no milk secretion and 16.19% thought it is harmful for the baby. Feeding on demand was practised in 68.9%

children, while 10.1, 6.6, 13.2 and 1.2% were fed after every 4h, 3 h, 2 h and 1 h respectively.

There was significant association between educational status of mother and initiation of breast feeding (p<0.018). Only 62.6% mothers knew about exclusive breastfeeding. There was significant association between education status of mother and knowledge of exclusive breastfeeding (p= .047). Weaning after 6 months was started by 53.3% mothers while 46.7% started after 4 months. Education had a significant association with age at weaning (p=0.018). 101 (39.3%) mothers used bottle along with breastfeed to feed their children

DISCUSSION

The study was done among the infant mothers. Most of the mothers were in the age group of 25-30 years. Similarly in a study conducted in rural area of Karnataka most of the females (60%) belonged to age group of 21-25 years[7]. 19.8% of mothers were illiterate and rest were literate up to different levels a shown in table. 87.9% were housewives.

There were 138 (53.7%) male and 119 (46.3%) female children. Out of total children, 56.4% belonged to joint family and 43.6% children were from nuclear family. Majority of the children (87.2%) were Sikh by religion and 12.8% were Hindus. It was observed that 45.9% mothers had one, 33.1% had two, 14.8% had three and 6.2% had four living children respectively. Immunization status of 87.2% children was complete till date.

While all the mothers started breast feeding their child after birth, 80.2% mothers were still practicing breast feeding at the time of study. It was observed that 53.7% mothers started breast feeding next day, 30.4% mothers started breast feeding the same day and 16% started breast feeding immediately. This is in contrast to the findings of study done among postnatal women in Southern India where 61% of mothers started breastfeeding within 1 hour.[8]The most common reason for delay in breast feeding was due to no milk secretion (58.8%), followed by caesarean section (26.1%), traditional practice (10.9%), baby asleep (2.3%) and mother tired (1.9%) respectively.In a study done in Meerut, among those (79.5%) who initiated breast feeding late, the most common reason was social custom and belief (52.8%). Other reasons were mother and baby illness (41.2%), breast milk insufficiency

(4.4%) and difficulty of infant to attach to breast (1.6%).[9]

Pre lacteal feed was given by most of the mothers (89.5%). The common pre lacteal feed given was honey (67.3%).In a study done in Warangal, TalanganaPrelacteal feed was given in 57% out of which 51.1% were given honey with fingers.[10]The colostrum was given by 59.1% of mothers. The most common reason for not giving colostrums was ceasarian section in 45.7% of mothers, while in 38.09% of mothers it was no milk secretion and 16.19% thought it is harmful for the baby. Feeding on demand was practised in 68.9% children. In a study done in a rural area of Puducherry demand feeding was practiced by 80.1% of mothers.[11]

Only 62.6% mothers knew about exclusive breastfeeding. There was significant association between education status of mother and knowledge of exclusive breastfeeding (p= .047). Weaning after 6 months was started by 53.3% mothers while 46.7% started after 4 months. Preferred food for weaning was homemade in 89.5% of mothers while in 10.5% it was ready to cook food. Similarly in a study done in rural Delhi, breast milk plus semisolids were being given to 65.1% infants 6-9 months of age.Homemade semisolids were more popular (72.6%) than commercial ones (24.5%).[12]39.3% mothers used bottle along with breastfeed to feed their children.

CONCLUSION

The present study revealed that various inappropriate feeding practices are prevalent in the community. Delayed initiation of breastfeeding, deprivation from colostrumand improper complementary feeding are practiced and this lead to under nutrition in children. Knowledge of mother, traditions, socioeconomic level of the family affects the feeding practices. Health and nutrition programmes should be concentrated on counselling of the mothers regarding breastfeeding especially exclusive breastfeeding.

ABSTRACT

This paper analyzes the effect of socioeconomic and demographic factors on infant mortality in India. The Paper also examines reasonable comparison of the three National Family Health Survey (NFHS), the largest sample survey of India from the 1993-1994, 1998-1999 and 2005-06 with respect to different determinants of infant mortality. Accelerated Failure Time (AFT) model is used to measure the direct effect of the above factors on the survival of infants. On the basis of Akaikes Information Criterion (AIC), the Weibull AFT model fits better to other selected models. In all the three NFHS, Weibull AFT model shows the significant effect of the factors on infant survival.

Keywords: *Infant mortality, determinants of infant mortality, NFHS, Cox proportional hazard model, AFT model*

INTRODUCTION

Study about infant mortality rate as a measure of infant death and its pattern recognition play a crucial role of health status scenario for any nation as infant mortality rate is widely accepted and longstanding indicator of well-being of children. In this perspective the infant mortality rate is an important indicator of a country's financial welfare too. The infant mortality rate is defined as the number of infant death among 1000 live births during the first year of life. The study about infant of a country is one of the main focus for the planners of the country. In 2015, 4.5 million deaths occurred in the infancy period (WHO, report). Infant mortality rate is high in developing countries like India, as compared to developed countries. India has experienced an impressive decline in infant death during the previous two decades but, it is still high as compared to other developed countries.

Thus, study of the overall picture of the survival of infant "Survival Analysis" provides the platform to move further in the same line. Survival analysis is defined as a collection of methods for analyzing the data where the response variable is time until the occurrence of death of infant. The field of survival analysis experienced tremendous growth during the latter half of the 20th century. The most profound methodologies so developed are Kaplan-Meier (non-parametric survival method) used to estimate the survival function (i.e. probability that an infant survive beyond a given time), and the Cox proportional hazard model (semi-parametric method) to examine the covariate effects on the hazard function (i.e. risk of death, in an interval after a specified time, condition on the subject having survived to that specified time).

Various studies on the basis of these models have been done, such as unsupplemented breastfeeding is more strongly associated with fewer infant deaths than supplemented breastfeeding[1]. In Egypt, the effect of household income on infant and early childhood mortality at household level is studied by incorporating the socioeconomic and demographic variables[2]. An attempt has been made to examine the impact of breastfeeding and maternal health care programs on infant mortality corresponding to other socio-demographic variables[10]. It is also essential to study the behavior of infant deaths in developing countries like India and determine the effect of demographic and socioeconomic factors on infant mortality.

Although the Cox-proportional hazard model finds widespread applicability in the survival analysis, it holds

some assumptions such as the regression coefficient is constant over time (proportional hazard assumption), combination of the covariates is linear and link function is exponential. Proportional hazard (PH) assumption received most attention in research and applications as well. Most research often ignored and not checked the assumption of proportional hazard that makes the result's accuracy questionable. Our study tests the assumption of proportional hazard on the basis of schoenfeld residuals and reaches to conclusion that the PH assumption is not fulfill. Therefore Cox-PH model could not be applied to test the effect of different covariates on the survival of infants. Thus, in this situation Accelerated Failure Time (AFT) model is a good alternative over these models, which relaxes the PH assumptions. AFT model is a parametric survival model used to see the pattern of the survival time of infants corresponding to different covariates. AFT models measure the direct effect of the explanatory variables on the survival time instead of hazard in Cox-PH models. This characteristic of AFT model makes easy interpretation of the results, because parameter measures the effect of corresponding variable on the mean of survival time.

DATA AND METHODOLOGY

The National Family Health Survey (NFHS) was carried out as the principal activity of a collaborative project to strengthen the research capabilities of the Population Research Centers in India, initiated by the Ministry of Health and Family Welfare, Government of India, and coordinated by the International Institute of Population Science (IIPS) Mumbai. There have been four rounds of the survey conducted, during 1992-93 (NFHS I), 1998-99 (NFHS II), 2005-06 (NFHS III) and in 2015-16 (NFHS IV) but, till now information on fourth round is not available. The main objective of the NFHS survey is to provide reliable and up-to-date information on various demographic events and their estimates for a comprehensive portrait of population, health, and nutrition in India as well as in each of its states. This paper utilizes three NFHS's (NFHS I, NFHS II and NFHS III) for the survival analysis.

AFT model is used to see the association of survival time of infants with covariates. For a random time to event T_i an AFT model proposes the following relationship between explanatory variables and $\mathrm{Y_i} = \log \mathrm{T_i}$.

$$\mathrm{Y_i} = \mu + \alpha_1 \mathrm{x_{1i}} + \alpha_2 \mathrm{x_{2i}} + \cdots + \alpha_\mathrm{j} \mathrm{x_{ji}} + \cdots + \alpha_\mathrm{k} \mathrm{x_{ki}} + \sigma \epsilon_\mathrm{i}$$

where μ is intercept term, x_{ji} is the value of the jth explanatory variable, $j = 1, 2, \ldots, k$, for the ith individual, $i = 1, 2, \ldots, n$, σ is the scale parameter and ϵ_i is a random variable assume to have particular distribution. On the basis of this relationship survival function at time t is defined as,

$$S_i(t) = P(T_i \geq t)$$

$$S_i(t) = P[\exp(\mu + \varphi x_i + \sigma \epsilon_\mathrm{i}) \geq \mathrm{t}],$$

where

$$\varphi x_i = \alpha_1 x_{1i} + \alpha_2 x_{2i} + \cdots + \alpha_k x_{ki}$$

Now $S_i(t)$, can be written in the form,

$$S_i(t) = P\left[\exp(\mu + \sigma \epsilon_\mathrm{i}) \geq \frac{t}{\exp(\varphi x_i)}\right]$$

$$S_i(t) = S_0\left[\frac{t}{\exp(\varphi x_i)}\right]$$

where $S_0(t)$ is the baseline survival function i.e. the survivor function of an individual at $x_i = 0$. $\exp(-\varphi x_i)$ is said to be the acceleration factor (Y) for the ith individual.

RESULTS

The survey included 11047, 7345 and 8301 live births in NFHS I, II and III respectively. Out of complete information, 2053 (18%), 975 (13%) and 1595 (19%) deaths have been occurred in the respective NFHS. Among the live births, 5672(5372), 3862 (3483), 4245 (4056) were male (female) and proportion of infants belonging to rural area was 76% in NFHS I and II while this proportion was 66% in NFHS III. 66%, 53% and 48% infants were those whose mothers were not educated in the three surveys. 15% of infants were not breastfed in NFHS I and III, while this proportion was 12% in NFHS II.

Table 1, shows the results of global Schoenfeld test regarding to NFHS I, II, & III which was used to test the independence between time and Schoenfeld residuals. An insignificant relationship between residuals and time supports the proportional hazard assumption. Breastfeeding, mother education, birth order and place of delivery have shown a significant relationship between residuals and time in all three NFHS. Global test was also significant which means that the proportional hazard assumption not met in whole the model. Results of Table 1, summarizes that the Cox-proportional hazard model could not be applied for infant mortality. Alternative approach of Cox-proportional hazard model i.e. AFT model was used which relaxed this assumption but required to determine the probability distribution of data set. Weibull versus exponential versus logistic were proposed distributions for the study. The selection of the distribution was done on the basis of Akaike's information criterion (AIC). Table 2, shows AIC value of different AFT models corresponding to each NFHS and it was minimum for the Weibull distribution. Therefore, this study included Weibull AFT models to study the effect of different covariates on infant survival.

Figure 1, which was based on NFHS I data, illustrates that the survival curve was highest for the infants who were breastfed, lower for the first and fourth order birth, higher when mother delivered their child in private hospital, lower for the infants whose mothers were not educated, higher for the infants who were born in first four years of marriage span of their parents, lower for the infants who came from small family size (i.e. 1-3 members in the household) as compared to other categories. Figure 2 and 3, show that the infant survival curves in NFHS II and III, have quite similar pattern as NFHS I.

In this study AFT model included nine covariates (breastfeeding, mother age, mother education, place of delivery, sex of infant, place of residence, marital status, birth order and family size) to see the effect of these covariates on the survival of infants regarding to each NFHS. Table 3, shows the results of AFT model on the basis of NFHS I, II and III data. Firstly, we will discuss the results of AFT Model related to NFHS I data. On the basis of these results, survival time for the infants who were breastfed was significantly increased by the factor 41.674 as compared to the infant who were not breastfed. Risk of death was high for first birth order and significantly decreased two times in second birth order as compared to the first. Survival of Infants having mother age 30-34 years was strong and significantly increased 1.519 times as compared to the infants of mother age 15-18 years. Survival of infant was high in the category where mother belonged to the secondary and higher level group of education and increased by 2.125 times as compared to the infant whose mother was not educated. Survival of infants who were born in a private hospital was significantly increased nearly three times as compared to the infant who were born at home. Survival time of infant where the duration of the parents marriage was 5-9 years and more than 9 years was significantly decreased by the factor 0.362 and 0.282 times respectively as compared to early married couple (0 – 4 years of parents marriage). Survival of the infant who belonged to family size of 4-6 members was significantly increased 1.5 times as compared to the infants who belonged to small family size of 1 – 3 members. Survival of the infant who belonged to the urban area was significantly better than the infant of rural area and also better for female child as compared to the male child. Behavior of AFT model related to NFHS II and III data was similar to NFHS I data except some significant results, which are discussed in the next section.

Discussion and Comparison among NFHS's

In all three NFHS, survival of infants was highly increased, where they were breastfed, even in the presence of control for several other demographic factors. Breast milk is nature's perfect food for the baby and it contains immunity boosting antibodies and healthy enzymes. Finding is consistent with the

finding from other authors[6,8]. In NFHS II, delivery in government hospital was not significantly associated with infant survival, while in NFHS I and III, survival of infants significantly increased when delivery took place in a government hospital as compared to home. In NFHS I and III, survival of female child was significantly increased, but in NFHS II it was not significant may be because of less careness, social taboos among the other reasons. Survival of infant belonged to small family size was decreased in each NFHS as compared to big family size. Small family does not have proper required care to infant may be one reason for less survival. Joint families have lower risk of infant mortality as compared to nuclear families[4].

Rural area has significantly poor survival of infants as compared to urban areas and this pattern was similar in all three NFHS. It means that till NFHS III there was no sufficient development of health improvement conditions as required in rural areas. Survival of infants significantly increased for those who were born from early married couples, may be due to the decrement of fertility in women after a fix period of time. Survival of infant of mother age 15 – 18 years was significantly decreased in NFHS I and II, but in NFHS III, result was not significant may be due to the medical awareness in the population. In all three NFHS, survival of infants significantly increased, when mothers were highly educated as compared to uneducated mothers. The educated mothers have better knowledge of health care facilities. They are expected to live in healthy environment and take more nutritious food. Maternal education results into rising the age at marriage, enhances socioeconomic status and emphasis on child quality[3] and hence reduces the risk of death in infancy.

CONCLUSION

It is observed from the study that the most relevant factor for the survival of the infant is breastfeeding, therefore it should be encouraged. For achieving the required reduction in infant mortality government should further make some policies to develop rural areas and to reduce the risk of survival of the first birth order, proper medical care should be implemented in addition to existing one. There is also an essential requirement to encourage female for the higher education level and discourage home delivery. On the basis of this study we may conclude that small family size has a negative impact and the couples who plan their child during the first four year of their marriage have a positive impact on the survival of infant.

ABSTRACT

Retinal degeneration is one of the vital cause of vision loss. Retinal degeneration is induced through the declension of the retina middle part. The aim of our proposed paper is to detect retinal degeneration by using image processing. This involves segmentation, plotting of histogram, edge detection. The performance measures are calculated and compared with those of normal eye by machine learning singular value decomposition and correlation..

Keywords: *Retinal degeneration, machine learning, histogram, edge detection*

INTRODUCTION

Now a day the main challenge faced by developing countries is to prevent the eye diseases like retinal degeneration. Generally most affected are senior citizens. Reason for degeneration is eventually demise of cells in retina. Other cause of degeneration is blockage in vein and diabetic. The degeneration causes blindness, starting with tunnel vision, peripheral sight loss. The main cause of these types of degeneration is genetic disorder and ageing. It is necessary for new approaches involving machine learning to diagnose and detect these effects in time for better health adjunct system. It helps the society. Damage of macula and a little blemish approximately close to the midpoint of eye in the retina leads to retina degeneration and subsequently vision loss. The retina degeneration progress is quick and might lead to vision loss in one eye or both eyes. The general symptom of retina degeneration is blurred region close to the mid of vision.

In past years researchers much attention about the sight of the eye [2,11,13]. Several attempts have been deal to search for eyes degeneration[5,7]. Contrast and balance of gray is useful to identify feature extraction[9,17,14]. in [3], discuss about the correlation between iris. Analyses of iries and eyelids are using Hough Transform [10-12]. Filters are used to identify the detection of edges [6], Fractal features extraction are used for image segmentation[4,8,16]. In[9] used the images of facial through dimension of fraction. In [15], a method to identify the shape of the iris images. This is done through image segmentation and edge detection[18]

Data Base

The data base in this work is Retina Gallery. Fig.1 depicts the iris of a normal person.

Fig:1 Normal Iris

METHODOLOGY

The methodology involves, machine learning and singular value decomposition. The images are selected from the database and processed using MATLAB-R2015a. For each image are computed. Singular value decomposition is used for comparison of normal iris and degenerated iris.

If a real symmetric n x n matrix and orthogonal matrices U and V and a diagonal matrix S then .

Any non-square matrix is converted as a square matrix through singular value decomposition in order to calculate the correlation coefficient. Detection is mainly based on the comparison of correlation coefficient normal iris and degenerated iris.

RESULTS AND DISCUSSION

The performance measures namely sensitivity, specificity and accuracy of the input image are calculated in order to diagnose the iris for detection of macular degeneration. Through the diagnostic test the result shows that the output is true positive that means not affected from disease. It measures the degree of veracity of a diagnostic test on a condition.

These measures are based on the results of edge detection described in the following

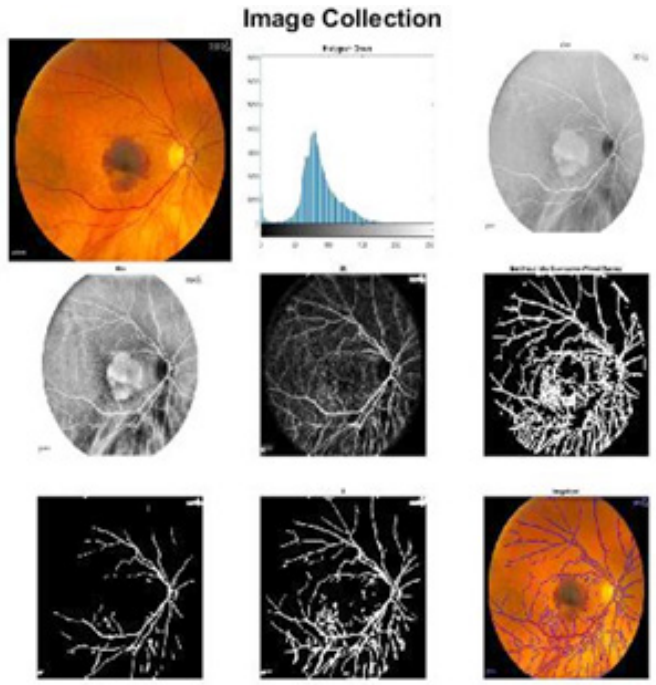

Fig:2 Stages of segmentation, edge detection

Fig :2 shows that the stages of segmentation, edge detection of degenerated eye through machine learning. It shows that it connects to the brain and the blood vessels are connect through the nerve. This ratio is a measure of the growth of macular degeneration. The histogram plot reveals the intensity of light distribution and peak of macular degeneration black spot.

The original image is converted from RGB to Green Channel. Complement structuring Element Morphological operation is done by Median Filter. Removal of background and image adjustment using intensity of the image is performed. It reveal that it show the segmentation of the retina blood vessels through morphological operation.

Below table presents to numerical measures for parameters A is accuracy, S is sensitivity, Sp is specification

Table1. Numerical measures of parameters

Image	A	S	Sp	Fpr 1-specificity	PPV
1	0.8118	0	1	0	0
2	0.7597	0	1	0	0
3	0.9348	0.7160	0.9919	0.0031	0.7377

Cont... **Table1. Numerical measures of parameters**

4	0.6624	0	1	0	0
5	0.8485	0	1	0	0
6	0.9355	0	1	0	0
7	0.8783	0	1	0	0
8	0.9614	0.0355	1	0	1

Histogram

Drusen identify through asymmetric distribution from histogram of an image .Compounding of like distribution in asymmetric kurtosis. The statement of the skewness is given below table3

Table: 3 Histogram distribution analysis

Skew is equal to zero	Playtkurtic	Output of an image is combining of more than two distribution
	Mesokurtic	Only one distribution is close to large drusen
	Leptokurtic	Incessant background
Positively skewed	Playtkurtic	Drusen in approximately equally distributed
	Mesokurtic	Difficult to differentiate
	Leptokurtic	Little area of drusen of eminent chroma
Negatively skewed	Playtkurtic	90 % of the area is in background
	Mesokurtic	90 % of the area is in background
	Leptokurtic	90 % of the area is in background

Normal image histogram

From the below Fig: 3 shows that according to shape of skewers is positive. So difficult to differentiate drusen from the images

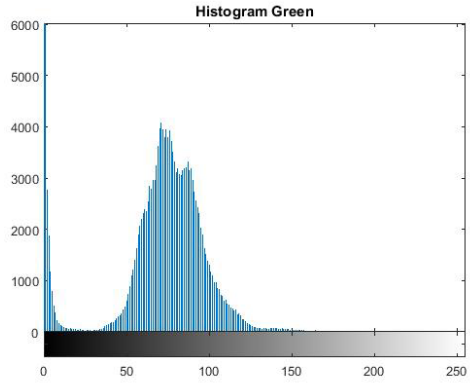

Fig:3 Normal Image Histogram

Abnormal image

From the below Fig: 4 shows that according to shape of skewers is negative and more 90 % of drusen is distributed in an image

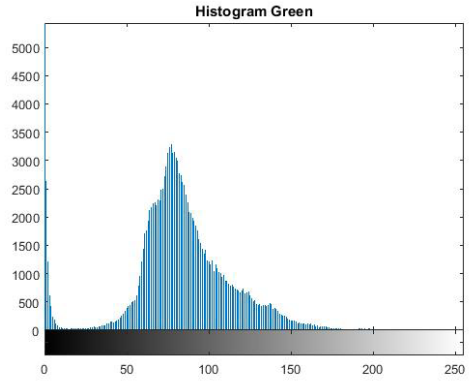

Fig :4 abnormal image histogram

CONCLUSION

The proposed robust methodology to detect retina degeneration using singular value decomposition and correlation coefficient is discussed. Singular value decomposition extraction is used to select the most significant segmentation method for identifying retina degeneration. From histogram analysis to identify the stage of degeneration . These results are very useful to finding the retina degeneration. .

To Study the Frequency of Cystic and Solid Lesions among Solitary Thyroid Nodules

Dinesh Kumar Singh[1], Anju Singh[2], Paras Kharbanda[1]

[1]Associate Professor, Pathology, [2]Professor, Forensic Medicine, Mayo Institute of Medical Sciences, Barabanki

ABSTRACT:

BACKGROUND: In practical and numerical terms, the solitary nodule is the most important target of thyroid FNAC. Since FNAC can provide an unequivocal benign diagnosis in 60% of patients with benign nodules, its potential to reduce the number of unnecessary operations is significant. Of all the thyroid glands that on surgical resection prove to contain solitary nodules, 70- 80% are benign adenomas and about 10-30% is malignant growth. Over the past two decades, fine needle aspiration cytology (FNAC) has become an essential step in the evaluation of thyroid nodules, due to its superior diagnostic reliability and cost effectiveness. **AIMS & OBJECTIVES:** The present study aims to explore the frequency of cystic and solid lesions among solitary thyroid nodules (excluding multiple nodular lesion). **MATERIAL & METHOD:** 140 patients of more than or equal to 15 years of age presenting with solitary thyroid nodule were the subjects of the current study. Subjects were referred for fine needle aspiration by the treating clinicians. **OBSERVATIONS:** Male: Female ratio was (18/122) 1:6.8 and age of the patients ranged from 15 years to 62 years. Maximum number of cases was in 3rd and 4th decades. 4 patients were in 7th decade. Cytodiagnostic break up of all 122 cases included colloid goitre 31 cases (25.5%), hyperplastic nodule 3 cases (2.5%), lymphocytic thyroiditis 2 cases (1.6%), Hashimoto's thyroiditis 7 cases (5.7%) and subacute thyroiditis 5 cases (4.0%), from non-neoplastic category. **CONCLUSION:** It was concluded that FNAC of thyroid is a safe, simple, cost- effective, reliable and accurate investigation for cases of solitary thyroid nodule.

KEYWORDS: *FNAC, Solitary Thyroid nodules, cystic , Solid , Histological Correlation.*

INTRODUCTION

The thyroid gland is a bilobed organ situated in the anterior neck in front of the upper trachea. The normal thyroid gland in adult weighs 15-30 gm.[1] Normal function of the thyroid gland is to secrete thyroxine (T4) and triiodothyronine (T3). FNAC is highly successful in triaging patients with solitary thyroid nodule into operative and non-operative groups.[2] It may also be diagnostic for certain thyroid lesions, such as colloid goiter, Hashimoto's thyroiditis, papillary carcinoma, anaplastic carcinoma, large cell lymphoma, and metastatic carcinoma. In practical and numerical terms, the solitary nodule is the most important target of thyroid FNAC.[3]

Over the past two decades, fine needle aspiration cytology (FNAC) has become an essential step in the evaluation of thyroid nodules, due to its superior diagnostic reliability and cost effectiveness.[4, 5] Since FNAC can provide an unequivocal benign diagnosis in 60% of patients with benign nodules, its potential to reduce the number of unnecessary operations is significant.[6, 7, 8, 9]

Palpable thyroid nodules occur in 4-7% of the population (10 to 18 million persons) but nodules found incidentally on USG suggest a prevalence of 19-67%.10 Thyroid carcinoma occurs in roughly 5-10 % of palpable nodules.[10] Thyroid cancers constitute only about 1-2% of all malignant neoplasms in most populations and are three times more common in women than in men.[11]The prevalence of thyroid cancer in patients undergoing fine needle aspiration biopsy is estimated to be about 4%. Of all the thyroid glands that on surgical resection prove to

contain solitary nodules, 70- 80% are benign adenomas and about 10-30% is malignant growth.[12]

AIMS& OBJECTIVES

The present study aims to explore the frequency of cystic and solid lesions among solitary thyroid nodules. (excluding multiple nodular lesion).

OBJECTIVES:

1. To study the distribution of thyroid lesions according to age & sex.

2. To study the frequency of cystic & solid lesions amongst solitary thyroid nodules.

MATERIAL & METHOD

This study was performed in the Department of Pathology, D.Y. Patil Medical College, Kolhapur during a study period of 2 year from June 2008 –to May 2010.140 patients of more than or equal to 15 years of age presenting with solitary thyroid nodule were the subjects of the current study. Subjects were referred for fine needle aspiration by the treating clinicians.

Observations

Table -1: DISTRIBUTION OF CASES ACCORDING TO SEX

S. NO.	SEX	NO.of cases	PERCENTAGE
1	Female	122	87.1
2	Male	18	12.9
	Total	140	100.0

Table -2 Distribution of cases according to Age

S.No.	Age (range)	No. Of cases	Percentage
1	10-19	6	4
2	20-29	49	35
3	30-39	41	29
4	40-49	28	20
5	50-59	12	9
6	≥60	4	3
	Total	140	100.0

Distribution of cases according to Age

Table – 3: FREQUENCY OF CYSTIC AND SOLID THYROID NODULES AND THEIR ADEQUACY

S. No.	Lesion	No. of cases	Percentage	Adequacy			
				Adequate		Inadequate	
				No.	%	No.	%
1	Solid	122	87.14	114	93.4	8	6.6
2	Cystic	17	12.14	7	41.2	1O	58.8
3	Solid /Cystic	1	0.71	1	100	0	0
	Total	140	100	122		18	

Cases were also divided into solid, cystic and solid/ cystic on the basis of the aspiration of fluid during procedure or on ultrasonographic findings.

Most of the nodules were solid accounting for 122cases out of 140 (87.14%) and of the remaining cases, 17 cases (12.14%) were cystic and only one case (0.71%) was partly solid cystic.

Majority of the aspirates from solid nodules were adequate i.e. 114 out of 122 (93.4%) and only 8 out of 122 (6.6%) were inadequate, where as most of the

aspirates from cystic nodules (10 out of 17 i.e. 58.8%) were considered inadequate and only 7 of the 17 (41.2%) were considered adequate. Aspirate from partly solid/cystic nodule was found to be adequate.

DISCUSSION

In the present study, a total of 140 cases of solitary thyroid nodule were subjected to fine needle aspiration cytology (without imaging guidance). Of these, 122 cases (87%) were found to be adequate by Goellner's criteria[13] and 18 cases (13%) were considered inadequate (Table-3).

Table - 4: **Comparision of Distribution of cases according to sex**

	Hussain Muhammad [13] (2001)	**Raza Sohail (2006)**	**Guhamallick M et al [8] (2008)**	**Uma Handa [9] (2008)**	**Foad Ali Moosa [7] (2010)**	**Present Study**
Female	78%	69.56%	66.66%	86.4%	69.4%	87%
Male	22%	30.43%	33.44%	13.6%	30.6%	13%
Female /Male Ratio	3.56:1	2.33:1	2.03:1	6.35:1	2.21:1	6.7:1

In all these studies no of females presenting as thyroid lesions is higher than males.

Table - 5: Comparision of no of cystic and solid thyroid nodules with other studies

	Silverberg[14] (1997)	**Bellantone R et al[15] (2004)**	**Raza sohail et al (2006)**	**Present study**
Solid	70%	-	70%	87.14%
Cystic	30%	15-37%	12.5%	12.14%
Solid/ cystic	-	-	17.5%	0.71%

In our study the percentage of solid lesion was obtained 87.14% which was higher to those quoted by Silverberg[14] (70%) & Raza sohail et al (70%).

In our study % of cystic lesion was 12.14% which was similar to those quoted by Raza sohail et al (12.5%) & lower than those quoted by Silverberg[14] (30%). In our study % of solid/cystic lesion was 0.71% which was lower than those quoted by Raza Sohail et al (17.5%). Bellantone R [15]et al (2004) mentioned the frequency of cystic thyroid nodules to be 15-37% of all surgically excised thyroid nodules.

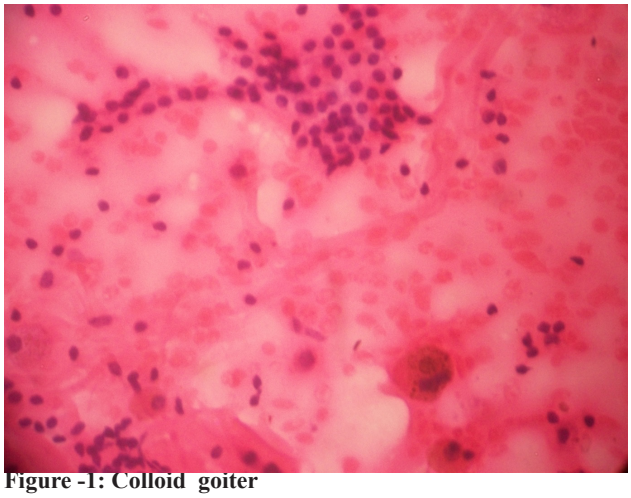

Figure -1: Colloid goiter

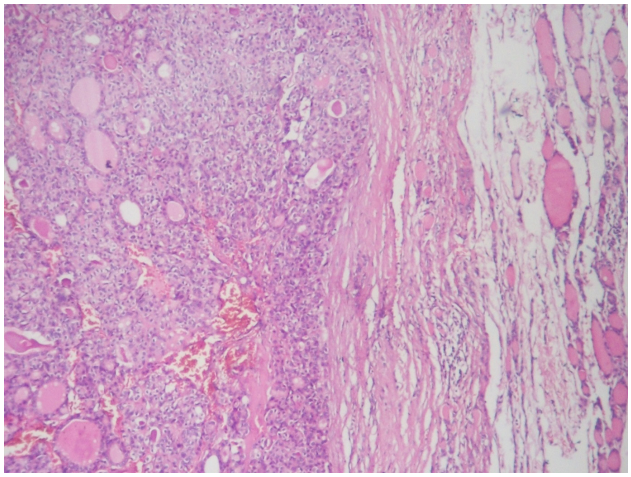

Fig- 2: Follicular adenoma

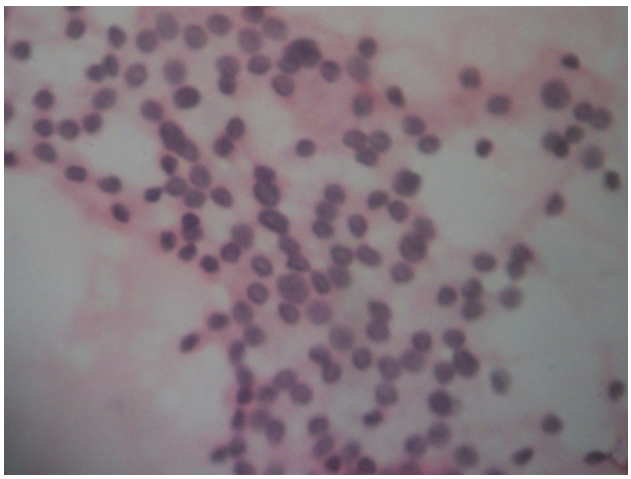

Fig – 3 Colloid goiter

CONCLUSION

Colloid goiter was the most common lesion amongst all non – neoplastic diagnoses. Great majority of these cases showed scant to moderate cellularity , good amount of colloid with or without histiocytes and monolayered honey comb sheets, thus enabling easy diagnosis Thus it was concluded that FNAC of thyroid is a safe, simple, cost- effective, reliable and accurate investigation for cases of solitary thyroid nodule as firm diagnosis can be made on cytology alone in vast majority of cases, thus obviating the need for unnecessary surgical procedures. Cystic lesions mandate careful clinical correlation.

Prevalence of Pregnancy Associated Listerioisis in and Around Puducherry, India

Balamuruganvelu Singaravelu[1], Sreenivasalu Reddy V[2], Geethavani Babu[3], S Kamala Kannan[4]

[1]Research Scholar, Bharath University, BIHER, Chennai, India & Professsor DM, Wayanad Institute of Medical Sciences, Wayanad, [2] Professsor, Bharath University, BIHER, Chennai, India, [3]Lecturer, Department of Microbiology, DMWIMS, Wayanad, Kerala [4]Assistant Professor, Government Tiruvanamalai Medical College and Hospital

ABSTRACT

Background: Listeriosis ranks the most frequent source of death among the bacterial food-borne illnesses with high Case fatality rate of 20% to 30% and neonatal death rate 50%. Listeriosis incidence in pregnancy has been reported 18 to 20 times higher than in general population. Hence the present study was planned to evaluate the prevalence of pregnancy associated Listeriosis in and around Puducherry India.

Method: A total of 335 pregnancy associated cases which includes 129 pregnant women, 34 women with miscarriage/ spontaneous fetal loss and 172 neonates from whom 147 blood samples,138 amniotic fluid or HVS, 2 diarrheal stool samples,19 CSF, 14 placental bits or umbilical cord and 15 abortus material were aseptically collected and processed for isolation of *Listeria spp.*

Results: The overall prevalence of pregnancy associated Listeriosis was 6.3%. Pregnant women accounted for 11.62% positive cases, 8.82% of women with spontaneous abortion /miscarriage and 1.74% of neonates were found positive for Listerioisis in the present study.

Conclusion: Considering the increased incidence of pregnancy associated Listeriosis in our setting, this disease should be considered as an important differential diagnosis in clinical practice especially among pregnant women and women undergoing miscarriage or fetal loss.

Keywords : *pregnant women, neonates, Listeriosis, miscarriage.*

INTRODUCTION

Listeriosis ranks the most frequent cause of death among all the bacterial food-borne illnesses[1] with case fatality rate of about 20% to 30%, neonatal death rate 50% and hospitalization rate 91%[2,3] Listeriosis incidence in pregnancy has been reported 18 to 20 times higher than in general population and moreover Listeriosis infection in pregnancy shows poor prognosis for the fetuses[4]. Listeriosis in pregnancy results in intrauterine infection leading to complications like spontaneous abortion, still birth, preterm labor and neonatal infections like neonatal sepsis or meningitis resulting in morbidity and mortality[5] .In India reports on human Listeriosis are scanty with only few documented cases and less than 15 publications such as isolation of this pathogen from women with premature birth, spontaneous abortions or miscarriage or from women with bad obstetric history patients in Mumbai[6], in Delhi[7] in south India[8] and few other places[9,10]. A report on Listeriosis in 2nd trimester pregnant women from Chandigarh[11]. Isolation of *Listeria* in cases with neonatal meningitis or meningoencephalitis from North India[12], from Mumbai[13] and from South India[14]. Listeriosis has been considered as an emerging foodborne disease in India and *Listeria monocytogenes* a growing threat[15]. Besides all Listeriosis in India largely remains ignored mainly because the clinical diagnosis

of Listeriosis is insufficient owing to its varied clinical forms and complex immunopathological aspects. Most often naturally occurring Listeriosis in humans has been unrecognized or unexposed owing to the lack of a rapid, simple, appropriate and reliable diagnostic tool[16]. Moreover the low incidence rate and failure to isolate the pathogen due to its rarity or lack of awareness or many a times it's been missed owing to lack of identification[17]. Till date the literature reviews suggest there is paucity of data pertaining to the *Listeria* infections among pregnant women and neonates in this subcontinent. The altering food habits, non-availability of vaccine for this disease, the capability of *Listeria spp.* to survive at refrigeration or low temperatures and its case fatality rate suggests that Listeriosis could be the single largest killer in humans and animals[18]. Moreover the increased food borne incidences of *Listeria spp.* has gained huge public health significance. Hence the present study was planned to evaluate the prevalence of pregnancy associated Listeriosis in and around Puducherry India.

METHOD

A cross-sectional study conducted over a period of 1 year from June 2015 to May2016 in the Department of Microbiology, Sri Lakshmi Narayana Medical College, Hospital and Government General Hospital, Puducherry, India. This study was approved by the Institutional Human Ethics Committee and Informed consent was obtained from all participants included in the study. In order to accomplish the objective a total of 335 cases which includes 129 pregnant women, 34 women with miscarriage/ spontaneous fetal loss, 172 neonates (infants aged≤ 4weeks) presenting with either fever/ flu-like illness, diarrhea , vomiting , with signs and symptoms of sepsis / meningitis / meningoencephalitis / encephalitis, who fulfilled the inclusion criteria from various hospitals in and around Puducherry such as Sri Lakshmi Narayana Institute of Medical Science, Rajiv Gandhi Government Women and children Hospital, India Gandhi Government General Hospital & Post Graduate Institute and Pondichery AIDS Control Society were accounted for this study. From the above mentioned cases 147 blood samples,138 amniotic fluid or HVS, 2 diarrheal stool samples,19 CSF, 14 placental bits or umbilical cord and 15 abortus material were aseptically collected, instantly transported to microbiology laboratory and processed immediately for the isolation of *Listeria spp.* following the USDA protocol proposed by Mc Clain and Lee in 1988 with certain modifications. Briefly the specimens were enriched by 2step enrichment method i.e, by inoculating in UVM broth -1 and incubating for 24 hrs at 30°C followed by enriching in UVM broth -2 with incubation at 30°C for 24 hours. Then a loopfull inoculum from enriched UVM broth- II was plated on to selective medium PALCAM agar and observed for *Listeria* colonies after incubation for 24 hrs at 37°C. Grayish glistening colonies surrounded with a diffusing black zone surrounding the colonies were presumptively taken as *Listeria* colonies[19]. The identified *Listeria* colonies were then subjected to Gram's staining and examined morphologically for Gram positive coccobacilli. Isolates showing tumbling motility at 20°C to 25°C was then confirmed for genus *Listeria* on the basis of Latex agglutination test using LK07- Hi *Listeria* Latex Test Kit -Hi-Media, India. The identified *Listeria* isolates were further subjected to biochemical characterization using KB012A-Hi *Listeria* identification kit to differentiate genus *Listeria* up to *spp.* level. The isolates exhibiting catalase, esculin, voges proskauer test and methyl red positive and nitrate test negative were considered as "presumptive" *Listeria* isolates. Isolates which showed α-methyl - D mannoside, glucose, rhamnose, lactose and sucrose positive reaction, xylose and mannitol negative reaction were considered as *Listeria monocytogenes* and the rest were categorized as other *Listeria spp.*

RESULT

The current study was conducted over a course of 1 year extending from June 2015 to May 2016 and was executed to determine the prevalence of pregnancy associated Listeriosis in and around Puducherry India. A total of 335 cases i.e., pregnant women, women with spontaneous abortion and neonates aged ≤ 4weeks presenting either with fever, flu –like illness, diarrhea, vomiting, with signs and symptoms of sepsis/ meningitis/ meningoencephalitis who fulfilled our inclusion criteria were enrolled for the study.

Table No.1 : Overall Prevalence of Pregnancy associated Listeriosis

No. of cases	No. of cases positive	Percentage (%)
335	21	6.3%

In this study out of 335 pregnancy associated cases screened for Listeriosis nearly 21 cases

were found positive for Listeriosis, with this the overall prevalence of pregnancy associated Listeriosis was 6.3% (Table No.1). The prevalence of Listerioisis among pregnancy associated cases included in the study is shown in Table No.2. Out of 129 pregnant women screened in the present study nearly 15 (11.62%) cases showed positive for Listeriosis. Of the 34 women with spontaneous abortion /miscarriage screened 3 (8.82%) cases turned positive for Listerioisis. 3/172 (1.74%) neonates screened were found positive for Listerioisis in the present study.

Table No.2 : Prevalence of Listerioisis among Pregnancy associated cases included in the study.

Pregnancy associated cases	No. of cases	No. of *cases positive*	Percentage (%)
Pregnant women	129	15	11.62%
Women with spontaneous abortion / miscarriage	34	3	8.82%
Neonates	172	3	1.74%

DISCUSSION

Listeriosis a dreaded disease of the west appears to have knocked the Indian subcontinent mainly due to rapid unplanned urbanization and globalization[20]. The disease in humans is chiefly through ingestion of food items contaminated with *Listeria* and the clinical spectrum of this disease varies from self-limiting febrile diarrhea to more serious invasive Listeriosis including bacteremia, sepsis, meningoencephalitis and abortion/ still birth[21]. The present study was proposed to determine the prevalence of pregnancy associated Listeriosis in and around Puducherry India. The overall prevalence of pregnancy associated Listerioisis in the present study was 6.3%. The results of the present study was found to be in agreement with the reports from most of the countries such as a report from Lombardy region Italy which reported nearly 15/134 were pregnancy-associated Listerioisis[22]. The number of Listeriosis cases recorded from 2004 to 2007 through the U S. *Listeria* Initiative has shown 16·9% of cases were pregnancy associated , reports from *Listeria* initiative during 2009 to 2011 reported through MMWR has showed pregnancy associated Listeriosis to be 14%[23]. Most reports from USA and Europe has shown about 15% and 6- 18% of Listeriosis cases respectively are pregnancy related[24,25]. Although the pregnancy associated Listeriosis is considered as a benign disease of the mother mainly because of its grave outcome in fetus, the pregnancy related Listeriosis is a major medical issue to be addressed that requires a deep clinical suspicion, highlighting the need for effective prevention in this category. Moreover the lack of awareness regarding the risk of certain food products in pregnancy would have contributed to pregnancy associated Listeriosis. Hence there is urgent requirement for preventive action among the pregnant women including the education on the avoidance of certain unsafe foods in pregnancy, as well as decontamination and food hygiene. Further steps addressing the decline in pregnancy related Listeriosis with improved industry and regulatory efforts to reduce *Listeria* contamination in foods is required. Hence a higher concern from the healthcare community or physician awareness towards pregnancy-associated Listeriosis is also mandated.

Pregnant women accounted for a considerable proportion of Listeriosis cases 11.62% followed by and women with spontaneous abortion / miscarriage accounted for 8.82% These results are concurrent with earlier published works where in the pregnant women accounted for a majority of all Listerial infection in humans , with the incidence of *Listeria* infection in pregnant women to be 12 per 100,000 in comparison to 0.7 per 100,000 in general public[26].The results are also in accordance with the recent published reports were an increasing incidence of pregnancy related Listeriosis has been furnished[26, 27]. Our report on isolation of *Listeria* from 8.82% of women with spontaneous abortion / miscarriage is well correlated with most studies conducted in India such as one reported by Krishna et al in 1966 with isolation of *Listeria* from 14% of cases with abortion or miscarriage or stillbirth in Mumbai[6] and isolation of *Listeria* from habitual abortions reported by several authors[28,29]. Whereas the results of the present study was quiet higher when compared to a report published by Bhujwala and Hingorani in 1975 who reported 1.34 % of cases with abortion or miscarriage screened were positive for *Listeria*[7]. The reasons for current rise in Listeriosis infection among pregnant women and women with spontaneous abortion or miscarriage could include the poor food hygiene practices, environmental and other host factors[4,27]. Hence

Listerioisis to be included in the differential diagnosis in clinical practices especially among pregnant women, women with spontaneous abortion / miscarriage.

Neonatal Listeriosis in our study was found to be 1.74% which is in par with few reports published earlier and the estimated prevalence of Neonatal Listeriosis is 8.6 per 100 thousand[30,31]. Thomas et al in 1981 from North India has shown 0.2% neonatal Listeriois in total live births[12]. Although, widely known that Listeriosis in pregnancy or maternal Listeriosis is extremely mild for pregnant women themselves, but it is of life- threatening with highly fatal outcomes for the neonates[26]. Moreover neonates and women during the antenatal period are highly susceptible to Listeriosis apparently due to their depressed or lack of CMI. Hence the present study emphasizes the need to screen for pregnancy associated Listerioisis in order to prevent further complications such as preterm labor, still birth, neonatal sepsis and meningitis which is extremely fatal as neonatal morbidity and mortality is possibly preventable with timely diagnosis and quick interventions. Hence care must be taken to report this pathogen in routine diagnosis.

Conclusion: Considering the increased incidence of pregnancy associated Listeriosis in our setting, this disease should be considered as an important differential diagnosis in clinical practice especially among pregnant women and women undergoing miscarriage or fetal loss. The pregnancy associated Listeriosis in our study was the highest that is currently described, signifying that effective or forceful preventative action against this group will have a great impact in lowering the abortion rates and fetal loss. This study concludes that a very high index of clinical suspicion and due diligence is mandatory in laboratory diagnosis of maternal or pregnancy associate Listeriosis.

Title: Dengue cases Treated in Sri Guru Ram Das Institute of Medical Sciences and Research, Amritsar in Year 2016

Harpreet Kaur [1], S L Mahajan[2]

[1]Statician Cum Lecturer, [2]Professor, Cum Nodal Officer, National Vector Borne Disease Control Program and Integrated Disease Surveillance Programme, Department of Community Medicine. Sri Guru Ram Das Institute of Medical Sciences and Research, Sri Amritsar

ABSTRACT

Introduction: Sri Guru Ram Das Institute of Medical Sciences & Research, Amritsar is a tertiary health care institution. Dengue is a viral infection mainly transmitted by female *Aedes aegypti* and *Ae. Albopictus* mosquitoes. It has spread globally in recent decades. Dengue virus (DENV) has four distinct and closely related serotypes i.e. DENV-1, DENV-2, DENV-3 and DENV-4. Severe dengue causes serious illness and deaths. Dengue has no treatment but can be prevented and controlled. **Materials and methods:** Data of confirmed dengue cases treated in SGRDIMSAR, Amritsar in year 2016 were collected; analyzed and valid conclusions were drawn. **Findings:** In year 2016, 198 dengue cases were reported. Maximum number of cases, 57 (28.8%) was found in age 21-30 years, majority, 118 (59.6%) were males and higher number of cases, 177 (89.4%) was found in urban area. All the cases were reported from August to November with the peak in September. Maximum cases 160 (80.8%) were found positive by NS-1 Ag. Mean gap between admission and testing of cases was 5 ± 2.1 days. Average length of stay of cases in hospital was 6.1 ± 2 days. **Conclusion:** Emphasize, to take all preventive measures, vector control, appropriate hospital care of cases and promote the use of NICD Coolers.

Keywords: *Dengue, Severe dengue, Aedes aegypti, Aedes albopictus.*

INTRODUCTION

Dengue is a human arbovirus disease transmitted by the female mosquito of the genus Aedes, mainly *Aedes aegypti* and *Ae. Albopictus*[1]. There are four distinct, but closely related, serotypes of the virus that cause dengue (DEN-1, DEN-2, DEN-3, and DEN-4). Recovery from infection by one provides lifelong immunity against that particular serotype. Subsequent infections by other serotypes increase the risk of developing severe dengue. However, cross-immunity to other serotypes after recovery is only partial and temporary[2].

Global burden of Dengue

The World Health Organization (WHO) considers dengue as a major global public health challenge in the tropic and sub tropic nations. Dengue has seen a 30-fold upsurge worldwide between 1960 and 2010, due to increased population growth rate, global warming, unplanned urbanization, inefficient mosquito control, frequent air travel and lack of health care facilities [3,4,5]. One recent (2013) estimate indicates that 390 million dengue infections occur every year (95% credible interval 284–528 million), of which 96 million (67–136 million) manifest clinically (with any severity of disease) [6]. Another (2012) study, of the prevalence of dengue, estimates that 3.9 billion people in 128 countries are at risk of infection with dengue viruses[7].

Situation in India

Dengue is endemic in all states and union territories (UTs) of India. Both Aedes aegypti and Aedes albopictus are the main competent vectors for dengue virus in India[3].

India receives 75% of its rainfall during the southwest monsoon period from June to September. Indian monsoon rainfall provides ample breeding habitats for *Ae. aegypti*, thus leading to high vector densities[8].

In the early 2000s, dengue was endemic in a few southern (Maharashtra, Karnataka, Tamil Nadu and Pondicherry) and northern states (Delhi, Rajasthan, Haryana, Punjab and Chandigarh). It has recently spread to many states, including the union territories. In addition to the increased number of cases and disease severity, there has also been a major shift in the geographical range of the disease. Dengue had been restricted to urban areas, but it has now spread to rural regions[9]. In year 2017, the spike in cases of dengue was the highest in the last one decade, according to the data from National Vector Borne Disease Control Programme (NVBDCP and National Health Profile 2018. From less than 60,000 cases in 2009, cases increased to 188,401 in 2017—more than a 300 per cent spike[10]. Cement water tanks, water coolers, plastic containers and tiers are the preferred breeding habitats of Aedes mosquitoes. Coconut shells and latex cups are important breeding sites in Kerala and Lakshadweep Island[11]. National Research Development Corporation of India found that in India about 60 to 70% of the Aedes mosquito breeding occurs in coolers in the urban areas and about 40% in rural areas[12]. National Centre for Disease Control (NCDC) has developed a modified cooler with a covered water tank which prevents breeding of mosquitoes thus very helpful in preventing vector breeding and contributes towards control of dengue as a public health problem particularly in urban areas. [13]

A dengue vaccine, Dengvaxia (R), has been registered in several countries[14]. But it has not yet been approved by the Ministry of Health and Family Welfare, Government of India, because more clinical trials are thought to be necessary in India[15].

Present study aims to describe the Epidemiological profile of confirmed cases of dengue admitted in year 2016 in medicine and pediatric ward at Sri Guru Ram Das Institute of Medical Sciences & Research, Amritsar, Punjab, India.

MATERIAL AND METHOD

A retrospective, descriptive study was conducted out in Sri Guru Ram Das Institute of Medical Sciences & Research (SGRDIMSAR), Amritsar. Epidemiological data of confirmed cases of dengue and deaths due to dengue in year 2016 were collected from dengue wards established in SGRDIMSAR, Amritsar. The study population included all the patients having their serum samples found confirmed for dengue by IgM Mac Elisa or NS-1 Ag test done in Government Medical College, Amritsar during this period.

Data Analysis: Data collected were analyzed by using SPSS software version 22 and the valid conclusions were drawn. $p < 0.05$ and $p < 0.01$ were considered significant and highly significant respectively.

FINDINGS

In year 2016, 198 confirmed cases of dengue were reported in SGRDIMSAR. No death was reported. Mean time gap in the date of admission of suspected dengue patients and testing of their blood samples for dengue was 5.01 ± 2.13 days. Average length of stay of dengue case in hospital was 6.12 ± 2.01.

Mean age of dengue cases was 33.21 ± 15.94 years. Maximum age was found to be 85 years and the minimum age was 2 months.

Table 1. Age wise distribution of confirmed cases of dengue

Age in years	No.	%
<1	1	0.5
1-5	1	0.5
6-10	8	4.0
11-20	35	17.7
21-30	57	28.8
31-40	38	19.2
41-50	35	17.7
> 50	23	11.6
Total	198	100.0

X^2 = 114.6 d. f. = 7 p = 0.000

Table 1 is showing the age wise distribution of confirmed cases of dengue. Maximum number of cases 57 (28.8%) were found in 21 to 30 years age groups and the minimum number, 1(0.5%) was found both in age groups < 1 and 5 years. The difference in the number of cases reported in different age groups was found highly significant statistically.

Table 2. Sex wise distribution of confirmed cases of dengue

Sex	No.	%
Male	118	59.6
Female	80	40.4
Total	198	100.0

$X^2 = 7.3$ d. f. =1

p = 0.007

Table 2 is showing the sex wise distribution of confirmed cases of dengue. It is evident from this table that higher number of males cases, 118 (59.6%) than the female cases, 80 (40.4%) was found. The difference in the number of cases reported in the male and female sexes was found highly significant statistically.

Table 3. Area wise distribution of confirmed cases of dengue

Area	No.	%
Urban	177	89.4
Rural	21	10.6
Total	198	100.0

$X^2 = 1.2$ d. f. = 1

p = 0.000

Table 3 is showing the area wise distribution of confirmed cases of dengue reported. Most of the cases 177 (89.4%) were reported from urban area and the difference in the number of cases reported from urban and rural areas was found highly significant statistically.

Table 4. Rural block wise distribution of confirmed cases of dengue

Block	No.	%
Baba Bakala	2	9.5
Lopoke	2	9.5
Manawala	5	23.8
Ramdas	2	9.5
Tarsika	1	4.8
Threawal	1	4.8
Verka	8	38.1
Total	21	100.0

$X^2 = 13.3$ d. f. =6

p = 0.03

Table 4 shows the block wise distribution of confirmed cases of dengue in rural area. Maximum number of cases, 8 (38.1%) was reported from block Verka followed by Manawala, 5 (23.8%) and the minimum 1 in each block Tarsika and Threawal. The difference in the number of cases reported from different rural blocks was found highly significant statistically.

Table 5. Month wise distribution of confirmed cases of dengue

Month	No.	%
August	20	10.1
September	138	69.7
October	39	19.7
November	1	0.5
Total	198	100.0

$X^2 = 225.6$ d. f. = 3

p = 0.000

Table 5 is showing the month wise distribution of confirmed cases of dengue. This table shows that all the cases of dengue were reported from August to November only. The peak of cases, 138 (69.7%) was found in the month of September followed by 39 (19.7%) cases in October. Only one case was reported in November. Rising trend of the reporting of dengue cases had been observed from August to September and there was a declining trend from September to November. The

month wise difference in the number of cases reported was found highly significant statistically.

Table 6. Test wise distribution of confirmed cases of dengue

Test	No.	%
NS-1Ag	160	80.8
IgM Mac ELISA	38	19.2
Total	198	100.0

$X^2 = 75.2$ d. f. = 1 $p = 0.000$

Table 6 shows the test wise distribution of confirmed cases of dengue. Maximum cases, 160 (80.8%) were found positive by NS-1 Ag while only 38 (19.2%) were found positive by IgM Mac ELISA. The test wise difference in the number of cases found positive has been found highly significant statistically.

DISCUSSION AND CONCLUSION

Mean time gap in the date of admission of confirmed dengue patients and testing of their blood samples for dengue was 5.01 ± 2.13 days. Average length of stay of dengue case in hospital was 6.12 ± 2.01. It is recommended that testing of the blood samples of dengue cases should be done on the same day of admission to reduce the dengue transmission to other non infected persons. This will also reduce the average length of stay of dengue cases in hospital. The impact of these effects will reduce the morbidity, severity and mortality of dengue and will give a useful economic effect by the reducing the expenditure of resources on the management of confirmed cases of dengue.

Age wise distribution in SGRDIMSAR in year 2016 shows the highest number of dengue confirmed cases, 57(28.8%) was found in age group 21-30 years which resembles the previous study conducted there in year 2015 and also a study conducted in Government Medical College, Amritsar in 2016 which also showed the highest number of cases in age group 21 to 30 years and most of the cases found in adult age [11, 19].

Sex wise distribution shows a male predominance (59.6%) in our study and this finding is in concordance with that of an earlier study done by Antony in a Medical College Hospital in Kerala, India[20].

Area wise distribution shows maximum number of cases, 177(89.4%) reported from urban area and 21(10.6%) cases reported from rural area in year 2016. Previous study done in SGRDIMSAR in year 2017, reported 13.1% cases from rural area, while in year 2008, district Amritsar, reported all the 196 suspected cases of dengue from the urban rural only[13]. These studies conducted in SGRDIMSAR have shown that the dengue is spreading from the urban to the rural areas. The findings pertaining to the present study also provide similar picture with other parts of the country and show the need to lay emphasis on prevention and control of dengue in rural areas also.

Our study shows that all the cases occurred from August to November with peak in September month. These findings are similar to the findings of studies done in Brazil in 2015 and Bengaluru in 2017 which show that dengue is highly seasonal and increases primarily during the rainy season when vector breeding rate is very high. Study done in Bengaluru showed maximum cases of dengue reported in September month which also resembles our study[16, 21].

CONCLUSION

Present study shows that dengue had affected the most economically productive age group, more males than females were being affected. It had largely confined to urban areas and all the cases were reported during monsoon and post monsoon season (August to November). Although there was no mortality but morbidity was fairly high. As vaccine is still not licensed to use in India so vector control and appropriate; and timely management of dengue cases is the only method of choice. The entire preventive and control measures should be started well before the onset of dengue season. Promote use of NICD Desert Coolers. Conduct campaigns for behavior change communication like use of personal protective measures, Insecticide treated bed nets and wearing of full sleeve clothes during the day, environmental sanitation, no water collections in small containers in the surroundings and vector control. Control measures like establishment of separate dengue wards in hospitals, availability of equipments, materials and drugs etc. for early diagnosis and management of dengue cases should be taken well before the onset of dengue season.

Mediating Effect of Social Support on Stress among Parents of Children with Intellectual Disability

Deepak Pandey[1], Pushkar Dubey[2]

[1]ICSSR-Post Doctoral Fellow, Pt. Sundarlal Sharma (Open) University Chhattisgarh, Bilaspur, C.G., India,
[2]Assistant Professor & Head, Department of Management, Pt. Sundarlal Sharma (Open) University Chhattisgarh, Bilaspur, C.G. India

ABSTRACT

Parents of children with intellectual disability put more care and effort in raising their children. The perceived stress faced by this segment of parents is more than that of the parents with normal child. It is therefore essential for the caregivers to release their burden to perform normal care giving functions. The objective of the study was to determine the effect of socio-economic demographics and social support on the perceived stress of parents of children with intellectual disability. The study was conducted in Chhattisgarh state among 100 parents of children with intellectual disability. Perceived stress scale and Social support scale were the toolsused in the study for data collection. Purposive sampling technique was the method adopted in the study for the selection of samples in the study. Multiple hierarchal regression analysis was used to test the proposed model. Structural equation modeling (SEM) was used to further confirm the mediating effect of social support on income and stress. Result indicated that socio-demographic variables income, education and gender significantly contributed to the variation of stress and showed negative association with stress. However age did not contribute significantly in the variation of stress. Result of mediating effect of social support showed significant association between income and stress.

Keywords: *Parents, Children with intellectual disability, Social support, Stress, Regression analysis.*

INTRODUCTION

Mental disability in children has been a curse for the parents and creates economic burden for the family.[1] Caregiver means an individual who provides direct care and support for chronically ill people.[2]Parents need to put extra effort and time in fulfilling the responsibilities towards their ward.The level of perceived burden is associated with higher risks of depression and lower quality of life for parents of children with intellectual disability.[3]Recently the American Association on intellectual and developmental disabilities (AAIDD) have approved a new nomenclature for mental retardation of children and have renamed it as intellectual disability[4]

Children with intellectual disabilities throw challenge on their parents, as they have more of adjustment problems.[5]It often upsets their life by increasing their perceived level of stress.[6]Parents of children with intellectually disabled account for more stress.[7]The behaviour and wellbeing of a child is found to have a greater impact on mother.[8] Intellectual disability of a children is remarked by ill communication and lack of academic and social skills.Parental stress is defined as "multidimensional response to physical, psychological, emotional social and financial stressors usually associated with the experience of caring". [9]

Emotional support is the one of the first type of support which is intangible in nature. Instrumental support is the second type of support and is regarded as tangible and direct ways of assisting others.[10]Its elements constitutes of financial boosting or materialistic gains.[11]Informational support is the third type of

E mail – drdubeypkag@gmail.com

support which is based on providing useful advice, guidance and suggestions to individuals,[12]which act as a prospect to solve problems.[13] The fourth type of support is companion support which inculcates social belongingness and calls for shared social activities.[14]

Many studies reveal that there are significant association between parental stress and social support. Families having children with intellectual disability experience more stress and less social support.[14,15]Care giving burden for mothers are associated with higher education and less social support.[16]Gross income and social support was found to have indirect overall effects on psychological health outcome.[17] Low levels of social support were the most influential predictors of depression and anxiety in mothers.[18] There is strong correlation between family support and parenting stress.[19] In a study contradictory result was found and the relationship between the amount of informal support and level of parental stress was not confirmed.[20] Moderation effect of social support was confirmed in perceived stress and resilience.[21] Psychological stress was inversely related to perceived social support.[22] Few other studies explore the influence of various socio-demographic variables and its correlation with stress in parents of intellectually disabled children.[23] Income is found to be clinically significant with stress among parents of children's with intellectual disability.[24]Gender was significantly associated with risk of stress among parents.[25]

METHOD

*Design:*Parents of intellectual disabled child were the sampling unit whereas purposive sampling techniquewas used for selecting samples for the study.

Population: All the parents of the children with intellectual disability of Chhattisgarh were considered for the study. For locating such population at primary level, hospitals at district headquarter were contacted. Information's obtained from rehabilitation centers in Chhattisgarh was considered for the study.

Tools: The Perceived Stress Scale [26]is used in the study. To assess social support a Social Support Scale [27]was used in the study. Internal consistency Cronbach α coefficient of the scale was found to be 0.92 which confirmed the internal consistency of data.[28] Both of the scales were found to be reliable and valid.

The Demographic details such as age group, gender, income and educational qualification were also used in the survey form. A detailed description of the purpose of the study and the information requested for was provided in the covering letter.

Procedure

A survey based method was used to collect the data from the sample which lasted for about 13 weeks (i.e., from May to July 2017). 150 respondent parents participated in the study. Data were collected through personal means by the distribution of questionnaire in the beginning of May and was collected, as a when completed till July, 108 questionnaires were collected in the end, with a response rate of 72%. 100questionnaireswere found to be completed in all aspects, and hence were considered for inclusion for the final study.

RESULT

The demographic details of the respondents are presented in Table 1. The total sample size for the study constitute of 100 respondent parents, which are equally distributed in terms of male and female group.

Table 1 Demographic information of the participants (N = 100)

Variables	Frequency	Percentage	Mean	SD	CI [95%]
Gender					
Male	50	50%			
Female	50	50%			
Age (Years)			35.19	2.733	34.65 - 35.73
31-35	56	56%			

Cont... **Table 1 Demographic information of the participants (N = 100)**

36 – 40	44	44%			
Income (INR)			25459.95	9099.37	23654 - 27265
10000 - 25000	36	36%			
25001 – 40000	64	64%			
Education level					
UptoHigher Secondary	53	53%			
Graduate and above	47	47%			

Hierarchical multiple regression analysiswas used in the study to predict the affect of study variables on stress as shown in the Table 2. [29]

Table 2: Hierarchical Multiple Regression analysis forPredictorsonStress

Predictors	**Model 1**			**Model 2**			**Model 3**			**Model 4**		
	β	**t**	**VIF**	**B**	**t**	**VIF**	**β**	**t**	**VIF**	**β**	**t**	**VIF**
Income	-.544	- 6.422	1.000									
Education				-.213	-2.532	1.042						
Gender							-.362	- 4.561	1.651			
Social Support										-.476	- 6.917	1.030
R	.544			.583			.748			.799		
R^2	.296			.340			.559			.639		
ΔR^2	.296			.044			.079			.220		
ΔF	F(1,98) = 41.241**			ΔF (1,97) = 6.410*			ΔF (1,96) = 20.800**			ΔF (1,95) = 47.844**		

In model 1, factor income made significant contribution in variation of the stress F (1, 98) = 41.241, p<0.01) and explained 29.6 % of the variance in stress (R = 0.544, ΔR = 0.296). The standardised beta value (β = 0.-544, p<0.01) indicated significant negative association between predictor income and stress level of parents; it means higher the income lower will be parenting stress.

In model 2, factor education made significant contribution in variation of the stress (ΔF (1, 97) = 6.410, p<0.05). The introduction of factor education explained additional 4.4% variance in stress with overall 34% (R = 0.583, ΔR = 0.044). The predictor education was found to have significant negative association (β = 0.-213, p<0.01) with stress; that is indicate graduate and post graduate parents showed less stress.

In model 3, factor gender (1 = Male, 2 = Female) made significant contribution in variation of the stress (ΔF (1, 96) = 20.800, p<0.01) and explained overall 55.9% of variance in stress (R = 0.748, ΔR = 0.079); the model explained additional 7.9% of the variance in stress. The results indicated significant negative association between predictor gender of the participants and their stress (β = 0.-362, p<0.01); that means mothers showed higher stress in comparison to fathers of children with intellectual disability.

In the final model, main predicting factor in the study i.e. social support made significant contribution in variation of the stress (ΔF (1, 95) = 47.844, p<0.01)

and explained overall 63.9% of variance in stress (R = 0.799, ΔR = 0.220); the model explained additional 22% of the variance in stress. The results indicated (β = 0.-476, p<0.01) significant negative association between predictor social support and stress; that means those who perceived higher social support in the society, family or friends their stress level was decreased.

Findings clearly indicated that age did not contribute significantly in the variation of stress; factors income, education, gender and social support were found to be significantly negatively and directly correlated with stress of the participants. Result indicates the explaining percentage of all predictors was 63.9%; this total of the variance included 29.6% for income, 4.4% for education, 7.9% for gender, and 22% for challenge.

Variance inflation factor (VIF) found, ranged from 1.000 to 1.651, which was distant from the 1.0 to 4.0, criteria that may indicate multicollinearity concern.[30] It means that multicollinearity found significant correlation between all predicting variables.

All 100 cases were also included for confirm mediation effectworked out by structural equation model (SEM).[31] Significance of mediation was examined by bootstrap.[32] AMOS licensed version 24 was used for data calculation. Figure - 1 suggested that the total effect is .639, p<. 01; direct effect found (.296, p<.01). In addition, figure - 1 suggested that the indirect effect is (.369, p< .01) of income on stress through social support was statistically significant. The mediation model showed statistical good model fit of data(CMIN/DF= < 2.01, RMSEA = .079, GFI = .984, NFI = .929 and CFI =.957).[33]

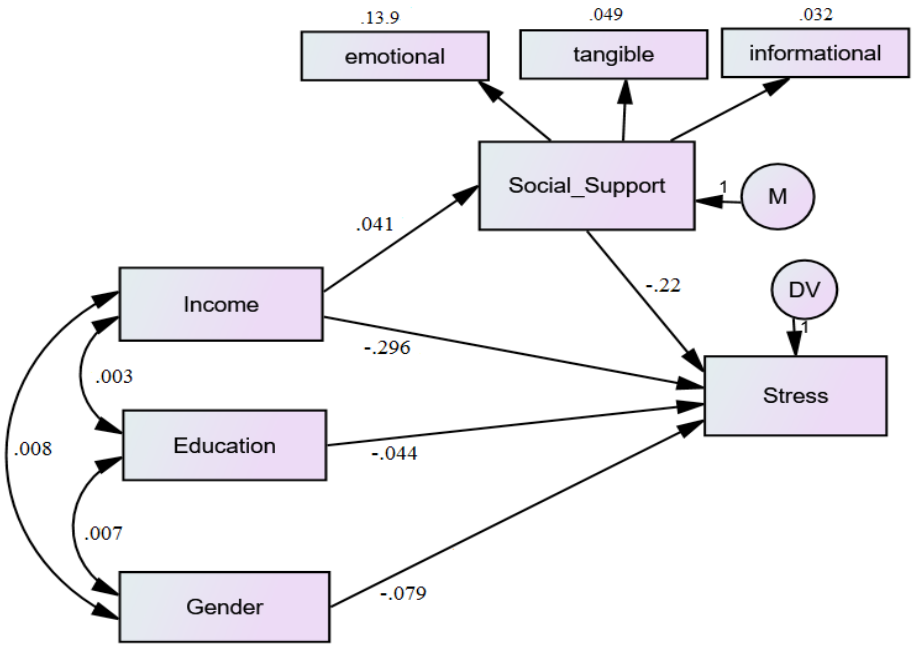

Figure 1 Mediating model of Social Support on the link between income and stress

DISCUSSION

The purpose of this study is to identify the effect of social support on stress level of parents of children with intellectual disability. It also studied the effect of various socio demographic variables like income, education and gender on the stress level of intellectually disabled children. The variable income is a significant predictor of stress and is negatively associated, which means that with the rise in income of the parents, there will be reduction in the stress or caregiving burden and is consistent with the previous findings of the related studies.[24] Similarly education was also significant predictor of stress and is negatively associated confirming that there is decrease in the stress level of the care givers with the rise in their education level.Researcher had similar findings in their studies.[17]Another demographic factor gender was significant predictor of stress is in keeping with the findings of other studies.[25]The impact of social support

on stress of the parents of children with intellectual disability was significant and is very much consistent with the past studies.[15,18]However the dimension age was insignificant on stress and was not found consistent with the earlier studies. The role of social support as a mediating variable between income and stress was found significant in the study.[22]

CONCLUSION

Stress has become an integral part of life. The condition of stress is developed within the environment. Parents of children with intellectual disability have an extra responsibility for caring their child and are subjected to more stressful conditions. As there is a relationship between social support and stress, the parents in order to reduce stress need more of emotional, tangible and informational support from the surroundings. Socio demographics of the parents also have significant relationship with the stress level. As income is a necessary condition of managing family, its increase leads to decrease in the stress level of the parents. Similarly with rise in the level of education, there is up gradation of knowledge component and thus decreases the stress level. Mother is subjected to more stress than the father as concluded in the study. Social support plays a satisfactory mediating role as a predictor between income and stress as concluded in the model fit. The model proposed in the study shows a good fit.

Conflict of Interest – No

Ethical Clearance – Data from the participants were obtained after taking their consent to participate in the research work. Ethical clearance was obtained from the departmental ethical committee.

Risk of HIV Infection among Tuberculosis Patients of Jaintia Tribes, Meghalaya

Arpita Mitra[1], Roumi Deb[2]

[1]Research Scholar, [2]Addl. Director & HOD, Amity Institute of Anthropology, Amity University, Sector-125, Noida, Uttar Pradesh, India

ABSTRACT

Tuberculosis (TB) and Human Immunodeficiency Virus (HIV) co-infection is associated with special diagnostic and therapeutic challenges and constitutes an immense burden on healthcare system of heavily infected countries like India. The association of TB with HIV is two-folded, and HIV infection being the most potent risk for a latent TB infection to convert to active disease. Aim of the study is to understand the risk factors associated with HIV infection among the TB patients of Jaintia Hills, Meghalaya. The data was collected from 317 TB patients belonging to the age group 15-50 years from different health centres of Jaintia Hills, Meghalaya. Out of all the TB patients, 39 (12.3%) were infected with HIV. The most important risk factors associated with HIV were found to be religion ($p<0.0$), marital status ($P<0.01$), education ($p<0.02$), occupation ($p<0.00$), income group ($p<0.05$). Early detection of TB and HIV co-infection is necessary to facilitate early treatment and ART initiation, thereby strengthening the control of TB and HIV.

Keywords: *Tuberculosis, HIV, Co-Infection, Jaintia Hills, Meghalaya.*

INTRODUCTION

India is the country with the highest burden of TB. It was estimated that globally around 9.6 million people were infected with TB, out of which 2.8 million cases were reported from India[1]. HIV is fuelling the global TB epidemic; the prevalence of this virus in TB patients is a sensitive indicator of the spread of the disease into the general population in many regions[2]. The effect of TB/HIV co-infection is bidirectional and synergistic/ aggravating[3]. Infected with both HIV and TB is one of the world's leading cause of death. The epidemic of AIDS has accelerated the rates of transmission and mortality due to TB. Although, the incidence of TB/HIV co-infection has decreased slowly with the implementation of antiretroviral therapy (ART), but unfortunately, in recent years globalization with economic and cultural exchanges has contributed to spread these diseases[4]. Both diseases are intricately linked to malnutrition, unemployment, poverty, alcohol consumption, drugs abuse[5]. Moreover, the prevalence of HIV among TB patients could be more in India, because 42% of these patients are unaware of their HIV status, the other reason being high rate of immigration from other states[6].

METHOD

A cross-sectional study was conducted among 317 patients receiving treatment for TB at the various health centres (District Tuberculosis Hospital, Civil Hospital, PHC, CHC, UHC) in Jaintia Hills (East and West), Meghalaya. Since, the present study was a part of ICMR funded project entitled "Prevalence and Risk Factors leading to HIV Infection among the Two Tribes of Jaintia Hills, Meghalaya and Ethical clearance for ICMR funded project was sought from Amity University Research Ethics Committee. The patients involved in study were the individual suffering from TB and was registered in the hospital between 2014-2016, all subjects belonged to the age group 15-50 years and belonged to the tribal community of Meghalaya (pnar, biate, khasi, garo). Before data collection written permission was sought from District Medical and Health Officer (DM&HO) and Medical officers (MOs) of all

the health centres. Informed consent was obtained from each patient prior to conduct the interview and gathered information kept confidential. Patients who refused to give consent and who were unable to understand the questions were excluded from the study. Structured schedule was used to collect the demographic data such as age, sex, religion, community, education, occupation, marital status etc. from each patient. Information related to risk factors associated with TB and HIV was gathered. HIV screening was done for all the tuberculosis patients using WHO evaluated "Rapid Test Kit" following NACO guidelines. Statistical analysis was carried out using SPSS V22. Differences between frequencies were tested using Chi-square test (significance level $p<0.05$). Multivariate analysis was used to evaluate the associated risk factors of HIV infection among the TB patients. Odds ratios were obtained with corresponding 95% confidence intervals.

RESULTS

The present study was conducted among 317 patients diagnosed with tuberculosis in Jaintia Hills, Meghalaya and among them 39 (12.3%) respondents were found to be infected with HIV.

Correlation of socio-demographic parameters with TB/HIV co-infection

The number of HIV infected TB patients were found to be more in the age group 25-34 years (16.1%) as compared to other age groups and was found to be statistically significant at 5% probability level ($p<0.05$). Most of the Christian community patients (20.7%) were infected with both TB and HIV while only around 5% Niamtre and Hindu population were infected with TB/HIV co-infectious diseases. Statistical analysis shows a significant variation of marital and HIV status ($p<0.05$), with increased risk of HIV among unmarried patients (20.3%). Another important parameter for HIV prevention is education, it was observed that the cases of HIV positive were found to be illiterate (9.5%) and 15.2% were informally educated. Around, 10.9% infected cases had their education below or up to secondary (including primary and middle level of education); however, 41.7% patients pursued or pursuing further education after secondary (higher secondary, diploma courses, vocational studies and post graduation level of education). The distribution of educational level among HIV positive and negative was found to be statistically significant ($p<0.05$). Majority of the HIV infected studied populations were unemployed (36.4%) and belong to lower economic group (16.7%). Statistically significant differences were observed with respect to occupation and economic status between the HIV positives and negative patients ($p<0.05$).

Sexual Practices and Behaviour

In the present study, around 95% of the TB patients were found to sexually active and risk of HIV infection was higher among them (10.7%). Promiscuous sexual behavior (more than one sexual partner) (79.2%) was found in the study population, out of which 13.9% were infected with HIV co-infection. This factor emerged as very important risk factors among TB patients. Although, the association between sexual relationship, numbers of sex partners with respect to HIV status was found to be statistically insignificant ($p>0.05$).Out of 300 sexually active respondents 33% had history of sexually transmitted disease; among them 18 patients were infected with this viral disease. The association between history of sexually transmitted disease with respect to HIV status was found to statistically significant ($p<0.05$). The study revealed that almost 13% TB patients infected with HIV had not used condom during sexual practices. Moreover, the history of alcohol abuse injectable drug use was found to be 10.8% and 26.1% (respectively). The association between alcohol abuse, intravenous drug use and HIV infection was found to be statistically significant ($p<0.05$) (Table 1).

Table 1: Risk Factors associated with HIV infection among the TB patients:

Variables	Patients infected with Only TB		Patients infected with both TB/ HIV		Total	p value
	N	%	N	%	N	
History of other sexually transmitted diseases (n=300)

No	261	88.8	33	11.2	294	
Total	278	87.7	39	12.3	317	

DISCUSSION

The present study indicates the prevalence of HIV (12.3%) among the tribal tuberculosis patients in Jaintia Hills, which is similar to the findings in the states of Odisha, Jharkhand and some areas of West Bengal[2]. In India, the number of HIV cases among TB patients is found to be high in Mumbai (30%), Pune (28.75%) and Mangalore (21%) compared to low prevalence in New Delhi (0.68%), Jammu and Kashmir (1.6%), Aligarh (2.8%), Indore (4%) and Tamil Nadu (4.7%)[7-12]. The association between marital status, education and HIV infection was found to be significant ($p<0.05$) in accordance with other studies conducted in all over the world[13-14]. However, Occupation was also found to be a risk factor for HIV infection in tuberculosis patients, such significant association was observe in other studies[15-16]. In the present study, a strong statistical significance ($p<0.05$) was found with respect to sexually transmitted diseases, alcohol abuse and injecting drug use and HIV infection among the TB patients of Jaintia Hills, which is also reported from different parts of world[17-18].

The most important risk associated with HIV infection in the present study was religion, education, occupation (high in unemployed, coalmine workers and truck drivers), low-socio economic status, marital status, presence of sexually transmitted diseases, use of recreational substances use such as alcohol before sex and injecting drugs. Whereas, there were no significant association with age, gender, community, multiple sex partners and use of condom though these parameters described as high risk factors in some studies[19-20].

CONCLUSION

HIV infection is on the rise among TB patients in all over the world. Based on the findings of this study there is a high HIV prevalence in this TB patient population. Majority of the friends of the local tribal people were from Nepal, Bangladesh, Assam, Manipur etc. and some of them were using injecting drugs on daily basis and shared the needles with the others; they at times forced others to use it. This is a great concern especially as it might affect both patient management and public health prospective. In view of associated risk of TB/ HIV co-infection, early detection and treatment of TB and HIV co-infection is necessary along with promotion of condom use and not using substance need to be considered as HIV prevention measures for TB patients in various infection prevention programmes in Jaintia Hills, Meghalaya. It is alo very important to make sure the availability of anti-tuberculosis regimens in all Health Centres of Jaintia Hills.

Conflict-of-Interest: NA.

Acknowledgement: Sincere thanks to ICMR for financial support. We are thankful, to Heads of the Jaintia Hills District Administrative and Health Centers for their support. Heartfelt thanks to the participants of Jaintia Hills for their cooperation in providing the valuable information.

Ethical Clearance: The present study was a part of Indian Council of Medical Research (ICMR) funded project, so, the Ethical clearance was sought for the project from Amity University Research Ethics Committee.

Does Ict Influences Rural Government School Teachers Beliefs?-Exploring Teachers Opinion on Usage of Ict as Teaching and Learning Tool

S.Sudha

Associate Professor, School of Management Studies, Vels Institute Of Science, Technology and Advanced Studies

ABSTRACT

The world is experiencing quick changes due to outburst of new technologies. These transformations are visible throughout biosphere together with rising countries like India, China, and Indonesia etc. These changes need to embraced by the developing countries in sequence to get better value in education and as well as to strengthen the classroom teaching and learning process.

Objective: The main objective of the study is to identify educators' viewpoint about advance technology introduction integration in Education

Method: The present survey was conducted in Tirutanni taluk among primary, middle and higher secondary rural government school teachers in order to identify their beliefs on ICT. 200 Questionnaires was distributed and 152 teachers participated in the survey. 48 teachers did not participate in the survey. The response rate for the study was 76%.CFA was used to analyze the research model. The study contributes to the research and fills the research gap of limited studies done in this research area.

Results: The findings reveal that teachers believe that ICT influences teaching and it can use as a teaching and learning tool.

Conclusion: Usage of ICT by teachers leads to quality education**.**

Keywords: *Teachers beliefs, Technology devices, educator and learning tools.*

OVERVIEW

The domain is undergoing quick fluctuations due to outburst of new technology software. These transformations are visible throughout biosphere together with rising countries like India, China, and Indonesia etc. These changes need to embraced by the developing countries in sequence to get better value in in education and as well as to strengthen the classroom teaching and learning process. ICT has become a universal theme and information technology has started to revolutionize all countries, reaching every person by giving an end to traditional methods of teaching.[1].

The Indian education system has started to realize the major advantages of Information and communication technology as a valuable tool to be used in schooling and knowledge that provides larger entrance to greater communication; the operation activities of learning and pedagogical improvement[2]. Students have their everyday usage in ICT through smart phones, social networks like Instagram, Facebook etc.[3]

The frequent challenges seen by the rural teachers are the need of awareness and familiarity how to employ internet and explore data. It discourages teachers from usage of ICT in classroom teaching process[4]. On the other hand the noteworthy changes implemented by rural teachers are changing their traditional teaching methods to application methods in ICT mode. The usage of advance technology in coaching and education process involves advance technology abilities known as ICT education that involves knowledge on fundamental computer operations and practice. Usage of advance technology devices in daily lives has made life easier[5]. Teachers need to use ICT as it is not value addition but it

has started to become essential in daily process.

As per the Indian advanced technological devices usage trendy education and its integration in to classrooms was much stressed in the national policy on education in 2016[6]. But its actual implementation started around 2 decades ago. In 1992 Programme of Action which was formed, stressed on usage of ICT in schools. Various smart schemes were introduced to make educators improve their skills on ICT. Though this initiative did not take up well the usage of SMART resources were started in higher education.

The author[7] has stated that usage of ICT leads to professional development and such technology skills need to be developed by teaching professionals. The researchers [8] in their study communicates teachers attitudes proved to be significantly positive towards the usage of ICT. With these positive attitudes the required skill sets for ICT need to be acquired by the rural school teachers.

MATERIALS AND METHOD

India is one of the fast growing countries in usage of internet. The spread of internet usage among them have seen rapid growth in urban areas when compared to rural. Rural India is still lagging behind in terms of internet services and availability of ICT. As per the census of India 2018, The Indian youth population who are 50% below the age of 25 years are the main users of Information and Communication. The number of internet users in India by 2022 would be 511.89 million [9]. Among the population usage of advanced technology by teachers in the ground of instruction has increased. Both state and central government has also framed policies on usage of ICT. The Education policy 2017-18 of Tamilnadu has also emphasized usage of ICT everywhere. But rural area has been experiencing limited connectivity of internet to urban areas. Various researchers have stated that the degree of digital competence of its teaching staff needs to be increased The researchers [10] have found that teachers are expected to equip themselves with the 21st century skills on computers.

This study was designed to analyze the beliefs of rural government school teachers advanced technology usage as instruction and knowledge tool. The study also helps route and explore about the beliefs on ICT integration in Education.

LITERATURE REVIEW

Educators viewpoint about Advance Technology usage as a Instruction and Knowledge Tool

Teachers are termed as demonstrators and they are the primary factor for implementing development and innovation in education. Their perceptions do play a vital role in implementation of educational technology in improving the performance of the students Among educators (teachers) male members proved to have more confidence in use of ICT to female[11].

It is also stated that technology has more value when utilized with subjects like mathematics, solving word problems[12]. Some quote Education Technology is effective but its effective usage in classrooms is associated to instructors' outlooks and their near wisdom.

Educators Beliefs about Technology Integration in Education

[13]The authors in their study has revealed that advance technology view point by educators and its implementation in the area of education.

Aim of the research study

The prime demonstrable aim of the research was to pinpoint educators' beliefs about ICT as a teaching and learning tool and Integration of ICT in Education.

Resources and method

Tool

This is assessable research learning and data was collected using survey method.

Population

One rural government coeducation school was considered for the study. 200 teachers participated in the survey and structured questionnaire were distributed. 152 teachers participated in the study. 48 teachers did not return the filled in questionnaire.

Data Assessment

Data was assessed using CFA. AMOS software was used version 21.

Research process

Assessment method was engaged to gather the data.

Inquiry forms were distributed to 200 rural government school educators for the force of determining the soundness and consistency of the inquiry tool. The soundness values for individually are: educators' beliefs about ICT as a teaching and learning tool (0.687), educators' viewpoint about advance technology usage in education (0.624). People for the real data collection were rural government school educators. Data was analyzed by using CFA with Amos version 21.

RESULTS

Confirmatory factor analysis was done with AMOS 21.0 software version to understand the teachers' beliefs.

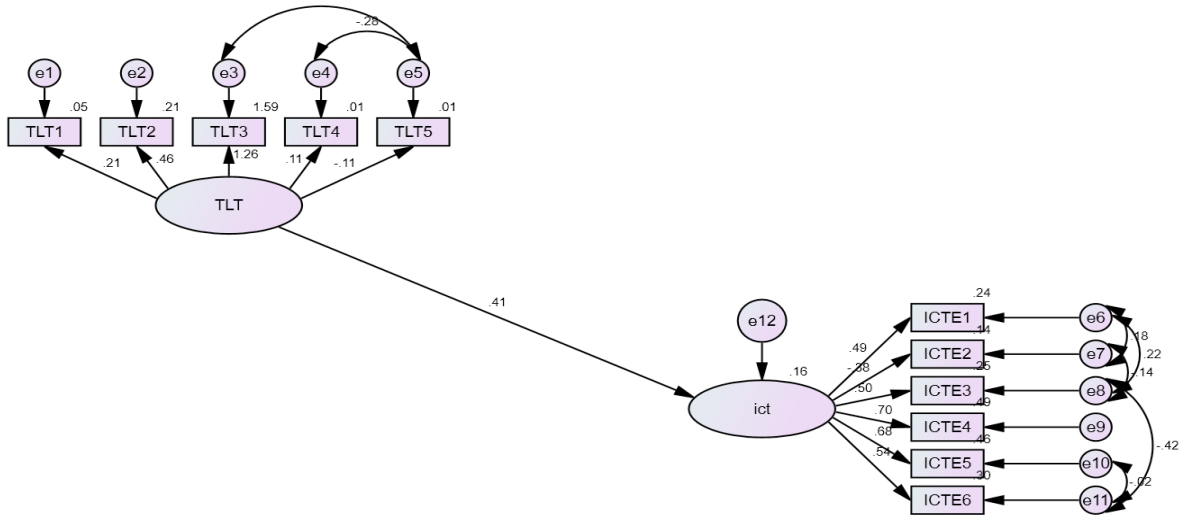

Diagram 1 showing Confirmatory Factor Analysis

Table 1: Showing significance of the model (Group number 1 - Default model)

			P
Ict	<---	TLT	.001
TLT1	<---	TLT	000
TLT2	<---	TLT	.001
TLT3	<---	TLT	.022
TLT4	<---	TLT	.099
TLT5	<---	TLT	.435
ICTE1	<---	Ict	.000
ICTE2	<---	Ict	.001
ICTE3	<---	Ict	***
ICTE4	<---	Ict	***
ICTE5	<---	Ict	***
ICTE6	<---	Ict	***

The results of the study reveals that the constructs on advance technology usage as a coaching and knowledge tool proved to be significant with alpha value less than $p<0.05$. The constructs on teachers beliefs on the implementation of ICT in education process is also proved to be significant with values less than $p<0.05$.

It can also be inferred from above table and diagram that teachers do strongly believe that ICT can be used as to tool of instruction in the subject matter in the curriculum. ICT helps to stimulate critical thinking of the students and it contributes substantially to students teaching and learning process. Hence teachers are strongly convinced is usage of **advance technology usage as a coaching and knowledge tool.**

The perceptions of educators on advance technology usage in their jobs in an effective manner are proved to be significant in the study. The study also provides insights in to usage of advance technology in the area of teaching will prove to be useful for the society in the future. At the same time teachers too believe that too much usage of ICT usage will isolate students and separate them from learning process. **Therefore ICT in usage of education process are believed to be effective but need to be used with caution.**

DISCUSSION

The results showed that educators believe that advance technology can be benefited as a teaching and learning tool. Teachers belief on using ICT for management and educators work preparation, ICT contribution as learning tool are significant as per the analysis.

Further in the study, teachers' beliefs on ICT integration in education are found to be significant. Teachers are interested to involving advance technology in instruction as it improves the teaching and learning process which is relevant to the study done by[14]. Teachers are ready and are always interested in learning new technologies which helps them to enhance their skills in technologies[15].

The study further reveals that rural government school teachers do have negative thoughts and they feel insecure in usage of ICT in education and they do face lot of challenges in using ICT for their respective subjects.

Hence it is important that government should take steps in solving the challenges faced by rural government school teachers by making regular investments in infrastructure facilities in government schools.

CONCLUSION

The study has shed light on two important things like advance technology as a coaching and knowledge tool and secondly ICT introduction in the field of education. The results discussed in the study also prove to be significant. However there are constraints found in ICT implementation practically due to lack of infrastructure facilities. ICT implementation in rural areas will lead to technological and skill enhancement of rural government school teachers and leads to quality education for rural children.

Author contributions: The author has collected the data on her own and she wants to specialize in the area of ICT.

Evaluation of Levels of Gunas in Indian Athletes Using Prakriti Concept

Tarun Jain, Ritu Sharma[1], Abha Singh[2], Karuna Mehta[3]

[1]Research Scholar, [2]Lecturer, Amity Institute of Psychology and Allied Sciences, Amity University Noida, UP, [3]Associate Professor, Zakir Hussain College, Delhi University.

ABSTRACT

Background: Our civilization has always recognized extraordinary individuals, whose performance in sports, arts, and science is vastly grander to that of the rest of the population. The present study was conducted to assess the levels of gunas of Indian athletes at three levels using the Prakriti concept.

Materials and method: The present study consisted of 107 school level athletes, 110 college level athletes and 76 Elite level athletes with age group of 15-18 years, 19- 24 years and 16- 45 years. Mathew IAS Rating Scale was applied. The instrument measures three broad behavioral tendencies (personality components, dimensions): Inertia (Tamas), Activation and Stability. Partial least squares structural equation modeling (PLS-SEM) approach was used to assess the coefficient regression values of the individual contributing factors to total personality values

Results: Factor loadings of all items presence of convergent validity. At school level stability was found to be negative with β= -0.494, activation was found to be positive with β= .352 and Inertia (Tamas) was found to be positive. Activation was found to be positive with β= .45 and Inertia (Tamas) was not significant in the elite athletes and negative.**Conclusion:** The performance of Indians at international level has been very mediocre and understanding the personality from school to elite level being predominantly result oriented (Rajas) can help in changing the approach at grass root level.

Keywords: *Athletes, Gunas, Prakriti*

INTRODUCTION

Personality has been defined as "psychological qualities that contribute to an individual's enduring and distinctive patterns of feeling, thinking and behaving"[1] whereas successful performance is defined as having both the development and mastery of knowledge, skills, and abilities and the capability to consistently and reliably deliver (i.e., perform) at the time of performance.[2]

Our civilization has always recognized extraordinary individuals, whose performance in sports, arts, and science is vastly grander to that of the rest of the population. Assumptions on the causes of these individuals' astonishing abilities and performance are as old as the first records of their achievements.[3]

Type based assessments in which personality has been assessed by categories an individual as one type or another. This fails to support the concept of "type" (e.g. introvert or extravert) as successful athletes have been both introverts and extroverts as shown in various researches. Thus type fails to support the concept of "type".[4]Samkhya theory of personality on the other hand provides the assessment of each individual of their present state and steps to proceed to next level in relation to traits to improve performance.[5]

Samkhya theory of personality shows the insights in accepting human nature as per Indian thoughts. Various Indian researchers have also deliberated on this concept

of Triguna in their writings.[6]

The Triguna concept shows the great teacher of classical yoga, Patanjali, says (Yoga Sutras II.18), "The world of objects is composed of the three gunas—the principles of illumination (Sattva), Activation (Rajas)) and Inertia (Tamas).

The guna are of three kinds and are present in all individual at all the time and these gunas act together and never exist in isolation. Based on the above understanding, personalities are categorized into three, viz., Stability (Sattvic), Activation (Rajasic) and Tamasic types. Individuals differ in their cognitive, affective, and personality aspects according to interplay of Triguna.[7]

Guna has its own effect on the intellect and action. Each guna has a balanced and positive state and excess or negative state.

Stability (Sattva) Guna

From the Bhagavad Gita (14.6): "Of these three, sattva, untainted, luminous, free from sorrow, binds by means of attachment to knowledge and joy." As balanced state: Stability (Sattvic) quality has been described as being "free from attachment and vanity and absolutely unruffled in success and failure." In excess Stability (Sattvic) generates self-righteousness, complacency and self-satisfaction. That means happy in finding the solution but not acting on it when required.[8]

Activation (Rajas) Guna

From the Bhagavad Gita (14.7): "Activation (Rajas) is marked by passion born of craving and attachment; it binds the embodied Self to never-ending activity. "Activation (Rajas) is described as an intermediary between Inertia (Tamas) and Stability (Sattva).[9]

Inertia (Tamas) Guna

From the Bhagavad Gita (14.8): "Tamas, ignorance-born, deludes all embodied beings; it binds them by means of dullness, indolence and sleep." Tamas present in a balanced state represents qualities such as ease, loyalty, patience, stability and being grounded. Shutting down or coming to rest brings forgetfulness and possibility of renewal.[10]

The present study was done to assess the reasons for poor performance of Indian athletes at international level using the Triguna concept with objective to assess the levels of gunas of Indian athletes at three levels using the Prakriti concept.

MATERIAL AND METHOD

The present study includes purposive sample of school level athletes (n=107), college level athletes (n=110) and Elite level athletes (n=76). The study protocol was approved from institutional ethical committee. All participants were informed and written consent was obtained. The participants in interschool and intercollegiate meet belonging to various states. Elite athletes were representing India at international level.

Age group of school level was 15-18, college levels were from 19-24 and elite level age varied from 16 to 45. Mathew IAS Rating Scale was applied. The instrument measures three broad behavioral tendencies (personality components, dimensions): Inertia (Tamas), Activation and Stability. They cut across cognitive, temperament and motivational modalities. It contains 35 items and allows the subject to discriminate and assess type and strength of guna for each questionnaire. Reliability was established as standardization details for athletes' assessment was not found in the literature.

STATISTICAL ANALYSIS

The obtained data was statistically analyzed using IBM SPSS Statistics for Windows, Version 21.0. Armonk, NY: IBM Corp. Partial least squares structural equation modeling (PLS-SEM) approach was used to assess the coefficient regression values of the individual contributing factors to total personality values.

RESULTS

Table 1 indicates Reliability and Validity. Here *Cronbach's Alpha* (CA) - Values of all the constructs exceeds or equivalent to the level of 0.75. *rho_A Reliability* – Measure of consistency all values greater than .75 *Composite Reliability* (CR) – All the values in the above table are greater than .75 . *Factorial Validity* - Factor loadings of all items in the present study are more than 0.5, thus indicating presence of convergent validity.

Figure 1 indicates Measurement Model Diagram showing the contribution of three broad behavioral tendencies personality components: Inertia (Tamas) (I), Activation (A) and Stability (S)

Table 2 indicates school level athletes displaying mean score of significant Regression (β) path coefficients, T statistics and p values obtained by estimating standard errors for the estimates-School athletes. The values are highly significant. At school level: Stability was found to be negative with β= -.494 (p = .000*), activation was found to be positive with β= .352 p*** highly significant and Inertia (Tamas) is found to be positive with β = 0.279 (p = .000*)

Tables 3 indicates for college level Athletes displaying mean significant Regression (β) path coefficients, T statistics and p values obtained by estimating standard errors for the estimates-College athletes. The values are statistically significant. At college level stability was found to be negative with β= -.46 (p = .000*), Activation is found to be positive with β= .19 (p = .000*) and Inertia (Tamas) is found to be positive with β = 0.45 (p = .000*)

Table 4 indicates Elite International Level Athletes which Displaying significant Regression (β) path coefficients, T statistics and p values obtained by estimating standard errors for the estimates-Elite athletes. At Elite level: Stability is found to be negative with β= -.46 (p = .000*), Activation is found to be positive with β= .45 (p = .000*) and Inertia (Tamas) is not significant in the elite athletes and negative with β = -0.09 (p = 0.31).

Tables 5 indicates Trend of Triguna at three levels of sports in India where Trend of the three personality aspects vis. Inertia (Tamas), Activation (Rajas) and Stability Sattvic) for the three distinct levels of sports (School, College & Elite) was compared. It indicates Stability is highly significant however perceived negatively at all three levels. Activation is highly significant and is perceived positively however activation is high at school level and highest at Elite level. Inertia (Tamas) is only significant at school and college level and not significant at elite level. Stability was found to be similar at all three levels. Activation was highest at the elite level and Inertia (Tamas) was found to be highest in college level.

Table 1 Reliability and Validity

Personality Components	Cronbach's Alpha	rho_A	Composite Reliability
School Level Athletes			
Activation	0.749	0.806	0.788
Inertia (Tamas)	0.742	0.779	0.775
Stability	0.823	0.85	0.851
College Level Athletes			
Activation	0.752	0.792	0.79
Inertia (Tamas)	0.913	0.919	0.923
Stability	0.894	0.902	0.907
Elite International Level Athletes			
Activation	0.968	0.973	0.971
Inertia (Tamas)	0.856	0.872	0.882
Stability	0.972	0.974	0.974

Cronbach's Alpha (CA) - Values of all the constructs exceeds or equivalent to the level of 0.75.

rho_A Reliability – Measure of consistency all values greater than .75

Composite Reliability (CR) – All the values in the above table are greater than .75 .

Factorial Validity - Factor loadings of all items in the present study are more than 0.5, thus indicating presence of convergent validity.

DISCUSSION

While assessing the result through the prism of the triguna concept one has to understand the fundamental in using this theory is that all the three gunas, namely Inertia (Tamas), Activation (Rajas), and Stability (Sattvic) are essential and necessary for the functioning of the human mind and body complex. An athlete has to use both his mental skill and physical skills equally and concurrently at a given time. Thus, in sports, the balance of each guna is a must to perform. The study highlights issues present in the Indian athletes based on the Triguna concept of personality.

We observed that the mean values of the gunas in the Indian athlete at all three levels suggest that stability is the most predominant guna, next dominant guna is activation followed by Inertia. However, Sattvic is highly significant at all three levels but have negative regression coefficients.

Stability denotes the quality of intelligence which creates harmony, staying calm, balanced, and control. It has also been shown that staying calm, being balanced and in control are vital traits for successful performance as it lower anxiety levels and improve performance. Higher levels of stability suggest that the Indian athletes are not in favor of approaching the sports in a detached, process-oriented and balanced manner.[11]

Activation, on the other hand, has a positive regression coefficient at all three levels suggests that they prefer approaching sport in an enthusiastic, excited, ambitious, alert, passionate, persevering and motivated way which are qualities of elite athletes as shown by various researches.[12] However, activation with positive coefficient and Stability with negative coefficient suggests that excessive activation which is characterized by being overactive, uncontrolled energy, impatient, hasty in planning things for the future, risk-taking, rash, go-getting, acquisitive, aggressive, greedy, competitive, , ego-involved assertiveness, dominance, inability to

be a follow a process, egoistic, which leads to result orientation , instant gratification and poor performance. It has been shown that too much of motivational level and result orientation narrows the cognitive skill and limits identifying the difference between result orientation and process orientation approaches which leads to failures in motor skills in sports.[13]

Nature of sports activities influence and cultivates different kind of abilities and thinking process among participants personality, group activities results in more social and democratically values, whereas individual activities make them to more rigid and narrow minded. But both nature of sports make sportsperson to have mastery over the emotion and learn how to regulate and control them according to situation. A study by Shankara Murthy[14] revealed that Sattva guna is positively related to organisational setup because Sattvic personality consists of passion, patience, control on behaviour, creative leadership, and intellectual ability.

Prasunavv et al[15] found that Sattvic personality performs better than Rajasic and Tamasic personalities. Authors concluded that trigunas and tridoshas directly control all the physiological processes, and individual motivation and cognitive levels are closely related with Prakriti.

It has been found that inertia (Tamas) is the quality of dullness, ignorance, and Inertia (Tamas) is highly significant however was not found significant in the elite group. The school and college level are still not entirely dedicated to sports as the elite is which justifies the presence of Inertia (Tamas) (tamas) guna in these two groups. Inertia (Tamas) also signifies a lack of knowledge and state of ignorance which will be prevalent at the school level due to lack of experience.[16]

This gunas represents Prakriti (personality) which suggest the Indian athlete believes in a more result-oriented approach than to a process orientated approach in sports. Activation which is result oriented approach and instant gratification are negating the Stability guna which is knowledge-based orientation and is the signification of delayed gratification. Sport is a lifelong process and not a onetime event and requires a patient and systematic approach which in the Prakriti concept denotes as Stability (Sattvic) guna.[17] The triguna scale can help each athlete to understand their gunas and that balancing the gunas is the key to consistent performance and any guna in excess leads to poor performance.

CONCLUSION

This study will serve to advance understanding and theoretically underpin the personality using Triguna concept to assess and provide intervention to improve sports performance in Indian athlete at individual level. Failures of Indian athletes at international level have not been assessed from individual athlete level rather has been assessed on a national level.

Effect of 8 Weeks Body-Weight Resistance Training on High-Normal Blood Pressure and Stage 1 Hypertension Subjects-Pilot Study to Validate the Protocol

Sonu Punia[1], Sivachidambaram Kulandaivelan[1]

[1]Assistant Professor, Department of Physiotherapy, GJUST, Hisar, Haryana, India

ABSTRACT

Background: Resistance training has shown to decrease the blood pressure (BP) in Indians, but assessing 1 repetition maximum (1-RM) and use of equipment is difficult for individuals who wants to do it in home. Body-weight exercises are simple yet provide resistance to exercising muscles. **Objective:** To see the effect of 8 weeks progressive body weight resistance training (RT) on BP in subjects with high-normal BP and stage I hypertension.

Materials &Method: A randomized controlled trial was conducted in Hisar, an urban area of Haryana and study was carried out during January to June 2017. 20 patients diagnosed with either high-normal BP or stages 1 hypertension were recruited after screening of inclusion &exclusion criteria. For resistance training (RT) group, participants were exercised 30-40 minutes/session and 3 Sessions/week for 8 weeks. Control group, there was no training for 8 weeks but offered exercise intervention afterwards. Outcome variable was BP which was measured at baseline as well as 2 week intervals thereafter up to 8 weeks. Data was analyzed using IBM SPSS v21.0 software. **Results:** There was a significant gradual SBP reduction in resistance training (RT) group up to 6 weeks (MD -11.36, p=0.001 at 6 week), but insignificant rise in BP at 8 week (MD -10.85, p=0.03). Resistance training (RT) reduced DBP significantly at 6th week (MD -6.36, p<0.001). **Conclusion:** In Resistance training group, current exercise protocol should be modified to reduce BP in this population. **Trial Registration:** CTRI/2017/03/008280. **Source of Fund**: None.

INTRODUCTION

Prevalence of cardiovascular disease (CVD) is increasing day by day in developing countries like India. High blood pressure accounts for the greatest proportion of deaths (about 30%) attributed to CVD risk factors in India.[1, 2] The percentage of risk increase in people with older age, gender, greater Body mass index (BMI $\geq$ 23 Kg/m^2), large waist circumference, sedentary occupation, illiterate envionment, diabetes mellitus and raised urine protein, serum creatinine. In order to abate the burden of hypertension and related health outcomes, it is important to understand and establish the relationships between major risk factors for elevated blood pressure. However, evidence regarding these relationships may not generalizable to developing countries, such as India because most of the evidence from developed countries.[3,4] Lack of awareness about hypertension, risk factors of hypertension (HTN), diet modification and treatment choice are important cause of increased prevalence. With increases in rate of literacy, rate of prevalence of hypertension decreased, thus education and community-based screening should be considered as having a potential role in controlling HTN in India.[3, 5]

Early screening of hypertension and development of affordable intervention program (pharmacological

and nonpharmacological treatment) is the need of time. One important part of non pharmacological treatment is exercise training that improves blood pressure. There are different types of exercises which may effectively to lower blood pressure (BP). Some other researcher also found benefits of physical activity and aerobic training in lowering blood pressure more than regular walking. [6,7] The results of various meta-analytical studies showed that isometric & dynamic resistance exercise and aerobic exercise does lower BP however, the sample sizes of the trials to date are generally small. [8,9,10,11] Resistance training has shown to decrease the blood pressure (BP) in Indians, but assessing 1 repetition maximum (1-RM) and use of equipment is difficult for individuals who wants to do it in home. Body-weight exercises are simple yet provide resistance to exercising muscles. In western countries, Nascimento et al et al (2014) suggested that 14 weeks of resistance training has positive effects on functional capabilities and limitations of the elderly by increasing muscular strength, cardiovascular function, decreasing coronary artery disease (CAD) risk, and preventing hypertension but Juliano Casonatto et al (2016) found that a single bout of resistance exercise can have a BP-lowering effect that last for up to 24 hours.[12] But the effect of dynamic resistance protocol is yet to be noticed in India. There are some resistance protocols that differ in periodization, volume, intensity, and training frequency. These contributing factors vary the control of BP in during short and long-term training periods. Hence there is need of an effective resistance training (RT) protocol that can be used to prevent and treat high blood pressure. Therefore, the objective of the study was to develop an effective resistance exercise protocol for the Indian community.

METHODOLOGY

Study design

A randomized controlled trial was conducted in Guru Jambheshwar University of Science & Technology (GJUS&T), Hisar situated in an urban area of Haryana. Participants were recruited from local hospitals and department of Physiotherapy, GJUS&T. Patients were selected by stratified random sampling and randomized into two groups: a control group (n=10) and resistance group (n=10). Since it was pilot study so sample size was not calculated.

Inclusion and exclusion criteria

The inclusion criteria for the study was any males or females of middle aged adults of 30-45 year, who was apparently high normal BP and stage 1 hypertensive diagnosed by physician and passed physical activity ready questionnaire (PAR-Q) developed by American Cardiology Society of Medicine and were willing to participate in the study. The exclusion criteria for the study if were chronic alcoholic or were having any other pathological conditions such as Musculoskeletal conditions, Neurological conditions and Cardio-respiratory conditions that prevent the subject to perform exercise training.

Ethical consideration

Ethical approval for the study was obtained from the institutional ethical committee of GJUS&T, Hisar vide letter no PTY/2016/555 on 14/10/2016. We followed Helsinki guidelines (1964) because our study was on human subjects. Present study protocol was also registered under clinical registry trial (CTRI/2017/03/008280).

Randomization and allocation concealment: Urban area was divided into four blocks and each block has five wards. After that physiotherapist randomly select one ward from each block by chit method. Physiotherapist recruited 1 participant randomly by her convenience. Recruitment for the study was restricted by block allocation (3 males and 3 females each in high normal BP and stage II hypertension) through order selection means first come and first selection. Same sequence of selection of participants was followed in each block. All participants were blinded to the treatment and also assessor was also blind to the treatment. Hence present trial was a double blinded, randomized and active controlled trial.

Procedure

The participants were asked for their consent prior to participating in the study. The participants were assured about the confidentiality of the information provided. 20 patients diagnosed with high normal BP (n=10, 5 male & 5 female) and stage 1 hypertension (n=10, 5 male & 5 female) were recruited from Department of Physiotherapy, G.J.U.S. & T., Hisar, by referral from the hospitals. A trained hospital staff and trained physiotherapy lab technician measured baseline data for various outcome measures for all subjects before the start

of the treatment process. Participants followed their usual medical treatment during the course of this study. Blood pressure and heart rate of the subjects was measured by using a Dr Morepen Blood Pressure Automatic Monitor Model. According to WHO 2013, subjects were asked to remain seated, positioning their left arm level with their heart, taking three measurements with at least a one minute gap between each measurement. In this study, mean systolic and diastolic BP were calculated using the average of three measurements. The four stages are normal blood pressure Stage (SBP≥120-129 mmHg; DBP≥80-89 mmHg), high normal HTN (SBP≥130-139 mmHg; DBP≥80-89 mmHg), Stage 1 HTN (SBP≥140-159 mmHg; DBP≥90-99 mmHg) and Stage 2 HTN (SBP≥160 mmHg; DBP≥100 mmHg).

Protocol

For Resistance training group, an experienced physiotherapist taught different types of exercise to the participants and after that they have done exercise in home based setting. Participants exercised 3 times per week for 8 weeks. Each session started with a 5 min warm up followed by eight exercises for major muscle groups- Push Up, Squatting, Sit-Up, Hamstring Curls, Trunk Extension in Quadrepod Position, Shoulder Press, Heel Raises and Bridging using body weight in sequence and followed 5 min cool down. Participants had performed 3 sets of each exercise per session. The progressive resistance training (PRT) protocol was designed to provide progressive increase in volume (6-8 repetition in first 2 weeks, 8-10 repetitions in next 2 weeks and 12-15 repetitions in last 2 weeks) and change in positioning (showing in Table 1-Annexure A). Participants of control group did normal daily activities without any specific training. Post intervention data was collected after completion of eight weeks of intervention for all outcome measures.

Table 1: 8 weeks resistance training Protocol

Type of Exercise	1-2 weeks	3-4 weeks	5-6 weeks	7-8 weeks
Push up	Wall push up	Table push up	Ground push up	Push up with weight
Squatting	Wall squat	Free squat	Lunges	Lunges with Weight
Sit-up	Sit-up with hand on side	Sit-up with hands on chest	Sit-up with hand behind neck	Sit-up with weight
Trunk Extension in Quadrepod	Trunk Extension in Quadrepod with hand raise	Trunk Extension in Quadrepod with leg raise	Trunk Extension in Quadrepod with hand & leg raise	Trunk Extension in Quadrepod with weight
Pull Up	Partial 50% BW*	75% BW*	100% BW* (Full hanging)	100% BW* (Full hanging)
Heel Raises	B/L** Heel Raises	U/L*** Heel Raises	U/L*** Heel Raises with weight	U/L*** Heel Raises with weight
Bridging	B/L Bridging with 10 sec hold	B/L Bridging with 20 sec hold	U/L Bridging with 5 sec hold to each leg	U/L Bridging with 10 sec hold to each leg

*BW-body weight; **B/L-Bilateral; ***U/L-Unilateral

Data analysis

Data were analyzed using IBM SPSS v21.0 software. An independent-samples t-test was conducted to compare the two groups (resistance and control). For a repeated measures design ANOVA test had been used. Results were explored as mean±SD. Data was reported with mean difference (MD) along with 95% confidence interval. Significant level set at "$p \leq 0.05$".

RESULTS

All participants were middle aged with age in between 30-45 years. Demographic details of participants were shown in table 2 (Annexure-A).

Table 2: Descriptive statistics of demographic characteristics

Group	Variables	Age (years)	Height (cm)	Weight(kg)	BMI**	WC*
Resistance training(RT)	Mean±SD	42.30±5.31	164.77±5.81	69.80±6.28	25.76±2.59	35.10±2.02
	Range	17.00	15.22	18.00	6.00	9.30
Control group	Mean±SD	39.80±3.22	166.06±12.5	68.20±12.23	24.59±2.38	35.10±2.60
	Range	10.00	30.48	38.00	8.50	8.00

*WC-waist circumference; **BMI-Basal metabolic rate

There was a significant gradual SBP reduction in resistance training (RT) group up to 6 weeks (MD -11.36, p=0.001 at 6 week), but insignificant rise in BP at 8 week (MD -10.85, p=0.03). Resistance training (RT) reduced DBP significantly upto 6th week (MD -6.36, p<0.001). When the resistance training (RT) results were compared with control, there was no statistically significant difference in BP (p>0.05).

In repeated measure of resistance group, when we compared Baseline SBP to 2nd week SBP (MD .27, p≥0.01; 95% CI -3.80-3.26), 4th week SBP (MD 7.82*, p≤0.01; 95% CI 1.74-13.9), 6th week SBP (MD 11.36*, p≤0.01; 95% CI 5.70-17.02) and 8th week SBP (MD 10.85, p≥0.01; 95% CI 1.28-20.4) then result is highly significant in contrast to control group up to 6th week but rise in BP seen after 6th week to 8th week. When we compared baseline DBP to 2nd week DBP (MD 0.0, p≥0.01; 95% CI -1.72-1.72), 4th week DBP (MD 3.18, p≥0.01; 95% CI -2.69-9.05), 6th week DBP (MD 6.36*, p≤0.01; 95% CI 4.13-8.60), 8th week DBP (MD 2.24, p≥0.01; 95% CI -3.53-8.02) then result is highly significant in contrast to control group at 6th week only.

DISCUSSION

The aim of study was to develop an exercise protocol for adults. Initially during 2 weeks, SBP and DBP rise because of the exercise pressor reflex to the cardiovascular center in the medulla from proprioceptors (mechanoreceptors and metaboreceptors) in active muscles. Arterial pressure rises to overcome the resistance to muscle perfusion caused by elevated intramuscular pressure interrupting arterial blood flow.[13]

The present study evaluated the effects of resistance exercise programs without dietary restriction on cardiac fitness variables such as blood pressure and heart rate. The results suggest that there was gradual reduction in SBP and DBP in resistance training group up to 6 weeks and was significant but during 6-8 weeks result is inconsistent (some patient's showed decrease in BP but rest showed increase in BP and the result was nonsignificant). The possible reason for this may be due to progression in intensity of exercise and it is not optimal for some patient. The findings of this study about the response of SBP and DBP to this resistance exercise protocol corroborate the results of Wilborn et al demonstrated that the BP is significantly higher after 85% of 1 RM than 65% of that 1 RM. They found no significant differences in the response of SBP between exercising at 65 and 85% of 1 RM.[14] The results of this study suggest that reasons other than mechanical compression and Valsalva maneuver may be the cause of the increase in BP due to the fact that 1 RM caused minor responses in BP and they concluded that the longer duration of exercise at 65% of 1 RM is most likely to cause the largest increase in SBP and HR at this intensity. Our study findings also supported by Mota and colleagues found 16 weeks of moderate intensity dynamic resistance training reduced SBP/DBP about 14/ 4 mmHg among 32 older women with controlled hypertension.[15] Moraes et al. found 12 weeks of moderate intensity dynamic resistance training reduced SBP/DBP approximately 16/12 mmHg among 15 middle-aged men with hypertension.[16] These findings suggest that moderate intensity and duration of dynamic resistance training may be viable as stand-alone antihypertensive lifestyle therapy among adults with hypertension.[17]

Strength of our study was stratification of sample i.e we included male & female hypertensive and high normal BP and stage 1 hypertensive patients, so results can be generalized to middle aged populations. To the best of our knowledge, we are first to study home based intervention in community dwelling hypertensive so this intervention saved time and benefit patients.

Limitation of our study was that duration of our study was relatively short for home based training but it was not possible to do long duration study in community and training of patients was not monitored although we had demonstrated it properly before start of treatment. But as there was significant reduction in blood pressure in resistance training group, result confirmed that patients had done it properly.

CONCLUSION

The results of the present study indicate that resistance training protocol is significant up to 6 weeks in reducing resting blood pressure but during 6- 8 weeks increase in BP revealed that volume or repetition of body weight resistance training exercise overload the patients so repiptition and intensity of exercise should be remained same as in 4^{th} to 6^{th} week. Hence we used this protocol as a preventive measure in patients who are at risk of prehypertensive and used in stage 1 hypertensive.

Management of Patient with Metabolic Encephalopathy – A Case Study

Ranjana Chavan[1], Manisha Vikrant Mistry[2]

[1]Nursing Tutor,, [2]Asst. Professor, Symbiosis College of Nursing, Symbiosis International Deemed University, Pune

ABSTRACT

The Metabolic Encephalopathy is a series of neurological disorders caused by systemic illness, such as diabetes, liver disease, renal failure and heart failure. Metabolic encephalopathy usually develops acutely or sub acutely. If left untreated, however, metabolic encephalopathy may result in secondary structural damage to the Brain. A 43 year-old patient was admitted to the ICU in a confused state with complaints of dyspnoea and weakness. On the day of admission, he complained of dry cough, fever, sore throat since 5 days accompanied by body ache, weakness and multiple episodes of vomiting since a day. On investigation, traces of ketones were detected in Urine and had increased PT-INR. Throat swab indicated Fungal stains. He had high fever and tachycardia. Tracheostomy was performed and was put on Ventilator to improve his respiratory functions. Nebulization was initiated BD. The case was reviewed for 5 days. His prognosis was very poor and deteriorating. His relatives were informed about his condition and the symptomatic treatment was continued.

Keywords: *Metabolic, encephalopathy, unconscious.*

INTRODUCTION

Encephalopathy is a difficult term because it can be used to denote either a disease or finding.[1]

The word metabolic encephalopathy was used for the first time in 1912 when Kinner Wilson tried to explain the state of global cerebral dysfunction. It is caused by systemic stress, that can vary in the clinical picture from a very mild disorder to a deep coma state with decerebrate rigidity.[2]

Metabolic encephalopathy is defined as a diffuse cerebral dysfunction, typically manifesting as changes in cortical functions and as disorders of consciousness, ranging from confusion to coma.[3] Others have suggested that metabolic encephalopathy is a temporary or permanent illness, more a symptom than a disease. It includes various forms of pathological conditions that are predominantly manifested by disorders of mental functioning. However, metabolic encephalopathy may also be defined as a systemic disorder with diffuse brain damage affecting the hemispheres, brain stem, and reticular activating system.[4]

Epidemiological and Demographic Data

Encephalopathy correlates with age. The number of patients with encephalopathy increase after the age of 65 years. People older than 75 years, who reside in nursing homes have 60% chance of developing encephalopathy, whereas in a population younger than 55 years, this proportion is 1.1%.[5,6] Encephalopathy occurs in 10–40% of hospitalized patients older than 65 years, whereas 8–70% of patients develop septic encephalopathy. According to a data from the United States, encephalopathy is being registered in 100–200,000 patients with anoxia and 12–16% of patients with thiamine deficiency, every year. In patients with cirrhosis, the development of hepatic encephalopathy is noted to be in 45–80% of cases, depending on the severity of liver damage.[1,5,6]

Etiology

Causes like Hypoxia, Ischemia, systemic disease, and toxic agents hepatic and renal insufficiency, pancreatitis, malnutrition, electrolyte imbalances sepsis, infection, vasculitis, and malignancy are common in majority of

the cases. Metabolic encephalopathy may also occur as a result of various toxic agents such as alcohol, sedatives (barbiturates, narcotics), psychiatric agents (tricyclic antidepressants, anticholinergics, phenothiazines), heavy metal poisoning, organic phosphates, and other drugs (anticonvulsants, corticosteroids, penicillin, etc.).[7,8]

Case Presentation of Metabolic Encephalopathy

A 43 year-old male patient was admitted to Intensive Care Unit in a confused state with complaints of dyspnoea and weakness. On the day of admission, he complained of dry cough, fever, sore throat since 5 days accompanied by body ache, weakness and multiple episodes of vomiting for 1 day. His medical history includes Diabetes, Hypertension and Hypothyroidism. Due to deteriorating condition manifested by irrelevant talk & breathing difficulty, he was shifted to Intensive Care Unit. The patient was thoroughly assessed; he was disoriented, had dyspnoea and high-grade fever. On investigation, traces of ketones were detected in Urine and had increased PT-INR. Throat swab indicated Fungal stains. A Rapid Sequence Intubation (RSI) was performed and patient was put on ventilator support to maintain respiratory function when he failed to maintain the saturation with CPAP. The patient was cautiously monitored and all the parameters were investigated as per the protocols.

Day 1

The patient presented with the complaints of dry cough, fever, sore throat since 5 days and accompanied by body ache, weakness and multiple episodes of vomiting since 1 day. He is a known case of Diabetes, HTN & Hypothyroidism. He had high fever (104.50F), Pulse – 140 beats/min and other vital parameters were normal. Patient was put on medications such as Tab Triolmesar 20 Mg OD, Tab Dimicron XR 60 OD, and Cap. Rifit CD OD. He was also put on IV fluids to correct the electrolyte imbalances.

Day 2

Patient shifted to Intensive Care Unit as his condition got worse with repeated dyspnoea & exhibited irrelevant talks. The patient was thoroughly assessed; he was conscious, irritable, confused, and had breathing difficulty. On examination there was a layer of pus formation on the buccal mucosa. His vitals were not stable with parameters like; temperature (1030F), Pulse (120 beats/min) and respiratory rate (24 breaths/min). His urinalysis reports depicted the positive for ketone bodies, elevated PT-INR and RFT values. His HBA1C level was 8.7. Pus drained and sent for investigation. He was put on CPAP to improve his respiratory functions and a RT was inserted for enteral feeding.

Day 3

Patient had altered levels of consciousness with dysarthria but was able to express in writing. ABG analysis & Blood sugar was monitored every 4 hours. There was no significant difference in hemodynamic parameters. Gradually his condition worsened and he became unconscious. The congestion in throat increased due to abscess formation and inflammation and later festering was seen. Due to this, RSI was performed and patient was put on ventilator. Nebulization was initiated BD. The prognosis was intimated to his relatives.

Transthoracic Echo Report depicted the following findings:

Left Ventricular Hypertrophy

Chamber Dimensions are normal

No regional wall motion abnormality is seen

Normally LV Systolic function; LVEF - 60%

No Pulmonary HTN

Normal Valves

No clots/vegetation/effusion

Impression:

Poor echo window

Left ventricular hypertrophy

DISCUSSION

The 43 year-old male patient admitted in Intensive Care Unit in confused state with complaints of dyspnoea and weakness. On the day of admission, he complained of dry cough, fever, sore throat since 5 days accompanied by body ache, weakness and multiple episodes of vomiting since 1 day. On investigation, traces of ketone bodies was detected in Urine and had increased PT-INR. Throat swab indicated Fungal stains. Patient was put on medications like Tab Triolmesar 20 Mg OD, Tab Dimicron XR 60 OD, and Cap. Rifit CD OD. He was also put on IV fluids to correct the electrolyte imbalances. On 3rd day, Patient's was in a state of confusion. Gradually his condition worsened and he became unconscious. The congestion in throat increased due to abscess formation and inflammation. An emergency tracheostomy was performed and patient was put on ventilator.

Similar case was encountered with a 29-year old man who presented within the thrombolysis time window to the emergency department (ED) with sudden-onset dysarthria, ataxic and left-sided weakness while smoking cannabis. He was assessed in the ED and found to have a NIHSS of 3. A CT brain scan and extra cranial CTA revealed no significant findings, however, as he was clinically improving, he was not given intravenous thrombolysis. Subsequent MR brain imaging confirmed marked acute bilateral white matter changes typical of drug-induced encephalopathy.

His initial lab investigations were normal. His thyroid function responded well to treatment with Carbimazole, Propanolol and Hydrocortisone and improved rapidly and was discharged with counselling on cannabis use but re-presented twelve hours later with worsening dysphagia, dysphonia, breathlessness and bilaterally weak upper limbs and requiring intensive care support. His symptoms significantly improved and

he was followed up by the endocrinology team.[9]

Multiple Massive Maxillary Exostoses – A Case Report with Complete Denture Rehabilitation

Ramesh Kumaresan[1], Balamanikandasrinivasan C[2], Priyadarshini Karthikeyan[3], Vini Rajeev[4]

[1]Associate Professor, Academic Unit of Craniofacial Clinical Care, AIMST University, Faculty of Dentistry, Jalan Semeling-Bedong, Bedong, Kedah, Malaysia, [2]Reader, Department of Oral and Maxillofacial Surgery, Vinayaka Missions Sankarachariyar Dental College, Salem, Tamil Nadu, India, [3]Lecturer, Department of Oral Medicine and Radiology, [4]Senior Lecturer, Department of Prosthodontics, AIMST University, Faculty of Dentistry, JalanSemeling-Bedong,08100Bedong, Kedah, Malaysia

ABSTRACT

Exostoses are benign, asymptomatic bony outgrowth arising from cortical bone and occasionally from spongy bone along the maxillary or mandibular arches. They tend to appear in early adolescence and may very slowly increase in size with age. Theyare not usually a concernto a patient with complete dentition. However, in an edentulous patient they may pose a major concern for denture placement over these areas, leading to pressure and ulceration, which demands their complete surgical excision. The following article presence a rare case ofbilateral massive buccal exostoses, which was incompatible with the patient ability of prosthetic rehabilitation and hence a resective osseous surgery was carried outfollowed by a complete denture rehabilitation.

Key words: *Bony outgrowth, complete denture, Exostoses*

INTRODUCTION

Natural tooth lost due to various reasons has to be restored by artificial means to rejuvenate the esthetic and functional profile of human face. However, in patients who cannot afford for implants, complete and partial dentures still remains the most popular modality of prosthetic replacement.[1] In situations where bony irregularities such as bony exostoses, tori occur the need for surgical correction becomes mandatory. These anatomical abnormalities which are more common in certain races such as Malaysians tend to remain insignificant in healthy dentition but become enigmatic in edentulism by interfering with denture fabrication.[2] Besides that, these bony prominences can compromise the oral health of the individual by traumatizing the overlying thin soft tissue. Hence the host bed (the alveolar bone and related soft tissues) has to be modified to an extent where the prosthesis can be accommodated without any compromise. Herewith a case of massive exostoses has been presented with complete denture rehabilitation.

CASE PRESENTATION

A 59-year-old, healthy male patient presented for a prosthetic rehabilitation of his missing teeth. On examination, the patient was partially edentulous with few mobile teeth and root stumps, necessitating extraction of the remaining teeth and replacement with a complete denture. Besides, intraoral examination also revealed multiple overgrowths located on the buccal aspect of the maxilla in the premolar and molar areas on the left side and from the canine to molar region on the right side. All the mucosal surfaces over the lesion appeared to be healthy[Figure 1].On palpation the lesions were bony-hard, lobulated, measuring approximately 2.5 cm x 1.5 cm on either side. The patient had not noticed this mass before since it did not interfere with his speech,

chewing, phonetics or other oral functions. He had no significant past medical history or family history of similar lesions. However, when enquired regarding his dietary habits, being a fisherman, almost every meal included consumption of seafood in various forms.

Radiographic examination showed multiple well-defined radiopaque areas in the premolar and molar region bilaterally [Figure 2]. A maxillary occlusal radiograph also revealed that these masses were the bony thickening of the cortical plate on the buccal surface of the maxilla [Figure 3].These enlargements of the cortical plate of the buccal surface of the maxilla without any systemic abnormality confirmed the diagnosis of bilateral buccalexostoses.

In view of the complete prosthetic rehabilitation, aresective osseous surgery was planned to excise the bony masses following the extraction of the remaining teeth. After explaining the potential risks and benefits of surgery, an informed consent was obtained from the patient. In the first appointment all the remaining teeth were extracted under local anesthesia. During the second appointment preprosthetic surgery was planned on the right side and in the following appointment surgery was planned for the lesion on the left side. Three weeks elapsed between each appointment.

After giving appropriate local anesthesia, a full thickness mucoperiosteal flap was reflected for a complete access to the exostoses by giving crestal incision and vertical releasing incisions [Figure 4]. Segmental removal of bony exostoses was done with carbide bur under copious irrigation followed by smoothening and debridement of surgical bed (to clear out the osseous debris) with football diamond bur and saline irrigation [Figure 5,6].The flap was sutured with 3-0 black silk. Pressure was given on the operative site with wet gauze to prevent fluid accumulation and also to facilitate adhesion of periosteum to the underlying bone. Routine postoperative instructions were given. Medications including systemic antibiotics and analgesics were prescribed. The sutures were removed after 1-week. As healing was uneventful bilaterally, [Figure 7] patient was recalled for complete denture rehabilitation after 4 weeks [Figure 8].

DISCUSSION

Anexostosis is a benign, localized, peripheral overgrowth of bone which frequently occurs in long bones where tendons and muscles are inserted. In the jaw bones it may be a nodular, flat or pedunculated protuberance located on the alveolar surface. Maxilla is shown to exhibit the highest prevalence rate of 5.1:1 in comparison to mandible and a male predominance with an incidence of 1.66:1 among the genders. Prevalence of exostosis varies greatly depending on the population studied, with higher incidence in mongoloids than in Caucasoid. Depending on the anatomical locationthey are termed as torus palatinus (midline of the hard palate), torus mandibularis (lingual aspect of mandible), or buccal/palatal bone exostoses.[3]

Buccalexostoses occur along the buccal aspect of the maxilla or mandible, usually in the premolar and molar regions yet occasionally they may occur in other parts of the jaw. Palatal exostoses are found on the palatal aspect of maxilla, most commonly in the tuberosity region.[3] These exostoses may present either as a smooth bulging of the bone surface continuous with the adjacent area or as discrete, multilocular spherical projections with a broad base that forms a nodular cluster in the similar form noted in our patient.[4]

Glickman and Smulow further classified buccal alveolar bone enlargement in to exostosis and lipping. Though their etiology is unclear, the authors considered it as buttressing bone formation in response to trauma from occlusion and suggested that bone formation occurs to reinforce bony trabeculae for functional adaptation.[5]

Though the etiology of exostosishas been investigated by several authors, no consensus has been reached. Several authors have postulated the etiology to be multifactorial where there is an interaction of genetic and environmental factors, masticatory hyperfunction and continued growth.[3] Gorsky et al. postulated that the etiology of osseous outgrowth might be multifactorial, including environmental factors acting in a complicated and unclear interplay with genetic factors. The quasi-continuous genetic or threshold theory states that the environmental factors must first reach a threshold level before the genetic factors can express themselves in the individual; hence both genetic and environmental factors determine expressivity, making the etiology multifactorial.[3] Literature reveals that the prevalence of these bony enlargements increases with age, indicating a relationship between age and their occurrence.[6] It has also been theorized that because some of these outgrowth are found with some frequency during the middle phase of life, suggesting an environmental and functional factors, particularly those related to masticatory stress.[6] A correlation between the presence of these bony enlargement in patient with parafunctional habits has also been demonstrated. Other causative factors include dietary habits (taking supplements or food rich in calcium) and nutritional disturbances.[7] Eggen et al. suggested saltwater fish consumption to be related to these on outgrowths, probably due to higher levels of polyunsaturated fatty acids and Vitamin D that is involved in bone growth.[8] In our patient, it was difficult to distinguish the true origin of the exostoses since it was on an edentulous region, presence of few attrited teeth and consumption of seafood may suggest masticatory hyperfunction and saltwater fish consumption as

cofactors in origin of the exostoses.

Patients with exostoses seldom complain of unaesthetic appearance, speech difficulties due to limited tongue movement and food lodgment leading to malodor. Few patients may experience trauma or ulceration when masticating hard or sharp food as the mucosa covering the bony protuberances is reported to be thinner than the surrounding mucosa.[9] Hence, when a patient presence with exostoses the overlying mucosa might have a normal appearance, but may appear whitish or ulcerated if exposed to any trauma. Furthermore, recording oral impressions and seating of dentures are difficult in these patients.

The diagnosis of a buccalexostosis is generally done by simple clinical examination. However, radiographs might be required in situations where the bony protuberances are extremely large, or multiple, or vary in consistency to rule out underlying bone pathology. Radiographic appearance will show a normal bony pattern or a slightly radiodense image with a higher density than that of the surrounding bone.[9] In our patient, orthopantomograph and maxillary occlusal radiographs were taken which revealed multiple radiodense masses near premolar and molar region bilaterally. Though not mandatory, few authors have suggested taking a cone-beam computed tomography as a helpful diagnostic tool to identify anatomical variations in exostosis. [10] Additionally, it can also be helpful in assessing the relationship of the exostosisto maxillary sinus.

Distinction between exostoses and similar pathology arising from gingival enlargement and bone outgrowths remains important. Other differential diagnoses include osteomyelitis, osteoma, osteosarcoma, osteochondromas, organized subperiosteal hematoma, mature ossifying fibroma, periosteal osteosarcoma, chondrosarcoma, sclerosteosis, fibrous dysplasia, Paget's bone disease.[1]

Patient with multiple bony growths or lesions not in the classic torus or exostoses location should be evaluated for Gardner's syndrome. This autosomal dominant syndrome shows other features like multiple osteomas, sebaceous cysts and soft tissue tumours of skin, intestinal polyposis and multiple impacted supernumerary teeth.[1] Though our patient presented with multiple exostoses, absence of other associated features ruled out the diagnosis of Gardner's syndrome.

Due to their benign nature, most exostoses do not require treatment unless any esthetic problems, functional problems or discomfort in hygiene maintenance or phonetics are raised by the patient. Other reasons for surgical intervention include periodontal or prosthodontics complications.[11] In our case surgical extirpation was necessary for prosthetic rehabilitation and hence decided to surgical remove the exostoses.

When treatment is elected, the exostoses may be chiseled off or removed by bone-burr cutting. Conservative surgical removal with bony recontouring is the treatment of choice, with occasional recurrences expected.[1] Besides, these exostoses masses can be used as a source of autogenous bone graft for correction of intraoral bone defects.The possible complications after surgery include hematoma, edema, wound dehiscence, oro-antral communication and infection. However, our patient did not encounter any such complications. Biopsy for diagnostic support is usually not recommended. However, biopsy of the excised mass shall be performed if there is any dilemma regarding diagnosis.

CONCLUSION

Rehabilitation of edentulous mouth is an arduous task especially in the presence of substantial anatomical interferences. Since in our patient the radiograph depicted adequate bone between the exostosis and maxillary sinus, total removal was feasible. Treatment planning and management often involves multidisciplinary approach comprising specialties from prosthodontics and oral surgery. The present case demonstrates that complete excision of huge exostoses can be accomplished with predictable results and least postoperative sequela. Radiographs should be used as an aid wherever necessary and a segmental approach has been recommended during surgical removal in the presence of massive exostoses to avoid oro-antral communication.

A Hybrid Ensemble Classification Approach to Determine the Impact of Asthma in Association with Gastro Esophageal Reflux Symptoms

K.Kasturi [1], S.Prasanna[2]

[1]Research Scholar, Department of IT, [2]Associate Professor, Department of Computer Applications, VISTAS.

ABSTRACT

Objectives: This implementation work focuses on the predicting severity of respiratory problems of asthmatic patients from the dataset of the PFT report with the significant parameters of Gastro Esophageal Reflux symptoms (GER).

Methodology: The pulmonary functionality test (PFT) report of the asthmatic patients is associated with the significant parameters of GER symptoms to determine the impact of GER symptoms on asthma using a proposed hybrid ensemble classification.

Methods/Statistical Analysis: Using R statistical tool a model has been developed for ensemble classification by stacking the SVM and Random Forest algorithms and boosting with the improved Gradient Boosting algorithm.

Findings: It has been identified that the asthmatic patients who have been reported as 'normal' or 'mild' in the PFT report also have the respiratory problems often and urge for frequent check – ups. This can be due to the implications of significant symptom parameters of GER.

Applications: The outcome of the developed model HMMC describes about the classification accuracy of the applied dataset of the asthmatic patients with GER symptoms and predicts the severity of asthma in asthmatic patients more accurately rather than the outcome of the existing classification techniques.

Keywords: *boosting, asthmatic Patients, PFT, GER, ensemble classification, HMMC.*

INTRODUCTION

Prediction and assortment of medical datasets serve in reducing the count of diagnostic issues to recognize the diseases there by affording economical solutions for healthcare systems and medical diagnosis software system. Data pre-processing operates an essential role in prime powerful and capable data for data mining. Feature selection aid in contributing essential characteristics for construction of extensive predictive models. The processing of medical data mining has more potential for exploring the hidden patterns in the knowledge sets of the medical domain. These patterns will be used for clinical diagnosing. However, the obtainable raw medical knowledge is heterogeneous and voluminous in nature. This collected information is often integrated to give a user orienting approach to novel and hidden patterns within the information. In my previous work the significant parameters of the GER symptoms have been identified [1] . And this work deals with the implications of the significant GER parameters of the asthmatic patients with their PFT report value. This leads to the way to find the accuracy of the classification prediction.

EXISTING METHODOLOGY

Chun-Rong Huang et al [2] proposed that "GER can be diagnosed by typical symptoms of acid regurgitation or heartburn sensation at the epigastric or mid chest regions".E.A.Boiler et al [3] proposed that "In western countries, 10–30% of the population experiences symptoms of gastro esophageal reflux (GER)". Sudha Pandit et al [4] propose that "The prevalence of GER

is primarily based on the acid reflux symptoms and these symptoms are not always present in patients with endoscopic evidence of esophagitis". D. Vincent et al [5] proposes that "Gastro-esophageal reflux (GER) has been suspected as a causal factor, but the relationship between GER and asthma remains controversial". The existing work focuses only upon the environmental factors such as living, working environment and parental history as the main causes of respiratory diseases [6] .But the fact is GER may cause, trigger or exacerbate pulmonary disease like bronchial asthma and many other diseases.

PROPOSED METHODOLOGY

A questionnaire can be scientifically accepted by following the standard criteria such as valid, responsive and reliable and it is well determined and established by psychometric methods elsewhere. Such a questionnaire is often administered directly by the patient, filled in, and is straightforward to know as these attributes guarantee prime quality information assessment. The GER symptoms are not always known in the endoscopy test and at the same time the asthmatic patient reported as 'normal' is not always having the normal respiration. This is due to the fact that GER has implications over asthma. This leads to conduct a prospective assessment of GER prevalence in a population of asthmatic patients and to find the prediction accuracy of severity of asthma using the proposed classification model called Hybrid Meta Model Classification(HMMC).

SELECTION OF ALGORITHMS

Random Forest is the flexible machine learning algorithm and produces accurate result with hyper parameter tuning. This supervised learning algorithm builds multiple decision trees, merges them together to get a more accurate and stable prediction [7]. It can also handle missing values and large dataset with higher dimensionality effectively [8].Support Vector Machine (SVM) is used in binary classification and also applied for pattern recognition and it is a promising classification approach for prediction purpose [9].

DATASET DESCRIPTION

- The PFT results for the asthmatic patients are got as raw data as .xps files from the Asthma and Allergy Resource Centre, Chennai, Tamil Nadu, India. Around 2000 raw data has been collected and entered in a spread sheet and stored as .csv file.
- The GER symptom parameters have been assessed to the above asthmatic patients through the questionnaire form and entered in a spread sheet and stored as .csv file.

The resultant significant GER symptom parameters from my previous research work and the PFT report data are taken under consideration for the purpose of classification.

The dataset comprises of

- PID(Patient ID)
- Age
- Gender
- Heartburn (GER symptom)
- Dysphagia (GER symptom)
- Nausea (GER symptom)
- PFT Report
- FreqCheckup

Heartburn	Dysphagia	Nausea	Report	Freq Checkup
voften often noften notAtAll	voften often noften notAtAll	voften often noften notAtAll	normal mild severe	yes no

Table 1: Possible values of attributes

EXPERIMENTAL RESULTS

CLASSIFICATION TREE

The Classification tree has the structure of a flowchart in which each node represents a condition test on an attribute and that each branch indicates the outcome of the condition test. Each terminal or leaf node indicates the class labels**.** Fig 1 shows the distribution of class labels of the PFT report with GER key attributes.

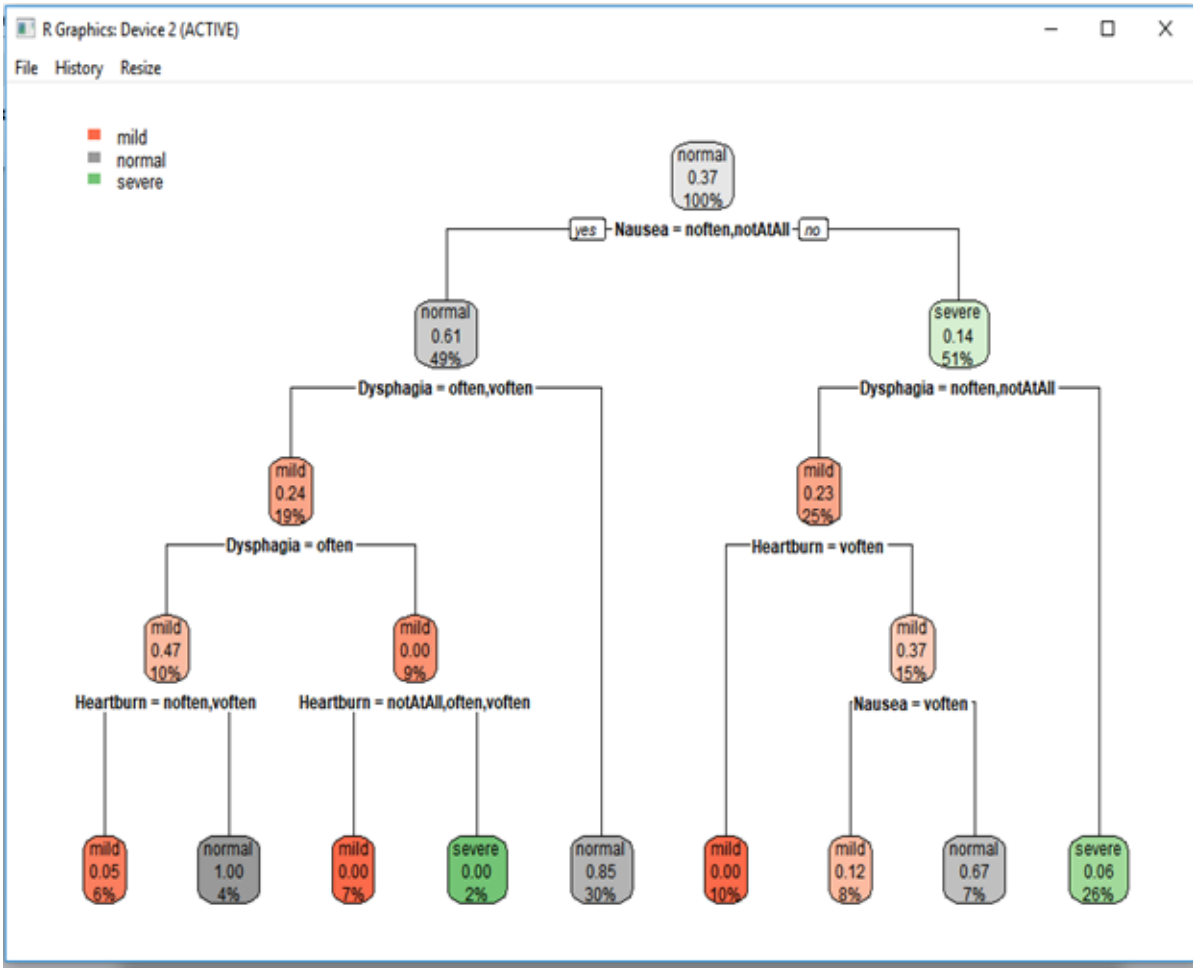

Fig 1: Classification Tree

CLASSIFICATION ALGORITHMS

In random forest algorithm the importance of a variable can be estimated by looking the rate of increase in prediction error when data for that variable is permuted while all the others are left unchanged. The calculations are carried out tree by tree as the random forest is developed [10].

"SVM converges fast and leads to high accuracy. When scores of multiple parameter datasets are combined, majority voting reduces noise and increases recognition accuracy" [11]. It also includes avoidance of over fitting effectively [12] .The built SVM model has the accuracy of 94.85% [Fig 2] and the accuracy of the Random Forest model has the greater accuracy of 95.15% [Fig 3].

BOOSTING ALGORITHMS

C5.0 is the extension of C4.5 algorithm. It gives a binary tree or multi branch tree and uses the gained information for splitting criteria. For estimating missing values it uses other attributes .It represents how the rules are generated with high accuracy and low memory usage [13] .Stochastic Gradient Boosting

is one of the powerful classification algorithms that attains maximum accuracy 96.97% whereas the accuracy of C5.0 is 93.64% which is lesser than SGB. SGB is powerful in terms of classifier and prediction at less execution time.

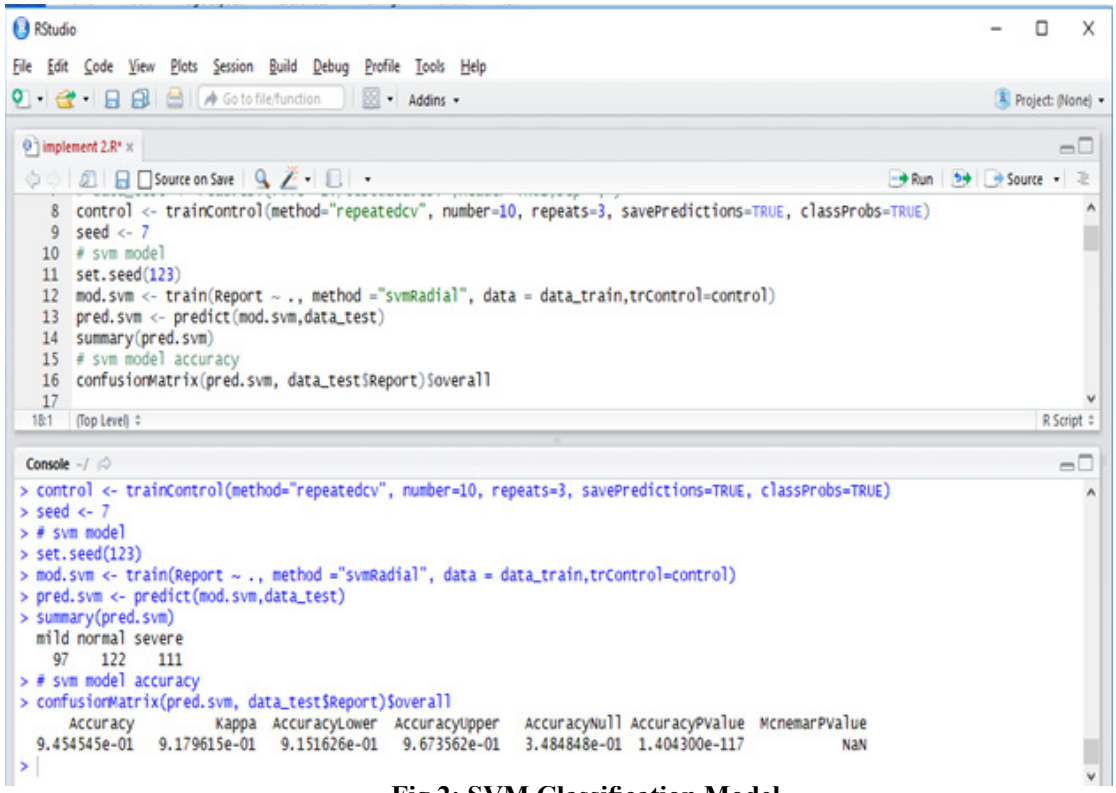

Fig 2: SVM Classification Model

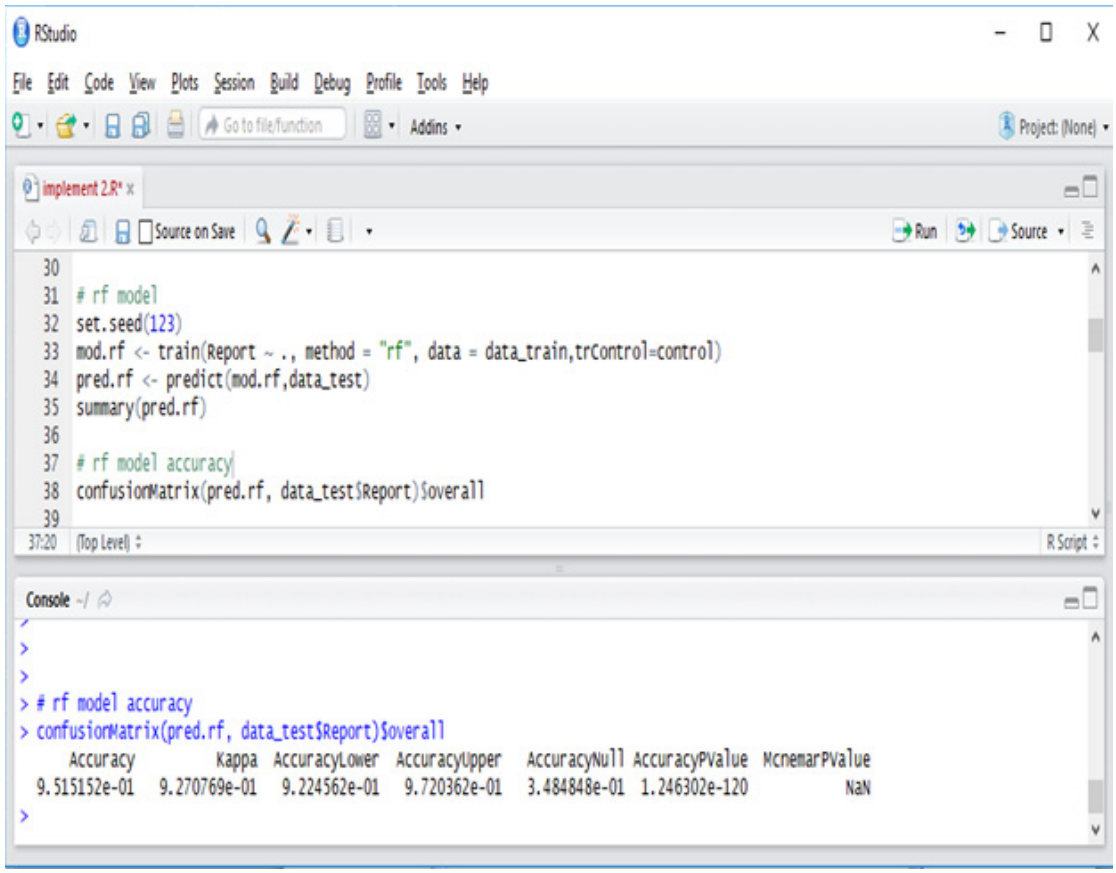

Fig 3: Random Forest Classification Model

PROPOSED MODEL

The hybrid function model can be generated for the predictive purpose with less error and high accuracy without affecting the data consistency [14]. Hybrid model reduces the diagnostic procedure to identify the diseases and to mine the hidden pattern of knowledge [15]. A Hybrid model is needed to diagnose the complexity of disorders and requires more empirical evidences before incorporated into clinical practise [16].

HYBRID META MODEL CLASSIFICATION (HMMC)

Step 1: Splitting the dataset into training and testing data.

Step 2: The developed Random Forest Classification Model and the SVM Classification Model is Combined by the ensemble classification technique called Stacking.

Step 3: Then the stacked outcome is fed into another ensemble classification technique called **Boosting.**

Step 4: The Boosting concept is implemented by the proposed **Improved Gradient Boosting algorithm** to get the maximum accuracy in less time.

PERFORMANCE ANALYSIS

Model Built Using	Accuracy
SVM	94.84.%
Random Forest	95.15%
HMMC	99.4%

Table 2: Classification Accuracy

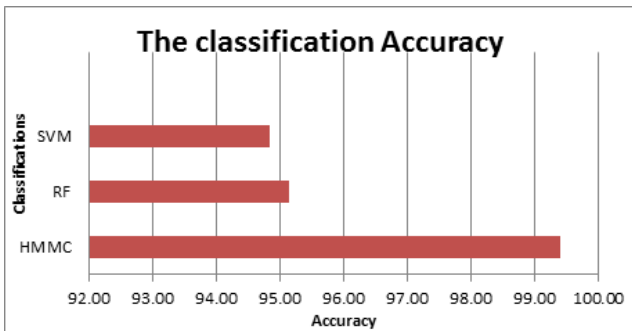

Fig 4: Classification Accuracy Graph

From the Fig 4 the classification accuracy depicts that the proposed model HMMC has the maximum accuracy rather than the existing classification techniques.

CONCLUSION

From the above implementation it has been interpreted that the results of the proposed ensemble model classification HMMC shows improved overall classification accuracy significantly rather than the existing model classification accuracy. This model confirms that the significant GER symptom parameters have high impact on asthmatic patients. Even though the asthmatic patient's PFT report says the condition of the patients as normal or mild, the existence of the significant GER symptom parameters makes the patient's respiration more worst and their by urging them for frequent check-ups.

Ethical Clearance-Not Required (only getting the test report from the hospital).

Prevalence of Dysmenorrhea among Female Medical Students and its Impact on their Day to Day Activities

Preetha Paul[1], Arul Sekary[2], Kannan I[3]

[1]Associate Professor, Department of Physiology, Tagore Medical College and Hospital; [2]CRRI, Tagore Medical College and Hospital; [3]Associate Professor, Department of Microbiology, Tagore Medical College and Hospital, Rathinamangalam, Chennai

ABSTRACT

Background: Dysmenorrhea refers to painful menstruation with associated symptoms such as backache, headache etc. and is quite common among young women. In many, it hampers normal day to day activities resulting in lost work-hours.

Aim: This study was taken up to estimate the prevalence of dysmenorrhea among female medical students, its impact on sufferers' daily activities and their knowledge of treatment options.

Materials and Method: This was a cross-sectional study conducted among 150 medical students of ages 18 – 21 in Tagore Medical College, Chennai. All subjects were given a questionnaire with questions pertaining to pain during menstruation, its severity, other associated symptoms, effect on day-to-day activities as well as management options. Using information from the questionnaire, grading of subjects into mild, moderate and severe dysmenorrhea was done.

Results and Discussion: Overall prevalence of dysmenorrhea among the study population was found to be 72.67 % with commonest symptoms associated being headache (88%) and backache (64%). Of the dysmenorrheic population, 42% had mild, 39% had moderate and 19% had severe dysmenorrhea. Low class concentration (59%), class absenteeism (34%), college absenteeism (20%), limitation of social activity (52%) and curtailment of sporting activities (57%) of sufferers were found, all of these being more in the severe dysmenorrhea group. Regarding knowledge of medication, only 12% and 20% knew that paracetamol and mefenamic acid were treatment options. Dysmenorrhea was managed mainly by rest (52%) while 19% used analgesics. The majority considered dysmenorrhea to be a normal female experience and did not think it warranted any treatment.

Conclusion: Painful menstruation is considered to be a normal female experience by young female medicos. They need to be educated on effective management methods and given knowledge of appropriate medications so that dysmenorrhea will no longer be the cause of lost work hours or poor quality of life.

INTRODUCTION

In the world of today, where women have made significant strides in education and professional growth, it appears that dysmenorrhea is one burden many of them continue to carry. Dysmenorrhea is quite common among young women. Shaw's textbook of gynaecology

defines dysmenorrhea as "cramping pain accompanying menstruation".[1] It is associated with symptoms such as lower abdominal pain, backache, pain in the thighs, nausea / vomiting, fatigue, headache, lightheadedness and even diarrhea.[1,2] In many young women, dysmenorrhea is so severe that it hampers their normal activities one to two days every month and is a major reason for school and college absenteeism.[2,3]

Going by the findings of different studies, the prevalence of dysmenorrhea appears to vary greatly between 45 and 95%[4] depending on the population under study and method of data collection. Many women, however, consider dysmenorrhea to be a normal phenomenon and do not feel it merits medical attention. Untreated dysmenorrhea results in lost work hours in schools, colleges and offices. It affects the person's personal and family life, and has social and economic consequences as well.[3]

This study was taken up to determine the prevalence of dysmenorrhea among female medical students in Tagore Medical College, Chennai, its impact on sufferers' daily activities and knowledge of treatment options.

MATERIALS AND METHOD

The study was done among 150 female first and second year medical students at Tagore Medical College and Hospital, Chennai, Tamil Nadu, using a cross-sectional study design and simple random sampling. Ethical approval was taken from the institutional ethical committee. Healthy unmarried nulliparous female students of age ranging from 18-21 years were included in the study after obtaining written consent from them. Students having polycystic ovarian disease, dysfunctional uterine bleeding, primary amenorrhea, any pelvic pathology, secondary dysmenorrhea or any other gynecological disease were excluded from the study.

Data collection:

After obtaining written consent from the participants, the structured and validated study questionnaire was administered. It carried questions on details pertaining to the menstrual cycle, pain during menstruation, its severity and other associated symptoms, effect on day-to-day activities as well as management options.

The severity of menstrual pain was estimated by the visual analogue scale and scoring for severity of dysmenorrhea was done based on information from the questionnaire using the multidimensional scoring system of Andersch and Milsom.[5] This system grades dysmenorrhea into mild, moderate and severe based on the pain score, effect on daily activities and requirement for analgesia. In mild dysmenorrhea, there is mildly painful menstruation, but daily activities are hardly affected and analgesia rarely required. The moderate category has more painful menstruation so that daily activities are curtailed. However, analgesics help to manage the symptoms. In severe dysmenorrhea, the menstrual pain is severe with associated vegetative symptoms, daily activities are clearly affected and analgesics are not effective.

Statistical analysis:

Data was entered in Excel sheet and analysis was done using SPSS software. Statistical analysis was performed using appropriate tests such as student t test and chi square. P value of < 0.05 was taken as statistically significant.

RESULTS AND DISCUSSION

A total of 150 students took up the questionnaire and all of them completed it. Overall prevalence of dysmenorrhea among the study population was found to be 72.67 % (109/150), while 27.3 % (41/150) said they experience no menstrual pain.

Cycle characteristics of the dysmenorrheic women are shown in Table 1. Of the 109 dysmenorrheic students, 102 reported normal cycle lengths; 22% reported a longer than normal duration of period; 10% reported using five or more pads per day and an overwhelming 58% reported the passage of clots in menstrual blood.

Table 1: Cycle characteristics in dysmenorrheic women

Parameters		Women with dysmenorrhea (n = 109)	Percentage
Age at menarche	<= 11 years	8	7.3
	12 to 14 years	90	82.6
	>14 years	11	10.1
Cycle length	21 to 35 days	102	93.6
	>35 days	5	4.6
	Don't know	2	1.8
Duration of period	<=5 days	85	78.0
	>5 days	24	22.0
Pad usage per day during menstruation	< = 4	98	89.9
	5 to 7	11	10.1
Presence of clots	Yes	63	57.8

Table 2 lists associated symptoms present along with their frequency. The commonest symptoms were headache (88%), backache (64%), abdominal cramps (64%) and mood changes (39%). Fatigue occurred in 27.5%. In the study by Singh et al fatigue occurred in 70.9%, backache in 62% and headache in 26.6%.[6] A study done among Thai adolescents showed abdominal cramps at 78 %, backache at 59%, mood changes at 57% and fatigue at 43%.[7]

Table 2: Associated symptoms in dysmenorrheic women

Symptoms	Women with dysmenorrhea (n = 109)*	Percentage
Headache	96	88.1
Backache	70	64.2
Abdominal cramps	70	64.2
Mood Changes	42	38.5
Fatigue	30	27.5
Nausea	20	18.3
Loss of Appetite	19	17.4
Diarrhoea	09	8.3
Fainting	09	8.3
Dizziness	07	6.4
Vomiting	05	4.6

*Most women had more than one symptom

Of the dysmenorrheic population in our study, 42 % (46) had mild dysmenorrhea, while 39 % (42) belonged to the moderate category. Nineteen percent (21) of the students had severe dysmenorrhea (Table 3). The prevalence of dysmenorrhea among 18-21 year old nursing students in Mumbai was reported to be 45% with 18% having mild dysmenorrhea, 40% having moderate and 42% having severe dysmenorrhea[8] while another study done in three medical colleges in India reported 73% prevalence with 63.3% having mild, 30.4% having moderate and 6.3% having severe dysmenorrhea.[6] A study done among adolescents in Rajasthan reported a rural prevalence of 81.5% and an urban prevalence of 76 %.[9] Of the rural category, 52 % had mild, 26.5 % moderate and 3 % had severe dysmenorrhea.[8] Of the urban group, 56.5 % had mild, 12.5 % moderate and 7 % severe. A Gwalior study reported an incidence of 79.6 % dysmenorrhea among adolescents there.[10] Our findings

are comparable with these earlier estimates.

Table 3 shows the impact of dysmenorrhea on the day to day lives of affected young women. We found 59% being affected by low class concentration overall among the dysmenorrheics with 85.7% from the severe category, 78.6% from the moderate and 30.4% from the mild category. These differences were statistically significant (p=0.000). The Thai study found a total of 63.6% of dysmenorrheics suffering from poor class concentration with 51.4% from the mild group, 73.4 % from the moderate group and 87.1% from the severe group being affected.[7]

Class absenteeism stood at 90.4% among the severe, 35.7% among the moderate and 6.5% among the mild dysmenorrheics. 76.1% of severe dysmenorrheics and 9.5% of moderate dysmenorrheics had to miss a whole day of classes. These differences also were found to be statistically significant (p=0.000). The Thai study showed 80.6% of the severely dysmenorrheic, 27.7% of the moderate and 11.7% of the mild group missing classes.[7] Singh's study revealed 31.64% college absenteeeism among dysmenorrheics and 8.9% class absenteeism.[6] Our study also found that normal daily activity was curtailed in 53% of the dysmenorrheics with 95.2%, 76.2% and 13% of the severe, moderate and mild categories respectively being affected. Social activity also was limited in 52% of sufferers and sporting activities in 57%. Singh et al found an overall 67.1% of subjects reporting withdrawal from academic, social and sports activites.[6]

Table 3: Impact of dysmenorrhea on students' daily activities

	Grade of Dysmenorrhea				
	Severe n = 21	**Moderate n = 42**	**Mild n = 46**	**Total n = 109**	**P value**
Low class concentration*	18 (85.7 %)	33 (78.6 %)	14 (30.4 %)	65 (59.6 %)	.000
Class absenteeism*	19 (90.4 %)	15 (35.7 %)	3 (6.5 %)	37 (33.9 %)	.000
College absenteeism for the whole day*	16 (76.1 %)	4 (9.5 %)	0 (0 %)	20 (18.3 %)	.000
Limits normal daily activity*	20 (95.2 %)	32 (76.2 %)	6 (13.0 %)	58 (53.2 %)	.000
Limits social activity*	14 (66.7 %)	33 (78.6 %)	10 (21.7 %)	57 (52.3 %)	.000
Limits sport activity	13 (61.9 %)	28 (66.7 %)	21 (45.7 %)	62 (56.9 %)	.121

* statistically significant

For management of dysmenorrhea, resting appears to be the preferred method with 52% opting for the same. 21% did nothing, while 19% used analgesics (Table 4). Other home remedies like heating pads and herbal remedies were used by 7% of the dysmenorrheics. In a study at a university in Ankara, 69% of female students used analgesics, 56.5 % used heat application and 71.4 % took rest to manage menstrual pain.[11] The Thailand study found 92% of dysmenorrheics opting for rest, 34% using heating pads and 32% using analgesics.[7]

Of the dysmenorrheic population in our study, 54% had no knowledge of pharmacologic agents that could be used for pain management in dysmenorrhea (Table 4). Only 12% and 20% knew that paracetamol and mefenamic acid were treatment options. Around 12.8% were aware of naproxen and other NSAIDs. In the Thai study, awareness levels were much higher at 98.8% for paracetamol and 85% for aspirin, though only 6% knew about mefenamic acid.[7] Our population has very low awareness regarding analgesics and their use in dysmenorrhea.

Table 4: Management methods and knowledge regarding pharmacologic agents for dysmenorrhea

Management of Dysmenorrhea		
	Frequency	**%**
Nothing	23	21.1
Only Rest	57	52.3
Rest and Analgesics	21	19.3
Other Methods	8	7.3
Knowledge of Drugs		
None	59	54.1
Paracetamol	14	12.8
Mefenamic Acid	22	20.2
Others	14	12.8

Surprisingly, 96% of mild, 93% of moderate and 67% of severe dysmenorrheics considered dysmenorrhea to be a normal female experience and did not think it warranted any treatment (Table 5). Only 4%, 7% and 33% of mild, moderate and severe dysmenorrheics respectively felt that they need not suffer, but could seek medical help to alleviate their pain. These findings were comparable with those of the Thai study.[7] This shows that an overwhelming majority of young women look on dysmenorrhea as normal and only a very small percentage opt for treatment.

Table 5: Attitude towards dysmenorrhea

	Grade of Dysmenorrhea			
	Severe (n = 21)	**Moderate (n = 42)**	**Mild (n = 46)**	**Chi Square P value**
Normal female experience	14 (66.7%)	39 (92.9%)	44 (95.7%)	.001
I need not suffer	7 (33.3%)	3 (7.1%)	2 (4.3%)	

Appropriate health education will go a long way in letting young women know that dysmenorrhea is not a normal female experience and needs to be evaluated and treated. Getting dysmenorrhea treated assumes more importance in the light of recent research findings suggesting that it might predispose sufferers to other chronic pain conditions as they grow older.[12]

CONCLUSION AND IMPLICATIONS

This study serves to estimate the prevalence and severity of dysmenorrhea in young medical students and assess its impact on their daily activities.

Going by the findings of our study, painful menstruation appears to be a burden carried by a majority of young female medicos. Our finding of 19% students having severe dysmenorrhea shows the extreme suffering that many of them experience on a regular basis. They need to be educated that this is not necessarily a normal female experience, but needs to be managed effectively by using appropriate medication. Knowledge of these medications also needs to be given them as well as the assurance that these are not addictive as fear of addiction seems to deter many from using analgesics. The possible role of dysmenorrhea in predisposing individuals to other

chronic pain conditions also needs to be highlighted.

Creating awareness and giving health education regarding symptom management could help students manage the pain better and minimize the work-hours lost due to dysmenorrhea.

It will be beneficial if this study could be done in other population groups and also in the general community. It will give an idea of the public health burden of dysmenorrhea and its impact on the lives of young women both in the personal and socio-economic domains, so that appropriate remedial measures could be promoted to help them have a better quality of life.

ABSTRACT

Purpose - The idea of the research is to look at the role of factors enhancing learners' presentation. The factors influence on academic performance such as teaching styles, communication method, assessment methods and ICT skills are considered. The Dependant variable academic performance is considered as univariate.

Research methodology- Purposive Sampling was used in the study to collect the data; structured Questionnaire was distributed to 110 respondents of students (male and female). 10 Questionnaires were found to be unfilled so total 100 respondents (n=100). CFA and SEM were the statistical tools applied for the analysis in AMOS-21 to check the hypothesis of learn.

Findings - This analysis shows a positive and significant relationship between the independent variables teaching styles and ICT skills and the dependant variable Academic performance.

The variable ICT Skills is a new variable used in review of literature in India. But it has started to gain momentum in all aspects. The study also reveals the significance of ICT usage through the study among management students.

Practical implication – The paper have definite confines. The study was pertaining to management students only. On the other hand the implications are the results of the study can be used for the purpose of developing new strategies in the field of academics in the management students. For researchers this study can be extended for future variables with more related variables. Secondly it can spread across to other educational institutions also.

Uniqueness – This study is an initial try to know, 'enhance of variables relating to academic performance of Post graduate Students in Indian context.

Keywords *– Teaching, pedagogy, academic performance, communication.*

INTRODUCTION

Many countries have different approaches towards teaching and learning. Research studies have been carried out to investigate the best ways of teaching. One such facet of teaching in teachers' personal qualities are directly related to the subject matter of teaching. Hence

choice of the method and teachers' through the substance of the issue becomes important under learning context. There is a collaborative interaction among individual traits, the process by teacher utilize to communicate the substance of subject matter, and the method's display as learner[1]. The Methods through the teacher was teaching as exacting instance of requirements, idea, and behaviors that instructor exhibit in study hall. This study was used in conceptual framework.[2] the teaching method's as explain by Teacher through the Methods styles handling in class and study environment[3]. In 20th century different learning methods were followed. Special pedagogy was change in modern trend, since the pupils call for to learning process. What? , When? , How? To instruct lessons? The authority method is related to lectures styles or teachers' styles. Demonstrated method means coaching styles. The facilitator style means action method. The delegator style means peer feedback[4]. Hybrid method is blended learning. Theoretical discussion of teaching styles as a focus of presentation and study has become a part of the vernacular in. As a part of coaching technique (ICTs-awareness) get into class-rooms. Now a day's learning process was continued in (www.) web based learning[4]. Student's personality development (emotion, attitude) to reference[5]

Statement of the problem

Many researchers analyzed student's presentation (performance) by Grade point average (GPA) and cumulative grade point average (CGPA) was found. In this articles followed by Grade point value[6]. Some researcher to examining the quarterly, half yearly and annually to collect the pupil progress in required research. The aim of the present study was concentrate pupil's learning and outcome of the performance (exam results) was calculated by GPA. The pupil attitude, skills, interest on listening skill and extra activities (NSS, sports and NCC and yoga[7]. Private institution vision is to be a hub of quality in the midpoint of Tamil Nadu. Though the academic deans and the excellence and declaration of commission have noted that while some Pupils do highly and other do not complete healthy. Describe the pupil to check the progress in calendar year. Every calendar year to check institute quality and student enrolment, mark sheet and degree awarded, maintained by university Grants commission (UGC).

Theoretical Model

A model framework recommended by Lebcir model was taken as a base model for the study. They are teaching styles, ICT-skills and academic performance. The researcher has tested this frame work in the form of questionnaire, distributed to the students of management studies in a University - education institution.

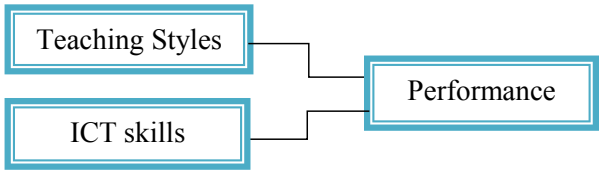

Figure 1. Theoretical Model

REVIEW OF LITERATURE

Review of literature explains the conceptual model for teaching styles[8]. For instance, had explained five various proceed towards learners. He had identified six categories which contain Task oriented common planner of the subject[9]. While institution of higher education pedagogical in management course current and alternative communicating approach, outcomes are weighted more[10]. He has shown examined Teaching with style in alliance with ICT as one of the most dynamic inventions which helps to tackle the challenges faced by world in 21st century and its application in academics has become a priority in most countries during the last decade. The usage of ICT tools in ME makes teaching and learning more effective. It also helps in wider dissemination of knowledge among students from all sections of the society. The literature review is divided into two parts independent as: Need for Teaching style in Management colleges, Benefits of using ICT in teaching and one Dependent as Academic performance.

Teaching styles:

Teaching method is a fundamental brick in teaching pedagogy, which has exposed to special details given by many research persons. Other research studies also highlight about teaching performance and the similarity between the instructing style and his or her thinking of the professor [11]. Furthermore, instructing style was specific and related with the different special sets of classroom instructing style' as explained[12]. 'Talk about the study submits to the person's enveloping instructional traits that continue to change the learning process'. On the other hand, the normal attribute get beginning these previous studies are the coaching behavior and wisdom

course of action.

ICT-Skills

The world of internet has shown tremendous growth and improvement over the past two decades[13]. The article focuses on the relativity and influence of ICT skills on academic performance of the students. A few previous studies on integration and usage of these skills in academic performance by students were found[14]. Hence this becomes one of the major research gaps of the present study. Study by Angeles highlights on usage of ICT skills has a major advantage[15]. According to the survey taken and highlights on the differences in the attitude in the usage of ICT skills in academic performance between boys and girls. ICT skills are fundamental for student and teacher inter related[16].

Academic performance:

There is a dearth in review of literature based on academic performance. Studies done on linguistic students' highlights the importance of academic performance among students. He has shown educative uses of ICT and its usage in academic performance and the results reveal there is a positive relationship between two variables[17].

Research question:

1. Does teaching styles and ICT impacts academic performance of students?

Objective of the study:

1. To analyze the association among teaching styles, ICT and academic performance.

Hypotheses of the study

H1. There is significant relationship between teaching styles, ICT and academic performance.

Materials and Methods

The research was carried out the association between teaching styles, ICT skills and academic performance measured among 110 post graduate students. The researcher administered a survey through questionnaire to discover the number of students learning skills and ICT skills in academic performance.

Sampling procedure

The respondents of this study consist of Management students' at the private university. Purposive sampling was used for the research study. The total number of students (male and female) of the management students' structured Questionnaire was distributed to 110 respondents of students (male and female). 10 Questionnaires was found to be unfilled so total 100 respondent filled quality questionnaire.

Data Analysis

Table I. Overall Reliability of the Data

Alpha(α) std. things	Number of things
.877	14

Variables	Cronbhach's Alpha	No of Item
Academic performance	.799	5
Teaching styles	.658	4
ICT-skills	.794	5

Overall reliability instrument study was 0.877.

The present paper to analyze reliability of the total Item is 0.875 is significant individual alpha (Teaching styles) is 0.70 and ICT-skills is 0.794 and dependent variable academic performance is 0.799 the on the whole 0.875.It is value note that 0.70 should be an good enough alpha value and coefficient still lower coefficients used in a few research Explain above the table.

Sample Adequacy Table II.(KMO test)

KMO test.	.836
Chi-Square(approx)	534.590
The (Bartlett's Test) Degrees of freedom(DF)	
Significance	91
	.000

The value received through KMO test was.836 which is above the threshold of .7. The Chi-square value was 534.590 and the significant p value is .000. Hence the sample taken for the study is adequate in nature.

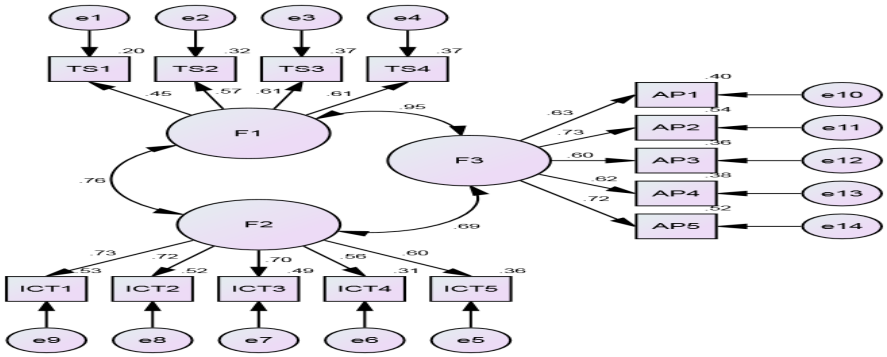

Diagram 1 showing CFA analysis

Table III showing testing of Hypothesis

Variables	The relation	Hypothesis
Teaching styles	Student's academic performance	Supported
ICT skills	Student's academic performance	Supported

The tested hypothesis as per regression analysis proves to be **significant.**

CONCLUSION

This study was carried to explain the role of teaching styles and ICT skills. Both the variables do play a vital role in the academic performance. ICT usage has been one of the weak areas in the field of Indian education, but it has started to gain momentum. Future studies with more mediation variables like gender and GPA can be used.

ABSTRACT

Introduction: *Staphylococcus aureus* is one of the most common human pathogen capable of causing a wide range of infections. *Staphylococcus aureus* is a common cause of both community and hospital infections. It was the endemic microorganism in several reports of nosocomial infections which induced high mortality and morbidity. This microorganism is a virulent bacterium that can cause serious infections including skin and soft tissue infections, wound infection, bacteremia, pneumonia and endocarditis. It is estimated that *Staphylococcus aureus* has developed the ability to acquire resistance to all classes of antimicrobial agents and methicillin-resistant *S. aureus* (MRSA) has become a major problem in many hospitals worldwide. Hospital acquired infection (HAI) due to multidrug resistant bacteria like MRSA are a growing problem in many health care institutes. **Materials and Method:** A total of 568 clinical isolates of *Staphylococcus aureus* were isolated from various clinical specimens received in the Department of Microbiology, Sri Lakshmi Narayana Institute of Medical Sciences, Pondicherry from April 2014 to December 2017, were included in the study. Isolation and identification of *Staphylococcus aureus* was done by standard conventional microbiological methods. Identification of MRSA was done as per standard guidelines of CLSI by using Oxacillin broth microdilution method. Antibiogram was determined by Kirby-Bauer disc diffusion method on Mueller-Hinton agar with zones of inhibition. **Results:** *Staphyloccus aureus* was susceptible to Vancomycin (94.7%), followed by Teicoplanin (91.7%), Linezolid (88.5%), Amikacin (85.7%). In case of MRSA all the isolates showed 100% susceptibility to vancomycin, followed by Teicoplanin (97.5%), Amikacin (84.7%) linezolid (80.3%) and Clindamycin (54.8%). In case of MRSA all the isolates were 100% susceptible to vancomycin followed by teicoplanin (97.5%), amikacin (84.7%) linezolid (80.3%) and clindamycin (54.8%).

Conclusion: MRSA infections are emerging as a serious health problem in health care set up. Joint efforts by clinicians, clinical microbiologists, hospital management and public health authorities are required to meet the challenge of MRSA on the forefront.

Keywords: *Staphylococcus aureus, MRSA, Oxacillin, Vancomycin.*

INTRODUCTION

Staphylococcus aureus has been renowned as an important cause of human disease for more than 100 years [1]. Alexander Ogston had first isolated *Staphylococcus aureus* from a surgical abscess in 1880 and described the role of *Staphylococcus aureus* in localized infection and septicemia, including the use of animal models for infection [2].

Staphylococcus aureus has emerged as one of the main important human pathogens, and has over

the past decades, been a leading cause of hospital and community-acquired infections. Staphylococcal infections give rise to a wide spectrum of symptoms and diseases in humans. The bacterium is well characterized and known to have a diverse arsenal of virulence factors that causes a prominent inflammatory response [3,4].This pathogen affects both immune competent and immuno compromised individuals, frequently resulting in high morbidity and with complications, which constitute problem to health care institutions. *S. aureus* has been reported by several studies as the causative agent of wide variety of diseases of supportive infections such as boil, wound infection, pustule, subcutaneous and sub-mucosa abscesses, osteomyelitis, mastitis, impetigo, septicemia, meningitis, bronchopneumonia, food poisoning, a common cause of vomiting, diarrhea, and urinary tract infections[5].

S.aureus was discovered in 1880, its effective treatment was started in1940, penicillin was the only drug used for treatment of the infections caused by this bacterium. After in late1940 and throughout 1950, *S.aureus* developed resistance mechanism to penicillin. Introduction of Methicillin was done in 1961 to treat these resistant strains nd within a year or later, clinicians had encountered methicillin - resistant *Staphylococcus aureus* which became a big threat. Now strains of MRSA are simultaneously resistant to a list of different groups of antibiotics, including vancomycin which is often considered our last line of antibacterial defence. Methicillin-resistant *Staphylococcus aureus* (MRSA) has been recognized as one of the major pathogens in both hospitaland community settings.[6]

In 1961, British scientists discovered MRSA, the first case of this "superbug" in the United States occurred in 1968.[7] MRSA is due to the acquisition of *mecA* gene that carried on a large mobile genetic element, the staphylococcal cassette chromosome, and which encodes a low affinity penicillin-binding protein 2a (PBP2a) to β-lactam antibiotics. The *mecC* gene when present, may also mediate methicillin resistance. The *mecA* complex also contains insertion sites for plasmids and transposons that facilitate acquisition of resistance to other antibiotics.[8] Hospital acquired MRSA is frequently multidrug resistant. This limits the therapeutic options to a few antimicrobials, which are toxic, complicated to administer and expensive. As a consequence patients have to be hospitalized for a longer duration, treatment costs are increased and associated mortality also rises. This has a significant impact on individual patients and institutions. An additional concern of grave significance is the emergence of vancomycin intermediate *Staphylococcus aureus* (VISA) and more recently vancomycin resistant *Staphylococcus aureus* (VRSA).[9,10] Hence this study was conducted to evaluate Antibiotic susceptibility pattern of *Staphylococcus aureus* and to determine methicillin- resistant *Staphylococcus aureus* (MRSA) isolates from various clinical specimens.

MATERIALS AND METHOD

A total of 568 consecutive, clinically significant, non-repetitive clinical isolates of *Staphylococcus aureus* were isolated from various clinical specimens (pus, urine, wound swabs, sputum,ear swabs, body fluids, throat swabs, catheter tip, nasal swabs, blood) received in the Department of Microbiology, Sri Lakshmi Narayana Institute of Medical Sciences, Pondicherry, during the period of April 2014 to December 2017 were included in this study.

Specimen collection:

The specimens were collected in sterile containers following aseptic measures and transported to the laboratory without delay and processed immediately. All the specimens were inoculated on 5% sheep blood agar and Mac Conkey's agar and plates were incubated aerobically at 37°C.

Identification of *Staphyloccus aureus* :

Colony morphology, Gram reaction, pigment production, catalase, and mannitol fermentation tests were performed and allocated to appropriate genera to the isolates. Golden yellow colored colonies on nutrient agar were noted and slide coagulase and tube coagulase was performed for differentiation of *S.aureus*.[11]

Identification of Methicillin-resistant *Staphylococcus aureus* by Cefoxitin disk diffusion method*:*

The MRSA strains were identified by using Cefoxitin (30µg) disc on Muller Hinton agar (Hi-Media Laboratories, Mumbai).Zone size was interpreted according to CLSI criteria, susceptible, ≥22 mm; resistant, ≤21 mm .[12]

Identification of MRSA by Oxacillin broth dilution method*:*

MICs of oxacillin for all isolates showing reduced zone of inhibition by cefoxitin didk diffusion were determined by broth microdilution method as described by Raghabendra Adhikari et al[13] and CLSI guidelines[14]. The concentrations of oxacillin used were 0.0125 μg/mL to 128 μg/mL.

Antibiotic susceptibility.

Antibiotic sensitivity was tested using the Kirby-Bauer disc diffusion method (1966) on Mueller-Hinton agar according to antibiotic Clinical and Laboratory Standards Insititute disc susceptibility testing guidelines (2013).[14] Bacterial suspension equivalent to 0.5 McFarland was prepared by mixing 3-5 well isolated colonies in 3-4 ml of sterile physiological saline. Each suspension was inoculated on Muller Hinton agar (Hi-Media Laboratories, Mumbai) using sterile cotton swab and antibiotic disks were applied and incubated aerobically at 37°C. Antibiogram was determined for the following antibiotics Teicoplanin (30µg), Vancomycin (30µg), Gentamicin (50µg), Amikacin (30µg), Linezolid (30µg), Ciprofloxacin (10µg), Cefotaxime (30µg), Clindamycin (2µg), Co-trimaxazole (25µg), Erythromycin (15µg), Penicillin (10units), Tetracycline (30µg) (Hi-Media Laboratories, Mumbai).

RESULTS

Out of 568 clinical isolates, 321 (56.5%) patients were from male and 247 (43.4%) were female. Majority of the patients were of age 41-50 (17.2%) as shown in **(Table- 1 and Table- 2).** Distributions of various clinical specimens were given in the (**Table- 3).**

Of the 568 *Staphyloccus aureus* recovered, 366(64.4%) exhibited resistance by Cefoxitin disk diffusion method and 361(63.5%) were found to be MRSA by broth microdilution method and the cutoff value is 4µg/ml. Among them 127 had high level resistance with MIC of >128µg/ml. The MIC of Oxacillin for ***S.*** *aureus* **isolates ranged from 0.064** µg/ml to 256 µg/ml.

Staphyloccus aureus was susceptible to vancomycin (94.7%), followed by teicoplanin (91.7%), linezolid (88.5%), amikacin(85.7%).

In case of MRSA all the isolates were 100% susceptible to vancomycin followed by teicoplanin (97.5%), amikacin (84.7%) linezolid (80.3%) and clindamycin (54.8%).

Table- 1: Distribution of *Staphyloccus aureus* according to the Age (n=568).

Characteristics	No.of isolates	Percentage
Age(in years):		
1 -10	37	6.5%
11-20	69	12.1%
21-30	81	14.2%
31-40	98	15.3%
41-50	102	17.2%
51-60	87	15.3%
61-70	72	12.6%
71-80	19	3.3%
81-90	3	0.52%

DISCUSSION

Staphylococcus aureus is one of the most infectious agents with high prevalence in various communities and healthcare institutions. MRSA is recognized as a major cause of nosocomial infections which result in significant morbidity and mortality rates. It is a very common cause of infection in hospitals and is most liable to infect new born babies, surgical patients, old and malnourished persons and patients with diabetes and other chronic diseases. The important reservoirs of MRSA in hospitals are infected or colonised patients and transient carriage and hands of health care workers is the predominant mode for patient to patient transmission.[15]

M

In our study prevalence of MRSA was found to be (63.5%),similarly such percentages have previously reported in studies from verma etal (80.89%)[16],Suresh Jaiswal et al (72%),[17] Dr.S.Kulkarni et al (70.3%),[18] Tiwari et al (69.1%),[6] Joshi.S et al [19] and Ali et al (68%),[20] Yadhav et al (66.84%),[21] Shilp Arora et al(59.3%),[24] Chandrasekhar et al (56.7%),[23] Anupurba et al (54.8%),[22] Rijal.K et al(51.6%).[2]

MRSA strains were predominantly isolated from pus samples (72.3%) which correlates with Yadav et al (86%),[21] Dr.S.Kulakarni et al (64.67%),[18] Bandaru S Rao et al (64.38%),[23] in contrast Ankur kumar et al [27] and Bilal Ahmed Mir et al [28]reported (21.42%) and (27.5%).

Staphyloccus aureus was susceptible to Vancomycin (94.7%), followed by Teicoplanin (91.7%), Linezolid (88.5%), Amikacin (85.7%).All the MRSA isolates were 100% sensitive to Vancomycin in the present study. The sensitivity followed by Teicoplanin (97.5%), Amikacin (84.7%), Linezolid (80.3%) and Clindamycin (54.8%) correlates with Bhatt CP et al [29], Gitau et al [30], Ankur Kumar et al.[27] and Bandaru S Rao et al.[26]

CONCLUSION

MRSA is emerging as a potential threat to our hospitals with a predilection for critically ill patients. Regular surveillance of hospital acquired infections, promotion of infection control precautions and formulation of definite antibiotic policy can be helpful in preventing MRSA infections from acquiring an alarming proportion. Good basic hygiene measures are extremely important, not only for hospital staff but also for patients and visitors, and it has a positive impact in infection control.

Effect of Retrowalking, a Non-Pharmacological Treatment on Pain, Disability, Balance and Gait in Knee Osteoarthritis: A Randomized Controlled Trial

Shabnam Joshi[1], Shailendra Kumar Singh[2], Jaspreet Singh Vij[3]

[1]Assistant Professor, Department of Physiotherapy, GJUS&T, Hisar, Haryana, India, [2]Professor, Department of Pharmaceutical Sciences, GJUS&T, Hisar, Haryana, India, [3]Associate Professor, University College of Physiotherapy, Baba Farid University of Health Sciences, Faridkot, Punjab, India

ABSTRACT

Knee osteoarthritis is a common condition in various orthopedic clinics and hospitals. Degenerative changes occur in the cartilage covering the articular surfaces of the joints leading to pain, crepitus, stiffness, limitation of movement and deformity. The purpose of the study was to examine the effect of treadmill retrowalking in patients suffering from knee osteoarthritis. Patients with age more than 40 years diagnosed with knee osteoarthritis by an orthopedician referred to or visiting the O.P.D, Department of Physiotherapy, Guru Jambheshwar University of Science & Technology, Hisar were assessed. Forty two eligible patients were randomly allocated to conventional group and retrowalking group. The conventional group received range of motion exercises, strengthening exercises, stretching and flexibility exercises. The patients in the retrowalking group underwent treadmill retrowalking in addition to conventional exercises. Both the interventions were given thrice weekly for six weeks. The data analysis was done using SPSS 16.0. Independent and dependent t-test was used to compare between and within group differences. Comparison of mean scores of conventional and retrowalking group showed statistically significant differences for all the variables. The study concludes that retrowalking when given along conventional exercise program alleviates pain, decreases disability, enhances balance and gait performance by improving step and stride length, increases cadence and walking speed in knee osteoarthritis patients.

Keywords – *retrowalking, knee osteoarthritis, conventional exercises, pain, disability, balance, gait.*

INTRODUCTION

Knee osteoarthritis (OA) is a progressive disease commonly encountered in the out-patient departments (O.P.D) of various orthopedic clinics and hospitals. The increasing prevalence of knee OA worldwide is suggestive of a physically crippled society [1]. Degenerative changes occur in the cartilage covering the articular surfaces of the joints leading to pain, crepitus, stiffness, limitation of movement and deformity which adds to the increase in knee replacements [2].The prevalence of knee osteoarthritis in India is 28.7% [3].

Patients with knee osteoarthritis modify their gait in response to pain. Such patients walk with shorter step and stride length, low cadence and have slower walking speed. These changes, which are possible unloading mechanisms, begin in early stages of medial knee osteoarthritis as identified by computerized gait analysis using spatiotemporal parameters [4-6].

Exercises are commonly employed in the management of knee osteoarthritis as they alleviate pain and physical disability in osteoarthritis patients without adverse effects produced by drugs and surgical procedures [7, 8].

Retrowalking or backward walking is used nowadays in the management of many orthopedic, neurological and sports conditions [9-12]. It changes muscle activation pattern, lowers knee joint compressive forces and improves strength of quadriceps muscle. The effects of retrowalking on pain, physical disability, quadriceps strength and balance in knee osteoarthritis have been studied [13-17]. However, none of the studies have investigated the effectiveness of a retrowalking program on spatiotemporal gait parameters in knee osteoarthritis patients. The present study aims to know the effect of retrowalking in combination with a conventional exercise program on pain, disability, balance, step length, stride length, cadence and walking speed in patients suffering from knee osteoarthritis.

MATERIAL AND METHOD

Settings and Study participants

Patients with age more than 40 years diagnosed with knee osteoarthritis by an orthopedician who were referred to or attended the O.P.D, Department of Physiotherapy, Guru Jambheshwar University of Science &Technology, Hisar were assessed. Patients having a history of any inflammatory, infectious, traumatic condition of the knee joint, with any previous surgery or any invasive procedure of knee joint, history of cardiac disease, lower limb injury or pathology, fixed deformity of knee, any skin problems around the knee joint, lacking independent ambulation or requiring use of any walking aid, neurological disorders, patients with severe knee osteoarthritis (grade 4 or those referred for knee replacement surgery) and those unable to comply with study protocol were excluded from the study.

In case of bilateral osteoarthritis, more symptomatic knee joint was considered for the study. Forty two patients fulfilling the eligibility were included in the study. The patients were explained the procedure of the study and gave their written consent.

Intervention groups

The patients were then randomly divided into two groups i.e. conventional exercise group and retrowalking group by computer generated random number tables. The Conventional group received conventional exercise program which consisted of hot packs for 10 minutes followed by exercises [18]. These consisted of range of motion exercises, muscle strengthening exercises in form of isometric and isotonic exercises, muscle stretching exercises and flexibility exercises. The patients in the Retrowalking group followed retrowalking protocol on a treadmill in addition to the conventional exercise program [14]. Prior to the treatment, every patient was made familiar with retrowalking on the treadmill. The intervention began with a session of 3-5 minutes forward walking on the treadmill for warm up followed by 10 minutes of retrowalking on the treadmill at a comfortable speed at 0˚ inclination under the supervision of the therapist. The treadmill was placed within a specially designed metal framework with handrails support for safety purposes. Patients were instructed to report any problem faced during retrowalking. Both interventions were given for three sessions in a week for a total duration of six weeks.

Outcome measures

Pre and post intervention testing was done for all outcomes measures for both groups at two time points i.e. at 0 weeks and after 6 weeks of intervention. Visual Analogue Scale (VAS) was used to measure pain intensity [19], Western Ontario and McMaster Osteoarthritis Index (WOMAC) was used for disability [20] and Timed up and Go Test (TUG) was used to assess balance [21]. The measurement of spatio-temporal gait parameters like step length and stride length was done using foot print method [22]. A ten meter walkway was used for step and stride length measurements. The measurements were taken using a measuring tape. The step length was measured as the distance (in cm) between the heels of two consecutive steps of both feet while the stride length was measured as the distance (in cm) between the heels of two successive steps of the same foot. The walking speed (m/s) was measured as the total distance (10 m) of the walkway divided by the time taken to cover the distance. Cadence was evaluated by counting the number of steps per minute during which the patient was made to walk in a corridor at a normal speed.

STATISTICAL ANALYSIS AND RESULTS

The data was analyzed using SPSS 16.0. Dependent t-test was used for comparing between group differences for all variables such as pain, disability, balance, step length, stride length, cadence and walking speed between conventional group and retrowalking group (Table 2) while Independent-t test was used to compare between group differences (Table 3). The level of significance

was set at $p<0.05$. All the values are presented in mean and standard deviation. The mean age, height and weight of study patients was 52.5±8.75 years, 161.15±9.45 cm and 73.69±.65 kg respectively (Table 1). The conventional group consisted of 8 males and 13 females. The retrowalking group included 12 males and 9 females. Pre and post comparison of study variables show significant improvement in both groups after intervention (Table 2).Comparison of mean scores of conventional and retro-walking group show statistically significant differences for all the variables thus showing better results in case of retrowalking group (Table 3).

Table1. Basic demographic data of patients

Characteristics	**Conventional Group (n= 21)**	**Retrowalking Group (n=21)**
Age(years)	54.3±10.2	50.7±7.3
Height(cm)	159.6±8.9	162.7±10.0
Weight(kg)	71.5±8.9	75.7±10.4
BMI(Kg/m^2)	28.1±8.9	28.6±10.2
Sex(M/F)	8/13	12/9

Walking speed(m/s)	0.09 ± 0.08	0.16 ± 0.09	- 2.57	≤ 0.05

DISCUSSION

Pain and disability were significantly reduced post intervention in both groups with a greater decline in the retrowalking group. The findings are in line with the former studies that have confirmed the benefits of retrowalking on pain and physical functions in knee osteoarthritis [13-14, 17]. Isometrics, range of motion and stretching exercises lead to an overall rise in the strength of the lower limb musculature thus reducing pain and disability [23-24]. Backward walking is a closed chain exercise capable of causing a decrease in the patella-femoral compression forces, reduced force absorption at knee, increase in quadriceps strength and reduced eccentric patellar tendon loading [25-29]. Thus, it possesses greater functional benefits which could be the possible reason for pain and disability reduction in the retrowalking group.

Balance was improved in both the groups after six weeks of intervention but a greater improvement was seen in retrowalking patients. The findings of the present study are consistent with conclusions of many previous researches. The integration of the sensory system, the motor system and the musculoskeletal system is related with improved balance after backward walking [10]. Retrowalking causes an increase in the knee extensor strength, alters the pattern of muscle activation, decreases compressive forces and thus pain in the knee joint, and improves motor control ability leading to an improvement in balance [10,12,16,30-32].

Greater improvement was evident in the retrowalking group for all gait parameters. This is the first study to evaluate the effects of retrowalking on gait parameters such as step length, stride length, cadence and walking speed in patients with knee osteoarthritis. The beneficial effects of backward walking on gait parameters have been investigated in stroke and cerebral palsy which have been attributed to reversal of temporal cycling of the muscle contractions and an improvement in balance as well as motor function of the lower limbs leading to improvised gait performance [11, 32].

A study concluded that backward treadmill walking was capable of achieving sufficient stimulus to augment hamstring flexibility [9].This reason may have increased the step length and stride length in knee osteoarthritis patients. Antero-posterior balance, step length and velocity in healthy adults were improved after backward walking in another study due to greater stimulation of lower limb muscles, greater activity of quadriceps muscle and high energy consumption [33]. A rectification in the abnormal gait after retrowalking in the present study enhanced the gait performance.

CONCLUSION

Retrowalking given along conventional exercise program for six weeks decreases pain, disability, improves balance, step length, stride length, cadence and walking speed in knee osteoarthritis. Although present investigation involved local patients who participated in study, a larger cohort study involving more number of patients of different races and diverse stages of osteoarthritis are required. Also, future studies could be done using gait laboratory for more accurate interpretation of results. The experimental outcomes of this study will be helpful for physicians and physiotherapists in deciding the exercise protocols

to achieve better results in patients suffering from knee osteoarthritis.

ABSTRACT

A healthy living and a healthy community complement one another. A healthy living can undoubtedly ensure the health of a community. A community's health is strongly affected and influenced by its members, their individual health and habits, morals and principles, their perspectives towards life in general and particular, the social capital, the immediate environment and of course the religious and spiritual bent of mind of its people. The deterioration of the health of a community may result in significant changes in its population rate. It is thus very imperative that such an important issue needs to be addressed. The unique Parsi community though an essential part of India's multi-cultural fabric and diversity, is perhaps the only minority outside Europe to have the combination of a higher proportion of older inhabitants and a lower fertility rate. This holds the possibility of a total ethnic extinction of this minority despite having the potential to contribute substantially towards the overall growth of the country. But no matter how alienated as a minority it feels, it must always be protected at any cost. The present paper makes a humble attempt to bring to community health improvement of the Parsi people an approach that emphasizes on identifying various factors held responsible for the rapid decline of the Parsi population. Such an approach would facilitate in protecting and subsequently intensifying the growth of the community.

Keywords: *Parsi community, Minority, Health, Declining population, Survival.*

INTRODUCTION

A community's health is greatly affected and influenced by its members, their personal health and habits, their ethics, perspectives towards life, their social capital, the immediate environment and of course their religiosity and spirituality. The small yet unique Parsi community is no exception. The community which had fled to India from Iran some 1200 years ago to escape religious persecution by the fanatical Muslim invaders could stand independent on the Indian soil on the execution of some terms and conditions: to adopt the local Gujarati language as well as the local dress code; to hand-over their weapons and embrace peace; to venerate cows; to not to spread their religion outside their community; and to perform their marriages in the dark as the Hindus do. A community which is well known for its uphill struggle, an astonishingly high presentation among the upper echelons of our society, for its honesty, integrity and fidelity, the Parsi emigrants had proved to be immensely loyal towards keeping their oath intact in all situations. This had in many ways prevented their complete assimilation into the Indian society and ultimately handicapped the growth of the community in terms of demography, which has become the most alarming issue of the community.

However, the community becomes the victim of its own success. Despite an illustrious past and an enduring success, their numbers are declining so fast that their survival in the next century has become a question of debate. According to the 2001 census, their numbers have fallen off from 115,000 in 1941 to 69,601 in 2001, out of which around 40,000 are scattered across the globe. The numbers are believed to have declined further since then. It has been declining by 12% every census decade. The consistent sliding represents a tragic loss of cultural diversity for the Parsis. The community, though an essential part of India's cultural fabric and diversity, is perhaps the only community outside Europe to have experienced a population and fertility decline. *The four minorities constitute 5 per cent of the country's total population. Of this, the Christians account for 2.3 per cent, Sikhs for 1.9 per cent, Buddhists for 0.8 per cent,*

while the Parsis stand at .007 per cent.[1] *This has become o*ne of the most alarming issues for the community. The community with its dwindling population has already entered the final stage of demographic transition. Late marriage, no marriage, low birth rate with a large number of aging population, fecundity, foetal loss, neonatal and infant mortality, urban medical problems like cancer, neurological disorders, leukemia, Alzheimer's, the desire to keep the bloodline 'pure' because of the 'No Conversion' commitment and of course an accelerated migration to the west often contribute to the drastic reduction in the population of the community.

Surveys show that late marriages and voluntary or involuntary childlessness are some of the prominent factors for the decline of population in the community. Deaths have consistently outstripped population replacement rate since the 1950s, possibly due to medical and socio-cultural reasons. Further, the percentage of elderly population in the total population is as high as 31.0 per cent, as per the 2001 Census (Paul). For every 4 deaths in the community only one child is born, which is quite low as a birth rate. Deaths have exceeded births in every year since 1955. While the ageing was at 23 per cent compared to the national average of 7.7 per cent the age group of children below 15 years was 10 to 12.5 per cent as compared to 33 per cent the ageing rate was rapid even compared to most advanced countries where Canada has 9.5 per cent, USA 11.5 per cent and 15.1 per cent in United Kingdom. Moreover, the replacement level of ageing population with the younger persons was merely 1.1 per cent.[2]

Another vital factor that leads to an alarming deterioration of the Parsi population is its socio-cultural aspect. As the community gets highly urbanized and polished in course of time, women become more conscious of their future and prefer higher education and a successful career to marrying at an early age. This, however, results in rising problems over the availability of brides to marry. A large numbers of women, who never get married or choose late marriage, have been identified as potential issues contributing to the reduced fertility, thus impacting the growth of the population. The average age at marriage in 1962 was 26.5 years for women and 31.4 years for men, and has hovered at about this level ever since (Patel 2010). This is the community which has unfortunately the highest number of bachelors and spinsters in the world. According to a research conducted in the year 1973, it has been proved that women among aged 31-45 years, 27% had never married.[3]

Researches prove that the total fertility rate (TFR) of the Parsis has been waning off for over a century. It has dipped below the viable rates. This is not because the Parsis are biologically infertile but because of their individual choice. Only one out of nine Parsi families has a child under the age of 10 years. Even couples who can have babies do not want to have because of other priorities. When in 1881, the total fertility rate among the Parsis in Bombay was 4.41 (Visaria, 1974), it comes down to 0.94 in 1999 (Unisa et al. 2008). 1961-70 was the first period when the TFR was found to be below replacement level (Visaria 1974).[4] Between 2005 and 2014, only 43 births were recorded, though there were 176 deaths. The first 50 days of 2015 recorded two deaths and no birth.[5] This is an outcome of the fact that more than the average Parsi women either do not get married or choose to marry between 35-40 years at which stage, a woman generally loss her important fertility years and find it difficult to conceive. Couples, who decide upon a baby, go for a single child (0.8) throughout their life time to avoid family obligations in their professional front. Apart, more than average couples have the responsibility to look after five or more elderly persons in the family. That could also be listed as one of the important reasons of not planning for a second baby. Aditi Kapoor in her article 'The Parsis; Fire on Ice', writes in the following manner "unless something is done to augment their fast depleting numbers and to revive their religion, the Parsis after an illustrious past could well just fade out in oblivion".[6]

On one side, no marriage and late marriage have become trends among the community members, while on the other side marriage outside of the community is frowned upon. The community fears getting merged with other dominant cultures. They believe that if their ethnic identity is lost, that may raise questions against their value system eventually leading to the collapse of a brand image. A pure Parsi blood is the key to protect the Zoroastrian root is what the Parsis have believed right from the beginning and they remain stick to this in order to avoid community crisis. Therefore, children born out of mix marriages are not considered to be Parsi as they are not allowed to enter the fire temple, neither are they allowed to perform their *navjyot* ceremony. As a result the community does not get any chance to escalate its number. As a homogeneous community, intra-family

marriages between cousins, uncles and nieces have become the demand of the community. Based on the genealogical database of the Parsi population, it has been studied that the Zoroastrians' breeding among themselves has led to an increased genetic traits often resulting in genetic diseases and disorders, longevity and reduced fertility.

As Parsis are thought to be genetically homogenous, a number of researches have been conducted on the community members to identify genes involved in various diseases like cancer, multiple sclerosis (MS) and neurological movement disorder like Parkinson, to develop new treatments and diagnosis for the same. It has been identified by a study conducted of by the Mumbai Cancer Registry that the community is particularly venerable to endometrium, lymphomas and leukemia, thyroid, pancreas, bladder, corpuis uteri, and prostate cancer, which is twice as susceptible as compared to the non-Parsis. The research was conducted by distributing questionnaire among a large group of Parsis regarding their life styles. It found that factors like literacy rate, socio-economic condition, living habits and westernized dietary are particularly contributing to the problem. Apart, the role of an increasingly limited pool also occupies an important role in accelerating the process of extinction in the community.

According to the Deputy Director, Mumbai Cancer Registry, the Parsi women are more prone to breast cancer than the non-Parsis. The affliction is present 1.6 times higher than that of the other communities.[7] In fact, it is the second commonest disease seen among the female Parsis of Bombay. Infrequent breast feeding, fecundity which leads to inbreeding are sighted as some of the major causes of breast cancer among the Parsi women. Apart, cancers of the cervix, corpus uteri, ovarian cancer, cancer of the fallopian tube are also quite frequently diagnosed among the Parsi females.[8] A review of literature on cancer risk among the Parsis in Bombay presents a direct estimation of the true level of cancer risk in this community as compared to the total population of Bombay. Surveys show that the Parsis rank second in broad ligament, ovarian, and fallopian tube cancer (Bombay Cancer Registry). As far as the Parsi males are concerned, they are more prone to prostate cancer. Age- specific rates illustrate that the prostatic lesions start occurring between the ages of 40- 50. However, the highest occurrence is found between 65-69 (Bombay Cancer Registry).

As a highly prosperous, philanthropic and civilized community with an abundant contribution to the growth of modern India, we perceive that the community members have proved to be so diligent that they ignore their social and biological life. On one hand, they marry late or do not marry at all and restrict themselves to a single child even if they do. On the other hand, the members of the community are playing against these deadly diseases, which have made its survival almost impossible in the next century. Thus, to increase the number in order to save the dwindling community from total extinction in the near future is the need of the hour. In this regard, the government, officials and community leaders have agreed to increase its birth-rate by adopting various possible methods to halt a decline towards extinction.

The following measures have been taken which may add substantial value to the population growth of the community while at the same time they would also check the further decline in the number.

The UNESCO Parsi Zoroastrian project namely Parzor Project has been jointly initiated by the Bombay Panchayat and UNESCO in the year 1999 to prevent population crisis in the community and to promote and preserve the great Zoroastrian culture and legacy. The project also intends to establish a connection among the people of Afghanistan, Uzbekistan, Pakistan, and Iran as these countries are the rooms for many Parsis.[9]

To help the Parsis increase their population and become an influential community the Ministry of minority affairs launched a scheme called Jiyo Parsi in 2013. The scheme is funded by the Government with an objective of creating awareness among the community members for lineage inflation. The scheme is executed in two parts: advocacy and medical assistance for reproduction and financial help for women health. The former works with a purpose to act upon family planning, convincing young Paris to get married soon and have more children at the right age, whereas the later offers financial support to the married couples facing fertility problems.[10] Adopting scientific protocols and structured interventions are what the community members are recommended to do.

The second phase of Jiyo Parsi that came up towards the end of 2017, covers expenses of child care as well as of elderly dependents.

Besides, enlightenment through different magazines, articles, books, counseling, giving a broader perception of the present demographic figure of the community, helps its members to realize their dwindling number, would attract young Parsis to breed more.

Though very rare, Intercommunity marriage has also been encouraged among the community members to boost up the population at any cost.

Couples undergoing infertility treatment prefer artificial insemination and surrogacy to boost up the population.

DISCUSSION AND CONCLUSION OF THE STUDY

In an age of globalization, Community health has become a major area of concern. As healthy living can significantly promote a healthy community, factors affecting the health of a community should always be eluded. Values and ethical factors powerfully influence a community's mental, physical and psychological wellbeing. Being a community that is staring at its extinction, Parsis need to stress their diminishing population so as to realize their existence in the near future and to act upon that. As a unique minority, which has essentially kept its religion unsullied and its core beliefs apart despite powerful influences from other cultures, the community deserves to be protected and preserved at any cost. There is a dire need to identify, introspect and comprehend the existing issues first at the individual level and then it needs to be addressed at the community level in order to strengthen the population and sustain the identity whose demise would be a major loss to world culture.

ABSTRACT

People believe that the new is better than the old, that the advanced is better than the simple, that more is better than little. How good is plasma glucose screening? Statistical medicine, sold all over as very scientific originates from scandal of poor research says Douglas G Altman, head of the medical statistics, London. Ayurvedic health care providers following International diagnostic criteria of Diabetes Mellitus for diagnosis of *Madhumeha* (Diabetes Mellitus). This was recently proved to be disease mongering and selling sickness. Many studies have consistently demonstrated that history taking and physical examinations are the most important factors in arriving at correct diagnosis, whereas lab tests play only minor role and too often palpably illogical laboratory findings are accepted without question. Ayurvedic physicians should strictly follow classical method of diagnosis of *Madhumeha*. The quotation from a Cardiologist Mimi Guarneri "Beyond the power of most sophisticated medical equipment is a physician's humanity – the listening ear, the healing touch, the devices of healers throughout time", holds good at this juncture

Key words: *Madhumeha; Diabetes Mellitus; plasma glucose; Screening; Disease mongering*

INTRODUCTION

Majority of Ayurvedic physicians, having a great influence of poor research[1] based western medicine gradually are going away from clinical symptoms of diseases in general and *Madhumeha* (Diabetes Mellitus) in particular based on laboratory results. If laboratory reports are abnormal, asymptomatic healthy person is medicalised and drugged or operated upon,[2] irrespective of truth whether he or she is suffering or not. It is unfortunate that such a great science Ayurveda which has existed for "times out of mind" in India is slowly deviating to follow the modern medical system of laboratory diagnosis even in the well segment of the population. Even in the western medicine treatment of asymptomatic hyperglycemia has been shown to be futile, if not dangerous. Even the newly invented disease in western medicine IGT (Impaired glucose Tolerance) has been shown to benefit more by life style changes rather than modern medicine like Rosiglitason in a large study.[3]

Euboxic Ayurvedic doctors have been neglecting the definition of disease defined in different classics of Ayurveda, as a state in which both the body and mind are subjected to pain and misery.[4-6] Chambers Dictionary also defines disease which is similar to Ayurvedic definition as an unhealthy state of body or mind; a disorder, illness or ailment with distinctive symptoms.[7,8] The laboratory diagnostic criteria of Diabetes Mellitus of western medical science which is flourishing with unscientific practice[9] should not be followed for diagnosis of Madhumeha because, the medical profession is being bought by the pharmaceutical industry, not only in terms of the practice of medicine, but also in terms of teaching and research, says Arnold Relman, a Harvard professor and former editor of the New England Journal of Medicine.[3]

Madhumeha vis-à-vis Diabetes Mellitus

"Prakarshen Prabhutam Prachuram Varam Varam Va Mehati Mutratwagam Karoti iti Prameha" Prameha is characterized by increased quantity of urine associated with or with out the increased frequency of micturition.[10] Poly urea *(Prabhoot Mutratwam)* and turbidity of the urine *(Avila Mutratwam)* are the two cardinal features of this disease.[11] *Prameha* refers to repeated, excessive and turbid urination in terms of frequency, quantity and clarity. The term *"Prameha"* has two parts. *'Pra'* meaning abundant and *'Meha'* meaning 'passing of Urine'. Thus *Prameha* means passing of large quantity of urine. Ayurveda fixed the normal quantity as four *Anjalis* (1600 ml) and puts frequency of at six.[12]

The aggravated *Bahudrava Shleshma* (liquid property of *Kapha dosha*) by its specific etiology initiates the process of manifestation of *Prameha* (poly urea with turbity) because of the *Saithilyata* (lassitude) developed in the body. The *Bahudrva Shleshma* comes in contact with *Rasa* (plasma), *Rakta* (Blood), *Mamsa* (Muscle), *Meda* (Adipose tisuue), *Majja* (Bone marrow), *Shukra* (Semen / Ovum) , *Kleda* (moisture), *Lasika* (lymphatic fluid), *Vasa* (type of fat) and *Ojas* (immunity) and while spreading it first gets mixed with *Medas* (adipose tissue) because there is an increase in the quantity of *Medas* which is also *Asamhata* (uncondensed) and *Aghana* (more liquid) and also because *Kapha* and *Medas* share identical qualities. The specific nature of *Samprapti* (pathophysiology) of *Madhumeha* (Diabetes Mellitus) brings *Sara* (essence of tissues) and *Dravabhaga* (liquid portion) of involved *Dhatus* (tissues) to *Basti* (urinary bladder) leading to *Prabhoot*, *Avila* and *Madhura Mutratwam (sweet urine)*.[13,14] Ayurvedic diagnosis of *Madhumeha* should have this *Samprapti* not mere increase in the plasma glucose.

Diabetes term is derived from Greek word dia and bainein means through and to go respectively and diabetes literally means pass through. Mellitus means sweet. Thus Diabetes mellitus means passing of sweet urine which gives similar meaning of *Madhumeha* which refers to literary meaning of honey like urine. Sweet taste of diabetic urine is noticed in 1670 by Thomas Willis and later is showed that sweetness of urine is due to sugar by Mathew Dobson in 1776. Bouchardt and Peligot in 1838 proved that the sugar of diabetic urine is glucose. Qualitative test for urine sugar was perfected by Hermann Fehling in 1848 and semi-quantitative test by Francis Benedict in 1908.[15] The understanding of diabetes mellitus also started with passing of sweet urine not plasma glucose but present day health care providers diagnosing it based on only plasma glucose level.[16] Diabetes Mellitus is known disease from very ancient times. Charaka in his treatise gives a very elaborate clinical description of *Madhumeha,* which cannot be surpassed by even modern text books.

Ghost of Plasma Glucose and Screening

Random glucose more than 200 mg/dl and Plasma glucose of 126 mg/dl or higher after an overnight fast, documented more than one occasion with associated symptoms are the essentials of Type 1 diabetes mellitus diagnosis. The essentials of diagnosis of Type 2 diabetes are plasma glucose of 126 mg/dl or higher after an overnight fast on more than one occasion and after 75 gm oral glucose, diagnostic values are 200 mg/dl or more 2 hours after the oral glucose. Polyuria, polydipsia, ketonuria and weight loss generally are uncommon at time of diagnosis. Candida vaginitis in women and Belanophosthitis in men may be an associated initial manifestation. Many patients have few or no symptoms.[17] This international diagnostic criterion with no symptoms takes liberty of life and puts healthy individual into bottom less pit till last respiration.

Total body scan (TBS) including plasma glucose has become a routine among educated, economically rich people and national program in developed countries. Whole body scanning is currently marketed in the medical field to make healthy individual ill and who will rarely become healthy as Professor Isan burg says. A study reported in Journal of the National Cancer Institute says that routine screening for prostate cancer using the prostate specific antigen (PSA) leads to over diagnosis.[18] In Netherland, in 1982 around 1000 children were referred to pediatrician after a positive screening result which was shown to be false for congenital hypothyroidism.[19] More test, more false- positive result.[20,21] This type new born and children screening programs with false positive results create potential parental stress.[22]

The Pap smear screening program for cervical cancer in Bristol to prevent cancer, where in 13000 women needed to be screened over 20 years to prevent one death.[23] To prevent one cardiac event per year about 1000 patients needed to treat with newly introduced Polypill which is nothing but old wine in new bottle.[24] This is the use of screening which could damage public health and nation treasure.[25] The plasma glucose screening will show natural normalcy in asymptomatic person as abnormal and encourages physicians with linear thinking to drug healthy mind and body by creating ghost fear.

Epidemiologists to cause epidemics[26] predicted that Diabetes affects one in 20 adults world wide and 333 million cases are predicted world wide by 2025[27] and to sell drugs to increase mortality rate which has been proved by recent clinical trail.[28,29] Statistical science is one of the leading causes of death in United States of America.[30] To prevent and stop disease mongering The Pew Charitable trust has given US$ six million campaign by name 'prescription project' to reduce the influence of pharmaceutical industry marketing on US physicians and doctors-in –training.[31]

Linear versus Nonlinear Science

Professor B.M.Hegde in his classic "What Doctors Don't Get to Study in the Medical School" says The problems lie in medicine's difficulties in defining normality, the devil of false positives, and our limited understanding of the natural history of disease. The most common way of defining normal is that the measure lies within two standard deviations of the mean.[3] Defining normal and abnormal plasma glucose level in a dynamic non- linear human body which has the natural super power to manage altered internal environment to great extent is impossible by linear science. Euboxic Ayurvedic physicians should follow the time honored diagnostic methods of health and make use of *Trvidha* (Three types), *Chaturvidha* (Four types), *Shadvidha* (Six types), *Ashtavidha* (Eight types), *Dashavidha* (Ten types) *Pareeksha* (Examination) and *Nidan Panchaka* (Five methods of diagnosis) for diagnosis of diseases in general and *Madhumeha* in particular except in rare conditions as Sushruta says to make use of other sciences to come to a conclusion.[32]

Twentieth century great physician, Lord Platt a great teacher of medicine at the university, in 1949 wrote that, if you listen to your patient long enough, s/he will tell you what is wrong with her/him, which supports Ayurvedic *Nidana Panchaka* concept. Later his students did prove that with a very well executed prospective, double blind, randomized, hi-tech based (even PET scanner) study of the role of history taking, physical examination, and investigations in medical diagnosis. The study showed that 80% of the final accurate diagnosis and 100% of the future management strategies could be arrived at the end of listening to the patient and reading the GP's referral letter. This is refined slightly by examination and investigations.[33]

Diabetic Medicine 1999 published a revolutionary study report on the effect of insulin on symptomatic and asymptomatic hyperglycemic patients. Quality of life and plasma glucose in insulin treated diabetics clearly showed real relief only in those patients who were symptomatic before treatment. Asymptomatic hyperglycemic patients experienced more problems with social functioning and pain with treatment[16] is the proof for efficacy of drugs in symptomatic hyperglycemia and adverse effect of medicalization. Author's humble request to Ayurvedic practitioners is to stick to their own diagnostic criteria rather than slavishly follow the modern medical criteria. In other words of Sir William Osler, It is a safe rule to have no teaching without a patient for a text, and the best teaching is that taught by the patient himself.[34] We must understand that Ayurveda is a Holistic, non linear dynamic science unlike the Reductionist science of Western medicine.

CONCLUSION

Madhumehi (Diabetic patient*)* needs a *Vedasindu* (Ayurvedic scholar*)* to understand *Madhumeha* (Diabetes Mellitus*),* not a machine. So Ayurvedic physicians should follow classical method of diagnosis of *Madhumeha* not euboxic diagnosis which is very recently born for disease mongering and to sell sickness.

Introduction of a Universal EMR Integrated Online Healthcare Management System Mobile App in Hospitals Throughout India and its Benefits to Patients, Hospitals and Governments

Basil Jacob[1], Rajesh Kamath[2]

[1]MBBS. Trainee- Master in Hospital Administration program. Prasanna School of Public Health,
[2]Assistant Professor, Prasanna School of Public Health, Manipal Academy of Higher Education, Manipal, Karnataka

ABSTRACT

Healthcare was,is and always will be a booming sector for business with a lot of scope for progress for the country.With the advent of mobile technology,it would be imprudent to not consider the integration of mobile technology into the healthcare system.This article looks to briefly explain the advantages of having a mobile app for the collection,processing & distribution of data to result in improved patient care on the patient's side,decrease in costs on the hospital's side and improvement in the overall condition of health on the country's side,through something as small as a mobile app.

Key words: *Universal EMR, Integrated online healthcare management system.*

INTRODUCTION

The penetration of smartphones into healthcare settings has increased due to the requirement for faster access to information,which could reduce morbidity,mortality and costs.Smartphone apps have transformed the way in which hospitals work by having an everlasting impact on the healthcare industry in various fields not only on the clinical side but also on the administrative and management sides of the hospital. Healthcare majors like Kaiser Permanente and Cigna have jumpstarted this part of the healthcare industry with innovative tech solutions to help doctors,hospitals and life science organizations become more efficient.[1] Previously,the healthcare sector was focused more on the manufacture of medical supplies and devices for various healthcare settings.But presently,trends have changed and they have transitioned to custom-tailored mobile applications that have higher functionality and ease of use to the point that it is contributing in bulk to the A.I. industry in the field of healthcare.The goal of these solutions is to slash healthcare expenditure and to cater to patients to bring about better quality and faster results in healthcare.

Quality

Many studies have looked at whether or not EMRs actually enhance the quality of healthcare delivered. [2]A 2011 study in diabetes care showed evidence that healthcare settings having an EMR system provide improved quality of patient care.[3]The EMR system will ultimately enhance care coordination as well. Since authorized personnel using an EMR system can electronically(even with a smartphone) view the patient's complete medical history,it reduces the chances of guessing histories and frequent and numerous specialist visits.It allows appropriate urgent care in emergencies. EMRs in a way promote prevention by presenting doctors and patients with faster and more accurate retrieval of test results,spotting of missing patient data and making available evidence-based suggestions for preventive services.

Time

Implementation of an EMR system can effectively bring about a drop in the identification time of patients after hospital admission.A research study in the Annals of Internal Medicine shows that after the adoption of an EMR system,a significant drop in time of 65% had been observed(from 130 to 46 hours).[4]

Countries like Australia,Canada,United States,Sweden,Finland,Netherlands,Denmark,Estonia and even the UAE had started implementation of EMR(Electronic Medical Records) as early as the 1990's.[5]In China,they have been able to create a system where EMRs from all primary,secondary and tertiary hospitals have been compiled to form 'Big Data' which is later used for various government projects.

Big data and its applications.

Big data has been defined as "high-volume,high-velocity and/or high-variety information assets that demand cost-effective,innovative forms of information processing that enable enhanced insight,decision making and process automation."[6]China is already making use of big data with almost 90% of its hospitals using an EMR system.Such systems are currently being used for public health promotion(disease monitoring and population management),healthcare management(quality control and performance measurement),drug and medical device surveillance,routine clinical practice(risk prediction,diagnosis accuracy, and decision support) and research.As of 2016,numerous academic research projects have used many national datasets collected by means of electronic software or apps(using desktops and smartphones) to predict and foresee the present and future clinical and economic burden of chronic diseases like cardiovascular disease,diabetes,kidney disease and chronic obstructive pulmonary disease.Moreover,other national administrative databases,inclusive of most of the national standardized discharge summaries of in-patients and the national death registry along with hundreds of millions of patient records,have been used by medical and public health researchers.

Such kind of big data that can easily be used to survey trends and correlations among major diseases in turn provides substantial evidence for healthcare policy making.Newer implementations of data analytics,like machine learning to replace much of the work of radiologists and anatomical pathologists,may also be used and is a booming area of study in China currently. Such applications need in-depth,higher-quality clinical information along with long-term follow-ups and hence need to be studied more in China's case.

Why the need for Universal EMR Integrated Online Healthcare Management System ?

Hospital Information System (HIS) is an essential component of healthcare that is responsible primarily for the administrative needs of a hospital or a healthcare setting.In various settings a HIS is also a comprehensive integrated data collection system pioneered to deal with most requirements of a healthcare setting's operation,including but not limited to medical,managerial,financial and legal concerns and also the related handling and delivery of services.

AHISusuallyhandlesofficialdocumentation,financial situation reports,personal data,utilities and sometimes even stock amounts.Of utmost importance to HIS is the security of information like patient data,patient medical history,prescriptions,procedures,operations and lab test results.By doing so,they also provide a universal source of information about a patient's medical history that can be accessed by authorized personnel like physicians or nurses (or maybe even the Government in the future for specific surveys).Such a system can multiply many folds the capability of healthcare workers to coordinate and efficiently provide care,by providing immediate access to the patient's health history and records.A patient's lab test data contains visually interpreted results like X-ray,CT,MRI etc,which may be accessible by means of digital versions available on the personnel's smartphone.A HIS also acts as a means of communication among healthcare providers internally within the organization.

METHODOLOGY

Review of literature,Online search and Interview.

DISCUSSION

Interview with Dr.Basil Peechakara,who is an Indian educated prospective US residency applicant.He has passed his USMLE steps and applied for residency positions in the US after completing quite a few clerkships at various hospitals of one of the best hospital groups in the United States:Cleveland Clinic.This interview is on the American healthcare system and "paperless

hospitals"- specifically the use of smartphones to collect, gather and process data in hospitals by means of apps.

Q)As a future medical resident working in the United States already using an app for hospital administration,what would be your opinion on the use of such apps?How has it helped the clinical side?

A)It helps the clinical side by reducing the clutter of clerk work which exists if there is no electronic medical record.It also provides a standard for documentation and orders to nurses/pharmacies which otherwise is ill defined if written on paper.

Q)How many other hospitals in your knowledge use this technology?

A)I have seen this system only in the US.But I have heard from my friends that at least lab reports are uploaded in a software in some Indian hospitals for prompt delivery to the doctors.I have not worked in many Indian hospitals.

Q)How likely are you and your peers to recommend such an app to others?

A)I would highly recommend such technology because it is time we embrace it and stop relying on outdated protocols involving human labor.

Q)How do you think it can benefit the hospital?

A)It would be useful to have centralized medical records accessible throughout the hospital by medical professionals..

Q)Would you want to add anything else?

A)The main hurdle in its implementation is changing the outlook of veteran doctors who have relied on paper their entire careers.Change needs to be embraced to push Indian hospitals to become on par with hospitals abroad.

Advantages of having Hospital Administration apps.

OPD Management

Theappcouldbecometheperfectsolutiontooutpatient management problems and help streamline processes including patient registration(online appointment booking through the app while using one's smartphone) and also appointment rescheduling and cancellation.The streamlining nature of the app would help in establishing a better queue management system(at admission and registration counters,billing counters,pharmacies,labs etc.) and inventory management system.Clinical consultation recording including patient history/ allergies,problems,examinations done,diagnostic tests prescribed,diagnosis,treatment plans,prescriptions and lab test requests and results,billing etc can all be entered/ordered using a smartphone from anywhere by authorized personnel.Inpatient care management solutions including admission,triage,nursing care and doctor care can be administered.Drug administration and prescription can be done entirely within the app with the help of integration with hospital pharmacy and billing.An integrated inventory management system can be operationalised along with bed and ward management,problem/diagnosis recording,surgery requests and scheduling.Discharge summary with billing and other care record inclusion before final sign-off all can all be done using a single app on the phone. In bed and ward management,colour codes can be used to distinguish between free,occupied and in-preparation beds.

Laboratory/Diagnostic management:The app could enable immediate lab/diagnostic requests,store results and send back reports online,decreasing the need of manpower for logistic of the said results or personnel rushing to the nearest computer.

Integration of OPD,IPD and radiology departments through main server with subsequent linkage to billing.

Invoice/billing management

Invoicing could be seamlessly integrated with the inpatient,outpatient and inventory management systems with the help of strong back-end support (large databases for excess data storage and stable servers for the app to run).

One could see in real time,paid and unpaid patient invoices along with advance payment and part-payment options reducing the need to physically go to the billing department and print invoices (and rather save a huge sum on stationary not to mention a reduction in requirement for manpower).

Inventory management

Stock keeping of various commodities such as pharmaceutical products,stationary,disposables,laundry etc.

Strategic compartmentalization of various stock types for more efficient allocation of resources to respective departments.

Real time updates on stock levels for future references.

Pharmacy management

An appropriate pharmacy management within the APP could include inventory and stock-taking,low stock alerts with the option to dispense batch closest to expiry earlier.

Eradicating errors caused by manual intervention or workarounds.

Avoiding drug diversion and manipulation.

Executing compliance protocols and monitoring compliance violations.

Ability to trace delivery of medical supplies in real time within an entire healthcare setting.

Online Point of sale (POS) module to manage and control sales,generate reports based on daily,day-wise,monthly,month-wise or yearly sales made. POS could incorporated along with inventory management system as well.

Enhancing inventory control and decreasing costs along with prior purchase order generation notifications for low-stock & new stock items.

Data analytics

Data analytics within a hospital setting could help better understand patient trends and the hospital's performance by means of data intelligence.

The app could be used to view multi-dimensional interdepartmental data and gain deep access into more specific details that might be important in strategic decisions

Graphical display of data like for eg:- most commonly prescribed medicines,most demanding issues,patient visit frequencies,demographics of patients registered with hospital,tests most frequently conducted etc.

Administrative settings

Easy to use administrative settings to assign rights and privileges to various hospital users e.g. front staff, nurses,doctors,surgeons,support staff etc.

Customize and/or add hospital letters such as Sick Notes,Referral Letters and Transfer Notes etc.

Improves on responsiveness and patient satisfaction.

Enhances patient care by sending data to the (POC) Point Of Care as opposed to an administrative location.

Creates a system devoid of miscommunication and confusions.

SMS services could be made available in app to communicate effectively with patients.

Apply and alter various hospital service rates and discounts

Deriving more efficient workflow processes.

Integration of all administrative work within the hospital.

With this,the costs generated on repetitive creation of reports,maintenance of physical records and the resource allocations for the same can be drastically brought down. This ultimately would aid the hospital management to minimize a large section of their expenditure.

Proper feedback systems may also be introduced to patients in lieu of small discounts on their next visit.

Patients could be offered special tier level benefits looking at their history and out of pocket spending at the hospitals.

How do hospitals benefit from this?

All of the above salient features of the app used by professionals within the hospital can help in reducing the hospital's spending on manpower and stationary in addition to saving a lot of time.This will enable the hospital to treat more patients and reduce the opportunity costs incurred.In addition,by adhering to industry regulations such as HIPAA (Health Insurance Portability and Accountability Act),a secure environment could be created for the efficient interchange of clinical data in various healthcare settings.Three level security is present on all major smartphones today which involves pattern drawing,passwords and fingerprint recognition which guarantees safety of data entry by any personnel within the hospital as compared to the non- secure

traditional way of stamps and signatures.Patients would be happier as they would not have to physically carry their documents throughout the hospital as everything can be accessed online.

Why the need for a common centralized app for all hospitals in India?

The government would have access to big data (discussed earlier) through the databases based on data that are collected by single universal app in real time at any given point of time. The advantages in addition to applications would include:

Constant health surveillance of the population. The scope for statistical analysis of the country's health in this case is boundless.

No need for large investment on data collection means like desktops as it can be collected on a smartphone which almost every professional would have in today's tech-savvy world.

Lesser manpower and time required to do surveys which could be done in a fraction of the time required now without the app.

It could also contribute a great deal to GOIs 'Digital India' Scheme.

This initiative would also help the government keep a tight leash on the limitless nature of the private healthcare sector by having constant access to the data of private hospitals (the bounds would, of course, be negotiated by government and private entities) as well,resulting in less manipulation of records as everything is electronic and has to be updated in real time.

Regular and random data audits of any hospital may be conducted from any place in the country by the Government as all records are available online thereby increasing the minimum healthcare standard of the country and ultimately increasing India's global healthcare and medical tourism appeal (butterfly effect).

Obstacles to be faced

Servers have to be stable and up and running at all times.

Backend tech for the commissioned app has to be very stable and ready for collection of Big Data.A list of homegrown tech companies could be approached for such services.

Strong intranet and internet connections are required everywhere in the hospital.

The hospital or healthcare setting needs constant and good quality access to the intranet and to the internet.

Veteran doctors need to embrace this idea keeping in mind the bigger picture.

One of the biggest obstacles to be faced would be the acceptance of such an idea among the more experienced veteran doctors who are used to ink and wood and prefer to stay within that framework.To get them out of that safe-zone by helping them to understand that it would make things a lot easier not just for their patients but also for themselves through the implementation of such tech would be a challenge.Training them to use such a system would also be something to keep in mind.

Initial costs to create electronic records and how to view them on devices like Desktops or Tablets.

Antibiotic Susceptibility Profile of Methicillin Resistant *Staphylococcus Aureus*- A Cross-Sectional Study

Kavitha E[1, 2], Srikumar R[3]

[1]Research Scholar, Bharath University, Chennai, India, [2]Department of Microbiology, Sri Venkateshwara Medical College and Research Center, Puducherry, India, [3]Department of Microbiology, Centre for Research, Sri Lakshmi Narayana Institute of Medical Sciences and Research, Puducherry, India

ABSTRACT

Background: Antibiotic resistance is a worldwide phenomenon observed among clinical isolates of *Staphylococcus aureus*. The increasing prevalence of Methicillin resistant *Staphylococcus aureus* (MRSA) demands the availability of other essential antibiotics for the treatment. Our study is conducted to find out the various antibiotic susceptibility pattern observed among MRSA isolates. *Methods***:** Kirby Bauer disk diffusion method was performed on all the clinical isolates to determine the antibiotic susceptibility pattern and D test to identify the inducible clindamycin strains. *Results***:** of the 573 clinical isolates of Staphylococcus spp, 191 (33.3%) were MRSA which showed maximum antibiotic resistance to erythromycin (60.2%) followed by cotrimoxazole (19.4%) and ciprofloxacin (14.7%). Inducible clindamycin was found to be 24.6% among MRSA isolates. *Conclusion***:** Monitoring of the antibiotic resistance and sensitivity pattern is essential for the effective disease management and complete recovery from the disease.

Key words: *D test, Kirby Bauer disk diffusion method, Staphylococcus aureus*

INTRODUCTION

Staphylococcus is a commonly isolated pathogen from most of the skin and soft tissue infections. There has been a widespread antibiotic resistance observed among these clinically isolated pathogens, more commonly among nosocomial pathogens[1]. *Staphylococcus aureus* is one such pathogen which shows remarkable propensity for the development of various antibiotic resistance[2]. Inappropriate choice of antibiotic therapy results in a higher rate of increased clinical morbidity and mortality among patients[3].Methicillin resistant staphylococcus aureus (MRSA) strains are frequently isolated from hospital and community acquired infections showing multiple drug resistance pattern[4]. With multiple drug resistance MRSA strains the treatment options become limited. Rapid spread of such antibiotic resistant strains have been reported worldwide especially from the developing countries owing to the misguided use of antibiotics and its easy availability over the counter of pharmacy[5,6].

Increased incidence of MRSA cases have been reported from various studies in India as well[6]. Such increasing incidence of resistance strains in the recent times produces a significant impact on the disease management and treatment of infections[7]. Hence, control of MRSA emergence is essential in order to manage the introduction and spread of new infections which could be achieved by following universal precautions and updating on the changing patterns of resistance mechanisms by means of regular epidemiological studies[8]. MRSA shows wide variations in antibiotic resistance patterns by developing chromosome resistance to commonly used antibiotics like penicillin and cepahalosporins which are extensively used in the treatment of skin and soft tissue infections[7,9]. Also, the increased emergence of inducible clindamycin resistance ($iMLS_B$) strains among MRSA cases widens the gap of treatment and management of such infections[10-15].

Corresponding author:
SRIKUMAR R (PhD)

To manage the treatment of MRSA and inducible clindamycin resistant cases, the resistant pattern can be easily determined by Kirby-Bauer disk diffusion method and D-test method. The inclusion of D test in the regular clinical diagnostic procedure will further improve the management of the treatment progression with the commonly used antibiotics. Our study thus would help to assess as well as manage the resistant cases and also determine the rate of such cases in this part of the country on a routine basis.

MATERIALS AND METHOD

The present study was conducted in the Department of Microbiology, Sri Venkateshwara Medical College and Hospital, Ariyur, Pondicherry. The study was initiated after getting the approval from the Institute Ethics clearance committee. We analysed 376 strains of *Staphylococcus aureus* which mainly included samples like pus and wound exudates, coming for routine culture and sensitivity to the Microbiology laboratory. The clinical specimens were inoculated on blood agar and MacConkey's agar, and were examined for bacterial growth after 24 hours of incubation. Colony morphology, gram staining, catalase test, coagulase test, mannitol fermentation, methyl red test, voges proskauer test, nitrate reduction test and urease test were performed to confirm the pathogen. Antibiotic susceptibility was performed for *Staphylococcus aureus* as per the as per the CLSI guidelines[16].

Methicillin resistance was detected by using cefoxitin disk (30µg) by Kirby Bauer disk diffusion method. Other antibiotics included for observing the various antibiotic resistance included- penicillin (10 units), amikacin (30 µg), ciprofloxacin (5 µg), co-trimoxazole (1.25/23.75 µg), doxycycline (30 µg), erythromycin (15 µg), clindamycin (2µg), vancomycin (30 µg & E strip) and linezolid (30 µg). *Staphylococcus aureus* ATCC 25923 was used for quality control.

Inducible clindamycin resistance ($iMLS_B$) was detected by using double disk diffusion method (D-test)[17]. Lawn culture of 0.5 MacFarland standard of bacterial suspension was made on Mueller-Hinton agar plate. Erythromycin disk (15 µg) and clindamycin disk (2 µg) were placed at a distance of 15 mm apart (edge to edge). The plates were incubated overnight and the zones of inhibition were measured. Flattening of the shape of clindamycin zone facing erythromycin disk giving a D shaped appearance is considered to be positive for inducible clindamycin resistance ($iMLS_B$) by D- test. Strains resistant to both erythromycin and clindamycin were considered as constitutive MLS_B resistant whereas strains resistant to erythromycin and susceptible to clindamycin were taken as MLS_B phenotype[18].

RESULTS

Among the 376 strains of *Staphylococcus aureus* isolated from the various clinical samples in our study, 191 were MRSA strains. Most of the isolates were from the age group 31-45 years. On comparision, males (68.6%) were found to be more commonly affected when compared to the females (31.4%). Most of the samples were from pus (47.1%) and exudates (39.3%). The antibiotic resistance pattern of MRSA is shown in Table 1.

Of the 191 Strains, 47(24.6%) exhibited inducible resistant to clindamycin. Table 2 shows the different phenotypes of MRSA based on the susceptibility pattern to erythromycin and clindamycin.

Resistance rates of MRSA strains for more than one antibiotic were also observed among as shown in Table 3. Antibiotic susceptibility pattern for the commonly used antibiotics were compiled and found to be more resistant among MRSA isolates than in methicillin sensitive *S.aureus* (MSSA)(Table 4).

Table1. Antibiotic resistance pattern of MRSA (N=191) for other antibiotics

Antibiotic	Resistant strains N (%)
Penicillin (10 units)	191 (100)
Amikacin (30µg)	24 (12.6)

DISCUSSION

Our study highlights the increased incidence of MRSA strains (191) isolated form skin and soft tissue infections as reported in previous studies[19,20]. Out of 191 strains, 24.6% were inducible clindamycin resistant. Though the isolation rate of MRSA strains was high, these strains showed good susceptibility to other antibiotics commonly used for the treatment. Antibiotics like amikacin, doxycycline, clindamycin and cotrimoxazole are great choices for treatment of such antibiotic resistant strains. In-vitro determination of antibiotic resistance of *Staphylococcus aureus* with special reference for MRSA is essential in selection of effective drugs for the staphylococcal diseases and infections[21]. Also such strains are becoming multi-drug resistant and developing increased resistance to second line antibiotics.

MRSA strains in our study also showed multidrug resistance as observed in other studies[22,23]. There is also an increase in resistance for vancomycin and linezolid which are the most important antibiotics for the treatment of MRSA infections[24,25]. In our study, 2.1% of MRSA strains showed resistance towards vancomycin and linozolid. All the strains were resistant to penicillin (100%). Inducible clindamycin resistance was found to be 24.6% which was in accordance with the other reported studies[26,27]. Detection of inducible clindamycin is essential in order to avoid treatment failure with this potent drug which could be absorbed by the system very easily. Though, the emergence of such strains is rampant with the MRSA isolation, judicious choice of antibiotics can help in the outcome of patient cure.

Strength of the study

As reported in various studies, simultaneous detection of antibiotic resistance and inducible clindamycin resistance among the clinical isolates proves very beneficial in the care and management of the clinical outcome which was also highlighted in our study.

Limitations of the study

Being a cross sectional study we could not indicate cause-effect relationship. Also, small sample size is a limitation in our study. Resistant isolates has to be studied at molecular level via PCR methods.

CONCLUSION

Increased rate of MRSA strains isolated in our

study with multiple drug resistance and also inducible clindamycin resistance indicates the importance of rapid identification of such strains before the initiation of antibiotic treatment.

The Multiple Ways of Constructing the Overmind

ABSTRACT

The priorities and focus given by our current neural set-up might help us to win the short-run; but in the context of the overall evolution, the self-centric focus looks absolutely meaningless. As per science and a genuine introspective analysis, the human system is made of nothing other than fundamental particles and the fundamental sensations. In the long run, therefore, one can only identify either with the interconnected cosmic processes or with the conscious energy that appears to direct it towards more valuable and sustainable structures. To control and direct our current levels of self-talk in accordance with the long-term objectives, one needs to develop the over-mind, after the module of many other control systems that have already developed in nature.

Keywords: *Teleological Motive, Voluntary and involuntary Memory, Synapse, Plasticity of Brain*

BACKGROUND

Despite the fast-track changes in the standards of life, we still need to walk up to the food, extend our hand to push it up to the mouth or to drive away the fly that might come on the way. There's nothing uniquely different in the manner in which the nervous and the muscular systems function in both animals and human beings for executing such actions.

That which sets us apart is probably something else. It's just the fact that human beings engage in the construction of statements even as they carry out these utterly mundane activities. Simplistic though it might sound, this facility in itself is a huge development over the previous brain structures. Language function may be seen as the additional layer built over the unconscious mental control of the body such as the reflex movements and the involuntary muscular excitements and inhibitions[1].

The conscious process was developed through attention and is regulated through the recruitment of dopamine in the pre-frontal cortex. However attention isn't entirely unique to the humans. The only tweak is that we have used the very same brain structure enabling us to pay attention as a convenient tool to build the semantic memory.

The art of language brought with it a whole lot of blessings and burdens as well. Undoubtedly, the type of self-talk we experience at present helps us to deal with much more complex situations than what the other animals can cope with. But it also fills us with endless anxiety and fear fueled by the prior expectations of the worst possible scenarios. Essentially, we are so absorbed in the meaningfulness made available through neural conditioning that we end up as puppets rather than thinkers.

By utilizing the same facility of attention modulated and supported by dopamine one can also elevate the current neural system to a still higher level of meaningfulness. The strategy may be seen as the reciprocal methodology. It is this human possibility and in some extra-ordinary individuals a skill already initiated that we would define as the over-mind.

Sri Aurobindo2 introduced the term, to mark the penultimate stage of the possible growth of mind, prior to the arrival of the supermind. Over-mind[3], for Aurobindo, is an intuitive way of finding the unity between the subject and the object. Laudable though it is, this way of description hardly delves into the fundamental elements that have built the macroscopic entities called the subject or the object, at least not in line with the findings of science, including cognitive neuroscience. And for this reason we wouldn't implicate the doctrine of Sri Aurobindo here. We would merely borrow the term for a different purpose.

Science has accomplished the immense task of finding the real connections in the stunning cosmic evolution even up to the point of the workings of the brain and has implicitly shown to each individual how they are nothing other than a speck of mechanistic and biological streak in the overall evolutionary forward march. It's high time, therefore, that we reassess the kind of inner talk spontaneously put forward by our neural conditioning. We are in need of re-working the human connectome, taking advantage of the fundamental plasticity of brain. One could call this the conscientious project of constructing the over-mind, which again implies nothing other than a possible new direction of attention, towards some specific objectives.

If attention is all that was required to build complex mental behavior and the language system, a renewed attention to reassess the entire module of self-talk is certainly possible. One can bring about an additional control system right in the midst of the outpouring of our mind similar to the growth of the master control genes and the DNA-binding proteins[4]. It is such deliberate attempt to build a new control system that we have defined as the over-mind.

MATERIALS AND METHOD

The Nobel laureate, Sir Charles Sherrington (1857-1952), would be our critical reference, for more than one reason. Sherrington was the first to show to the world that "muscle excitation was inversely proportional to the inhibition of an opposing group of muscles"[5]. The remarkable discovery was termed the 'reciprocal innervation'[6]. The objective of this article is also nearly similar, although on a purely conscious plane. As neuroscience has come up with all the evidence to show that our current level of self-talk is the excitation of a carefully selected and continually reinforced neural pathways, guided especially by the self-interests of the individual, it just calls for invoking a renewed scheme of attention paid in terms of reciprocal application to fit the self-talk in the context of the overall workings of the entire cosmic system. The moment I recognize that whatever I considered as myself has fallen into one of the many types of the cosmic formulae – in this case, minute sensations building up a huge mental construct as it similarly occurs in billions and billions of other individuals -- there's no ground on which the traditional 'self' can stand any longer, except, of course, the ground of the universe itself. It is this kind of reciprocal deflection of attention, turning an utterly limited concentration to its genuine extensions of all kinds, we would be dealing with here.

In addition, Sherrington has explored the concept of the teleological motive of Nature in The Gifford Lecture5 series. This is an exceptional work for no other Western scientist of the post-modern era has given us a bold and straightforward approach to the divine starting right from the system of Nature. However, the arguments given here might be still wanting, as eminently pointed out in the review given by William Elis[7].

The reason again is not far to seek. Sherrington couldn't move out of the dualistic conception of Descartes, expounded three centuries earlier. Rather than analytically splitting down reasoning and willing back to the minute sensations and the language system built on a specific group of sensations, Sherrington attributed such activities to the soul[8]. This would be unacceptable to any credible scientific methodology, for the current evidence clearly shows that the whole of nature including our mental judgments are made of atomic parts, such as electrons and protons in our neural system or the memory of sensations caused by them.

The argument of the Teleological Drive - traditionally known as the Divine -- can only arise as an analogical one after the module of the mental skills experienced by us, although ours is just an evolutionary set-up. We can also raise the irresolvable question of how the totally varying types such as electrons and sensations finally managed to instruct and influence each other. How the whole lot of minute sensations convert into meaningful summary statements about the entire universe. The Divine motive that has gone ahead and achieved all its works stands out loud and clear, not

only from the fundamental intentional set-ups of nature but more especially from the unnatural links such as electric conduction and the meaningful association of sensations. And it comes out equally impressive when we reflect on the highly inexplicable Big Bang in which all known laws are expected to collapse. Sherrington, for one, hadn't gone into such acid test arguments.

The crucial data preserved through the historical events of world religions powerfully suggesting the presence of something more fundamental to the universe is an extra boost to any positive conclusion we would make in this direction. The reciprocal control of meaning that we wish to develop as the over-mind stands only to be enriched by clarifying the concept and the material available through religions as well.

THE REASSESSMENT OF SELF-TALK

Nature has consistently built one beautiful structure over the other. The manner it does so is a spell-binding story, with each step getting even more intriguing than the previous one – far more brilliant than any human machine that we have managed to build so far. The habitual workings of our mind is just the top-most achievement of nature until now. And it's seriously doubted if anything more complex and brilliant than this could be produced through any other lineage of cosmic evolution. But that doesn't imply the human mind can't be developed further. The reason why we couldn't take it to a higher level of operation until now has to do with our failure to see the continuity of all developments. It isn't a bad idea therefore to list out the significant milestones of cosmic evolution before describing how mind itself can be oriented towards yet another jump-start.

The rapid developments of the very first second of the universe have been theoretically described. From utter fluidity and the highest energy state possible, things got progressively cooler and more expansive, leaving the very first configurations called nuclei and atoms9. It took 240,000 years for hydrogen and traces of lithium to be formed and about 240 million years for the first generation of stars to set fire. The medium sized third generation stars such as the sun came into picture 9 billion years later and it took another one and a half billion years for the early forms of cells to appear.

If the self-replicating cell is something unique in all of cosmic configurations, its existence and operation is just unthinkable without the essential prior stages through which the universe had expanded earlier. The planet earth that turned itself into the fitting abode for the arrival of the cell, is held in its rotational movement within the cosmic balance of galaxies and solar systems. It's obvious therefore that more complex realities have been continuously built within the bedrock of the previous arrangements. Nothing new can ever arise except in and through the laws prevailing earlier.

In the context of the evolution of life, the manner in which the central nervous system finally emerged provides an equally breath-taking story. From the nerve nets[10] and ganglion serving specific functions of the body in lower species, the complex system of cerebellum, the hemi-spheres of cortical lobes and the deep brain parts such as thalamus, hypothalamus, hippocampus and amygdala were gradually put in place. The frontal lobes that enable the executive actions are the latest addendums to this magnificent structure.

While the diffuse nervous system and even the non-human central nervous system were meant only for the co-ordination of the body movements, the control of visceral fluids, detection of food, partner and alarm signals, human beings managed to carve out specific regions in cortices and other brain-parts to produce a new type of memory. It is thanks to the extra-ordinary invention of language and the parallel support system that developed in the brain due to its fundamental plasticity, human beings could go ahead with acquiring knowledge about the whole of universe and converting all of it in verbal notation.

The conscious realm appears to have developed based on the pain and rewards that surrounds the individual. The way to get over this highly concentrated drama is simply by learning all the neural set-ups that favor this specific module and by observing the kind of thoughts and emotions that spontaneously spring up at different moments of life. The closer one captures through the power of attention, the programmed modules of self-talk put forward by the neural system, the more prepared we would be to challenge it and to take it forward to a new scale. The age-old practice of imagining an exclusive entity called 'self' or attributing the self-talk to something as mysterious as the soul would begin to thin out under the power of science combined with an introspective analysis.

The Reciprocal Control

This is not to imply that the over-mind is something entirely new to be developed. The extent of inhibitory processes already at work in our pre-frontal cortices has enabled us to choose the most appropriate action, word and behavior, suppressing a whole lot of other possibilities. The over-mind in this sense is already at work in us. What we are suggesting here is that this role could be further refined towards some specific objectives.

It's only after perfecting hundreds of involuntary muscular controls, one particular section of the sensual data relating either to the sound or the picture of alphabets has catapulted us to a world-wide-web of thoughts, emotions and values. To enjoy the chillness of a bath, one may have to shut down the automatic thought processes that side-track us from the immediate pleasure. Such wisdom was rightly advocated in Buddhist traditions more than two millennia earlier. Attending to just one split second is a brilliant way of avoiding the mega story spun by the mind.

But we also have the freedom to reflect over the beauty of inter-connectedness starting all the way from the early stages of cosmic evolution. The moment we know that the self we had relied on is a construct of nature taking no more than bits and pieces of particles making up the DNA of our cells and bits and pieces of sensations including the language-sensations, the question of the teleological motive in all of universe is bound to haunt our attention.

The meaningfulness given by the language system supported by neurotransmitters and neuromodulators is defining no more than an utterly limited circle at present. Reflecting on the long chain of evolution that has cleverly brought about the construct of the individual self, you would not only feel one with all physical and chemical designs, it would be impossible thereafter to separate yourself from the essential undercurrents of Nature.

The Indian tradition reached out to these truths in its own inimitable style. As per Mandukya Upanishad[11], the wakeful and the dream states are caused by the various organs and limbs exposed to the world, while Atman is identified with that which lies beyond deep-sleep. Something keeps you alive even when you deep-sleep. It brings back to you the right kind of memories the moment you wake up. That ultimate base is Brahman, as per the inspiring dialogue between Uddalaka and his son Svetaketu in Chandogya Upanishad[12].

The remarkable intuition of the pre-scientific era doesn't mean one can progress much by going to sleep and acting as if the identity with Brahman is already achieved. On the contrary, right in the wakeful state, if you start focusing on the essential fact that chemical designs are the base of each of your thought and that something else ought to have planned even the complex brain structures, there's no other go but to find yourself united with the cause of all causes. Again the Upanishadic wisdom is hard to come by without reflecting on the Buddhist ideal of looking at the utterly limited minute parts that build up the whole or without reflecting on the absolute certainty of mind over matter as demonstrated through Jesus of Nazareth or without wondering over the divine act of dismantling some of the misleading statements of Christianity through the Book of the Holy Quran.

CONCLUSION

The human system is dangling between two extremes. It can only split up into the basal elements from which it evolved or it can unite itself with the topmost conscious energy that appears to have guided from within one beautiful construct after the other. The priorities and focus given by our current neural set-up can only give us a façade of meaning and joy. It stands utterly ill-prepared for any of the long-term objectives or significance. To control and direct it as per the huge knowledge available through science, one needs to develop the over-mind, which is already at work in us through some of the religious teachings, social norms and behavior.

Are Soft Drinks Soft on Teeth? A Study on Dental Erosion Caused by Soft Drinks Marketed in India

Prajna P. Nayak[1], Nishu Singla[2], K.V. V. Prasad[3], Nandita S Rao[4]

[1]Senior Lecturer, [2]Associate Professorr, Department of Public Health Dentistry, Manipal College of Dental Sciences, Manipal Academy of Higher Education, Manipal, [3]Professor and H.O.D., Department of Public Health Dentistry, SDM college of Dental Sciences and Hospital, Dharwad, [4]Dentist, (DDS) Loma Linda University, California, U.S.A

ABSTRACT

Introduction: Awareness of dental erosion by public is still not widespread, and there is paucity of information on how much erosion do various soft-drinks marketed in India cause.

Objectives: To quantify the amount of erosion that various soft-drinks may cause, in relation to their baseline pH, titrable acidity and calcium contents.

Method: Six types of drinks- Coca-cola, Sprite, Maaza, Lipton iced lemon tea, Tropicana orange juice and yoghurt were used, with water as control. Baseline pH was determined by pH electrode, baseline titrable acidity was determined by amount of sodium hydroxide (NaOH) required for making pH of 5.5 and calcium content by Atomic Absorption Spectrophotometry. Five teeth each of maxillary premolars were randomly allocated into each of 7 groups. After incubation in 100 ml for 2 hours, 12 hours and 24 hours, amounts of calcium released was determined.

Results: Mean calcium release after 24 hours was highest for Coca-cola with lowest pH, followed by Maaza, Sprite, Orange juice, Lemon tea, yoghurt and water, which released 1.38µg/ml/mm^2, 1.28µg/ml/mm^2, 1.04µg/ml/mm^2, 0.91µg/ml/mm^2, 0.49µg/ml/mm^2, 0.34µg/ml/mm^2 and 0µg/ml/mm^2 of calcium respectively. Statistically significant differences were found for calcium release in coca-cola, maaza, sprite and orange juice from baseline to 2, 12 and 24 hours (p-value < 0.00).

Conclusion: Beverages with lower baseline pH and lower baseline calcium concentration showed higher calcium release. Though, direct application of the results of this study to in-vivo conditions cannot be fully made due to other host and dietary factors.

Key words: *Dental erosion, Soft drinks, pH, calcium concentration.*

INTRODUCTION

One of the most important outcomes of modern lifestyle is the changed eating habits. To keep pace with an expeditious lifestyle, people are resorting to more and more processed foods and bottled beverages. This in turn, has resulted in an ever increasing prevalence of dental erosion.[19]

Dental erosion (DE) is defined as the tooth wear occurring by chemical dissolution caused by acids of any origin.[11] Being an inorganic tissue, the integrity of enamel is greatly influenced by the pH and presence of minerals in saliva. Whenever there is a drop in pH of saliva below the critical value of 5.5, tooth enamel is demineralized. The pH above critical pH is regarded as supersaturated and favors crystallization of mineral. Under normal conditions, a tooth does not lose its mineral

Email: nishu.singla@manipal.edu

since saliva is usually supersaturated with respect to its mineral concentration.[2] At this pH, the ionic product *(Ip)* of the mineral is said to be equal to its solubility product *(Ksp)*.[15] Whenever oral cavity is exposed to acidic foods and beverages, the pH of solution becomes less than critical pH *(Ip<Ksp)* and saliva becomes unsaturated with respect to mineral, which then precipitates out into the solution.[2] Frequent and prolonged exposure to low pH may result in a more rapid demineralization of the enamel surface.[2, 15]

Initially DE is manifested as loss of tooth shine, followed by flattening of convex structures. With the continuing acid exposure, concavities form on smooth surfaces and cupping occurs on incisal/occlusal surfaces.[1] DE can be caused due to external or internal factors. Extrinsic factors being frequently consumed acidic foodstuffs or beverages and acidic contaminants present in the working environment. Intrinsic factors are acids regurgitated due to gastro-esophageal refluxes.[1, 12] In the modern societies extrinsic factors are becoming an important cause for erosion due to the increased consumption of acid drinks as soft drinks, sport drinks, fruit juices and fruit teas.[5]

There are studies done in developed countries which measure the erosive potential of soft drinks marketed in their countries. [5, 10, 13-14] Hence, this study was conducted with an aim to quantify the amount of enamel surface demineralization that various beverages may cause, in relation to the baseline pH, titrable acidity and calcium contents. The objectives were: i. to measure baseline calcium content of various soft drinks by Atomic absorption Spectrophotometry. ii. to measure baseline pH by pH electrode. iii. to measure titrable acidity (neutralizable acidity) determined as the volumes of 0.1 M sodium hydroxide (NaOH) required to increase the pH of 50 milliliter (mL) of beverages to 5.5. iv. to measure and compare calcium concentrations in the drinks after 2 hours, 12 hours and 24 hours.

MATERIALS AND METHOD

This invitro study was conducted to quantify the amount of enamel surface demineralization that various soft-drinks and juices may cause, in relation to their baseline pH, titrable acidity and calcium contents.

Analysis of pH, Titrable Acidity and Calcium:

Six commonly available soft drinks and juices in the Indian market were chosen for study. The following drinks were used: Coca-cola™, Sprite™, Maaza™, Lipton Iced tea™, Tropicana orange juice™ and Danone yoghurt™. Water was used as a control.

Immediately after opening the bottles, their pH was determined at 25º C by pH electrode (Micropro – Gradmate). Three pH readings were measured for each beverage and the mean value calculated. The buffering effect of each drink was determined by monitoring pH after serial additions of 0.025 mL of 0.2 mol/L of sodium hydroxide (NaOH) to 5mL of each drink. Then, their Calcium concentrations were determined by Atomic Absorption Spectrophotometer (Thermo Jarrel Ash Atomic Absorption Spectrometer). Five readings were taken for each beverage and the mean value was calculated.

Preparation of Enamel Specimens:

A total of 35 freshly extracted human premolars were collected from young adults, who got their teeth extracted for orthodontic reasons. Immediately after tooth extraction, surrounding soft tissues were removed and were placed in a 0.9 % sodium chloride solution for up to 7 days. All teeth were then examined microscopically for any irregularities of mineralization, especially for genetic diseases of enamel mineralization, for cracks or for other defects.

All the teeth were covered with three coats of acid resistant nail varnish, except for a 4 × 4 mm window left for exposure. This was done to standardize all teeth, so that, calcium can leach out from the same amount of surface area from all teeth. Five teeth each of maxillary premolars were randomly allocated into each of the 7 groups.

Study design:

Each tooth was incubated in 100 mL beverage for upto 24 hours at 37º C in air tight containers. After incubation at 2 hours, 12 hours and 24 hours, the amounts of calcium released from each beverage was determined by selecting the median value of the five readings taken using Atomic Absorption Spectrophotometry. The increase in calcium in the drinks, as a result of erosive action was then calculated.

Statistical Analysis:

The collected data were computerized and processed

using MS Excel and Stata 10.0 version. Kruskal Wallis ANOVA was applied to test any significant differences in calcium release from baseline to 2 hours, 12 hours and 24 hours. Wilcoxon Matched Pairs test was applied to test if there is any significant difference in the percentage change in calcium levels from baseline to 2 hours, 12 hours and 24 hours. Pearson's correlation coefficient was applied to compare the DE caused by various drinks, in relation to their baseline pH, titrable acidity and calcium contents.

RESULTS

In this invitro study on determination of erosive potential of drinks, 6 drinks were analyzed for their baseline calcium concentration and pH value and titrable acidity. The pH values ranged from 2.32 to 6.45, with coca-cola having the lowest pH and water, the highest. Coca-cola had lowest titrable acidy (1.06 ± 0.75) and orange juice had the highest (3.02 ± 0.87). Baseline calcium contents ranged from 22.07µg/mL for coca-cola to 251.31µg/mL for yoghurt. (Table 1)

The increase in calcium as a result of erosive action was measured after 2 hours, 12 hours and 24 hours. It was seen that after 2 hours, Sprite showed highest calcium release of 7.09µg/mL followed by Coca-cola which released 6.2µg/mL and Yoghurt showed lowest calcium release of 1.49µg/mL and water, 0µg/ml. Statistically significant differences were seen in calcium release between baseline to 2 hours, in all the drinks, except in maaza and yoghurt (p-value< 0.05). And that, after 12 hours, coca-cola showed the highest calcium release of 12.81µg/mL followed by maaza and sprite. After 24 hours also coca-cola showed the highest calcium release of 22µg/ml. Again here, after 12 hours and 24 hours, statistically significant differences were seen in calcium release in all the drinks, except yoghurt (p-value< 0.05). (Table 2)

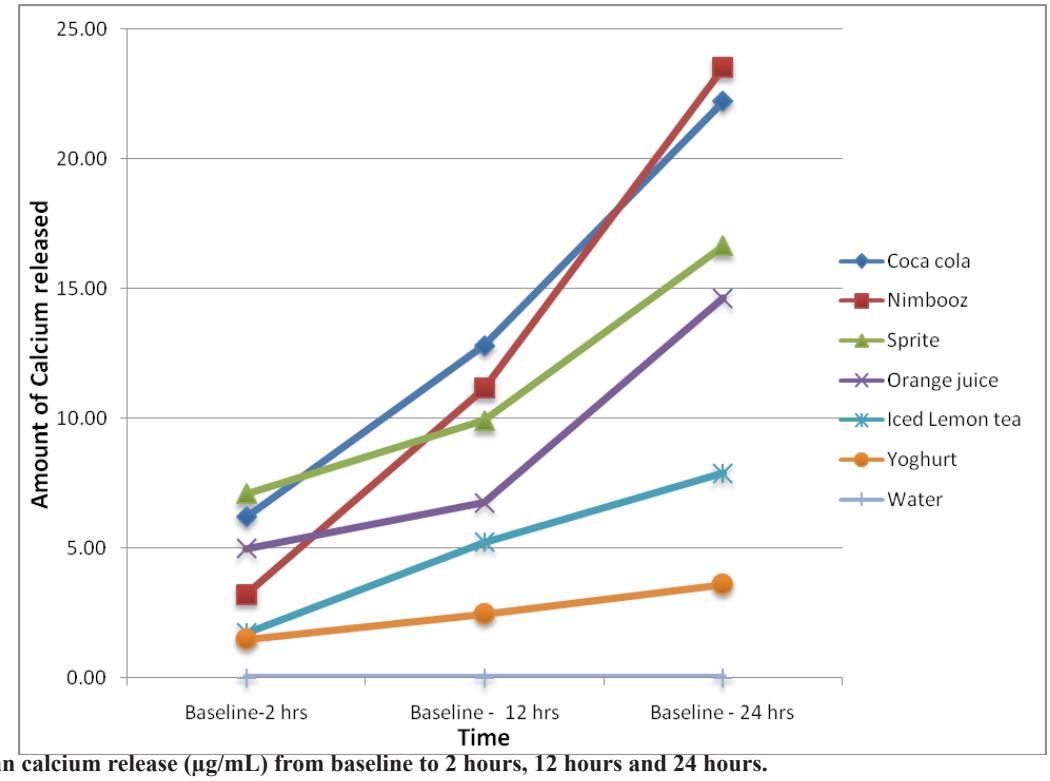

Table 3 gives the percent gain in Calcium in the drinks after 2, 12 and 24 hours. It was seen that, statistically significant differences between baseline to 2 hours, 12 hours and 24 hours were found in all the drinks, except in yoghurt at all times and maaza from baseline to 2 hours. Pearson's correlation coefficient showed no significant correlation in the amount of DE caused by various drinks, in relation to their baseline pH, titrable acidity and calcium contents.

Table 1: Mean baseline calcium concentration and baseline pH of the drinks.

Groups	Baseline Calcium (µg/mL)	Baseline pH	Baseline Titrable Acidity at 5.5 (ml)
Coca-Cola	22.07	2.32	1.06 ± 0.75
Maaza	89.79	3.08	1.93 ±0.17
Sprite	25.56	3.22	1.12 ± 0.33
Orange juice	62.13	3.67	3.02 ± 0.87
Iced lemon tea	35.63	3.35	1.87 ± 0.54
Yoghurt	251.312	4.34	2.71 ± 0.39
Water	0	6.45	_

Table 2: Percentage gain in Calcium after 2, 12 and 24 hours

Groups	% gain in 2hrs	% in 12 hrs	% in 24 hrs
Coca-Cola	28.118*+	58.05*+	100.64*+
Maaza	3.59	12.45*+	26.21*+
Sprite	27.76*+	38.83*+	65.14*+
Orange juice	8.04*+	10.89*+	23.57*+
Iced lemon tea	4.87*+	14.70*+	22.19*+
Yoghurt	0.59	0.99	2.23
Water	0.00	0.00	0.00
*p<0.05; + Applied Wilcoxon Matched Pairs test

DISCUSSION

The loss of dental hard tissue as a consequence of changed eating habits is increasingly gaining importance. Unusual drinking habits like that of holding acidic beverage in the mouth before swallowing increases the contact time and thus amplifies the risk of erosion. Bedtime consumption of acid beverages is considered as a risk factor among children. [19] Also, studies conducted previously suggest that the length of time the teeth are suffused in acidic environment is more decisive to erosion than the volume of beverage consumed. [5] It is known that carbonated drinks are frequently held in the mouth until all bubbles have dissipated. Hence the contact time of carbonated drinks with teeth can be much longer than that for non-carbonated beverages.[5, 19] On account of such shifts in eating habits in recent years, it is very important for dental professionals to alarm the public on harmful effects of these beverages on dental health. Hence, this study was conducted with an aim to quantify the amount of erosion caused by various beverages.

A large number of techniques have been developed in order to determine both the change in and loss of tooth surface structures induced by erosion. Some of the techniques used most frequently are: surface roughness measured with an Optical Profilometric Device, determination of Micro Hardness, Scanning Surface Microscopy, Microradiography, Confocal Laser Scanning Microscopy (CLSM) and Chemical Analysis of leached out minerals.[3-4, 7-8, 10, 13-14, 18, 20] The quantitative light-induced fluorescence (QLF) and the Nano Indentation techniques are some recent methods.

Enamel consists of 34 to 39 percent calcium by weight (dry weight) and 16 to18 percent phosphorus by weight. [20] Chemical analyses have an advantage over other methods that they are not only sensitive and precise, but also DE of natural enamel surfaces can be investigated as there is no need of polishing [4]. Therefore, a quantitative determination of calcium and phosphorus dissolved through erosive procedure is one of the most apposite methods in order to measure erosion. [6]

In this in-vitro study, pH of all the test beverages ranged from 2.32 to 4.34, which was below the critical pH of 5.5. Those beverages with lowest pH and baseline calcium concentrations showed the most pronounced erosive effect on the enamel. This is in accordance with the studies conducted by Sales-Peres et al (2007) [7] and Fatilah AR and Rahim ZHA. (2008).[6]

Titrable acidity is another important aspect that has a role in causing DE. Higher titrable acidity was observed for orange fruit juice and fruit based drinks, because of which they are expected to have higher erosive potential than carbonated beverages, but was not so in our study. This could be because of the higher pH of orange juice and iced lemon tea as compared to that of carbonated beverages which is in accordance with the study conducted by Tadakamadla J et al (2015) [17] and Jensdottir T et al (2006).[9] Yoghurt showed the lowest calcium release, which had the highest ph, titrable acidity and calcium concentration of all the test drinks. Thus, decrease in DE was seen with decreasing baseline calcium concentrations in the drinks, similar to the study done by Pereira HS et al (2013), where, soft drinks supplemented with metallic ions reduced dissolution of bovine enamel.[16]

Yet, the present study is not without any limitations. There are other factors that protect the oral environment from DE, like pellicle and salivary components preventing dissolution, frequency and time interval between beverage consumption, the simulation of which in invitro conditions is not feasible.

CONCLUSION

From the present study, it can be inferred that coca-cola, which had the lowest baseline calcium concentration and lowest pH showed the most pronounced erosive effect on dental enamel. Other than water, yoghurt showed the lowest calcium release, which had the highest ph and calcium concentration of all the test drinks. Baseline pH and baseline calcium concentration showed a significant correlation with the amount of calcium released.

Based on these analyses, personalized preventive programs may be suggested to the individuals who consume such beverages frequently. It may comprise dietary advice, optimized fluoride therapy, use of buffering medication and emphasis for nondestructive tooth brushing habits with low abrasive toothpastes.

ABSTRACT

The Internet of things (IoT) is the network of physical devices, vehicles, home appliances, and other items embedded with electronics, software, sensors, actuators, and network connectivity which enable these objects to connect and exchange data. It is estimated that by 2020 IoT will consist of 30 billion devices with a global market value of $7.1 trillion. With large number of devices connected to the internet, security becomes a major factor to consider. Along with security micro- payments via the internet of things becomes a huge risk. Our target with this project is to rectify both problems with the use of Blockchain technology. We want to create a decentralized peer-to- peer network of IoT devices which share a common distributed database. This database is known as a blockchain. Blockchain ensures the ownership and integrity of the data solving the security problem faced by IoT. Also, cryptocurrency written over this blockchain would solve the micropayments problem of IoT. The cryptocurrency design methodology takes into account that most IoT devices would be embedded systems thereby optimizing cryptographic standards for embedded systems. With this project we aim to improve the security risks which relate from data sharing and to reduce data redundancy by above 80%.

Keywords—*Distributed Systems, Internet of Things, Decentral- ized, Blockchains.*

INTRODUCTION

A blockchain is a continuously growing list of records, called blocks, which are linked and secured using cryptogra- phy. Each block typically contains a cryptographic hash of the previous block, a timestamp and transaction data. By design, a blockchain is inherently resistant to modification of the data. It is an open, distributed ledger that can record transactions be- tween two parties efficiently and in a verifiable and permanent way. For use as a distributed ledger, a blockchain is typically managed by a peer-to-peer network collectively adhering to a protocol for validating new blocks. Once recorded, the data in any given block cannot be altered retroactively without the alteration of all subsequent blocks, which requires collusion of the network majority [1].

We aim to use this technology to implement it in Internet of Things. We do this to improve the security risks which relate from data sharing and to reduce data redundancy. We tend to create a decentralized peer-to-peer network of IoT devices which share a common distributed database [2]. Blockchain ensures the ownership and integrity of the data solving the security problem faced by IoT.

METHODOLOGY

To maintain a distributed ledger/database a mesh network is created. Each node need not be aware of every other node in the network. Although, every node should be connected to every other node directly or through nodes. Whenever a node creates a new firmware/ file it notifies the closest nodes which in-turn notifies the other nodes. Thereby, every node on the network receives the new file. Every node then checks the consistency of the file using proof-of-kernel algorithm. Once a node checks the file it adds the hash of the file to the blockchain. At least 50% of the nodes on the network must verify the file and add it to their blockchain to make it immutable. This phenomenon is known as consensus. Once consensus is achieved the file becomes immutable and available to everyone. Every node minimally consists

of a Node MCU, SD card reader and SD card, battery, battery charging circuit [3].

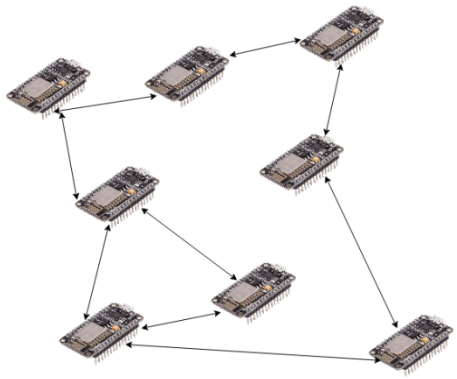

Fig. 1. Mesh network on NodeMCU nodes

Node MCU

Node MCU is an open source IoT platform. It includes firmware which runs on the ESP8266 Wi-Fi SoC from Espres- sif Systems, and hardware which is based on the ESP-12 module. The firmware uses the Lua scripting language. It is based on the eLua project, and built on the Espressif Non-OS SDK for ESP8266. It uses many open source projects, such as lua-cjson and spiffs[4].

SD card

This SD Card module can make your SD application easier and simple. It is easily interfaced as a peripheral to your arduino sensor shield module. Through programming, you can read and write to the SD card using your arduino

TP4056 - Li-ion battery charger

This module is made for charging rechargeable lithium batteries using the constant-current/constant-voltage (CC/CV) charging method. In addition to safely charging a lithium battery the module also provides necessary protection required by lithium batteries.

Li-ion battery

A lithium-ion battery or Li-ion battery (abbreviated as LIB) is a type of rechargeable battery in which lithium ions move from the negative electrode to the positive electrode during discharge and back when charging. Li-ion batteries use an intercalated lithium compound as one electrode material, compared to the metallic lithium used in a non-rechargeable lithium battery.

SYSTEM DESIGN

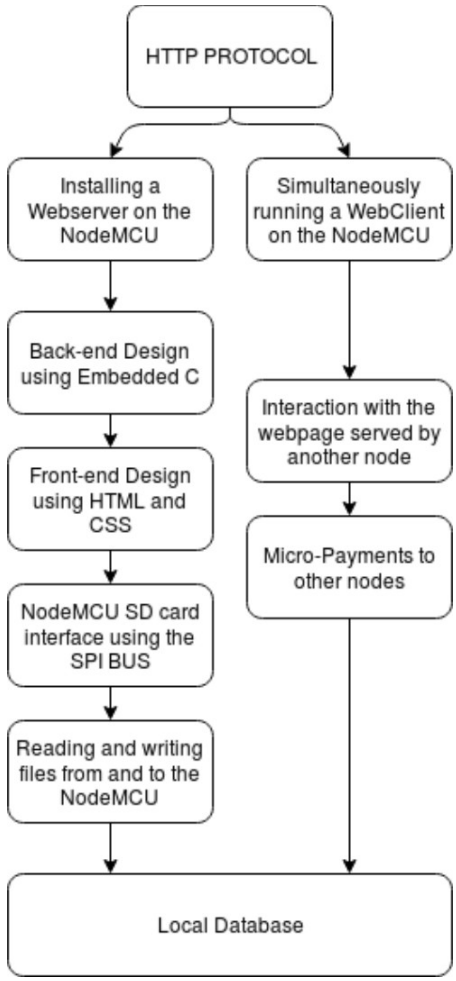

Fig. 2. Flowchart representing system design methodology

HTTP and File Storage

The HTTP Protocol runs both the web server and the web client on the on the NodeMCU. While normally we use a web server on the NodeMCU, we use a web client on the same NodeMCU. This is done so that the NodeMCU can send files and make payments in the same node[5].The web server has the complete back-end design in Embedded C. This is to interact with the various independent nodes created by the NodeMCU's. The Front-End is designed such that it can display the values received by the NodeMCU. We use HTML and CSS for the data retrieval and designing the user interface [6].

We will be using SD card in SPI mode, first we need to connect the SD card breakout board with NodeMCU. By de- fault FatFS module is disabled in nodemcu firmware, and we build the firmware with FatFS support using an online build tool. We load the new firmware and enter the following commands in the serial console;

it will list the files in root directory of the SD card [7]. We can open a file using file. open and can check out the file API for list of functions available.

We then store these values on the local database which is our SD module in the NodeMCU. The web client interacts with other nodes and is builds on the interface similar to the web server. Micro-Payments are done to the other nodes.

Blockchains

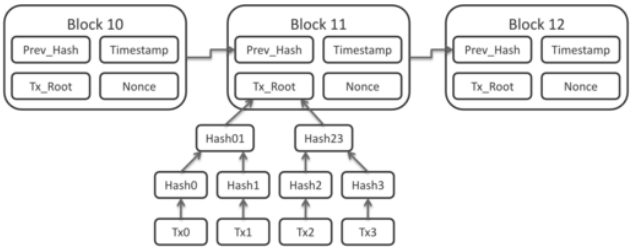

Fig. 3. Interlocking of blocks

A blockchain is a continuously growing list of records, called blocks, which are linked and secured using cryptogra- phy. Each block typically contains a cryptographic hash of the previous block, a timestamp and transaction data. By design, a blockchain is inherently resistant to modification of the data. It is ”an open, distributed ledger that can record transactions be- tween two parties efficiently and in a verifiable and permanent way”[8].

For use as a distributed ledger, a blockchain is typically managed by a peer-to-peer network collectively adhering to a protocol for validating new blocks. Once recorded, the data in any given block cannot be altered retroactively with- out the alteration of all subsequent blocks, which requires collusion of the network majority [9].Decentralized consensus has therefore been achieved with a blockchain. This makes blockchains potentially suitable for the recording of events, medical records, and other records management activities,such as identity management, transaction processing, documenting provenance, food traceability or voting [10].

RESULTS

We executed the code on two nodes to verify the working of the blockchains. Before we could upload the blockchain code we had to write in the genesis block into the NodeMCUs. If a node didn't have a genesis matching with the network it would not be able to buy or contribute to the network. For a node with the genesis block in existence successive blocks would be added to the text files (initial blocks from the balance.txt are added below)

be added to the text files (initial blocks from the balance.txt are added below)

```
{"from":"","to":"","amount":"50",
    "fileName":"blinkesp.bin",
    "description":"Helloworld"}
{"from":"chirag","to":"chirag",
    "amount":"50","fileName":"blinkesp.bin",
    "description":"Helloworld"}
{"from":"chirag","to":"swaroop",
    "amount":"50","fileName":"blinkesp.bin",
    "description":"Helloworld"}
{"from":"swaroop","to":"swaroop",
    "amount":"50","fileName":"blinkesp.bin",
    "description":"Helloworld"}
{"from":"swaroop","to":"chirag",
    "amount":"50","fileName":"blinkesp.bin",
    "description":"Helloworld"}
{"from":"chirag","to":"aditya",
    "amount":"50","fileName":"blinkesp.bin",
    "description":"Helloworld"}
```

As soon as new blocks are added to the balances.txt or the common ledger they would read by the front-end javascript and be presented on the browser page for the user.

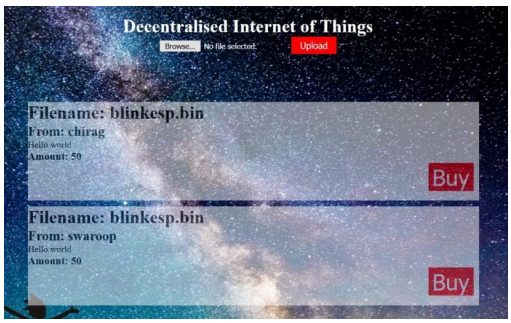

Fig. 4. **Front-end of the blockchain**

```

CONCLUSION

With the proposed blockchain design we have proved that the security risks related to data sharing and reduction in data redundancy have been reduced by above 80%.In future more blockchain can be added and further reduction in redundancy rate can be achieved

ACKNOWLEDGMENT

We would like to express our deepest gratitude to our guide, Mr. M. Manigandan his valuable guidance, consistent encouragement, personal caring, timely help and providing me with an excellent atmosphere for doing research. All through the work, in spite of his busy schedule, he has extended cheerful and cordial support to us for completing this research work. J.Selvakumar has been of tremendous help for giving us a clear understanding of cryptography on embedded devices too.

Ethical Clearance: I testify on behalf of all co-authors that our article submitted to Indian Journal of Public Health Research & Development.

Self Reported Oral Pain and Dysfunctions Associated with Radiation Induced Oral Mucositis among Head and Neck Cancer Patients - A Prospective Observational Study

Prabha Lis Thomas[1], Karthik .S. Rishi[2]

[1]Research Schola , Vice Principal Krupanidhi College of Nursing,Chikkabellandur, Carmelaram, Bangalore, Dr. Harmeet Kaur, Principal, Chitkara School of Health Sciences, Chitkara University, Punjab, [2]Radiotherapy. Consultant, Radiation oncology, Sri Shankara Cancer Hospital and Research Centre, Bangalore

ABSTRACT

Objectives: This study aimed at identifying and describing self reported oral pain and dysfunctions associated with oral mucositis among patients with head and neck cancer treated with radiation .

Method: A prospective observational study was conducted on 30 head and neck cancer patients who were undergoing radiation therapy and consented to participate. Data was collected by using a baseline proforma, WHO Oral Toxicity scale and Patient reported oral mucositis symptom scale .The patients were followed up during the entire course of radiation therapy and were monitored for the development of oral mucositis and were asked to rate their pain and associated dysfunctions on 100 mm scale.

Result: The present study findings revealed that all the subjects developed oral mucositis at the end of third week which was progressed to grade 3 or 4 mucositis by the end of therapy. The scores of oral pain and oral dysfunctions were progressively increased during the course of treatment with its peak at the end of treatment. Cumulative dose of radiation therapy and receipt of concurrent chemotherapy were found to have a significant association with oral dysfunction. The study also noted a significant positive correlation with severity of mucositis and oral dysfunctions.

Conclusion: Severe and painful oral mucositis is a dose limiting adverse effect of radiation therapy and its detrimental effect on oral functions is significant .Hence adequate preventive measures of mucositis to be identified to enhance the quality of life of head and neck cancer patients receiving radiation therapy.

Keywords: *oral pain, oral dysfunctions, head and neck cancer patients*

INTRODUCTION

Head and neck cancer treatment generally consists of a combination of radiotherapy, surgery, and chemotherapy. Majority of patients with head and neck cancer exhibit local or regionally advanced disease and hence the treatment option is usually a multimodal therapy including radiotherapy, surgery, and chemotherapy to achieve maximum tumour control. This multimodal and aggressive cancer therapy causes a plethora of short-term and long-term oral and oropharyngeal sequelae which adversely affects the oral functions and results in poor quality of life [1].

Oral Mucositis is the most common and debilitating reaction arising from the cancer treatment. Mucositis is described as an inflammation of the oral mucosa resulting from chemotherapy or ionizing radiation[1]. Earliest manifestation oral mucositis appear with a dosage of radiation equivalent to 1000 CGY, which generally occurs in the first week of treatment and clinically manifests as a rash in the oral mucosa which

Corresponding author:
Prabha Lis Thomas,
Research scholar, Vice Principal Krupanidhi College of Nursing, Chikkabellandur, Carmelaram, Bangalore-35
E mail: Prabha0575@gmail.com

often progresses to skin loss and ulceration. Ulcers are typically covered by a white pseudo membrane[2, 3].

Mucositis is a clinical challenge with an incidence of 36-100% among head and neck cancer patients receiving radiation therapy[4] and is a major burden on head and neck cancer patients as it adversely affects the oral functions. Oral pain associated with radiation therapy induced mucositis is a significant contributor to emotional distress and often leads to lower food intake potentially resulting in undernourishment and weight loss[5] .In radiotherapy-induced mucositis, the pain intensity escalates at week 3 ,peeking at week 5 and persists for weeks. Pain is intense and interferes with oral functions[6] and results in dry mouth, dysgeusia , dysphagia , altered speech , and chewing or eating difficulties[7].

Oral mucositis, pain, dysphagia, and altered taste perception may lead to loss of appetite, malnutrition , reduced treatment compliance and radiation treatment breaks with a possible interference on tumour control. A systematic review conducted on literature on pain in chemo radiation therapy treated head and neck cancer patients reported that mucositis pain is frequent (80%), and interfere with daily activities (40%) and social activities (60%) [8]. These consequences greatly affect the patient's total quality of life[9] and may lead to severe disability which can increase the costs of care, tube feeding, extended hospitalization, or unanticipated re-hospitalization, and can cause modification to or interruption of the cancer therapy itself [10].

Hence an investigation of self reported oral pain and oral dysfunctions associated with radiation induced oral mucositis could help to reduce the patients anxiety by explaining them how the oral pain will affect their oral function .Addressing the patient reported clinical outcomes during cancer therapy helps the care givers to identify and institute possible novel protocols for reducing and managing the complications during head and neck irradiation .

METHOD

Population and sampling of study

The study employed a descriptive approach and 30 histopathologically confirmed patients of head and neck cancer scheduled to receive radiotherapy at Sri Shankara Cancer and research institute, Bangalore were selected randomly as per the inclusion criteria. Exclusion criteria included patients younger than 18 years, patients who had oral surgery within the previous 6 weeks, and patients with co morbid conditions. The study was approved by the hospital ethical committee. Informed written consent was obtained from the subjects and the subjects were followed up during the entire course of radiation therapy

DATA COLLECTION METHODS

Base line Performa was used to collect demographic data and the clinical data regarding the site of cancer, daily and cumulative dose of radiation therapy, type of chemotherapy medications were obtained from the subjects' medical records. The clinical manifestations of oral mucositis was evaluated by WHO toxicity criteria every week till the end of radiation therapy and was graded in to 4 categories ranging from 0-4 based on soreness, erythema, presence of ulcerations, ability to swallow solid food and the extent to which alimentation is not possible. At each clinical examination the participants completed a Patient reported oral mucositis symptom scale (PROMS) to appraise how oral mucositis affected common oral functions. The PROMS scale consists of 10 questions that are answered on a visual analogue scale (VAS), by setting a mark on each horizontal line measuring 100 mm. Two questions focused on mouth pain and change in taste and the other 8 questions focused on how much their mouth sores affected different oral functions on the day of the clinical examination.

DATA ANALYSIS

The data were typed into spreadsheet and SPSS (Statistical package for Social Science, IBM Corporation) version 23 was used for statistical analysis. Descriptive statistics using frequency, mean and standard deviation were employed to summarize the demographic and clinical characteristics of the participants and severity of oral pain and dysfunctions. Chi square test was computed to determine the association between oral dysfunctions and clinical characteristics .Spearman rank correlation was computed to identify the correlation between oral mucositis and oral dysfunctions.

RESULTS

Description of characteristics of the subjects

A total of 30 patients who fulfilled the eligibility criteria were included in the study and the study comprised of 77% males. The mean age was 60.9 years and 23% of them were educated up to higher secondary. The participants were diagnosed with carcinoma of oral cavity (63%), Laryngeal cavity (23%) and pharyngeal cavity (13%). A high proportion of tumours were classified as T2 (44%), followed byT3 (30%); T4 (23%) and T1 (3%) and 92% of the subjects had undergone surgical resection of the primary tumours site. Majority (47%) of the patients received a cumulative dose of 70 Gy and a fractionated dose of 2Gy per day (73%). 46.66% of the subjects received concurrent chemotherapy during radiation therapy and all of them received Cisplatin and 5 Fluorouracil.

Onset and severity of oral mucositis

The analysis revealed that the early manifestations of oral mucositis (grade 1 or grade 2) appeared in 43% of the patients by the end of first week and all the subjects developed Radiation induced oral Mucositis at the end of third week. Grade 3 or 4 mucositis was present in all the subjects by seven weeks and Ryles tube feeding was initiated for 4 subjects who developed grade 4 mucositis. (Fig1) The cheeks, lower lip and ventral and lateral tongue were the predominant sites of ulceration. Mean mucositis score was increased from 0 at baseline to 3.4 ± 0.31 at the end of the treatment. (Fig2)

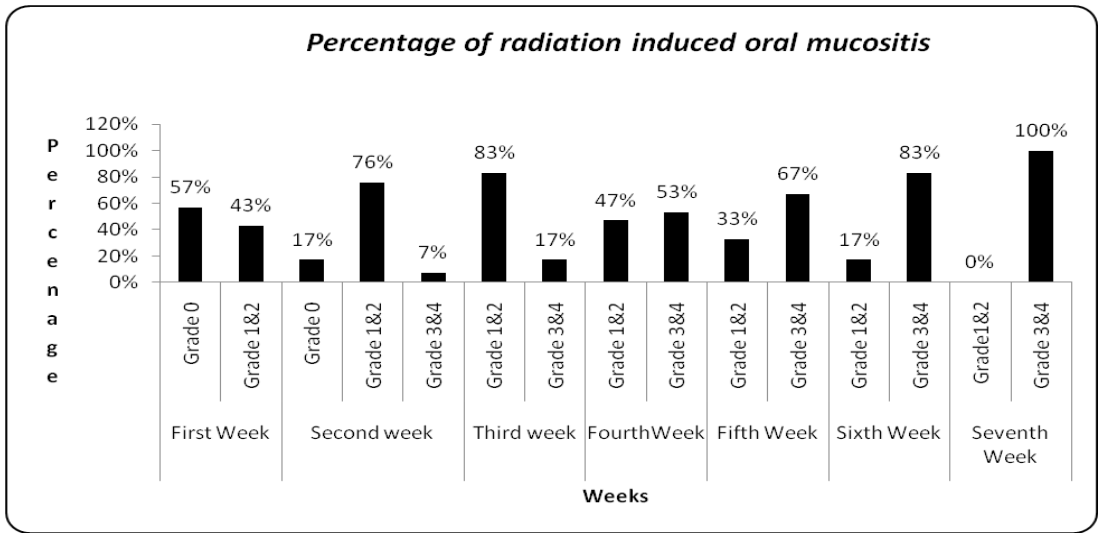

Fig1. Onset and severity of radiation induced mucositis

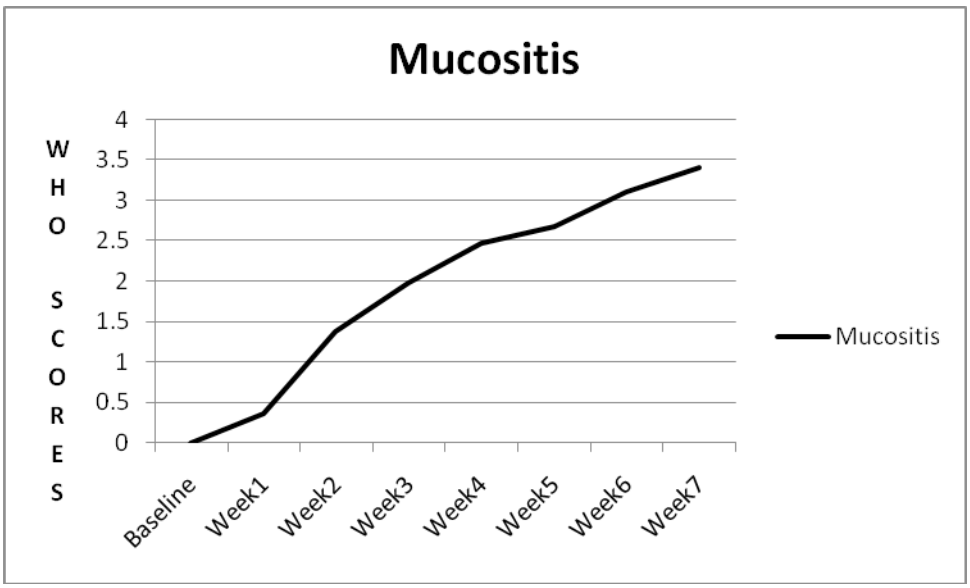

Fig 2: Mean mucositis scores during the course of radiation therapy

Oral pain and oral dysfunctions associated with radiation induced oral mucositis.

The scores of all the ten components of PROMS increased gradually during the cancer treatment period. Oral pain scores associated with mucositis were progressively increased from 17.3± 1.53 at the end of first week to 75.45 ± 1.95 at the end of seven weeks. Ninety percent of the subjects (n=27) were taking analgesic medication more or less constantly during the course of radiation therapy and despite this medication the participants reported consistently increasing pain score throughout the entire period of radiation therapy. Difficulty eating hard foods, Change of taste and difficulty in swallowing were considerably more affected by oral mucositis than the other components of the Patient reported oral mucositis symptoms scale (Table.1)

Table1: Comparison of mean scores of oral dysfunctions during the course of radiation

SL No	Items	First week	Second week	Third week	Fourth week	Fifth week	Sixth week	Seventh week	Mean score
1	Oral pain	17.3	26.6	38.65	46.14	57	63.93	75.45	46.44
2	Difficulty speaking	16.13	22.3	32.73	40.7	49.7	57.15	63.25	40.28
3	Restriction in speaking	8.33	17.66	28.88	48.13	56.17	59.85	60.25	39.9
4	Difficulty eating hard food	23.16	35.46	53.3	64.1	78.8	85	88.9	67.59
5	Difficulty eating soft food	13.56	21.1	36.07	46.8	58.93	66.2	77.1	45.68
6	Restriction in eating	11.37	20.9	38.7	50	66.2	66.56	69.6	46.19
7	Difficulty in drinking	12.7	18.8	32.67	41.33	48.76	55.43	60.45	38.59
8	Restriction in drinking	9.2	17.16	29.06	37.56	48.4	54	56.25	35.95
9	Difficulty in swallowing	15.46	27.26	40.5	54.26	65.06	75.8	82.85	51.59
10	Loss of taste	17.4	27.76	50.56	63.7	76	85.03	91.47	58.84

Chi square analysis revealed a significant association between daily & cumulative radiation dose and receipt of concurrent chemotherapy with oral dysfunction among head and neck cancer patients (Table2). Spearman rank correlation was computed and revealed a significant correlation between mucositis and prom aggregate score at the end of therapy (r=0.79, p=0.02)

Table 2: Association between selected clinical variables and oral dysfunction among head and neck cancer patients N=30

Variables	Less than median	More than median	Chi value	P value

DISCUSSION

Head and neck irradiation is often accompanied by significant and profound acute oral mucositis which adversely affects many of the oral functions. Clinical significance of oral mucositis is attributed to a complex interaction of the patient's perception of the altered oral function[11].The present study observed that all the subjects developed oral mucositis by the end of 3 rd week and intensified in severity by sixth or seventh week of radiation therapy. This finding supports the previous findings that oral mucositis is a distressing condition which is observed at the first week of head and neck irradiation and reaches its maximum intensity at the end of the treatment[12].

The suffering caused by oral mucositis is multifaceted. Pain due to oral mucositis is the most frequently reported patient related complaint affecting quality of life[9]. In the present study the subjects reported a consistently increasing pain score during the course of radiation therapy despite the intake of analgesics. These findings corroborates the observations made by a previous prospective observational study conducted on head and neck cancer patients which reported a poor pain control and high intake of analgesics during radiation therapy indicating neuropathic nature of pain which adversely affect activities of daily living and require a greater dose of analgesics[13].

Severe and painful oral mucositis is associated with a high level of oral dysfunctions and in general, the most common presentations of oral mucositis-related dysfunction are dysphagia, changes in food tastes, dry mouth, eating and drinking difficulties and inability to speak[12, 14]. It is observed in the current study that the oral functions eating, drinking, swallowing, speaking and sense of taste were affected and change of taste, difficulty eating hard foods and difficulty in swallowing were the most affected dysfunctions. Previous studies have reported similar findings that dysphagia (88%), change of taste (92%) [12], and difficulty in eating solids (90%) [13, 15] were the most prevalent oral dysfunctions among patients during head and neck irradiation. A cumulative dose of more than 30 Gy can cause damage to the taste buds and salivary glands and impairs the individual's ability to detect basic tastes (sweetness, sourness, saltiness, and bitterness)[16].

Dysphagia combined with loss of taste can interfere with the patients' food and fluid intake with significant weight loss and malnutrition[12].

Cumulative radiation dose and receipt of concurrent chemotherapy were found to have a significant association with the severity of oral dysfunctions (p =0.01)and the study also observed a significant positive correlation between mucositis and oral dysfunctions. Similar findings have been reported in a cross sectional study on eighty eight head and neck cancer patients with oral mucositis receiving cancer therapy in which intensity of oral mucositis were significantly correlated with distress score of oral dysfunction (r = .791, P < 001) ,dysphagia (r = .513, P < 001) and loss of taste (r = .578, P < 01)[12]. The findings indicate that oral mucositis adversely affects oral functions and an altered oral function is common sequelae of oral mucositis.

The current study is limited to a small sample size of 30 and to a single setting. The study was aimed to quantify the severity of oral dysfunctions perceived by head and neck cancer patients during radiation therapy and hence did not involve any objective measurement of these dysfunctions .

CONCLUSION

The findings have demonstrated that the intensity of oral dysfunction during head and neck irradiation were moderately high from the patients' point of view and hence increased attention and treatment of oral dysfunctions are essential to achieve the best outcomes of cancer therapies.

Conflicts of Interest: The authors declare no conflict of interest

Ethical Clearance: The study was approved by the hospital ethical committee. Patients and their caregivers indicated their willingness to participate in the study after the details of the study had been explained to them. The subjects were also informed that they had the right to withdraw from the study at any time during the course of the study and written informed consent was obtained from them.

ABSTRACT

Introduction: *Staphylococcus aureus* is a major human pathogen that causes a variety of suppurative (pus-forming) infections had evolved as a major cause of hospital acquired (nosocomial) infection humans. MRSA, a resistant variant of *Staphylococcus aureus* is resistant various classes of antibiotics such as penicillins, methicillin, cephalosporins and the fluoroquinolones, it is often reflected as a superbug. Methicillin-resistant *Staphylococcus aureus* (MRSA) posed to be an uncontrollable, nuisance in serious public concern. Vancomycin, a glycopeptides is the treatment of choice for MRSA infections. In recent times development of vancomycin resistant *Staphylococcus aureus* (VRSA), strains all around the world with highest being reported in health-care settings, the alternatives are Oxazolidons which includes Linezolid and polycyclic compounds such as Tetracycline and Tigecycline. **Materials and Method:** A total 620 *Staphylococcus aureus* isolates employed in this study was conducted at Department of Microbiology, Sri Lakshmi Narayana Institute of Medical Sciences, Pondicherry All the isolates were collected between July 2014 to April 2017 in the study. All the isolates were identified as *S. aureus* by culture and biochemical tests which included test for clumping factor, free and bound coagulase and mannitol fermentation. **Results:** The average resistance seen in Ampicillin(93.8%), Cephelexin(88.6%), Cefotaxime(86.4%), Cloxacillin (17.9%), Erythromycin(82.4%), Gentamicin(10%), Ciprofloxacin(50.2%), Clindamycin(44.6%), Penicillin(90.5%), Tetracycline(84.8%). **Conclusion:** The present study shows health care institutions face constant and evermore problems because of *Staphylococcus aureus* . Active screening and proper infection control procedures need to be adopted to control *Staphylococcus aureus* infection.

Keywords: *Staphylococcus aureus, MRSA,Antibiotic resistance.*

INTRODUCTION

Staphylococcus aureus belongs to the family *Micrococcaceae* and is part of the genus *Staphylococcus*, which contains more than 30 species such as *S.epidermidis*, *S. saprophyticus* and *S. haemolyticus*. Among the *staphylococcal* species, *S. aureus* is by far the most virulent and pathogenic for humans.

S. aureus is a 1 μm, Gram-positive cell that in the laboratory may be observed as single cells, in pairs or as grape-like irregular clusters. It is characterized as coagulase and catalase positive, non-motile, non-spore-forming and as facultative anaerobic. It grows in yellow colonies on nutrient rich media and is referred to as the yellow *staphylococci*.[1]

Alexander Ogston presented in 1880 at the Ninth Surgical Congress in Berlin his work establishing

Corresponding author:

Ph.D Scholar, Sri Lakshmi Narayana Institute of Medical Sciences (Affiliated to Bharath University) Pondicherry – 605502, Mobile: 91 7780512600, 91 8143730134, Email: omomom005@gmail.com

the causative role of bacteria in wound infection and subsequent septicemia. Building on the teachings of his senior contemporaries,Louis Pasteur and Joseph Lister,Ogston had observed pus from 88 human abscesses under his microscope and noted Gram-positive spherical "micrococci" [2 3] .Ogston named them staphyle, the Greek expression for a bunch of grapes. In 1884, Rosenbach succeeded in isolating yellow bacterial colonies from abscesses and named them *Staphylococcus aureus*, "aureus" from the Latin word for golden.[4]

S. aureus has the ability to adapt to different environments and it may colonize the human skin, nails, nares and mucus membranes and may thereby disseminate among recipient host populations via physical contact and aerosols[5]. Colonization with *S. aureus* is an important risk factor for subsequent *S. aureus* infection.[6] [7] *Staphylococcus aureus* has been recognized historically as a virulent and important humanpathogen.[8]*S. aureus* causes a variety of infections ranging from skin and soft tissue infections to invasive diseases such as bacteremia, endocarditis, pneumonia,visceral abscesses, osteoarthritis and septicaemia.[9]

MRSA, a resistant variant of *S. aureus* is resistant to various classes of antibiotics it is often referred to as a super-bug.During the last three decades, many articles have been published describing and debating the epidemiology of methicillin-resistant *Staphylococcus aureus* (MRSA).[10]This work was stimulated by the ongoing impact of infections caused by MRSA and the difficulties in preventing or treating them.[11] [12] Nevertheless, uncertainties regarding the transmission and control of MRSA remain.[13] For instance, new epidemic strains of multi resistant *S. aureus* have continued to emerge and decline for unknown reasons in different places since 1961.[14] [15] [16] It remains unclear why some European countries such as the UK are affected by the rising occurrence of epidemic invasive strains of MRSA,[17] whereas countries like Denmark have nearly abolished their MRSA problem.[18] Moreover, some local MRSA outbreaks have disappeared without any particular control efforts or antibiotic restriction,[19] while others institutions report MRSA propagation or reappearance despite various attempts to contain it.[16]

Almost 40 years after the first report of MRSA in the UK, the study by Farrington and colleagues published in this issue of QJM, describes another astonishing MRSA experience, and presents new insights into the never-ending struggle to prevent MRSA infections. Several aspects of the retrospective study by Farrington and co-authors attract our attention. First, this paper describes in a very detailed and careful manner a 12-year experience with MRSA at Addenbrooke's Hospital in Cambridge.[20] The authors demonstrate that sporadic or epidemic strains of MRSA could be controlled over 10 years through the use of a stringent, but labour-intensive control policy including screening of high-risk patients, transfer of patients to isolation rooms, and ward closure to new admissions in case of MRSA transmission. Since 1993, however, an increase of patients admitted with MRSA halted the initial `search and destroy' strategy, resulting in a dramatic hospital-wide MRSA outbreak.[21]

The present study was designed to investigate the incidence of a comparative evaluation of Antibiotic susceptibility Pattern of Methicillin sensitive and Methicillin resistant *Staphylococccus aureus* isolated from clinical Specimens in a Tertiary Care hospital.

MATERIALS AND METHOD

This study was carried out to determine the antimicrobial susceptibility pattern of Methicillin sensitive and Methicillin resistant *Staphylococcus aureus isolated from different clinical specimens (Table: 1)* between April 2014 to January 2018 in the Department of Microbiology, Sri Lakshmi Narayana Institute of Medical Sciences, pondicherry were included in the study.

Isolation of *Staphylococcus aureus* from clinical samples: A total of 620 consecutive isolates of *S.aureus* were isolated from clinical specimens. All the specimens were inoculated on nutrient agar, blood agar and incubated at 37°C overnight. The biochemical tests such as haemolysis, Gram's stain, catalase, coagulase, and sugar fermentation were done for further confirmation.[22]

Antibiotic Susceptibility test by disc diffusion assay:

The antimicrobial sensitivity testing was carried out by disc agar diffusion technique using Mueller-Hinton agar plates and the results interpreted according to clinical laboratory standards international (CLSI) guidelines.[23] [24] The clinical isolates of *S. aureus* were Gram-stained before the test. The *S. aureus* cultures were inoculated in peptone water and incubated at 37°C, the inoculums was adjusted to a turbidity equivalent of

0.5 McFarland standard. The entire agar surface was swabbed. The following antibiotic discs were applied Ampicillin (10mcg), Cephelexin (30mcg), Cefotaxime (30mcg), Vancomycin (5mcg), Erythromycin(30 mcg), Gentamicin (10mcg), Ciprofloxacin(10 mcg), Clindamycin (2mcg), Penicillin(10 units), Tetracycline (30mcg) and the plates were incubated at 37°C and examined after 18–24 h.

Identification of MRSA

All the isolates of *Staphylococcus aureus* isolates were subjected to Cefoxitin disc diffusion testing using a 30µg Cefoxitin disc.[24] The results were interpreted according to CLSI guidelines 2014. An inhibition zone diameter of ≤ 21 mm was reported as methicillin resistant and ≥ 22 mm was reported as methicillin sensitive.Since Kirby Bauer disc diffusion method is not recommended for susceptibility testing of *Staphylococcus aureus* to vancomycin, determination of minimum inhibitory concentration (MIC) has to be done either by broth dilution method.

RESULTS

Out of 620 clinical isolates 363(58.3%) patient were from male and 257(41.4%) were female patients. Majority of the patients were age of 61-70 years. The distribution of clinical specimens were given in the below table (Table- 1). Of the 620 isolates of *Staphylococcus aureus*, 268 isolates were found to be methicillin-resistant *Staphylococcus aureus* (MRSA) and 352 were MSSA. The prevalence of MRSA and MSSA were 43.2% and 56.7% respectively.

Table- 1: Characteristics of specimen (n=620)

S.No	Characters	No	Percentage
1.	**Age(yrs):**		
	1-10	24	3.8 %
	11-20	32	5.1 %
	21-30	86	13.8 %
	31-40	72	11.6%%
	41-50	104	16.7%
	51-60	78	12.5%
	61-70	126	20.3%
	71-80	98	15.8%
2.	**Sex:**		
	Male	363	58.5%
	Female	257	41.4%
3.	**Distribution of samples:**		
	Urine	192	30.9%
	Pus	167	26.9%
	Wound	33	5.3%
	Nasal swab	19	3%
	Throat swab	21	2.5%
	Sputum	96	15.4%
	Blood	37	5.9%
	Cathertip	09	1.4%
	Vaginal swab	04	0.6%
	Bodyfluids	42	6.7%

Table 2:Antibiotic Susceptibility profile of *Staphylococcus aureus* from clinical specimens (n=620)

S.No	Antibiotic	Sensitivity of MSSA No% (n=352)	Resistant of MSSA No % (n=352)	Sensitivity of MRSA No% (n= 268)	Resistant of MRSA No % (n= 268)
1	Ampicillin(10mcg)	28(7.9%)	324 (92%)	256(95.5%)	12(4.4%)
2	Cephelexin (30 mcg)	58(16.4%)	294(83.5%)	64(23.8%)	204(76.1%)

10	Tetracycline (30mcg)	194(55.1%)	158(44.8%)	68(25.3%)	200(74.6%)

DISCUSSION

MRSA is a major nosocomial isolate in hospitals which is responsible for higher morbidity and mortality. (Costantini). MRSA strains are resistant to several antibiotics like macrolides, lincosides, aminoglycosides and beta-lactum penicillin and cephalosporins. The MRSA isolates subjected to antibiotic sensitivity pattern in the present study reveals that the isolates have also developed resistance to other antibiotics tested.

The present study showed that males had a higher isolation rate of *S. aureus* than females. Different studies have depicted variations in the prevalence rates of MRSA in different countries. The overall relative proportion of MRSA was 43.2%. The overall relative proportion of MSSA was 56.8% similar findings were seen by Arora.S et al [25] from North India, reported 46% MRSA.

The isolates of MRSA and MSSA exhibited 100 percent resistance to Penicillin similar results were reported by Chandrashekar et al.,[26] in contrast a study by Jayatilleke K et al reported 17% sensitivity.[28] The lowest drug resistant was observed for Vancomycin (3.3%), where as a study from North India by Ankur Kumar et al [27]reported 100 percent sensitivity.

CONCLUSION

Regular surveillance of antibiogram of both community acquired and hospital-acquired infections of *staphylococcus aureus* is required in formulating and monitoring the antibiotic policy. As these pathogens acquire resistance to new classes of antimicrobial agents controlling the usage of glycopeptides and linezolid is necessary in avoiding the emerging resistance trends.

only in MRSA cases should be encouraged

Preservation of glycopeptides and linezolid for use

only in MRSA cases should be encouraged

ABSTRACT

Tumor is one of the most prevalentdiseases in the brain.It is the reason why the diagnosis and treatment of the brain tumor have critical importance. MRI (Magnetic resonance imaging) is a scientific maneuver used to produce a computerized image of internal body tissue. MRI image is a diagnostic approach is used for detection ofa brain tumor and classifies it as atype malignant and benign. There aredifferent processes to detect the brain tumor.Image processing, feature extraction, and many algorithms havebeen implemented for the detection of brain tumor, but a convincing and accurate technique to detect thetumor'sprecise position and to diagnose in minimal time is in great need. The execution and complexity involved in the medical image segmentation process are enhanced by applying feature extraction techniques and mathematical models. Furthermore, to improve the accuracy and performance of detection of brain tumor using existing Artificial Neural Network and Naïve Bayes Classifier, In this article we propose a novel technique using mathematical analysis to predict and enhance the better models. The proposed method has been implementedfor detecting the type of brain tumor and its specific location in the brain. The proposed system will be used to diagnose the patient's brain tumor with goodaccuracy success rate.

Keywords—*Magnetic Resonance Image, Braintumor, Malignant, Benign, Feature extraction, Preprocessing, Artificial Neural Network, Naïve Bayes Algorithm, Canny Edge Detection.*

INTRODUCTION

Brain tumor appears when an abnormal cell is formedin the brain,known as intracranial neoplasm. There is a dual category of brain tumor cancerous tumor or malignant and benign tumor.All category of brain Tumor may produce a syndrome that varies lean on the portion of the braininvolved. The origin of most of the brain tumor is unknown. The tumor iscategorized by the tumor's origin and if its malignancy as a benign and malignant.

Malignant or cancerous tumor consists of a cancerous cell that cannot be eliminatedquickly, eventually leading to death. Hence malignant are more harmful then benign. MRI is a widely used technique in neurosurgery& neuroscience. It gives a computerized view of tissue, thus helps to detect a human brain tumor. The MRI scanning is more appropriate than CT scanning for diagnosis; it does not affect the human body because it does not use any radiation.The Treatment of tumor starts with the doctor obtaining the family and personal medical history and performing a complete physical examination.The brainis dividedinto four parts - frontal lobe, parietal lobe, Temporal lobe, Occipital lobe,and the Cerebellum, pituitary gland and Brainstem..

The typical Existence rate for malignant brain tumor patients is only 34.7%. Nearly 16,620 people will expire from a malignant brain tumor in the year 2018 in the United States.In this paper,we useFuzzy C means, and K means for segmentation of the MRI Images.The artificial neural network is a proficiency classifier used to categorize the tumor. This paper is organized as follows: covers Literature Review, Analysis on recognition of tumor following the Proposed methodology, with expected output and finally the conclusion with acknowledgment.

LITERATURE REVIEW

Dr. Babuanto et al [1] the MRI brain image using anisotropic diffusion filter discrete wavelength transform based feature is extracted and the extracted feature are given as a input to the segmentation stage SVM(Support vector Machine) was used for tumor segmentation and classification. The result came as a showing output that brain tumor is either critical or normal stage further on basis of that treatment will be executed or the accuracy of proposed method is 86%.

Prof. Akshta, et al [2] they detect a brain tumor by thresholding method application of morphological operation and extraction of tumor region for further analysis and shrinking the image and calculation of the area is efficient parameter in detecting the stage of brain tumor patient. Histogram used to summarize the data, the lapsed time for entire program is 9.14 sec but not able to normalize the category of tumor and not applicable for color images.Warintorn phusomsai, et al [3] the investigation possibilities to improve the recognition and its exactitude performance is established against SVM and a traditional ELM that is 90% against 64% and 70%. Later to improve in H-ELM in aspect of computational complexity with high dimension and large data sets.. ELM with sigmoid accomplishes the finest performance the highest precision is around 70% comparable to hard limit, radial basis sine and triangular basis.

R Manikandan, et al [4] usingof clustering method of grouping a set of pattern into a number ofcluster. To intention anautomatic tool for brain tumor recognition using MRI image data sets. Classification region using their multi parameter value make the study of region of physiological and pathological interest and definable for future enhancement.Sanjeevkumar, et al [5] including hybrid approach includes discrete wavelet transform (DWT) to be usage for abstraction of feature. The suggested hybrid approach is functional to brain MRI images to classify that tumor is either malignant or benignant and the linear accuracy vary from 80% to 90%.B. Hema Kumar, et al [6] have refined a Non-invasive grading and prognosis prediction methodology using CT and MRI images that preclude the necessity of biopsy to certify the survival of tumor and there by helps the Diagnostic in accurate diagnosis. The result generated from the FETGS System. The FETGS proposed method as 92.6% sensitive and 82.38% specific with the entire image set in case of benign and malignant. Pawar,Ganbote et al[7] used feature extraction to obtain most relevant data from the unique data set KNN Algorithm and C means algorithm has been used for showing the space of interest. They overcome with the restriction of the existing system and enhancing the detecting the tumor and providing the size and space of the tumor. B Devkota, et al [8] they used mathematical morphological reconstruction. The image is being preprocessed to disregardthe noise and then segmented to find an interest point of region with probable tumor. The limitation in the separation method such as deprived accuracy and high computational rate, asubstitute method for segmentation was being proposed. NarkhadeSachin, et al [9] their objective is to perceive the location and boundary of tumor automatically. Based on symmetric and unsymmetrical region it able to define that whether the tumor is detected like if symmetric then brain tumor is weekend and when unsymmetrical then it is recognized as a brain tumor. MRI of healthy brain has an almost bilateral symmetry. Nilesh B, et al [10] they optimized extracted feature only the relevant feature are held for advance analysis thus lessen the numerical unpredictability of arrangement of cerebrum tumor.

Anupurba Nandi et al [11] uses K-means clustering where the perceived tumor display certain abnormality which is then modified by the use of morphological operator along with basic image processing technique to achieve the objective of splitting the normal cell with the tumor cell. EmanMaksoud et al [12] they introduced an well-organized image segmentation methodology using k-means clustering technology assimilated with Fuzzy c means algorithm. Following by thresholding and label set dissection stages to deliveraccurate brain tumor detection.Limitationisn't able to diminish the time strategy so it will propose to demonstrate in several experiments. Garima Singh, et al [13] Efficient MRI is done with the help of SVM and naïve Bayes Classifier algorithm to provide accurate prediction and classification of the brain tumor. Many algorithm has been implemented and the further research work is going on to get a better result to detect and recognize the tumor's place and to diagnosis it with help of MRI images and CT scan.

ANALYSIS ON RECOGNITION OF TUMOR

The segmented images are then subjected to feature extraction. The feature for the classified images is analyzed through the algorithm and [2] CT scan using

ionizing radiation while MRI using a strong magnetic field to arrange the nuclear magnetization followed by a change in the calibration of the magnetization by radio frequencies that can be detected by the scanner.

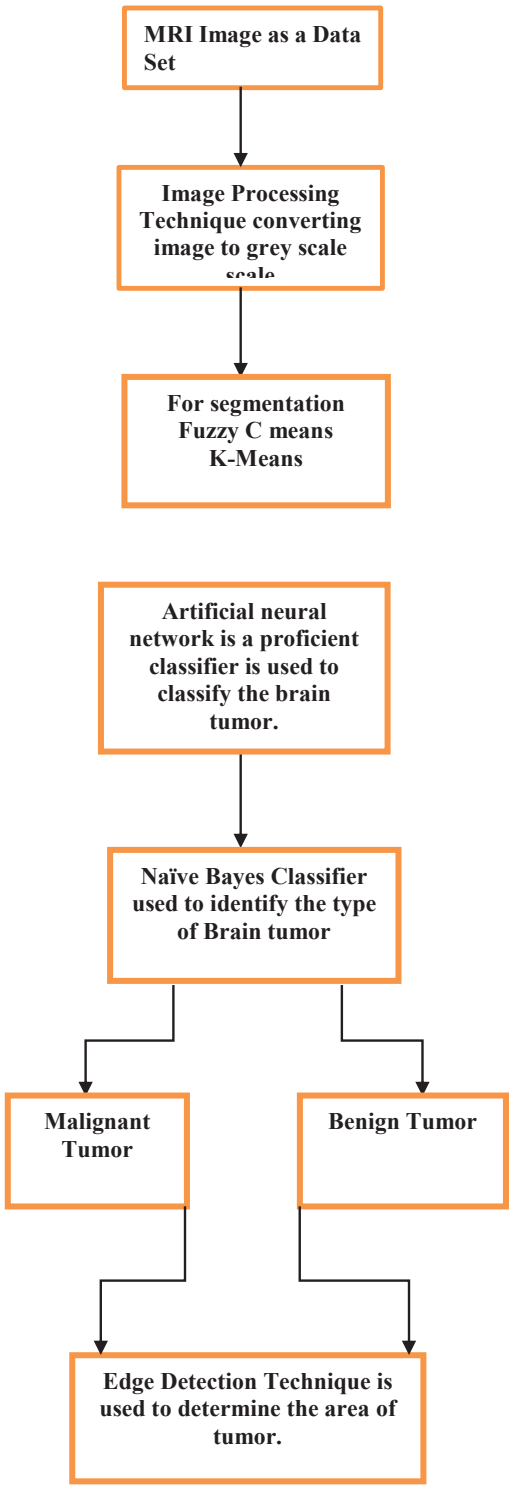

Figure 1. Architectural Diagram of the Proposed System

PROPOSED METHODOLOGY

The proposed methodology of brain tumor detection is implemented. The process to detect the tumor and classify it with the stage and forms of tumor. It is essential to know the category of tumor to diagnosed it, and to retrieved the stage then it is easy to rectify or to diagnose the tumor it need further process and as shown in figure 1 will standard to deliberate it in descriptive way.

MRI Image Data Set: The MRI image can usually be obtained from the patient's database on the computer when the person undergoes the MRI scanning.MRI images are usually black and white, single-channel images. Description of gray shading in a black and white image is done by reading the image as a grid of black spots on a white background vice-versa.

Image Preprocessing Technique: MRI image cannot be used directly as an input for the proposed system. The captured image be passed through the noise removal filter. With the assistance of a median filter, the image is being filtered, thus improving the image quality and increasing the accuracy.The median filter is less delicate than other outliers as the rate of every pixel is gained by the moderate of the near-by pixel.

Feature Extraction: [7] Feature Extraction is used to obtain the mostappropriate information from original data by using different techniques. This technique is used when the image size is large, and feature illustration is needed to complete the tasks quickly. [4]Segmentation it is to partition the filtered image into its constituent region or objects. It should end if point of interest has been isolated.

Analysis of Algorithm:An enormous number of algorithms has been executed to recognize the brain tumor and to classify the tumor and the stage.Artificial neural network and KNN algorithm is usedfor detecting the tumor and further,Bayes Classifier and edge detection techniques are used to classify and give a better accuracy in the detection of tumor. Genetic algorithms also arrange the solutions to search and optimization of the problems. These operators are crossover, mutation, and regeneration etc. The genetic algorithm originates with the initialization of the population which is an iterative system. The iteration is referred to as a generation and in each such generation; the capability is evaluated corresponding to each. In the optimization problem, the

fitness reflects the rate of the objective function in the optimization problem. K-NN Algorithm is also feasible because it combines k nearest points based on their distances and joins them in a cluster and these clusters are then evaluated. The fuzzy c means is also used topredict the tumor accurately.Mathematical models such as least square method, Entropy, Correlation and Cramer's rule to prophesyare also used to enhance a better system to detect the brain tumor.

Statistical features are used, except the features are applied as an input of Artificial neural network. The features are discussed below

Contrast: It is described as the separation of the darkest and brightness area of the image.

Contrast $=\sum_{i,j=0}^{n=1} P_{ij}(i-j)^2 \sum_{i,j=0}^{n=1} P_{ij}(i-j)^2$ ---------- (1)

Where P_{ij} = Probability i=training data j= testing data.

Correlation: It is computed into what is known as a correlation coefficient, which ranges under the value -1 and +1.

Correlation$=\sum_{i,j=0}^{n-1} P_{ij} \frac{(i-\mu)(j-\mu)}{\partial^2} \sum_{i,j=0}^{n-1} P_{ij} \frac{(i-\mu)(j-\mu)}{\partial^2}$ ---------- (2)

Homogeneity: Homogeneity iscalculated from gray scalelevel of image to simplify the classification.

Homogeneity$= \sum_{i,j=0}^{n-1} \frac{P_{ij}}{1+(i+j)^2} \sum_{i,j=0}^{n-1} \frac{P_{ij}}{1+(i+j)^2}$ ---------- (3)

Entropy: The entropy is extreme when everyentry in P_{ij} is equal, such as a matrix resembles to an image, when there is no preferred gray-level pair of the image.

Entropy $=\sum_{i,j=0}^{N-1} -\ln(P_{ij}) P_{ij} \sum_{i,j=0}^{N-1} -\ln(P_{ij}) P_{ij}$ ---------- (4)

Variance: Variance is regularly used to identify how much pixel varies from the neighboring pixel and used to classify in a different region.

Variance $= \sum_{i,j=0}^{N-1} P_{ij}(i-\mu)^2 \sum_{i,j=0}^{N-1} P_{ij}(i-\mu)^2$ ---------- (5)

Where,

Mean $\mu = \sum_{i=0}^{N-1} i, P(i) \sum_{i=0}^{N-1} i, P(i)$ ---------- (6)

Classification of tumor: SVM is one of the most prevailing classification algorithm which is competent of giving greater enactment in terms of certainty when compared with the other classification algorithms.. SVM classifier identifies the trouble by discovering out ahyperplane with biggest limit, i.e.the maximal limit of hyper-plane SVM has the certain property of concurrently minimizing the classification fault and higher range of the geometric limits. By reconstructing it into high dimensional area, it searches for a linear optimal unscrambling hyper-plane. With the support of Naïve Bayes Classifier, the brain tumor is classified as benign, malignant. Bayesian Classificationevaluates the class of unidentified data items using probabilistic statistical model. The challenge in Bayesian classification is to regulate the class of data sample which have some count of attributes. It evaluates the class of this undefined data item on the base of recognized data item which areproviding with the class label for training purpose [10].

Let consider D be the dataset of n objects such that $X_1, X_2, X_3 \ldots\ldots\ldots X_n$. Each objects has t attribute such that $A_1, A_2, A_3 \ldots\ldots\ldots A_t$. There are m classes $C_1, C_2, C_3 \ldots\ldots\ldots C_m$. Naïve Bayes Classifier predicted the unidentified data sample X which is without the label to the class C_i. if an only if

$P(C_i | X) > P(C_j | X)$ for $1 \leq j \leq m; j \neq i$. ---------- (7)

Then X is assigned to C_i. This is called Bayes Decision Rule.

Edge detection means finding the object boundary in an image. Canny Edge Detection technique is a conventional edge detection technique. It is improved techniques which doesn't trouble the feature of edges in an image. It is then applied to the propensity to find the edge and serious value of threshold. Canny Edge detection algorithm produced the same edge map. Scaling technique is used to detect the outer limit boundary of the tumor part to define its size by which it isable to know that the stage of tumor. As all the block is being discussedto detect the brain tumor and to resolve it,the next following section deal with the expected outcome of the proposed system to give a good accuracy result to recognize a brain tumor.

CONCLUSION & FUTURE WORK

Existing method provides the recognition of tumor with the assistance of MRI image, it's number of pixels and the space of tumor. The proposed system recognizes the exact size of tumor and space of tumor in brain using artificial neural network algorithm.Classification methods as a naïve Bayes classifier, canny edge detection technique for scaling purpose and mathematical model such as entropy contrast homogeneity and correlationis also used to improve the accuracy of the system. The proposed technique is useful to the physician for treatment of patients.The development of better techniques comes under future work. the existing systems for detection of brain tumor & the related algorithms which is used to detect brain tumour is viewed upon. Many algorithmsare proposed, but there is recognition of accurate size and stage of the tumor for curing it so that the abnormal cell never developis still a challenge.The proposed system used in the genetic algorithm and classification based technique to detect the tumor which gives an idea to physicians to cure the tumor. The future work will focus the analysis of the stored data with some mathematical formula which helpful to define the exact position of the tumor in brain.

Ethical Clearance: I testify on behalf of all co-authors that our article submitted to Indian Journal of Public Health Research & Development.

Association between Socio-Demographic Variables and Alcohol Dependency among Alcoholics attending Alcohol Deaddiction Camp Held at Gundlupet, Karnataka, India

M.C. Smitha[1], M. P. Somashekar[2], Nagendra[3]

[1]Assistant Professor, Department of Community Medicine, JSS Medical College, SS Nagar, Mysuru, [2]HOD, PG Department of Social Work, JSS College of Arts, Commerce and Science, B.N. Road, Mysuru, [3]Medico Social Worker, Department of Community Medicine, JSS Medical College, SS Nagar, Mysuru

ABSTRACT

Introduction: Alcohol drinking is common practice in many parts of the world including India. It leads to serious social, physical and mental consequences as per the survey of WHO 2011. Many studies have shown that alcohol use exposes the individual to acute health conditions like road traffic accidents and risk of acquiring chronic diseases. Hence the present study was conducted to determine the association between socio-demographic variables with severity of alcohol dependence among the chronic alcoholics. **Methodology:** It is a cross sectional study conducted at Gundlupet, rural part of Mysuru District. Severity of Alcohol Dependence Questionnaire (SADQ) was used to measure the severity of alcohol dependency among the chronic alcoholics. Information on socio-demographic variables was obtained by a self-administered questionnaire. The obtained data was entered in Microsoft excel and analyzed using SPSS version 23. Descriptive statistics and Chi-Square analysis was used to find the association between socio-demographic variables and severity of alcohol dependency. **Results:** 78% of alcoholics had Severe Alcohol dependency, 8% had Moderate and 4% had Mild alcohol dependency. Residence and Education were found to be significantly associated with severity of alcohol dependency. **Conclusion:** Morethan ¾ of the alcoholics are having severe alcohol dependency while remaining are having mild and moderate alcohol dependency. Place of Residence and Education were found to be significantly associated with severity of Alcohol dependency.

Key words: *Alcohol dependency, Socio-demographic variables, Rural India*

INTRODUCTION

Even today consuming alcohol is a common practice in the history of mankind. It affects the individual physical, social and psychological health status. It is a progressive disease where an alcoholic finds a lot of difficulties to quit drinking and falls in to its effects knowing its bad effects. Alcoholic faces various problems due to his addiction to alcohol. If he stops drinking, he will face withdrawal symptoms.[1] Systematic reviews of various longitudinal studies show that different socio demographic variables have differential effects on the alcoholics and they are very influential in motivating them to an alcohol dependency status.[2] Smith study indicates that alcohol users are increasing in the world wide and there is a urgent need to curb this progressive disease. According to their study conducted among alcoholics who have visited the OPD of Savitha medical college Chennai found that 65% of alcoholics are having substantial dependency on alcohol and 3% of alcoholics are severely dependent on alcohol.[3] Hence in this present study we try to understand if the socio-demographic variables influence the dependency on alcohol.

OBJECTIVE

To determine the association of the socio-demographic variables with severity of Alcohol dependency among chronic alcoholics attending the Deaddiction camp at Gundlupet Taluk

METHODOLOGY

The present community based cross sectional study was conducted among 50 alcoholic participants who participated in a community based Alcohol Deaddiction camp held at Gundlupet, Mysuru district from 07-07-2017 to 14-7-2017. Purposive sampling was adopted. Informed consent was received before conducting the interview. Confidentiality and voluntariness were the guiding principles of the study. The study was approved by the institutional ethical committee. Severity of Alcohol Dependence Questionnaire (SADQ) was used for collecting the details of dependency. The SADQ is a short, easy-to-complete, self-administered, 20-item questionnaire designed to measure severity of dependency on alcohol. There are five subscales with four items in each. They are physical withdrawal, affective withdrawal, withdrawal Relief Drinking, alcohol consumption, and rapidity of reinstatement. Each item is scored on a 4-point scale, ranging from Almost Never to Nearly Always, resulting in a corresponding score of 0 to 3. Thus the total maximum score possible is 60 and the minimum is 0. A score of 30+ indicates severe alcohol dependence and scores between 16 -30 indicates moderate dependence and score below 16 indicates a mild physical dependency.[4]Interview was conducted on 13th and 14th of July 2017 to ensure that the respondent was psychologically fit to respond to the questionnaire.

STATISTICAL ANALYSIS

The obtained Data was entered in Microsoft excel and analyzed using SPSS V.22. Descriptive statistics like mean, proportion and standard deviation was used and inferential statistics like Fisher Exact Test was used to determine the association between socio-demographic variables and severity of alcohol dependency. The difference in the proportions was considered statistically significant at $p \leq 0.05$.

RESULTS

The mean age of the study participants was 37.8 ± 9.6 yrs, the range being 22-71yrs with 64% less than 40 yrs. All the study participants were males. 50% belonged to rural area and 76% of them had completed Pre-University education. There was equal proportion of skilled and semi-skilled professionals and majority had evening and night shifts. The mean income was 1, 04,308 ± 69,306 Rs. 68% were married and all the married participants had children. 74% belonged to nuclear family and the rest to joint family and three generation families.

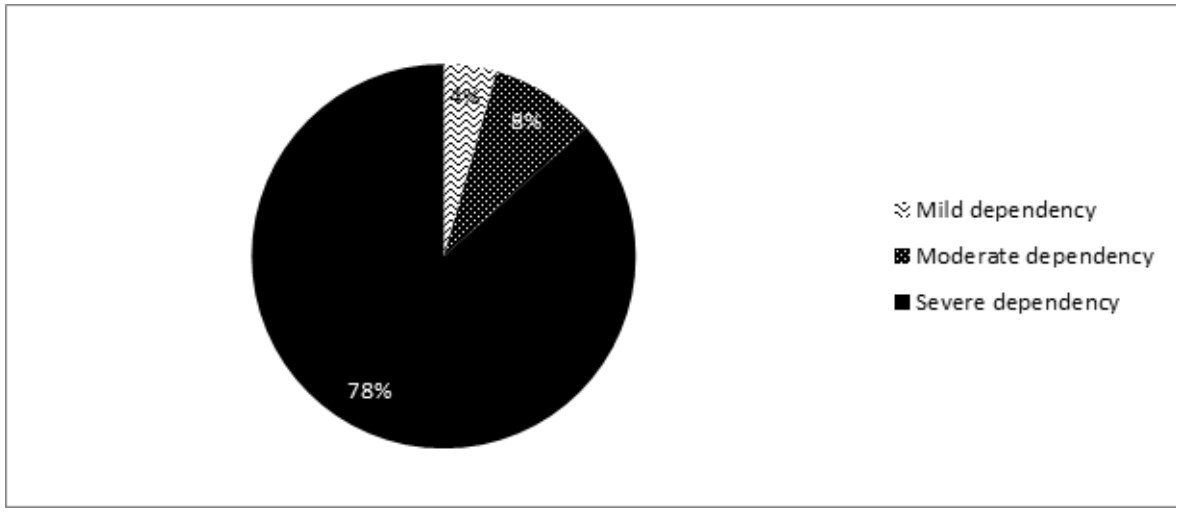

Fig- 1 Showing Alcohol Dependency among study subjects according to SAD Questionnaire

Among the study participants 78% had Severe Alcohol dependency as determined by Severity of Alcohol dependency Questionnaire (SAD Questionnaire), 8% had Moderate and 4% had Mild alcohol dependency

Absent	5	16	

**significant at p-value <0.05*

Residence (p=0.017) and Education (p=0.013) were found to have significant association with severity of alcohol dependency

DISCUSSION

WHO Statistics reported that there is significant association between SADQ score and annual income (p= 0.005), marital status (p=0.04), education (p< 0.0001), occupation (p=0.008) and work timings (p=0.002). WHO also reported that severe dependency of alcohol among urban inhabitants is due to lack of family support, increased peer pressure and easy availability of alcohol. Residence (urban or rural) and education are found to be significantly associated with severity of alcohol dependency.[5] Pillai, et al., showed that significant associations between ADS score and annual income (p=0.001), education (p=0.001)and work timings (p< 0.0001). Further he proves that alcohol dependent men take more sick leave than other employees and men with

lower education and lower standard of living would opt for a risky usual quantity of alcohol (c60 g/ drinking day).[6]In our study Education and Residence were the two socio-demographic variables found to be statistically associated with severity of Alcohol dependency. With respect to Education it was seen that lesser the education more severe is the dependency. This could be attributed to educated individuals being better informed about the ill effects of alcohol compared to the counterpart; it was also found that individuals belonging to urban area had a more severe dependency. This may be due to better availability of alcohol in urban areas, peer pressure and lack of monitoring due to nuclear family which is mostly the type of families at the urban setting. Froms the above studies and our study we conclude that socio-demographic variables influence the individual to addiction. The strength of our study is that it tries to find the association of various socio-demographic variables with severity of alcohol dependency in rural area which is a less explored research question .The limitation would be the small sample size and since all the study participants were males the influence of socio-demographic variables in female alcoholics has not been explored.

CONCLUSION

Among the study participants it was estimated that 78% had severe dependency, 8% had Moderate dependency and 4% had mild dependency of alcohol. Place of residence and education of an individual were found to be significantly determine the severity of alcohol dependency.

Prescription Pattern of Antibiotics for Upper Respiratory Tract Infection in Shah Alam, Malaysia

Kavitha Ashok Kumar[1], Mohammad Rafiq Bin Baderu Khisam[2], Ashok Kumar Jeppu[3]

[1]Head of the Unit, Otorhinolaryngology, International Medical School, Management and Science University Shah Alam Malaysia, [2]BMS, International Medical School, Management and Science University Shah Alam, Malaysia, [3]Associate Professor and Head of the Unit, Biochemistry, International Medical School, Management and Science University Shah Alam, Malaysia

ABSTRACT

Background: Upper respiratory infection (URTI) is a contagious infection of the upper respiratory tract which includes the nose, pharynx and larynx. Most of these infections are viral in origin yet treated often with antibiotics. Overuse of antibiotics is a worldwide problem. The aim of this study is to evaluate the prescribing pattern of antibiotics in management of URTI among doctors in Shah Alam and to determine the antibiotics most often prescribed for URTI.

Material & Method: A cross sectional study was conducted at two private hospitals and seven clinics in Shah Alam. A total number of 128 doctors participated in this study. The data was collected through well–structured questionnaires. Analysis of data was done by using descriptive statistics.

Result: This study showed few prescriptions for antibiotics in treatment of URTI as most of doctors (89%) did not recommended it. Although the number of cases of URTI diagnosed weekly was high, yet most of them were non-bacterial and did not require any drugs. However, most of the doctors interviewed had not attended clinical antibiotic training though they were well aware of the latest Malaysian Antibiotics Guidelines. Amoxycillin was the most prescribed antibiotic in certain cases of URTI which needed antibiotic prescription.

Conclusion: Most of URTI cases do not require antibiotics for treatment. The prescription pattern of antibiotics in Upper Respiratory Tract Infection showed no difference between the doctors involved in hospitals and clinics.

Keywords: *Antibiotics, Upper respiratory tract infection, doctors*

INTRODUCTION

Upper Respiratory Tract Infection (URTI) is a contagious infection of our upper respiratory tract which includes the nose, pharynx, larynx, and bronchi. It may manifest as common cold, pharyngitis, laryngitis, epiglottitis, laryngotracheobronchitis (Croup), otitis media and sinusitis. Most of these cases are caused by viruses like rhinovirus, adenovirus, parainfluenza virus, herpes simplex virus, respiratory syncytial virus, Epstein-Barr (EB) virus, influenza virus, Coxsackie A virus, coronavirus and cytomegalovirus. Only 10% of these cases are caused by bacteria and warrant antibiotics. The common bacteria causing URTI are Beta-hemolytic streptococci, Pneumococci, Staphylococci, H. influenza, Corynebacterium diphtheria, and Chlamydia trachomatis[1]. Overuse of antibiotics is a worldwide problem[2]. Hence, WHO has used antibiotic prescription for URTI as an indicator for assessing the optimum

University drive, Shah Alam, 40100, Malaysia
E-mail: drashokkumarj@mail.com

or overuse of antibiotics[3].According to WHO report on prescription pattern of antibiotics in developing countries, over the period of 1982 - 2006, had shown increase in the rate of antibiotic prescription by 71%[4,5]. Antibiotic use in URTI was 85-90% in developing countries like China, India, Thailand and South Africa[6,7]. This can cause adverse effects, increase healthcare cost and may result in increased resistance to antibiotics. This study was conducted with the aim to evaluate the current trend in prescribing of antibiotics for URTI in Shah Alam, Malaysia.

MATERIAL AND METHOD

This is a cross sectional study, conducted on 128 doctors working in two private hospitals and seven clinics in Shah Alam evaluating the prescription pattern concerned with the use of antibiotics in the management of URTI. The convenient sampling technique was used. Medical officers in general medicine, otorhinolaryngology, pediatrics and emergency departments were included in this study. Houseman officer and other hospital staff who are not involved in drug prescription were excluded. Permission was taken from the heads of department of all the hospitals and clinics to conduct thestudy. Ethical clearance was obtained from the institutional ethical board.

Study tool: A questionnaire was developed after extensive literature search. It was pilot tested on a small group of 10 doctors and revised for ambiguity. The questionnaire included questions on their educational status, experience, status of their training on their antibiotic use, the frequency of treating patients with URTI and attitude towards prescribing antibiotics. A written informed consent was attached to each survey form that was answered by the respondents. A random selection of prescriptions from URTI patients treated in these healthcare institutions were collected to verify the actual prescribing behaviors and compared with the answered questionnaire.

Statistical Analysis: All the data collected was statistically analyzed by using SPSS version.

RESULT & ANALYSIS

In this study, a total of 128 doctors participated from 2 hospitals and 7 clinics in and around Shah Alam, Malaysia. 62.5% had >5 years of experience in clinical practice while 37.5% had 3-5 years of experience. Most of them (82%) had no special training on use of antibiotics .114 of the 128 doctors were aware of the latest Malaysian antibiotic guidelines (Table1).

Table 1 shows the number of doctors with their experience, clinical training on antibiotic use and familiarity with latest Malaysian Antibiotic Guidelines.

		Number of doctors
1	Working experience	3–5 years 48 (37.5%)
		>5 years 80 (62.5%)
2	Have clinical antibiotic training	Yes 23 (18%)
		No 105 (82%)
3	Familiar with latest Malaysian antibiotics guidelines	Yes 114(89%)
		No 14(11%)

URTI was encountered frequently by our study population. The number of cases of URTI treated by the doctors per day is shown in Figure 1. Fifty-five doctors claimed to see more than 10 cases of URTI per day, while forty said they saw about >5-10 cases per day. Eight doctors dealt with 1-5 cases while twenty-three treated less than 1 patient of URTI per day.

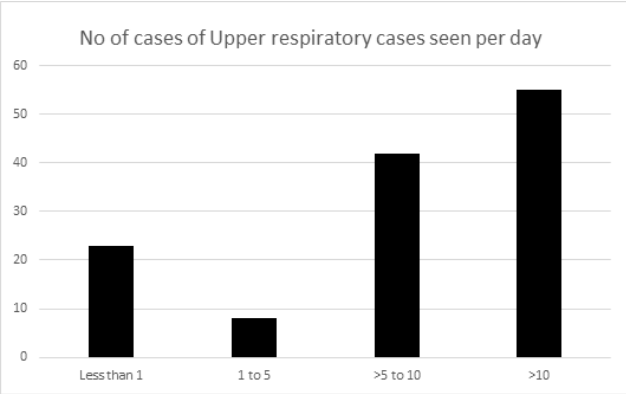

Figure1: No. of URTI cases seen by the study population per day.

Recommendation for antibiotic use:

In our study, only 14 out of 128 doctors (11%) recommended antibiotics for URTI treatment while the vast majority 114(89%) did not prescribe it. The diagnosis for which antibiotics prescribed were acute tonsillitis, acute sinusitis and otitis media. Among the antibiotics prescribed, the most common drug was of penicillin group (amoxicillin), followed by cephalosporin and macrolides (Figure2).

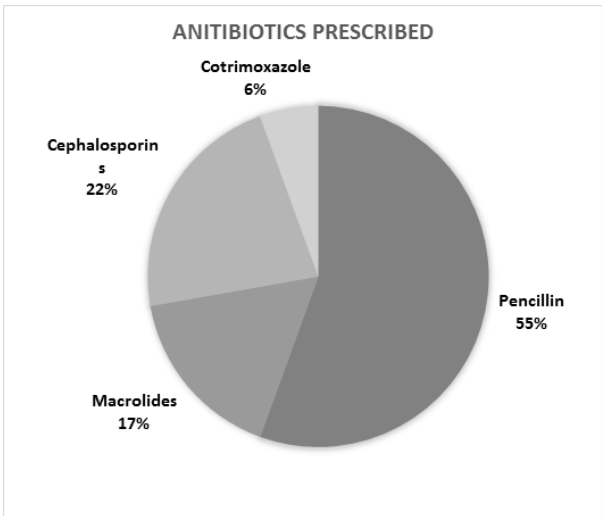

Figure 2: Antibiotics prescribed by the study group.

Alternative treatment methods used in the treatment of URTI:

The doctors in our study group used alternative options to provide symptomatic relief to patients with URTI. Seventeen recommended high dose of vitamin C, forty-three prescribed antihistamines, twenty-five suggested hydration therapy, fifteen traditional remedies while twenty-five recommended rest and allowing self-recovery (Figure3).

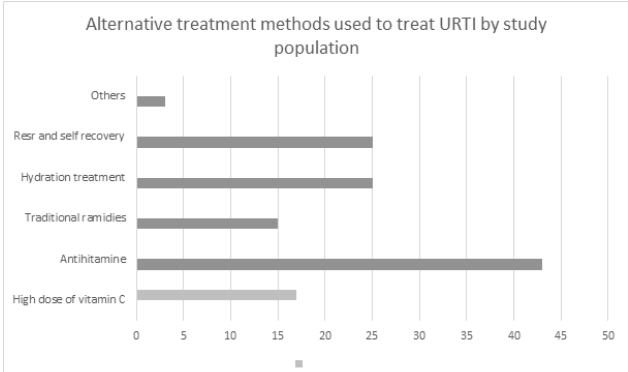

Figure 3: Alternative treatment methods used to treat URTI by study population.

DISCUSSION

In this study, a total of 128 doctors participated. Most of them were expert in the treatment of URTI with 80 having 5 years or more experience, while 48 had about 3-5 years of clinical experience. Due to their vast experience, they were aware of the latest Malaysian National Antibiotics Guidelines (NAG). However, majority of them had never attended any workshop / training on antibiotic use. It is a challenge for clinicians to identify between viral and bacterial infection. Most of the drugs given are aimed to minimize the symptoms and promote effective recovery. In our study, most of the doctors (89%) did not recommend antibiotics for URTI cases with only 11% preferring to use antibiotics in treatment of URTI. An earlier study in primary care settings in Malaysia by Teng et .al reported use of antibiotics in 33.8% of URTI cases [1]. In a similar study in India, Kotwani and Hollaway reported use of antibiotic in 45% and 57% of uncomplicated URTI cases in public and private hospitals respectively[8].Similar data was presented in a systematic review from China where 83.7 % of patients with URTI were prescribed antibiotics. An alarming 18.4% were prescribed 2 antibiotics while 1.1% got 3 antibiotics. The authors however mentioned about the downward trend in antibiotic prescription in recent years[2]. Mohitosh et.al in Bangladesh too reported URTI to be a common cause for antibiotic prescription[9].Even in a developed country like France a study on antibiotic use in paediatric age group between 2008-2012 reported an unacceptable higher use of antibiotics [10].

We have observed a decrease in the prescriptions for antibiotics in our study. This may be attributed to the study being conducted in an urban area with availability of specialist care and the doctors being aware of the antibiotic guidelines. The reasons cited by the respondents for not prescribing antibiotics were to

prevent antibiotic resistance among patients, to prevent side effects especially to infants and young children, the type of causative microorganism and the level of severity of the case. Instead of antibiotics, some of the doctors in our study preferred to use alternative methods to treat URTI and provide symptomatic relief. Prescription of anti-histamines was the commonest among them. Others included giving high doses of Vitamin C to help boost the immune system, hydration treatment or fluid replacement, anti-inflammatory drugs or suggesting rest as they believed in self-recovery. Similar observation was made by Reshmi et al who also reported the use of symptomatic treatment for patients with URTI[11].

In our study, there were 14 cases of URTIs where antibiotics were used. In some cases of tonsillitis, laryngitis and sinusitis antibiotic coverage was needed to prevent complications in immunocompromised individuals or when virulent organism was suspected.

The most prescribed drug was of Penicillin group (amoxicillin), followed by cephalosporin and macrolides. Similar prescription pattern has been described by Teng et .al [1], The choice of antibiotics given maybe due to the commonest causative organisms being gram-positive type of bacteria such as *Streptococcus*. In Bangladesh, Mohitosh[9] reported cephalosporins to be the commonest antibiotic prescribed. In a similar study in Kerala by Reshmi et .al[11], azithromycin was the commonest antibiotic prescribe

This is in contrast to the observations of Shamsuddin et.al [12] who in 2013 reported inappropriate use of antibiotics in 18% for URTI.

CONCLUSION

This study reveals that most doctors in Shah Alam are familiar with Malaysian Antibiotic Guidelines, which is reflected in fewer prescriptions for antibiotics in the treatment of URTI cases. When dealing with URTI, alternative symptomatic treatment like vitamin C, antihistamines, good hydration were advocated by our study group. However, a similar study in future on a larger population including both urban and rural healthcare settings as well as both private and public hospitals would be able to substantiate the changing trend in the prescription pattern of antibiotics among doctors for URTI in Malaysia.

Limitation of the study:

This study was conducted on a small population of doctors. All the doctors were working in urban, private health care settings. Hence the findings of this study do not reflect on the rural and public healthcare settings.

Acknowledgement: We acknowledge the contribution of the respondents for their participation in this study. We place on record our sincere thanks to International Medical School, Management and Science University for their support.

Re-Standardization Makassar Healthy City based on Local Needs

Sukri Palutturi[1], Muhammad Alwy Arifin[2], Nurhayani[2]

[1]Professor, [2]Senior Lecturer, Health Policy and Administration Department, School of Public Health Hasanuddin University, Makassar Indonesia

ABSTRACT

This study aimed to develop Makassar Healthy City standards and indicators based on local needs, including key indicators, general indicators and specific indicators according to the settings choices. Through in-depth interviews and focus group discussions, this study found that general indicators only change indicators regarding the level of awards, from national and international awards to provincial, national and international awards. Furthermore, the main indicators still refer to national policies. Seven of nine settings were identified in Makassar City based on local needs. There are changes or additions to indicators in almost all settings. Re-standardization of healthy districts/cities should be carried out in all districts/cities based on the local conditions.

Keywords: *Re-standardization, Healthy Cities, Local Needs*

INTRODUCTION

The Healthy Cities movement in Indonesia has long been carried out, even though it was officially effective since the publication of the Joint Regulation between the Ministry of Home Affairs and Health [1,2]. Adipura and Healthy Cities are different but the goal of Adipura can strengthen the Healthy Cities goal [3]. Indonesia has a Healthy Cities concept that is different from other countries [4,5]. Although Healthy Cities in Indonesia has been running for more than a decade [4,6], the environmental and social health problems are the still main problem in urban areas, but the districts/cities receive the Healthy Cities award from the central government, how is the Healthy Cities really in Indonesia? How does the central government assess and determine the indicators used? The central government can set national indicators and standards, but it can be different from local governments because they have different needs, resources, capacities and even values and cultures so that different solutions can occur [7].

Several previous studies relating to Healthy Cities in Indonesia have been conducted [1,3,6], but specific research especially studying the Healthy Cities indicator used is rarely done. This study aimed to develop Makassar Healthy City standards and indicators based on local needs, including key, general and specific indicators according to the settings choices.

MATERIALS AND METHOD

This study was carried out in Makassar City, namely at Regional Planning and Development Board (Bappeda), Health Office, Tourism Office, Social Service, Food Security Service, Sanitation Office, City Planning Office, Healthy City Trustees and Healthy City Forum. Data to be collected consists of primary data and secondary data. Primary data was collected through depth interviews, observations and Focus Group Discussion (FGD). In-depth interviews were conducted with heads of agencies related to healthy cities structures such as Bappeda, Health Office, Tourism Office, Social Service, Food Security Service, Cleanliness Office, Healthy City Trustees and Healthy City Forum. This study used a qualitative research method with a case study approach where qualitative researchers conducted face to face interactions throughout the study [8]. The variables or concepts in this study refered to the main indicators,

general indicators and specific indicators of Makassar Healthy City. Special Healthy City indicators refer to the settings of healthy districts/cities in Indonesia and can be developed based on local needs. Data analysis was conducted qualitatively with thematic analysis.

RESULTS

Seven of nine healthy city settings have been identified for Makassar City, namely:

a. Healthy settlements, public facilities and infrastructure

1. A clean air program

2. Appeal for the use of low-sulfur fuel and energy efficiency, through circulars, decrees, billboards, or leaflets.

3. Regulations governing non-smoking area

4. Incidence pneumonia

5. Frequency carry out an ambient air quality test for a moment

6. Implementation of clean air programs through 5 movements: 1 billion trees, car free days, areas without smoking, cycling and walking facilities

7. Use of environmentally friendly alternative energy: solar cells, methane

8. The air quality index category

9. The existence of monitoring activities for chimney emissions in industrial activities

10. The existence of motor vehicle emission testing activities

11. River management policy

12. River cleanliness conditions

13. Riverbank conditions

14. Carry out river monitoring

15. Water Quality Index Value

16. Community involvement in river management

17. Carry out conservation activities around the river banks

18. Clean water service coverage

19. Coverage of drinking water quality

20. Drinking Water Access Coverage

21. Percentage of population using healthy latrines 64%

22. Stop Defecation Village

23. The efforts of the Regional Government to encourage people not to open defecation

24. Drainage Planning Noting the Eco-Drain Concept

25. Local Government Program in encouraging Community Participation in the construction of drainage

26. The active role of the community reports the existence of inundation

27. Public & Private Engagement in Maintenance of Drainage Systems

28. The functioning of the drainage canal

29. Community involvement in the process of maintaining drainage

30. Services and public access to waste water infrastructure and facilities

31. Domestic Waste Water Treatment Plant

32. Quality Test of Communal IPAL Waste Water Effluent

33. Availability of Fecal Treatment Plant

34. Stool trucks operate into the Fecal Treatment Plant

35. General environmental conditions in residential environments

36. Waste handling includes activities

37. Implementation Waste management with the 3R principles

38. Final processing sites Waste does not pollute the environment

39. Management of methane gas in landfill

40. Length of garbage collection at TPS

41. Aides larva numbers in settlements

42. PSN and Routine Work

43. Incidence) of filariasis cases

44. Housing / settlement Free of floods

45. Number of healthy houses

46. Incidence / case of pulmonary tuberculosis

47. Outbreaks of diarrheal diseases

48. Outbreaks of DHF

49. Outbreaks of Malaria

50. Number of villages that have health service facilities

51. Percentage of posts in the regency in accordance

with the number of health centre

52. The number of active alert villages

53. Health centre with Sanitation Clinic services

54. Tree planting program for the community

55. Available parks and urban forests

56. Percentage of schools implementing healthy schools (UKS)

57. Percentage of schools that take part in the "Adiwiyata program"

58. Availability of Healthy Canteen

59. Availability of adequate toilets (separate between men and women)

60. Availability of places of worship in schools

61. "Saptapesona School "security, order, cleanliness, beauty, and hospitality

62. Availability of segregated bins

63. Waste Management in schools

64. Available public facilities (sports and play)

65. Market management policy program

66. Supervision regarding market management

67. Market community involvement in participating in market sanitation

68. Clean urban market environment

69. Enough toilets and meet the requirements on the market

70. Parking lots available in urban markets

71. Avalilable play facilities for children

72. The arrangement of informal traders

73. Regulations on handling street vendors

74. Availability of Healthy Canteen

75. Availability of adequate toilets (separate men and women)

76. Availability of disaggregated bins

77. Waste management in traditional markets

78. Availability of places of worship

b. Traffic Order Zone and Transportation services

1. Car free day area

2. Clean, orderly and neat terminal conditions

3. Public facilities in the terminal

4. Availability of traffic signs

5. Special facilities for nursing mothers at the terminal

6. Crime in the terminal decreases

7. Availability of smoking ban in the terminal area

8. Availability of smoking ban on the vehicle

9. Examination of the feasibility of public transport vehicles

10. The number of traffic accidents decreases

11. The existence of suitable pedestrian facilities

12. Non-smoking public transport vehicles

13. A routine health inspection program for public transport drivers

14. Availability of bus stops that meet the requirements

15. Availability of an orderly traffic area

16. Availability of a workshop to monitor exhaust emissions

17. Availability of a smart driving training program for the driver

18. The awarding of exemplary public vehicle crew training awards

19. Giving an award of obedience to the driver

c. Healthy industries and offices

1. Locations specifically for industrial zones

2. A smoking ban in the office environment

3. Places of worship in offices

4. Special arrangements for the informal sector

5. Health insurance for workers in all industries

6. The presence of industrial waste pollutes the environment

7. Community complaints about cases of industrial pollution

8. Decreasing work accident rates

9. Decreased unemployment

10. Availability of training activities in the vocational training center

11. Implementation of Environmental Management

12. Special room for nursing mothers

13. Enough Toilets (separate Men and Women)

14. Availability of Parking Lots

15. Availability of Healthy Canteen

16. Maintain cleanliness

17. Availability of first aid

18. Availability of Green Open Space

19. Availability of disaggregated bins

d. Healthy Tourism

1. Availability of tourist information in public places

2. Information on health facilities for tourists at the location

3. The entire hotel is worthy of health

4. Availability of healthy restaurants

5. Increasing number of tourists per year

6. Tourists have been insured

7. Food poisoning in tourists for the past year

8. Decreased cases of accidents in tourism objects

9. Transportation available in tourist areas

10. Emergency response/safety hall in tourist area

11. Public facilities available

12. Waste disposal facilities available

13. Clinic/first aid facilities available

14. Telecommunication facilities available

15. Souvenir facilities available

16. Worship facilities available

17. The presence of tourism police

18. Smoke-free zone

19. Availability of Parking Lots

e. Food Security and Nutrition

1. Increased food crop production

2. Food Production Supervision

3. Food Diversity

4. Food Processing Monitoring

5. Cases of malnutrition

6. Availability of food reserves and storage

7. Food availability

8. Cases of pesticide poisoning on farmers

9. An extension of integrated pest control and use of pesticides

10. The functioning of food distribution institutions in the community

11. Food Distribution Monitoring

12. The existence of organic farming programs by the government and the community

f. Healthy-Independent Community Life

1. The existence of a regular sports movement in the community/office

2. Decreased cases of drug use

3. The existence of community groups for drug and HIV/AIDS prevention

4. Availability of community compliance not to smoke in public places

5. Availability of an anti-smoking movement

6. Coverage of clean water services

7. Availability of a routine inspection of the quality of clean water

8. Increased quality of clean water

9. Healthy food, restaurant Food Management Place services

10. Government program on healthy home improvement

11. Increased coverage of the use of health services

12. Availability of youth counseling service facilities

13. Availability of a routine health check on school children

14. Childbirth assistance by trained personnel

15. Availability of mental health services at health centers

16. A functioning sanitation clinic service

17. Availability of an anti-alcohol movement by the community

18. The existence of an anti-drug movement by the community

19. Availability of is a special drug prevention service

20. Decreased drug use cases

21. Increased immunization coverage

22. The functioning of an active Posyandu

23. Coverage of visits to health centre

24. PSN movement in schools, households, public spaces

25. Free aides larvae at school, household and public spaces

26. The existence of community movement in preventing degenerative diseases

27. Information on risk and efforts to prevent degenerative diseases

28. The existence of community groups in overcoming nutritional problems

29. Increased Protein Energy Deficiency for pregnant women

30. Cases of pregnant women who are anemic and lack iodine

31. Decreased people lack of vitamins

32. Decreased weight of low birth baby

33. Increased awareness of nutrition families

34. Number of health centre that provide basic services for the poor

35. The existence of health insurance for the community

g. Healthy Social Life

1. Decreasing poverty rate (4% -6%)

2. The existence of beggars and homeless people in public facilities

3. Decreasing number of drug users

4. The decline in the number of prostitutes

5. Availability of a halfway house for street children

6. The existence of informal workers

7. The existence of children's creativity development and elderly productivity

8. The existence of an education program dealing with disability

9. Availability of facilities for people with disabilities in public places

10. Regional government policy on handling communities in remote areas

11. Public transportation facilities to remote areas

12. Health facilities in remote areas

13. Adequate Child Care Facilities

14. Special programs for abandoned, elderly

15. Disaster preparedness program for the community

16. Incidents of riots/anarchists

17. Having a contingency plan for a disaster problem

18. Availability of facilities for disabled people

19. Availability of street children control program

DISCUSSION

Environmental infrastructure facilities are places used by the general public to function properly. Specific indicators of the settlement area arrangement of healthy facilities and infrastructure nationally are 59 assessments while based on the results of FGD 78 special indicators are obtained. This environmental aspect is very important because it is a determinant of public health status[9-11].

Additional indicators of this setting include monitoring activities for chimney emissions in industrial activities, motor vehicle emission testing activities, access to drinking water. Other indicators include the availability of healthy canteens in schools, the availability of places of worship in schools, waste management in schools, availability of play facilities for children in traditional markets, availability of healthy canteens in traditional markets.

Indicators of the setting area of traffic and transportation services, nationally, there are 16 indicators of assessment while based on local needs there are additions to 19 indicators. These additional indicators are the availability of traffic signs, the existence of smoking bans on vehicles and the existence of a rider compliance award. The problem of transportation and traffic congestion is a big issue, especially in large cities [12,13]. The impact is quite complex on health both from the social aspect and the incidence of disease [14] . Furthermore, there are 11 indicators for industrial estate and office buildings, while based on in-depth interviews there are changes to 19 assessment indicators. The additional indicators include the availability of separate toilets between men and women, and availability of parking spaces, availability of healthy canteens.

Specific indicators of the setting of healthy tourism, nationally, there are 13 assessments, while based on focus group discussion there are 19 indicators. The indicators are available telecommunications facilities, available souvenir facilities, available facilities for places of worship and the availability of parking spaces. Healthy tourism is one indicator of healthy cities set globally [15,16].

Specific indicators of the setting of food and nutrition security, nationally, there are 8 indicators while based on in-depth studies identified 12 indicators, namely: the supervision of food production and processing, and the existence of a variety of foods.

Specific indicators, the setting of healthy-independent communities independent, nationally, there are 38 indicators of assessment, while based on the study there are only 35 indicators. Some indicators are not valid in the Makassar City, such as the presence of new cretin patients; this is because cases of cretin patients have not been found in Makassar City. Finally, the indicators for a healthy social life, nationally, there are 17 indicators of assessment while based on local needs there are 19 indicators. The indicators include the existence of facilities for disabled people, and the existence of a street children control program. One of the biggest problems in implementing healthy cities is social problems [17,18].

CONCLUSION AND RECOMMENDATION

This study found that the main indicators still refer to national policies. Seven of nine settings have been identified for Makassar Healthy Cities. There are changes or additions to indicators in almost all settings. This study recommends that the standardization of healthy districts/cities should be carried out in all districts/cities based on the local needs.

The Effect of Progressive Muscle Relaxation in Reducing Fatigue among Nurses in Mental Hospital

Rosinta Uli[1], Robiana Modjo[1]

[1]Occupational Health and Safety Department, Faculty of Public Health, Universitas Indonesia, Kampus UI, Depok, Indonesia

ABSTRACT

Nursing, an occupation dominated by women, is typically high in job demands, work stress levels, and fatigue. Fatigue on nurses affect the neurocognitive function and also the performance of the nurses.

Progressive Muscle Relaxation, a technique involving sequential tensing and relaxation of major skeletal muscle groups, aims to reduce feelings of tension, to lower perceived stress, and to induce relaxation.

This research aimed to find out the effect of progressive muscle relaxation in reducing fatigue on nurses at Mental Hospital with indicators of pulse rate, oxygen saturation, and subjective feelings of fatigue. This quasi-experimental study was performed on 42 nurses within-subject design with a pre-post test, which was conducted in two treatment i.e. routine activity (without progressive muscle relaxation) and progressive muscle relaxation that performed in one group of the same subjects at different times.

The progressive muscle relaxation consists of two basic parts to progressive relaxation: 1) the tension in muscles, and 2) the relaxation of each muscle group. The results showed that the progressive muscle relaxation may reduce fatigue. It can be observed that the progressive muscle relaxation had influence in the decreasing of pulse rate, increasing of oxygen saturation, and decreasing of the subjective feeling of fatigue score.

Keywords: *Nurse Fatigue, Progressive Muscle Relaxation, Pulse Rate, Oxygen Saturation, Subjective Feeling Fatigue*

INTRODUCTION

Fatigue implies in negative impact in short and long term. Short-term impact, for example, the emergence of discomfort, decreased strength and decreased motor control. The impact of short-term leads to reduced performance, productivity, quality of work, and an increase in the incidence of accidents and human error. In the long term, prolonged fatigue can lead to absenteeism, skeletal muscle disorders, and disability.

Fatigue is commonly observed in nurses. Workload, work hours, work structures, and many other factors can indirectly or directly cause fatigue in multiple industries and affect safety [(1)]. Fatigue on nurses can lead to medical errors, performance setbacks, decreased mental acuity, and social issues [(2,3)]. That becomes an issue that stimulate efforts to examine and deal with the problems of fatigue on nurses to improve the quality of service to patients and improve patient satisfaction as well as to find management approaches a comprehensive fatigue to create a supportive work environment for nurses to prevent fatigue and improving performance [(4)].

Based on a previous study conducted in September 2017 about fatigue of nurses in Mental Hospital, the result which has been obtained showed that 52% of nurses experienced moderate to heavy with fatigue, while the rest experienced mild fatigue. The fatigue experienced by nurses include a physical or psychic fatigue-related workload, lack of personnel and the working environment with the smells of the less savory originating from the patient's body that sometimes cause nausea and dizziness, as well as internal factors, be age, gender, educational level and marital status.

Progressive muscle relaxation techniques (Progressive Muscle Relaxation) is one of the non-

pharmacological intervention and is a systematic technique that can be used to reduce stress and achieve a state of relaxation [5]. Some of the results of the study mentioned that the progressive muscle relaxation therapy is effective for losing muscle tension, reduces stress levels and lower blood pressure [6] and provide immediate and significant effects against fatigue marked with a decrease in pulse rate [7]. The purpose of this research is to implement and to find out the effect of progressive muscle relaxation on nurses at Mental Hospital. The results then could be a recommendation in the preparation of the program of health promotion in the workplace.

METHODS

The study design was quasi-experimental with a pre-post trial within the subject, which was conducted in two treatment i.e. routine activity (without progressive muscle relaxation) and progressive muscle relaxation that performed in one group of the same subjects at different times. This study aimed to know the direct effect of progressive muscle relaxation on the nurse's fatigue objectively with the indicator of pulse rate, oxygen saturation, and subjectively with the subjective feeling of fatigue.

This research was conducted on 42 nurses at Mental Hospital. The criteria of a sample is a nurse managing staff; the sample does not have a history of infectious diseases or degenerative; minimum 1-year working period and at the time of research, not just finished running on leave (± 1 month before).

Measurement of fatigue was done after the respondents have the activity or work approximately 2 hours (pre-test) and after the treatment (post-test) (Figure 1). The instrument used to measure the fatigue objectively is the Pulse Oximeter with the aim to measure oxygen saturation and pulse rate. Meanwhile, the subjective measurement was carried out using the Subjective Self-questionnaire Rating Test (SSRT) from the Industrial Fatigue Research Committee which consists of 30 items of questions. The questionnaire consists of 10 questions that described the decreased activity (decrease in the level of activity), 10 the question illustrated the decline in the motivation of work (symptoms of weakening motivation) and 10 questions described the physical fatigue symptoms (symptoms of physical fatigue).

The analysis was carried out with the application of SPSS statistics version 22.0 to find out the difference in the average of the measurements before and after treatment as well as the measurement of the average difference between the treatment routine activity and progressive muscle relaxation treatment.

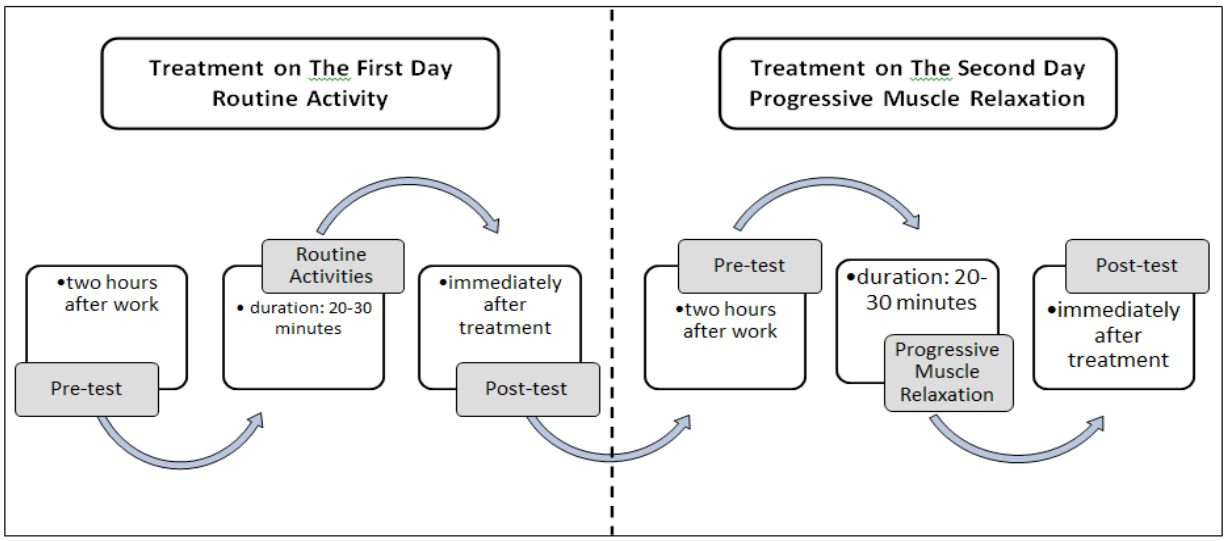

Figure 1 Quasi-Experiments Design with Pre-Test and Post Test within The Subject.

Progressive muscle relaxation techniques are sequential contractions and relaxation movements consisting of 14 movements and involve 5 muscle groups, namely arm/hand muscles, facial muscles, upper chest-abdomen, hips and thighs, and legs and feet. Progressive muscle relaxation sessions lasted for 20 to 30 minutes. The relaxation process started by tensing the muscle group; hold that tension for 5-7 seconds, then relaxing the muscles slowly for 20-30 seconds. Each movement is done 2-3 times. The fourteen of progressive muscle relaxation movements were: 1) exercising the hand muscles; 2) training rear hand muscle; 3) training the large biceps/muscles on the upper part of the arm; 4) training the shoulder muscles to relax; 5 and 6) relaxing facial muscles, such as the forehead, eyes, jaw, and mouth; 7) relaxing the tension experienced by the jaw muscles; 8) relaxing the muscles around the mouth; 9) relaxing the front and back neck muscles; 10) training the front neck muscles; 11) training back muscles; 12) relaxing the chest muscles; 13) training the abdominal muscles; and 14) training the leg muscles such as thighs and calves.

RESULTS

Characteristics of Respondents

Table 1 Frequency Distribution Based On The Characteristics of Respondents

Variable	Percentage	SD	Mean	(Min-Max)
Age				
25-35 years	78,6 %	5,33	32,48	25 – 46
36-45 years	16,7 %			
≥ 45 years	4,7 %			
Sex				
Male	31%	-	-	-
Female	69%			
Nutrition Status (by Body Mass Index)				
Underweight	0 %	3,65	25,11	18,90 – 34,29
Normal Range	57,14 %			
Overweight	28,57 %			
Obesity	14,29 %			
Length of Work				
0-5 years	28,57 %	5,55	8,48	2 – 25
6-10 years	50 %			
≥ 10 years	21,43 %			

The Objective and Subjective Measurements

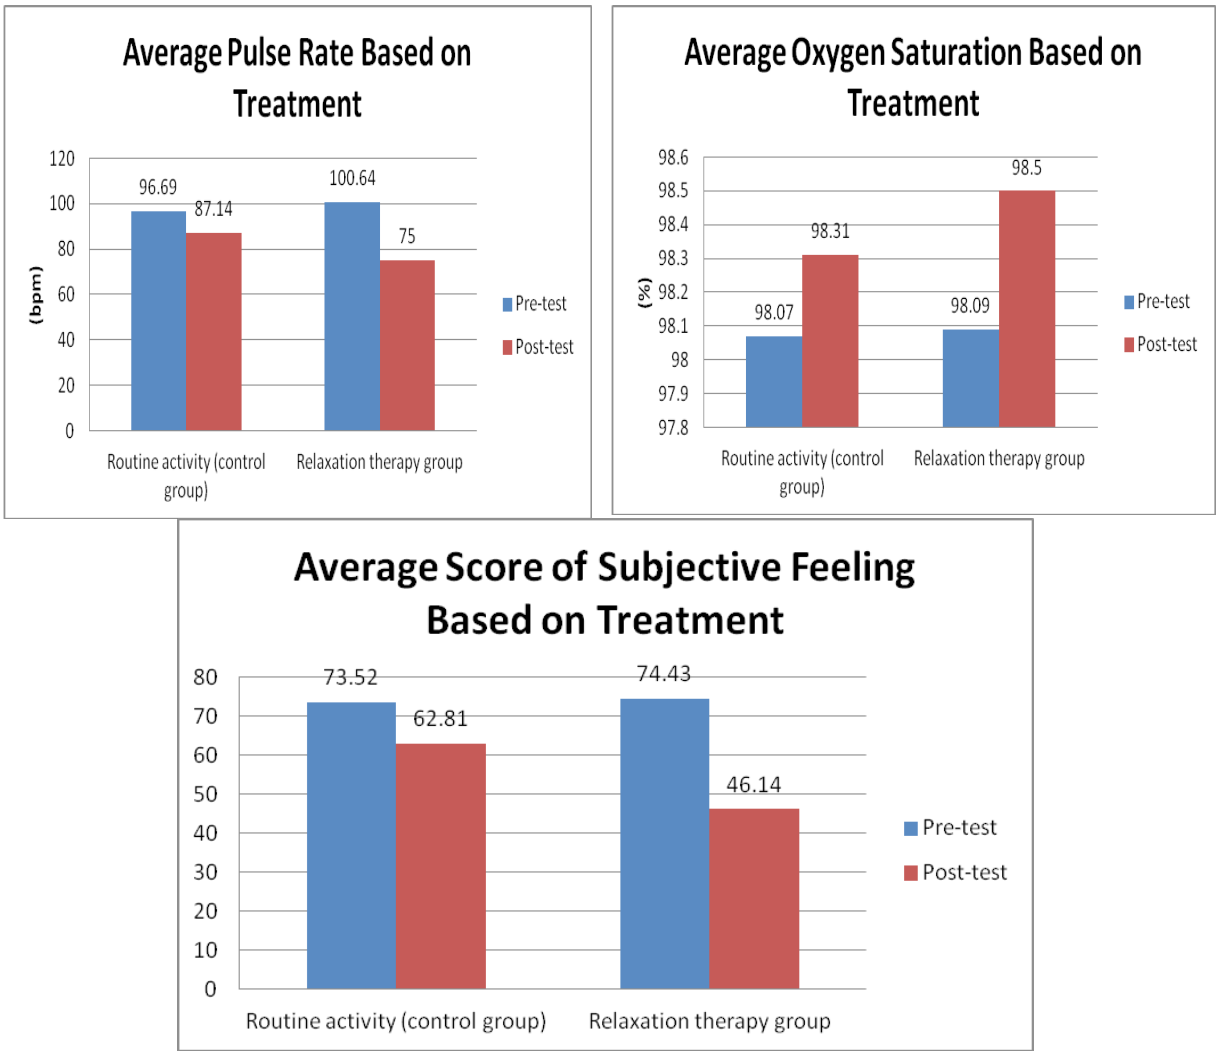

Figure 2. Above right: Average Pulse Rate Based on Treatment, above left: Average Oxygen Saturation Based on Treatment, below: Average of Score of Subjective Feeling Based on Treatment

From the Figure 1 above shows that there is an increasing exhaustion of the respondents on measuring pre-test on the first day of treatment (routine activity) and the second day of treatment (progressive muscle relaxation) compared with the initial measurement (baseline). It can be observed from the increase in the average frequency of the pulse, a decrease in average oxygen saturation as well as an increase in the average score of subjective feelings of fatigue. Instead, on the measurement of post-test showed a decrease in fatigue for each treatment (frequency of the pulse oxygen saturation is reduced, increasing and decreasing the subjective feeling of fatigue score) compared the results of the pre-test.

Table 2 Measurement According to The Treatment

Treatment	Pulse Rate (times per minute)		Oxygen Saturation (%)		Subjective Feelings of Fatigue (Score)	
	Mean Difference Pre-Post	SD	Mean Difference Pre-Post	SD	Mean Difference Pre-Post	SD
Routine activity (n= 42)	9,548	4,660	0,238	0,692	10,714	12,208
Progressive Muscle Relaxation (n=42)	25,643	5,318	0,405	0,798	28,286	9,759

Table 3 Decreased Fatigue Level Based on The Treatment

Variable	Routine Activity		Progressive Muscle Relaxation		Mean Difference	R^2
	Mean	SD	Mean	SD		
Pulse Rate	87,14	2,58	75,00	4,55	12,14	0,778
Oxygen Saturation	98,31	0,84	98,50	0,99	0,19	0,434
Subjective Feelings of Fatigue	62,81	13,28	46,14	11,42	16,67	0,623

Based on treatment, measurement results on indicator pulse and the subjective feeling of fatigue showed a significant difference between routine activities with progressive muscle relaxation (see Table 2). The magnitude of the influence of progressive muscle relaxation in reducing fatigue can also be observed from the coefficient of determination (R^2) shown for the respective indicators (see Table 3).

DISCUSSION

Characteristics of Respondents

The range of age of respondents in this study was between 25 to 46 years. A person's age is very influential factors towards the pulse which is an indicator of the work of the heart. This is similar to research conducted by Houghton, et al. which explained the function of the vascular decreased significantly with aging and contribute to decreased heart rate [8]. Age also influence on physical strength and mental muscles, that showed that there was a certain age at which a worker would experience changes work achievement. At an older age generally occurs a decrease in muscle strength, but it was balanced by a better emotional stability than a young workforce that can be positive in doing work [9]. This is in accordance with the research done by Chang, et al. which mentioned that work fatigue related to age and physiological symptoms [8], a lot of health problems [10]. This was in accordance with the research conducted by Hunter mentioned that gender contributes to muscle strength [11]. In addition, other studies also mentioned that at a particular age and sex, children, adults, and men are more resistant to fatigue the muscle than older people and women [12].

The calculation based on nutritional status, 42 of those respondents, 18 people were categorized as respondents with excess body weight and obesity (42.86%) according to Indonesian Ministry of Health criteria year 2013. Consequently, it might affect the ability and endurance of the respondents in their work performance which closely related to the status of nutrition.

The influential working period significantly related to fatigue. The longer working period effect on work fatigue levels caused the level of monotonous work that has accumulated over the years [13]. Workers with a longer working period has more experience and more familiarity with the work which prevent the occurrence fatigue [9]. The previous study also mentioned that nurses working with less than 2 years have a fatigue score higher than the nurses who work for more than 6 years [14]. Another research showed a statistical relationship between nurse fatigue with age and work experience. The results show that the longer work experience and older age related to the lower the perceived fatigue. This is because with increasing experience in the work, the less pressure of the job [15].

The Effect of Progressive Muscle Relaxation on Pulse Rate

Pulse rate was affected by the presence of stress or at the rest or break time. The factors that affect the pulse of which are gender, age, physical activity, fitness level, ambient temperature, body posture, emotion, body size, as well as the consumed drugs [16].

This result was in line with the results of previous research which showed a decrease in the frequency of the pulse on nurses after making the progressive muscle

relaxation [17]. The other studies have also proved that the progressive muscle relaxation therapy give immediate and significant effects against fatigue is characterized by a decrease in pulse rate [7]. Furthermore, research shows that the progressive muscle relaxation can heart rate, blood pressure, oxygen consumption and regulate the activity of sweat glands, changing patterns of brain waves, and finally, it lowers the activity of physical motor [18].

The Effect of Progressive Muscle Relaxation on Oxygen Saturation

The results of this research were not in accordance with the previous which mentioned that at the time of relaxation happens, there was an increase in oxygen levels [19]. Other studies also mentioned that at the time of relaxation of muscle fibers, the extension occurs with declining conductance of nerve impulses to the brain, decreasing brain activity, and other body functions as the response of relaxation. The other responses to relaxation were the declining number of pulse, breathing, decreased blood pressure, and increased consumption of oxygen [20].

The absence of any significant differences between the average oxygen saturation (post-test) when just doing routine activity when done with progressive muscle relaxation may occur due to oxygen saturation values in each person is different and many factors influence, among others 1) internal factors, i.e., age, gender, diseases of pulmonary function disturbance, acidity (pH), and the partial pressure of carbon dioxide (CO2); and 2) external factors, namely food intake to increase the levels of Hb, early mobilization and gymnastics parturition [21]. However, these results may differ when progressive muscle relaxation did more often and regularly.

The Effect of Progressive Muscle Relaxation on Subjective Feelings of Fatigue

The results of this research are consistent with research done Ivancevich, et al [22]. which mentioned that progressive muscle relaxation psychologically could produce a feeling of a healthy, quiet and peaceful, a feeling that everything was in control as well as a decrease in the tension and anxiety. The study mentioned that progressive muscle relaxation technique to effectively cope with tension, anxiety, insomnia, depression, fatigue, irritable bowel syndrome, muscle spasms, neck and back pain, high blood pressure and mild phobia; the study mentioned that progressive muscle relaxation was a systematic therapy effective for overcoming the stress on nurses to reach a state of deep relaxation [17]. Another study revealed that Progressive Muscle Relaxation was one of the non-pharmacological intervention and a systematic technique that can be used to reduce stress and achieve a state of relaxation [5].

CONCLUSION

The results showed that the progressive muscle relaxation technique was more effective for reducing fatigue on nurses, compared with just doing routine activities without relaxation. It was observed from the decline of its influence on the frequency of the pulse and lowers the subjective feeling of fatigue score respondents indicating a more significant result than routine activity.

Conflict of Interest: Hereby the authors declared that there is no conflict of interest in this research with any other parties.

Situational Analysis of Career Choices among Indonesian Nurses Returnees

Ferry Efendi[1], Nursalam Nursalam[1], Elida Ulfiana[1], Rista Fauziningtyas[1]

[1]Faculty of Nursing, Universitas Airlangga, Surabaya, Indonesia

ABSTRACT

Background: There are few studies about the Indonesian nurse returnees' career after working and living overseas. Therefore, the present study addressed the current status of their employment. **Purpose:** This paper explores the situation of return migration among Indonesian nurses who return to the country of origin. **Methods:** Descriptive study using the latest survey of Indonesian nurse returnees. **Results:** The career situation of Indonesian nurse returnees varies on the post-migration stage. Half of the returnees were working out of nursing areas (57.2%) at the time of the survey. Returnees predominantly work as own account worker when they get back into the labor market. While the rest were working as private employees, Japanese translators, Indonesian state own enterprises employee, hotel staff, insurance agent, and teacher. **Conclusion:** The result of this research inquiry adds new understanding and knowledge in an area of return migration of nurses that has been relatively unexplored. Returnee career situations were relatively similar number between nursing and non-nursing areas.

Keywords: *return migration, career choices, Indonesian nurses.*

INTRODUCTION

In regard to the international nursing migration, Indonesia has become an exporter of nurses to economically developed countries[1-3]. The United Arab Emirates, Netherlands, Kuwait, Great Britain, and Saudi Arabia have been among the receiving countries since 1996[4]. The active recruitment of Indonesian nurses abroad is dominated by private recruiters followed by government facilitation[5]. Regulation of international nurse migration under bilateral agreement has grown through national regulatory bodies which started with Japan followed by East Timor [6, 7].

The generalizability of much-published research on the return migration issue is problematic, not only in the Indonesian context but also in the global landscape. Return migration is often discussed as a new strategy to get a brain gain. However, early evidence indicates this could also lead to brain waste[8]. Following the current review, it was apparent that published studies failed to gain insight on return to practice for nurses in the post-migration stage. This indicates a need to understand various circumstances among nurse returnees under workforce migration flows. This present study seeks to remedy these problems by analyzing Indonesian returnees on their current occupational choice.

METHODS

A descriptive study design was conducted to describe the current occupational of Indonesian nurse returnees. A survey involving Indonesian nurse returnees were conducted to track the latest returnees' occupation.

RESULTS

The career situation of Indonesian nurse returnees varies on the post-migration stage (Table 1). As can be seen, half of the returnees were working out of nursing areas (57.2%) at the time of the survey. Returnees predominantly work as own account worker when they get back into the labor market. While the rest were working as private employees, Japanese translators,

Indonesian state own enterprises employee, hotel staff, insurance agent, and teacher. Respondents who chose not to return to nursing cited bad working conditions (86%), poor salary (74%), lack of confidence with their nursing skills (62%), unclear career paths or stalled career progressions (55%), difficulty in finding nursing jobs (58%), shift work (44%), unrecognized working experience in Japan (40%), feeling neglected by officials (40%), lack of respect (38%), and difficulty dealing with the certificate of registration (*Surat Tanda Registrasi)* process (22%). These reasons were repeated among returnees who opted out altogether from the nursing field. Deskilling was also cited by returnees who worked in Japan by stated they had lost their technical skills such as the ability to administer Intra Venous (IV) therapy. An emphasis on basic nursing care was voiced by returnees as an example of deskilling, as this activity was associated with lower grade work in Indonesia.

On the other hand, for those who stayed in nursing areas based on their employment setting the majority now work in private hospitals (27.2.6%). In contrast with previous respondents, those who stay in nursing jobs said they are passionate about nursing (92%), have a desire to help others (90%), expect to transfer skills and knowledge from Japan (88%), are aligned with their educational background (80%), have opportunities to open private nursing practices (67%), have opportunities to develop nursing specialties (particularly in geriatric nursing) (77%), have opportunities to develop long-term care services (54%), and have pride and noble works (41%).

Table 1 Career choices of participants (N=250)

Variables	n	%
Non-nursing area	143	57.2
Own account workers	66	26.4
Private employee	30	12
Japanese translator	24	9.6
Indonesian state own enterprises	4	1.6
Hotel	5	2
Insurance agent	7	2.8
Teacher	7	2.8
Nursing area	107	42.8
Nurse in private hospital	68	27.2
Nurse in district hospital	28	11.2
Nurse in Japanese company	9	8.4
Community health center	2	1.9

As Table 2 illustrates, the nursing specialties of returnees are widely spread out into different specialties. These include medical and surgical nursing (10.4%), general nursing (10.4%), mother and child nursing (4.8%), emergency nursing (4.8%), and community health nursing (0.8%).

Table 2 Nursing area based on specialties (N=107)

Nursing specialties	n	%
General nursing	26	10.4
ICU/Pediatric care nursing	7	2.8
Emergency nursing	12	4.8
Operating theater	9	3.6
Medical & surgical nursing	26	10.4
Mother and child nursing	12	4.8
Management nursing	8	3.2
Geriatric nursing	5	2
Community health nursing	2	0.8

DISCUSSION

This study provides a profile of the career choices of Indonesian nurses after their return from overseas. The choice of nursing and non-nursing areas is quite similar with regard to numbers. One study in Jamaica showed a slightly higher proportion (76%) among returnees who come back into bedside nursing [9]. While other studies on the return migration of nurses did not clearly mention how many returnees came back into nursing[10-12]. Findings from this present study show that the majority of returnees were working in various settings, including hospitals, clinics and communities. The highest numbers were working in private hospitals, followed by district hospitals, clinics in Japanese companies and community health centers. This data is similar in vein to the labor market for the Indonesian health workforce, which is dominated by the private sector[13]. The introduction of a zero growth policy on civil service numbers, liberalization of hospital ownership, and the passing of decentralization law in 1999 has significantly contributed to the dramatic growth of private health providers in Indonesia [13]. The presence of few returnees in district hospitals might reflect the low capacity of local government to employ nurses. On the other hand, nurses who work in Japanese clinic companies might feel interested in utilizing their skills and acquisition of the Japanese language. Returnees might possibly gain benefits by receiving a higher salary in Japanese company rather than a local business. With regard to returnee specialties in nursing, the dominant numbers were in medical and surgical nursing, and the fewest were in community health nursing. Further analysis on the competency of returnees and availability of job market are deserved to be done.

Returnees who work in non-nursing areas were dominated by the self-employed or those who were their own account worker. Piracha and Vadean (14) viewed that returning migrants have a higher propensity to become self-employed. Those who opted out from nursing areas, also found work as private employees, Japanese translators, insurance representatives and teachers. A number of the most highly qualified nurses who work outside of nursing were evident in this study, especially those who were titled in *Kangoshi* and *Kaigofukushishi* positions. These returnees had excellent nursing competencies and a great opportunity to contribute to the development of nursing. They cited some reasons such as low salaries, unrecognized working experience, and lack of appreciation from the government as reasons for choosing to leave nursing jobs. This feeling of being uncared for and neglected among returnees might lead to demotivation toward the nursing profession itself. From the point of view of the nursing profession, brain waste was observed within this group. They could not transfer the skills and knowledge they had acquired abroad. Most health professional migration studies have highlighted that brain waste occurs during the immigration stage [15-17]. In contrast to earlier ideas, this study observes that brain waste exists during the post-migration stage. This finding supports previous research which found that return migrants who were qualified could not find opportunities in their field of specialization [18]. In order to derive the maximum benefits of bilateral labor migration, Indonesia should manage migration of professional nurses by improving skill matching and recognition of skills. At the same time, in order to maximize the potential positive outcome of return migration this issue must be addressed with the Japanese counterparts through bilateral meetings.

CONCLUSION

The result of this research inquiry adds new understanding and knowledge in an area of return migration of nurses that has been relatively unexplored. Returnee career situations were relatively similar number between nursing and non-nursing areas. However, the brain waste phenomenon was evident among nurses as many were working outside nursing areas.

Analysis of Factors Affecting Malnutrition among Elderly in Panti Werdha Mojopahit Mojokerto

Arif Wicaksono[1,2] ; Muhammad Sajidin[1]; Heri Tri Wibowo[1]

[1]Institute of Health Science Bina Sehat PPNI Mojokerto, [2]Faculty of Nursing & Medical Ramathibodi Hospital, Mahidol University

ABSTRACT

Background: Old age as the final stage of the cycle in life is the natural development stage that will be experienced by every individual who reaches old age and is a reality that cannot avoid. In 2020, the number of elderly humans is predicted to be 28.8 million (11.34%) with a life expectancy of 71.1 years. The increase in the number of elderly populations is due to the rise in the socio-economic level of the community, progress in the field of health services, and an increased level of public knowledge. In 2020-2025 it is estimated that Indonesia's elderly population is ranked fourth after China, India and the United States.

Material and Method: The research method uses factor analysis. The technique of sampling used in research is purposive sampling, with the elderly population at the Nursing Home. The purpose of this study is specifically to find out; Appetite; change in body weight; old cars; stress; neuropsychological disorders, BMI. The Collecting data using instruments, the questionnaire was used. Analysis results using SPSS version 25.0.

Findings: The research can be said that the variables and samples used to allow for further analysis. This evidence by the KMO value of 0.504 which means higher than 0.5. after that, we can see Rotated Component Matrix[a]

Conclusion: Malnutrition of Risk factors in the elderly people at Mojopahit Mojokerto nursing home can be described as follows, Informal factors for the elderly: mobility, neuropsychological disorders; External factors: control nurses about elderly body weight.

Keywords: *Elderly, Nursing, Nursing Home, Malnutrition.*

INTRODUCTION

Malnutrition is a problem that always arises and becomes a serious thing for parents, elderly as the final stage of the cycle in life is the natural development stage that will be experienced by every individual who reaches old age and is a reality that it cannot avoid.[1] Regarding population in the elderly, malnutrition appears today as the primary basis for public health. Mal-nutrition is caused by insufficient or inadequate nutritional intake which makes various damaging effects such as muscle wasting and body defenses. The same means that mal-nutrition in the elderly causes and worsens the state of weakness or dependence and contributes to the development of self-morbidity,[2-5] a large number of older adults in Indonesia in the future brings positive and negative impacts. The positive effect, if the elderly population is in a healthy, active and productive condition. Seen from the other side, the large number of elderly people is a burden. if the elderly has health problems that result in an increase in the cost of health services, a decrease in income/ income, an increase in disability, the absence of social support and an environment that is not friendly to the elderly population.[6]

Aging is a process of gradual or continuous change, personal, physical and social experiments and a unique perception of life, which is happy for some people and others, it is the initial value of a dark and sad stage of life.[7] The aging process associated with changes in body composition, precisely due to a decrease in lean body mass. Malnutrition is a multifactorial disease, and in the elderly, many risk factors can worsen physiological performance that affects muscle mass and fat (FM), which globally seen for weight loss and body mass index (BMI). There are other things to note, the existence of chronic diseases, many drugs, cognitive impairment, depression, loss of role, and social isolation can act systematically with a decrease in digestive function, smell, and saliva, as well as hormonal profiles, which affect the nutritional status of the elderly.[8] For this purpose, it seems essential to identify malnutrition factors experienced by the elderly in high risk; In this case, a necessary step to promoting elderly health is gaining knowledge of their experiences and concerns during the aging process. The first step to identifying malnutrition at this age is to use reliable instruments and methods.[9]

The world population is rapidly aging with estimates that this year until 2050 the proportion of the world's population above 60 years will increase from 11% to 22%. The expected increase in the absolute number of older adults will triple from 605 million to 2 billion during this period.[10] Based on population projection data, it estimated that in 2017 there would be 23.66 million older adults in Indonesia (9.03%). It predicted that the elderly population in 2020 (27.08 million), in 2025 (33.69 million), in 2030 (40.95 million) and 2035 (48.19 million).[6] Because the number of older adults continues to increase, the provision of a better healthcare process for the elderly at both the hospital and the community is an obligation. Often, the focus of nutrition in the elderly is a healthy diet and exercise to minimize the risk of developing breast cancer from a lifestyle (such as cardiovascular disease, type 2 diabetes mellitus). Thus, there is ample evidence to suggest that energy-protein malnutrition (PEM) is a common and frequent problem in this age group, including in hospitals, nursing homes, and community environments.[11]

The primary challenge along this line of research is to find out the most influential factors in malnutrition in the elderly in nursing homes using the mini nutritional assessment. There are 18 the Mini Nutritional Assessment (MNA) items grouped in four parts: anthropometric assessment (weight, height, and weight loss); general assessment (lifestyle, drug use, and mobility); evaluation of diet (amount of food, food and fluid intake, and feeding autonomy); and subjective assessment (self-perception of health and nutritional status).[12]

Malnutrition in old age will become a more complex problem in the physical and psychological advanced age. However, researchers only want to see what factors impact on elderly seen from questionnaire MNA in nursing homes.

As a result, due to several malnutrition tests in the elderly, the current study was conducted to analyze the malnutrition factors with MNA. As a basis for state policy and the effectiveness of future interventions. Therefore, the present study aims to develop and evaluate MNA from instruments used to determine the most dominant factors in cases of elderly malnutrition

MATERIAL AND METHOD

This research is a Factor Analysis study to determine the factors that have the most impact on the case. Factor analysis (FA) is a multivariate method and can use as an extension of the primary component analysis. The primary purpose of the FA is to describe the relationship between a set of variables that observed with a small number of unobservable variables called factors.[13] The research community, both in the quantitative phase, included those in the Mojopahit nursing home in Mojokerto, East Java, Indonesia 2018. The research sample was older adults in nursing homes. The participants gave their informed verbal approval. Inclusion criteria are elderly, not those who experience total communication disruption and bed rest.

The exclusion criteria were refusing to continue the interview. To find out assessing nutritional status as part of an evaluation of the standard of elderly patients in clinics, nursing homes, hospitals, or among those who were evaluated for nutritional status, weak and fast, MNA was validated and developed jointly by the Internal Medicine Center and Clinical Gerontology of Toulouse (France), Clinical Nutrition Program at the University of New Mexico (United States), and the Nestle Research Center in Lausanne (Switzerland).[14-17]

The data collection process, researchers, used MNA which is complete in less than 15 minutes. Each response point has a numerical value and contributes to the score, which has a maximum value of 30. In people with advanced age with cognitive impairment, the test requires help from families from old age or the health nursing team. Older adults interviewed are classified into three nutritional levels based on a score between 0 and 30. A score of 24 or higher means satisfying nutritional status; a score of 17 to 23.5 means the risk of malnutrition; scores below 17 conclude protein-energy malnutrition. Guidelines for determining height according to knee height and body mass index (BMI) for all patients are included to facilitate using the tool. MNA is easier to manage, patient-friendly, inexpensive (no laboratory tests required), susceptible (96%) and specific (98%) and reproduced.[17-20]

Interviews are written carefully according to the questionnaire and then analyzed in the shortest time possible or approximately 15 minutes. Interview analysis is carried out by 2 participants (member checking) and 3 teaching staff members or researchers (external verification). In the third step, each questionnaire point is determined and entered by guiding the results of the interview and literature review. In this study, the first inductive and deductive method used. Data were analyzed using SPSS 25.0 software. Data from questionnaires that have completed and then tabulated, 27 elderly are asked to comment on this instrument, and then an examination is carried out by the MNA questionnaire examined. The classified data will proceed to the data analysis process (factor analysis). The factors that have known the results will be adjusted in value with other factors so that the dominant factor obtained.

To determine that 2 research members can carry out an assessment correctly, the principal researcher conducts a common perception in data retrieval, so that there will be no errors during the field assessment. The time used in this perception equation is 1 day in the campus class. The stages that are carried out are pre and post-test understanding of MNA instruments. in the event of any misunderstanding, it carried out until the member can carry out field assessments.

MNA only shows malnutrition in humans and here in parents. If the total score is> 23.5, 17-23.5, <17, it means that there is no malnutrition, the risk of malnutrition, or malnutrition, respectively.[21] MNA was validated to determine mal-nutrition for Turkish geriatric patients in 2015.[22] The calculate body mass index, height measured to centimeters (cm), and body weight weighed to half a kilogram (kg) with the same measuring instrument. MNA is performed in all respondents or the elderly even if their MNA-Short Form (SF) scores ≥ 12.

The structure evaluation of the questionnaire factor, exploratory factor analysis was applied. To answer this question "whether the measurement scale for malnutrition in the elderly with several factors or not," we use factor analysis that directly uses SPSS 25.0.

The final step includes determining the reliability of the questionnaire with internal consistency. KMO and Bartlett's Test calculated for the sig level. Research. The current article with the Code of Ethics STIKes.PPNI. LPPM.1316.13 approved at the Community Service Research Institute of Institute of Health Science Bina Sehat PPNI.

FINDINGS

Panti Werdha Mojopahit is a technical implementation unit of the Health and Social Welfare Office of the Mojokerto Regional Government that provides services to all people, especially those who are disadvantaged. Socially, this institution provides services to the elderly. In this place the elderly get love, physical and spiritual care, so they can enjoy their old days and get inner and inner peace. This Nursing Home located on Jl Raya Brangkal No. 862 (Front of Sooko Police Station), District Sooko Kab. Mojokerto Postal Code: 61361 Tlfn: (0321) 328894. The northern part of the nursing home located not far from the Kedungmaling market. The south of this institution adjacent to the Masjid Raya Desa Gemekan, Sooko District, Hospital and DIAN HUSADA, Sooko sub-district health center which has the advantage for 47 health services, and dealing with the Sooko District Police Station and the Sooko sub-district office in Mojokerto Regency and the location of this nursing home is right on the side of the inter-provincial highway, with the busy streets of both private and public vehicles.

a. Rotation converged in 5 iterations.			

Determination of variables to certain factors follows the magnitude of the correlation between variables with coefficients, namely to the significant association. It was the conclusion of the table. 2 then the member factors and variables are:

1. First factor:

a. Mobility

b. Body Period Index

2. Second Factor:

a. Weight loss

3. Third Factor:

a. Neuropsychological

DISCUSSION

The first factor consists of activities that must be done by the elderly and body mass index; this means that the elderly and controlling the elderly interpreted as more elderly. The second factor is almost the same as the monitoring of body mass index, and the third factor is the aging process itself which is experiencing neuropsychological disorders. In conclusion, the factors that affect malnutrition among elderly people at Mojopahit Mojokerto nursing home can be described as follows:

Informal factors for the elderly: mobility, neuropsychological disorders

External factors: control nurses about elderly body weight

CONCLUSION

Nutritional status assessment with Mini Nutritional Assessment (MNA) is a multiparameter in screening as well as field assessments of malnutrition in the elderly. This MNA questionnaire consists of 18 questions divided into 4 domains: evaluation for anthropometry, evaluation for food intake, general evaluation of old lifestyle and subjective assessment of advanced age. MNA scores are reliable and can be relied upon to detect the risk of malnutrition in the elderly. In conclusion, using this MNA to look at the factors that cause starvation is better than malnutrition in the elderly. there are 2 malnutrition factors in the Mojopahit Mojokerto nursing home, namely informal elements of the elderly: mobility, neuropsychological disorders, and external factors: controlling nurses about elderly body weight

The Development of the Vestibular Stability in Children Who are Engaged in Football Taking into Account their Nervous System

Georgy G Polevoy

Department of Physical Education, faculty of Physical Culture and Sports, the Vyatka State University, Kirov, Russia

ABSTRACT

In this study, we investigated the effect of typological peculiarities of manifestations of properties of the nervous system of young football players the ability to accurately and consistently perform motor actions in conditions of vestibular irritation. 32 young football players of 10-11 years participated in the pedagogical experiment. 16 athletes were engaged in experimental methodic which is based on using the same exercise and methods development of the ability to react quickly, but different components of the load, for players with a strong nervous system (8 people), the load was intensive, but for players with a weak nervous system (8 persons) - volumetric load. The other 16 football players made up the control group. For 8 months of the experiment there was a significant increase in the ability to react quickly football players 10-11 years old in the experimental group, which was engaged in by a special methodic. The football players with a strong nervous system indicator has improved from 10.1±0.6 time to 12.0±0.4 time ($P<0.05$), and football players with a weak nervous system – from 9.1±0.3 time to 10.1±0.4 time ($P<0.05$). In the control group also occurred the positive, but not significant changes ($P> 0.05$). The study proved the effectiveness of the use of the typological properties of the nervous system as a differentiated method of developing the ability to ability to accurately and consistently perform motor actions in conditions of vestibular irritation of young football players. This approach allows to improve the quality of the training process of young football players.

Keywords: *Typology, Vestibular stability, Football players, Differentiated approach.*

INTRODUCTION

Football is the most popular sport in all the world. Football is played at different levels, amateur and professional. Football is played by men, women and children. In order to become a great football player must be persistently engaged from childhood. The general level of training of a football player consists of such types of training as his technical training, physical training, theoretical knowledge, tactical thinking and some other types of training.

One of the most important types of training for a football player, especially at a young age, is his technical level of preparation[10,20]. Technical training of an athlete, a football player is a level of coordination abilities[4,7,26].

Each sport has its own characteristics. However, it is the specific coordination abilities that make up the technical training of the athlete. While General coordination abilities are the Foundation for the development of specific abilities.

In the modern literature there are a number of classifications of specific coordination abilities, one of the most popular classifications is the classification proposed by Hirtz and Lyakh. One of the most important abilities the authors distinguish is vestibular stability[8,17].

Age 10-11 years is the most favorable for the development of children's ability to One of the most important abilities the authors distinguish is accurately and consistently perform motor actions in conditions of vestibular irritation[5,11,23].

The game of the football players is carried out in the constantly emerging unexpected situations, which require the manifestation of the speed of reaction, the ability to concentrate and switch attention, space-time accuracy. It is necessary to have the ability to accurately and consistently perform motor actions in conditions of vestibular irritations[22].

In order to fully reveal and realize the athlete's ability to use an individual approach to training activities. In children's and youth sports, as a rule, this approach is called differentiated. That is, during the training session, children are divided into groups, taking into account some criterion, for example, in terms of technical training, physical development, growth, physical training and some others[1,3,13].

Criteria for dividing players into groups can be very diverse. However, in our opinion, it is necessary to rely on the typological features of the manifestation of the properties of the nervous system, that is, the strength-weakness indicators of the nervous system in the process of excitation. This is a new and poorly understood approach in the training activity of athletes. The use of typology in the training process was studied on athletes - in sprint track and field athletes[12], basketball[16,19], gymnastics[14], table tennis[25].

In all the studies listed above, the effectiveness of the typological criterion was proved. At the same time, we were unable to find studies on football players, the preparation of which is carried out based on the difference in the properties of the nervous system (strength and weakness of the excitation process).

The aim of the study is to improve the technical training of football players, using a differentiated approach based on typological features of the manifestation of the properties of the nervous system due to the development of the ability to accurately and consistently perform motor actions in conditions of vestibular irritation.

MATERIAL AND METHOD

The study used empirical and theoretical methods.

1. Theoretical methods - the study of materials on the problem being studied, the study of the training system for young athletes involved in football, analysis of literary sources.

2. Empirical methods:

a) Basic pedagogical experiment - determination of the strength of the nervous system[24], determination of the level of development of the ability to vestibular stability[8];

b) Mathematical and statistical methods[21,27].

Criteria for evaluating the effectiveness of the methodic

The nervous system of players was determined by the method of "Tapping-test".

Sheet A4 is divided into six arranged three in a row of equal squares, according to the signal, the players begin to put dots in each rectangle. 5 seconds of work in each squares. The work is the rapid putting points in the square. You can move from one rectangle to another by command only. After the sixth rectangle the exercise ends. Result - count the number of points in each rectangle, build a work schedule. The type of nervous system is determined according to the schedule[24].

The ability to balance was evaluated in "turns on the gymnastic bench".

The subject must perform on the narrow surface of the gymnastic bench and not fall. The turn is complete when the subject returns to the starting position. The bench is located narrow side up, and the wide side lies on the floor. Result: the best of two attempts is taken into account, the number of turns performed in 20 with an accuracy of 0.5 turns[8].

Description of the experiment

In total, 32 football players of 10-11 years took part in the experiment. Prior to the experiment, the players were divided into KG and EG by random sampling[2, 28]. Each group had the same number of players with a strong and weak nervous system of the process of excitation.

During the training year, the CG players were engaged in the standard program 6, and the players in the EG were engaged in an experimental methodic. In football training in EG, a differentiated approach based on the typology of the nervous system was used. During the experiment, 130 training sessions were conducted for 90 minutes each training session.

Mathematical and statistical processing of the

experimental results was carried out using the parametric criterion (t-student)[21,27], used by Microsoft Excel 2007. Correlation analysis was performed using the Bio Stat 2009 program. The result was significant at a value of P> 0.05.

Feature of training in EG:

1. After a short warm-up, the football players of the EG performed exercises for 20 minutes on the development of vestibular stability in different subgroups strong and weak nervous system:

1) a Series of 6-10 jumps on the site with turns left and right, performed by different schemes: a) left 90 degrees + 90 degrees (the amount of turns can be varied within 45-360 degrees); b) the same right; C) 90 degrees left + 90 degrees right (such as "turn-turn").

2) Jumping on the spot and moving forward or backward with a turn of 540-720 degrees.

3) Run with turn (signal) for 180-360 degrees.

4) Running with rotation left and right and other exercises[18, 29].

2. The main methods of developing the reaction were repeated, varied and playing methods[9,15].

3. The main methodical admission were - the introduction of new exercises or the complication of old exercises, changing the speed of the exercise and the introduction of new targets[9,15].

4. The main difference in the training of football players with a strong and weak nervous system were the load components. The load for players with a strong nervous system was intense, and for players with a weak nervous system - a voluminous load.

The intensity of the load increased by increasing the number of exercises and reducing rest, and the volume increased due to the increase in the number of repetitions and rest intervals.

The intensity of the exercise is 150-170 beats per minute. The duration of the exercise for football players with a strong nervous system 20-30 seconds, for weak 30-40 seconds. The rest-time - until complete recovery; the character of the rest-time passive.

RESULTS

At the beginning of the study groups and subgroups were formed. Then, between EG and KG was played a friendly match. This match showed an objective level of possession of the technical skills of young football players. The meeting ended with a score of 1-1. Before the beginning of the pedagogical experiment, all football players passed a control test "turns on the gymnastic bench", which shows the level of development of the vestibular stability. There were no significant and significant differences between the indices of soccer players of CG and EG and within the groups (P> 0.05).

Table 1. Indicators of the ability to vestibular stability of football players 10-11 years old (M±m)

Indicators	The strength of the nervous system	KG			EG			P (2-5)
		Before	After	P	Before	After	P	
		1	2	3	4	5	6	
turns on the gymnastic bench (number of times)	Strong	10,1±0,6	12,0±0,4	**t=2,85 P<0,01**	9,9±0,4	10,2±0,4	t=0,58 P>0,05	**t=3,1 P<0,05**
	Weak	9,1±0,3	10,1±0,4	**t=2,20 P<0,05**	9,4±0,6	9,6±0,6	t=0,35 P>0,05	t=0,7 P>0,05
		t=1,55 P>0,05	**t=3,36 P<0,05**	–	t=0,7 P>0,05	t=0,78 P>0,05	–	–

The results in the test "Stop rolling the ball with a foot" (from 9.1 to 10.1 time) correspond to the average level of development of the ability to accurately and consistently perform motor actions in conditions of vestibular irritation[18].

Indicators of the ability to vestibular stability to football players 10-11 are presented in Table 1.

After the experiment was over, positive changes occurred in the test "turns on the gymnastic bench".

In KG in football players with a weak and weak nervous system, the indicators improved, but not significantly (P> 0.05).

In football players of the EG with a strong nervous system, the indices improved from 10.1±0.6 to 12.0±0.4 time (P <0.01), and for players with weak nervous system - from 9.1±0.3 up to 10.1±0.4 time (P <0.05). Such indicators correspond to a high level of development of the ability to accurately and consistently perform motor actions in conditions of vestibular irritation for the age of 10-11 years[18].

After the end of the pedagogical experiment of the boys' team, the EG and KG again played a friendly match among themselves. The game ended with a confident victory of football players EG with a score of 5-0. In the game, the guys from EG looked much faster, agile and more technically than the football players from the KG. Such a result allows us to judge the effectiveness of the methodic.

DISCUSSION

In different sports, General and specific coordination abilities are very important, especially in team sports such as football. For football players, one of the most important specific coordination abilities is the ability to vestibular stability[4,7,10]. Vestibular stability-the ability to accurately and consistently perform motor actions in conditions of vestibular irritation (somersaults, throws, turns)[11,20,26].

In training work with athletes, especially with children, an individual or differentiated approach is very important. It allows the effective use of hidden functionality and physical reserves of the body[1,3,13].

When using a differentiated approach, there may be different criteria, such as the growth of a player, his technical training and some other criteria. One of the effective criteria for dividing athletes into groups is the type of nervous system in the process of excitation[12,14,16,19,25].

To date, there are methodic in which tools and methods, the components of the load that are aimed at developing the abilities of athletes with different types nervous system are briefly described. In our methodic, for the first time in detail, we specified all the parameters of the means, methods and components of the load when performing physical exercises for athletes 10-11 years, involved in football.

It is important to understand that athletes with a strong nervous system better tolerate the load - intensive. Athletes with a weak nervous system work better with a volume load[12,14,16,19,25]. In our study, this theory is fully confirmed.

In the course of the experiment, new results were obtained and specific recommendations were given on working with young football players 10-11 years old, who have different types of the nervous system.

CONCLUSION

The experimental methodic of differentiated development of the ability to vestibular stability in football players aged 10-11 with different types of nervous system had a positive and progressive impact on soccer players EG (P <0.01).

In terms of football players in the KG, who were engaged in the standard methodic, the results of the ability to accurately and consistently perform motor actions in conditions of vestibular irritation also improved, but not significantly (P> 0.01).

The victory of the EG over the KG with a score of 5-0 indicates that the football players of the EG surpassed the players of the CG in all respects, including technical training.

Conflicts of Interest - The author declare that hi have no conflict of interest.

Ethical approval - All procedures performed in studies involving human participants were in accordance with the ethical standards of the institutional and/or national research committee and with the 1964 Helsinki declaration and its later amendments or comparable ethical standards.

Patterns of Mortality Caused by Natural Disasters and Human Development Level: A South Asian Analysis

Masum Billah[1], Pedro Arcos González[2], Rafael Castro Delgado[2]

[1]Lecturer, Department of Sociology, East West University. A/2 Jahurul Islam Avenue, Jahurul Islam City, Aftabnagar, Dhaka, Bangladesh, [2]Unit for Research in Emergency and Disasters, Department of Medicine, University of Oviedo, Oviedo, Spain

ABSTRACT

This study aimed at exploring the correlation between the patterns of mortality and affected people caused by natural disasters and human development level at country level in South East Asia (SEA). The study utilized quantitative data on deaths and affected people caused by natural disasters from CRED and other databases. Huge deaths and affected people concentrated on lower HDI countries in comparison with middle ones in SEA. Desegregated disaster subtypes, overlapping data, no universal scale about severity and magnitude measurement demonstrated lead barriers for conducting statistical test between impact variables and development level with value. With the combination of all parameters of natural disaster scales, a universal and accepted scale might be suggested to avoid misleading in disaster data collection and thereby develop scientific techniques for vulnerability assessment.

Keywords: *Natural disaster; Mortality; Affected people; South East Asia; Human development level*

INTRODUCTION

Large scale natural disasters have demonstrated unprecedented deaths and affected people based on severity and magnitude for the past decades around the world. Though natural hazards are connected with geographical fault lines, climatic shifts and meteorological extreme events, decrease in widespread deaths and affected people largely depends on country specific health system, existing logistics, coping strategies and human development level. Globally, 4000 massive natural disasters had been accounted for estimating 1.5 million deaths during 2005-2015. Several studies on natural disasters related mass causality and affected people have often turned into hazard and event specific disasters in the global settings.[1] Existing disaster documents reveal that there is a great gap of adequate information on country specific mortality and affected people caused by hydro-meteorological and geophysical disasters and its relation with human development value.[2] Disaster management logistics and preparedness initiatives have carried conviction for few people in low resource settings. In high income settings, people's exposure to deaths and affected people accounts for estimating lower rates due to strong disaster policy, existing coping resources. SEA is one of the most disaster-prone regions in the world. Geologically, the subcontinent is situated in the active tectonic plate movements in the India Ocean, which have been the source of major earthquakes and tsunamis. Climatic variability, tropical monsoons, and proximity to the coastlines are the direct risk factors for generating tropical cyclones and storms in the Indian Ocean.[3]

Natural disasters pose for occurring sudden or slow onset furious impacts with atmospheric, hydrologic and geologic roots.[4] Around five million deaths and millions more injuries worldwide are the direct consequences of disasters since 1960. Most of the deaths have concentrated in developing countries. As a single disaster, drought has killed over 2.5 million people

URL: http://www.ewubd.edu

while earthquakes caused 1 million more fatalities. Furthermore, storms and cyclone claimed over 750, 000 deaths during the last decades.[5] Over the past twenty years, more than 50% of all fatalities were reported in low human development countries though they shared only a tenth of those exposed to natural disasters. Subsequently, around 85% of the people exposed to natural disasters are the inhabitants of medium and low human development countries.[6] Deaths are the direct result of sudden onset natural catastrophe while affected is an aggregated figure of all injured, homeless and affected during the period of disaster.[7] The HDI refers to the geometric mean of normalized indices for three dimensions separately.[8] As a dimension of health for HDI, life expectancy has observed a disproportionate increase over the past quarter century. Education and standard of living, based on mean of years of schooling and per capita income[8] respectively are attributed to promise improved socio-economic status through increasing livelihood capacities, housing in low risk areas, expensive disaster insurance and adequate access to warning and evacuation information system. The overall objective of the study is to explore the patterns of mortality and affected people caused by natural disasters and their relationship to the level of human development at country level in SEA.

MATERIALS AND METHOD

The study approached a content analysis of academic research articles, conference papers and scientific documents based on mortality and affected people caused by natural disasters in the duration of 2014-2015. This study employed quantitative method of data collection. Deaths and affected data had been primarily collected from CRED database (EM-DAT). For measuring the severity and magnitude of each disaster, the study also used quantitative data from Relief web, OCHA, UNDP, Flood list, Wikipedia and different media sources. The researcher checked and rechecked data repeatedly from multiple sources for verifying the validity.

Concentrating on multiple scales for measuring magnitude level, a general scale valued 1 to 5 had been adopted for combining original disaster magnitude levels into a standardized benchmark. This piece of work utilized human development value from UNDP country reports and correlated impact variables caused by disasters for the duration of 2014-2015. The duration of data collection took two months, May to June, 2016. The collected data had been analyzed by using descriptive statistics in SPSS version 20. Multi variate analysis was administered for correlating impact variables caused by natural disasters with the value of country specific human development index.

RESULTS

Table 1: Profile of deaths caused by natural disasters 2014-2015

Disasters	Frequency	Deaths	Percent (%)
Earthquake	13	9457	52.84
Extreme temperature	6	3796	21.21
Flood	40	3160	17.66
Landslide	15	997	5.57
Storm	17	483	2.70
Total	**92**	**17, 897**	**100.00**

The table 1 shows that there was no relation between number of disaster episodes and number of deaths occurred in SEA. Out of 92 natural disasters recorded, approximately 53% deaths occurred due to earthquakes while 21.21% fatalities occurred due to extreme temperature in the past two years. More frequency of disaster episodes does not demonstrate incidence of deaths higher or lower in the current study. In the study, 17.66%, 5.57% and 2.70% deaths were reported from flood, landslide and storm respectively.

Patterns of Mortality and Affected People and HDI

Mortality and HDI

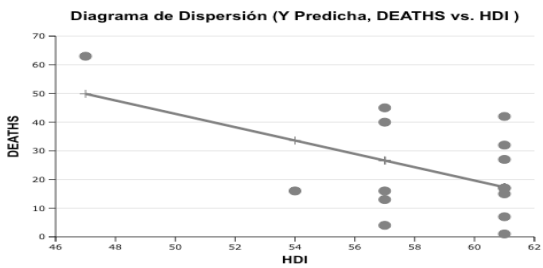

Figure 1: Number of deaths and HDI

The figure 1 shows that over 60 deaths were reported for HDI 0.47 in Afghanistan while around 40-0

deaths were noted for HDI 0.61 in India and Bhutan respectively. The number of deaths lowered when the value of HDI showed an increase in the line graph data. It was observed that deaths caused by natural disasters had a positive correlation with the level of human development for each country. It was an inverse or indirect correlation between deaths and HDI variables. This relationship was considered statistically significant in the study. So, it was clearly found that deaths caused by natural disasters followed a positive correlation with the value of human development for each specific country.

Flood occurred mortality and HDI level

In the case of floods, there was also an inverse correlation between the value of human development index and the number of deaths and this correlation was shown as statistically significant.

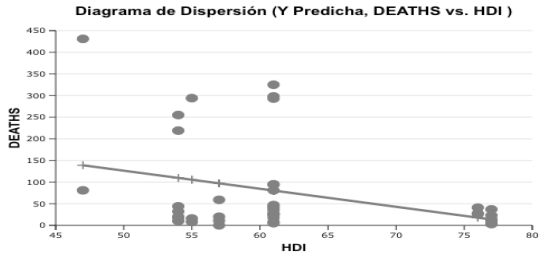

Figure 2: Deaths caused by flood and HDI

With regard to explaining deaths caused by flood during 2014-2015, it was clearly found that nearly 450 deaths were identified for lowest HDI 0.47 while less than 50 deaths were reported for the highest HDI 0.77 in the study line graph 2. The study data on flood demonstrated that deaths followed an inverse statistical relationship with the level of HDI in quantitative study.

Storm induced deaths and HDI value

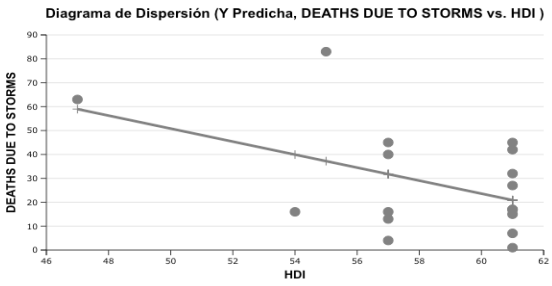

Figure 3: Correlation between deaths and HDI

In the graph 3, it was clearly noted that over 80 deaths caused by storms were identified for HDI score 0.55 of Nepal while around 60 deaths caused by storms were reported for HDI value 0.47 of Afghanistan in the study. Most of the reported deaths caused by storms followed a slight declination for higher HDI countries in the figure. In addition, more deaths caused by storms demonstrated for lower HDI values in comparison with higher ones in the study. The relationship between variables was negative or indirect but reported as statistically significant.

Correlation of Mortality based on Standardized Magnitude (SM) and HDI

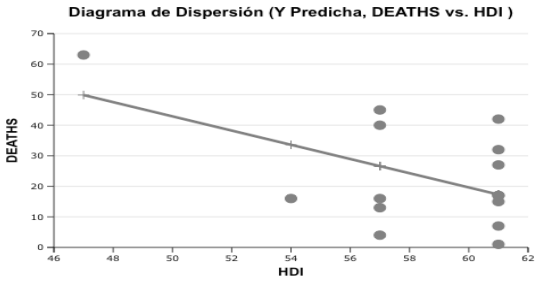

Figure 4: Deaths of SM 1 and HDI

Overall, it was found that over 60 deaths caused by disasters of magnitude one were reported for low HDI score 0.47 in Afghanistan focused in the graph 4. The number of deaths of magnitude one declined sharply following higher HDI value in the study. It was an indirect or negative correlation between deaths caused by disasters and HDI level. It was considered as statistically significant in the study.

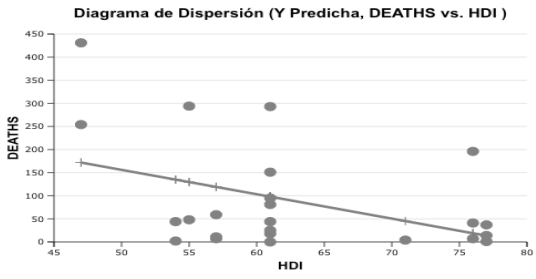

Figure 5: Deaths of SM 3 and HDI

In case of disaster magnitude 3, approximately 450 deaths were noted for lowest HDI value 0.47 in Afghanistan while around 5 deaths were reported for highest HDI values in Iran and Sri Lanka respectively (Figure 5).

DISCUSSION

Mortality Trends and Human Development Level

The SEA has experienced large scale disasters and widespread deaths and affected in the past couple of years. The frequency and destructiveness of natural hazards have found a considerable increase during the last 30 years.[9] Likewise, in comparison with disaster impacts in 2014, a higher proportion in deaths and affected people caused by natural disasters was found in 2015. Overlapping in data records, misleading in database records and multiple characters of similar natural disasters usually limit higher statistical analysis to connect disaster impact factors with development variables. In World Health Organization's estimation, statistics of death and affected people vary widely due to technical challenges. Limited resources for collecting and compiling disaster related data, inadequate vital registration system, political biases and misleading in reporting were noted as the challenging barriers for reporting country wise natural disaster data.[10]

The number of deaths caused by flood, earthquake and storm were found to be statistically correlated with country specific HDI value. The relationship was indirect or negative and found statistically significant. Exposure to disasters and deaths caused by natural disasters concentrated a lot on low human development countries while more impact factors concentrate in middle human development countries in comparison with that from high human development countries. Bangladesh and the United States experienced tropical cyclone 3.4 times and 12.1 times respectively, resulting consecutive deaths of 7,468 and 223 people on average per year during the twenty years 1980-2000.[10] Landslide and extreme temperature did not find any correlation with the value of human development.

Flooding showed a significant correlation with the level of human development for country specific profile. India, a middle HDI country has experienced a fairly proportion of flood related impact factors in the past years. With the highest frequency and magnitude, deaths and affected people caused by flooding undoubtedly concentrated on the level of development. But, the correlation between level of development and impact factors were focused as inverse or indirect statistically. In case of earthquake, the findings reveal that the correlation between deaths and affected people caused by earthquake as well as structural factors becomes apparent more rather than the level of human development value. Most of earthquakes concentrated on low middle human development countries like Nepal, Afghanistan, Pakistan and India and caused large scale deaths and injuries across the region. However, the yearly approximate 250 deaths were noted from storm, in the past couple of years. Another regional study finding from SEA reveals the different results. The yearly average deaths from storm were reported approximately 2000 during the periods 2010-2014 [3].

Human Development Level and Affected from Disasters

The correlation between human development level and affected people from flood, earthquake and landslide respectively was considered indirect or inverse. It was not statistically significant relationship. In addition, no correlation was found between HDI level and affected people from storm. The most affected people from natural disasters were found for middle HDI in India during the past two years 2014-2015. Flood, the frequently occurred event in India made a significant difference with all other disaster affected people for SEA countries. It was a bit confusing to correlate all the data from affected people with development level. Limitation of data on affected people from different natural disasters had been the great barrier for correlating with development level for country specific explanation. The most obvious finding showed that affected people from natural disasters appear mostly in middle HDI countries in SEA context.

Correlation between Deaths and Affected People

Deaths caused by natural disasters demonstrated a direct or positive correlation with affected population in the past couple of years. When deaths from natural disasters find an increase, the number of affected people also finds a positive increase in the same direction. These findings are quite similar with the statistical results of yearbook 2011. Between 1991-2000 and 2001-2010, around 10 and 60 deaths per million people respectively were reported in comparison with 21 and 22 affected people per thousand people respectively from natural disasters in SEA.[11] Overall, the higher the number of deaths reported in natural disaster situations, the largest the number of affected people appeared in the database.

HDI Value and Mortality Analysis

In SEA, countries with lower HDI value experiences more deaths caused by natural disasters of lower magnitude in comparison with countries with higher HDI value. The number of deaths caused by natural disasters demonstrated comparatively higher in Afghanistan, Pakistan, Nepal, and Bangladesh in comparison with other countries in SEA in the periods 2014-2015. The correlation of deaths caused by disaster magnitude 3 with HDI value was approached negatively in the study. However, majority of deaths of disaster magnitude 3 occurred in lower HDI countries like Afghanistan, Pakistan, Nepal and Bangladesh for the past two years. Conversely, higher HDI countries Iran, Sri Lanka, Maldives, Bhutan and India experienced lower deaths for disaster magnitude 3 in the same periods. The inverse relationship was indirect and statistically significant. On the basis of standardized magnitude 2 and 4, it was noted that there was correlation between the variables. It was an indirect or negative correlation. It was not statistically significant. Fatalities from earthquake 2015 in Nepal made a considerable difference for showing more significant relationship between human development value and deaths.

CONCLUSION

SEA countries continue to experience disproportionate impacts of natural disasters. Most of the deaths from natural disasters concentrated on low human development countries like Afghanistan, Nepal, Pakistan and Bangladesh in comparison with fatalities from other middle human development countries in SEA. Disaster affected people dominated in middle HDI countries in comparison with that from low HDI backgrounds. Limitation of data on affected people, overlapped disaster data among disaster subtypes, misleading in reporting in database, and misreporting in newspapers and journals demonstrated perceived barriers for considering statistical significant and positive correlation between impact variables and HDI level. Considering different disaster indicators for measuring severity and magnitude, a universal and well accepted scale for aggregating large scale disaster data and framing benchmark might be suggested for avoiding misleading in disaster data collection and developing scientific tools for vulnerability estimation.

Conflict of Interest: None declared

Financial Disclosure: None declared

Ethical Clearance : The study was dependent on recorded data from EM-DAT database as per institutional rules. So, the study did not look for any individual consent. But, it took officially recognized institutional permission for using their reserved dataset.

Isolation and Identification of the Fungi Associated with Mosquitos and Utilizing their Filtrates in the Biocontrol of *Culex molestus* Forskal

Maysaa Taqi Al-Khazali[1], Sarah Kadhim Al- Rahimy[1], Aseel Kariem Alsultany[1], Hawraa Hasan Atiyah[1]

[1]Department of Biology, College of Science, University of Kerbala

ABSTRACT

The following study included the isolation and identification of the fungi associated with the adult mosquito spread out throughout the Kerbala Governorate \ Iraq. A total of 94 samples were collected from different areas . Of these samples 69 fungi were isolated and laboratory identified to belong to 6 genera . *Aspergillus spp.* scored the highest rate reaching 56.5%, whereas *Trichoderma viride* scored the least *rate* of 2.8%. Three species of the *Aspergillus* were Isolated and identified, where the *A.niger* was the more frequent as its rate was 44.9% .The two neighbourhoods of Towayreg and Alhussainiya recorded the highest rate up to24.6%,and 20.2% *respectively*. As regards the effect of the isolated fungal filtrates on the percent of mortality of the adult of *Culex molestus*, the results also explained the superiority of *A.flavus* filtrates by spray and feeding the adults with food containing that filtrates where the mortality percent reached72.97% and70.83 %respectively. The concentration 100 % of the fungal filtrates resulted in the highest mortality rate up to 100 % after 96 hours of the treatment .

Key words : *A.flavus , A.niger , Culex molestus Forskal.*

INTRODUCTION

Mosquitos are considered blood-sucking arthropods which belong to the order Diptera [1] of the family Culicidae which is of great importance both in the medical and veterinary fields because they are a bio vector for several dangerous pathogenic pests ,and *are* the most prevalent among human environment [2] . Due to the medical importance of mosquitos, scientists were interested in combating both them and the damages resulting from utilizing chemical pesticides suffered by the environment, humans and the non targeted organisms [3] , thus the need arose to use bio control [4] where the fungi were utilized in insect control as they have the ability to infect nearly 200 types of insects which belong to order of Coeloptera andLepidoptera, wherebyfungi act as insect pathogens through contact, producing spores that attach to the insect's body and dissolve the proteins,chitin and fat incorporated in the insects body [5] .

In view of the lack of previous studies concerning the isolation and identification of the fungi accompanying the mosquitos spread out in the Kerbala Governorate, this study aims at:Isolation and identification of the fungi associated with the mosquitos spread in different areas in Kerbala Governorate,Testing the efficiency of various concentrations of filtrates in affecting adult *Cx. molestus* by utilizing different methods.and Determination of the relation between the effect of the concentration and the period of exposure and their effect on the percent of mortality.

MATERIAL AND METHOD

Collection of samples

A total of 94 samples were collected from adult mosquitos from different areas of the Kerbala Governorate which are Towayreg, Alhussaineya, districts of Al- Zahraa, Albobyat, qantart Alsalam,Ramadan and the old city center using a specialized insect collection trap. brought to the laboratory and treatment in accordance with [6] then each 5 insects were put in a Petri dish containing Potato dextrose agar added to the

antibiotic Chloramphenicol at a concentration of 250 mg/lt, and incubated at 27 ℃ for an interval of 5-7 days, after which they were examined, the growing fungi isolated and purified on a new growth medium .

Identification of fungi

The isolated fungi were identified according to the standardized method [7] ,utilizing the categorization key [8,9] .The percentile was calculated according to the following equation [10]

Percentile of encounters =(number of times the fungus is encountered / the total number of samples) X 100

Preparation of fungal filtrates

A broth potato dextrose agar was prepared according to the standard doctrine [11] , it was distributed in 250 ml beakers in the amount 150 ml in each beaker, and the medium was inoculated with discs of the isolated fungal cultures at the age of 7 days, each alone, at a rate of three discs for each beaker. The beakers were incubated at 27 ℃ and shaken every three days to distribute the fungal growth. After two weeks filtering the inoculations using the Whatman No.1 filter paper using a bechner cone with the assistance of a vacuum pump, the filtration was repeated utilizing the fine filter containing a fine filter paper and then the concentrations were prepared: 25 %, 50% ,75 % ,and 100 % [12].

Collection and identification of mosquito samples

Egg rafts were collected from the*Cx. molestus* from one of the heavy sewage discharge locations in the district of Ramadan ,Kerbala Governorate. The rafts were placed in strict laboratory conditions in order to hatch and were breeded until reaching the adult.To confirm the identification process, a biological phenomenon was utilized, namely the ability of this type of females to lay its first raft of eggs without needing a blood meal [13] .

Effect of the fungal filtrates on the mortality of the *Cx. molestus* adult by spraying

The effect of the **filtrates** on the adult mosquitos was examined at the age of 24 hours after spraying them with the **filtrates** , where 10 insects were placed in a glass bottle of 250 ㎝³. The refined items were sprayed at a rate of 5 ml **filtrates** / refined, at an amount of three refined items for each concentration using a small sterilized atomizer from an approximate height of 15 cm. As to the control treatment, they were sprayed only with sterilized distilled water.The percent of mortality scored after 48 and 96 hours from treatment were recorded, and the values corrected according to [14] .

Effect of the fungal filtrates of some fungi introduced through nutrition on the percent of adult mortality of *Cx. molestus*

Filtrates of two isolated fungi introduced through nutrition were used and their effect on adult *Cx.molestus* was tested,where 5㎝³ of the fungal filtrates of each concentration prepared was mixed with 5 ㎝³ of a sugar solution at 10% concentration The mixture was distributed in sterilized plastic Petri dishes of a diameter of 9 cm, then the dishes were placed in breeding boxes containing 10 adult with three refined items for each fungal filtrates. The percent of mortality were calculated after 48 and 96 hours of treatment [14] .

All results were analysed according to the complete randomized factorial design, and calculated by using the Least significant difference at a probability level of 0.05[15]

RESULTS AND DISCUSSION

In the current study 69 isolates of the fungi were isolated and they were found to belong to 6 genera, the most prevalent percent belonged to the imperfect fungi followed by the cystic ones(table1).The reason for this is that the imperfect fungi produce vast numbers of small sized reproductive units in addition to their ability to spread over extended distances and their ability to form certain structures to resist environments hostile to their growth [16] .

Table(1) shows as well that the most frequently encountered fungus was the *Aspergillus*, where the percent of its encounters was 56.5 % while the least fungi to appear were both *Fusarium solani* and *Trichoderma viride*, as the percent of their encounters was 5.7 % and 2.8 %, respectively.

These results were consistent with other studies that indicated the isolation of several fungi from different insects , one of those is [10, 17, 18, 19] .As for the types, the same table shows that *Aspergillus spp.* was diagnosed through three types which are *A.niger*, the most frequent encountered at 44.9 % , followed by *A.flavus* at 8.6 %

, then *A.candidas* at 2.8 % . This result contradicts the findings of [18] and [20] , [21] stated that the reason of the frequent encounters of *Aspergillus spp.* which exceed the other species is due to the fact that they are one of the widespread fungi abundant in the warm places, in addition to them producing great numbers of spores.

Table 1.The percent of isolated fungi from adult mosquitos

Percent of encounters %	**Number of encounters**	**The fungus**
56.5	39	Aspergillus sp.
44.9	31	A.niger
8.6	6	A.flvus
2.8	2	A.candidus
13.0	9	Penicillium sp
11.5	8	Candida sp.
10.1	7	A .alternaria
5.7	4	Fusarium.solani
2.8	2	T.viride

The results of the study also showed significant differences in the percents of encounters of fungi in the samples examined according to the locations(table 2),. The highest rate of encounters was also recorded for the areas Altowayreg, Alhussainiya and Albobyat with a significant gap separating them from other areas at rates of 24.6 % ,20.2 % and18,8 % respectively. The reason for the high rate of them being rural areas with an abundance of gardens and fields , as well as the relatively high humidity rates there due to the presence of rivers and small streams in them,

Table 2. The effect of the districts studied on the percent of the encounters of the isolated fungi

	fungi %	**Districts**							**Fungi**
		Old city center	**Kantarat Alsalam**	**Ramadan district**	**Alzahra-a district**	**Albobyat**	**AlHuss-ainiya**	**Towayreg**

5.7		0	1.4	0	0	0	**1.4**	**2.9**	***F.solani***
2.8		1.4	0	0	0	0	0	1.4	***T.viride***
		5.6	7.1	8.6	14.5	18.8	20.2	24.6	Rate of district effect
	For interference = 0.5712			For fungi = 0.2019			For district = 0.2019		L.S.D. 0.05

Table 3 demonstrated the superiority of the fungal filtrate of *A.flavus* with significant differences separating them from the rest of the treatments with a mortality rate reaching72.97 % ,and that the concentration 100 % showed a perceptible superiority in the mortality rates than the rest of concentrations used, while the fungal filtrate *Candida sp*. produced the least mortality rate at 23.76 % in comparison with the rest of the concentrations. The same table showed as well that the interval of 96 hours was the most effective compared to less intervals as the mortality rate in that interval was88.88 % which is significantly different from the rest of the time intervals as confirmed by the results shown in the table itself indicating the significant overlap between the effect of the fungal filtrate and the interval elapsed after the treatment where the greater the increase in the interval of the treatment and the concentration of the filtrates, the more the increase in the mortality rate whatever the different types of fungi. The reason of this disparity between these fungi could be the ability of these fungi to secrete analysed enzymes and fungal toxins which affect the biological activities of the living organisms leading to their demise [22].

Our current studies confirm with [23] who confirmed that the fungus *B.bassiana* is effective against the adult of *Haematobia irritans* which produced mortality rates of 98.4 % after 4 days from treatment and 100 % after 7 days from treatment and [24] determined the superiority of the concentration 100 % for the fungal filtrate *B. bassiana* to the rest of the other dilutions where the highest mortality rate for the adult of *Cx. pipienspipiens* was 100 % during 2 and 4 days, respectively and the least mortality rate was 16.33 % and 50.00 % during 2 and 4 days respectively.

Table 3. The effect of the fungal filtrates using the spray method in the percent of mortality for the adult mosquito *Cx . molestus*

Concentration	**Percent of adult mortality after**								**Average**
	48 hour				**hour 96**				
Filtrates of fungi	25	50	75	100	25	50	75	100	
A.niger	19.9	41.25	41.42	60.0	35.0	55.5	80.0	100	56.63
A.flavus	28.75	65.0	80.0	90.0	40.0	90.0	90.o	100	72.97
A.candidus	16.11	16.11	41.25	67.5	21.24	48.01	61.5	100	38.16
Penicillium sp	33.33	33.33	45.0	55.5	33.33	45.00	71.43	100	52.12
Candida sp	16.25	16.25	30.0	36.6	24.25	24.25	37.5	100	23.76
A. alternaria	22.5	45.0	50.0	65.0	29.25	66.66	80.0	100	57.30
F.solani	21.66	33.33	35.0	67.5	33.33	43.57	87.5	100	52.74
T.viride	10.0	16.25	50.0	90.0	23.33	50.01	68.75	100	51.04
Control	0	0	0	0	0	0	0	0	0
Average intervals	19.00	29.61	40.85	61.29	26.65	47.01	64.07	88.88	
L.S.D. 0.05	For filtrates = 0.1997			For intervals = 0.1584			For concentrations = 0.1395		

Results of table (4)showed that the highest mortality rates increase by the increase of the concentration of the fungal filtrate and the increase of the interval after the treatment ,which were 31.67 % for the concentration 25 % and increased to 47.78 % and 95.00 % and 100 % for the concentrations 50, 75 and 100 %, respectively after 96 hours from treatment compared to the mortality rates in the lesser intervals. The effect of these fungi may be due to their ability to produce toxins which affect the insect pests and the mortality rate increases with the increase of its concentration as well as the interval of exposure [22].

Table 4. The effect of some fungal filtrates using the nutrition method on the percent of mortality for the adult mosquito *Cx . molestus*

Concentration	Percent of adultl mortality after								Average
	48 hour				hour 96				
	25	50	75	100	25	50	75	100

Clinical and Molecular Profile of Patients with Breast Cancer in Tikrit Province

Ali Abbas Ali

Samarra General Hospital, Ministry of Health, Iraq

ABSTRACT

Background: breast cancer is the most frequently diagnosed cancer and the leading cause of cancer death in women, a good description of the patients' clinical and molecular characteristics is essential to better understanding of the disease.

Patients and method: A retrospective study that included 79 patients diagnosed with breast cancer, the study carried out during the period of 1st January 2014 to 1st December 2015.

The aim of the study: evaluate the patients' clinical profile and molecular profile for females with breast cancer.

Results: Mean age of the patients was 52.9 ± 10.1 years and the BMI was 28.8 ± 4.7 kg/m^2, 73.4% ER positive, 70.9% with PR positive, and 24.1% Her2 positive. T-staging was 13.9%, 57.0%, 25.3% and 3.8% (T1 to T4 respectively) while N-staging was 32.9%, 39.2%, 10.1% and 17.7% (N0 to N3 respectively).

Conclusion: The clinical and molecular profile of Iraqi women patients with breast cancer was similar to reported in the literature, with mean age at diagnosis in the six decade, 73.4% ER positive, 70.9% with PR positive, and 24.1% Her2 positive.

Key words: *age, estrogen receptor, progesterone receptor, her2, Iraq*

INTRODUCTION

Globally, breast cancer is the most frequently diagnosed cancer and the leading cause of cancer death in women. In the United States, breast cancer is the most commonly diagnosed cancer and the second most common cause of cancer death in women. In addition, breast cancer is the leading cause of death in women ages 40 to 49 years. Breast cancer is treated with a multidisciplinary approach involving surgical oncology, radiation oncology, and medical oncology, which has been associated with a reduction in breast cancer mortality [1].

Breast cancer is the commonest cancer in women worldwide[2]. Its incidence has increased over several decades, while the death rate has fallen because of improved survival [3]. Survival has probably improved because of a mixture of earlier detection of the disease (both through screening and earlier symptomatic presentation), biological changes that have made the disease more susceptible to hormonal therapy, and improved treatment [4, 5].

Incidence rates vary from 19.3 per 100,000 women in Eastern Africa to 89.7 per 100,000 women in Western Europe and are high (greater than 80 per 100,000) in developed regions of the world (except Japan) and low (less than 40 per 100,000) in most of the developing regions[6]. According to the International Agency for Cancer Research and GLOBOCAN 2008, the Age-Standardized Incidence Rates (ASR) in Iraq was (31.1/100,000), similar as compared to the countries surrounding Iraq, Kuwait (47.7), Saudi Arabia (22.4), Jordan (47.0), Syria (23.0), Iran (18.4), Turkey (28.3) [6]. The current work aimed to evaluate the patients' clinical profile and molecular profile for females with breast cancer.

METHOD

A retrospective study that included 79 patients diagnosed with breast cancer, the study carried out in Tikrit Teaching Hospital during the period of 1st January 2014 to 1st December 2015.

The patients enrolled in this study were already diagnosed with breast cancer either on adjuvant chemotherapy, hormonal therapy or on regular follow up, all of them were females. The data of all the patients were obtained included the histopathological reports that confirm their diagnosis regarding breast subtypes, grading and staging. Also, immunohistochemical (IHC) reports that confirm their hormonal status (ER, PR HER2). The patients in this study underwent surgical intervention either by biopsy or mastectomy with axillary clearance, and then the formalin-fixed paraffin-embedded tissue blocks were sent to the hospital laboratory for H&E and IHC. Male patients with breast cancer were exclude from this study.

RESULTS

Mean age of the patients was 52.9 ± 10.1 years and the BMI was 28.8 ± 4.7 kg/m^2, both the molecular and clinical profile and staging are illustrated in table 1 and 2.

Table 1: molecular profile of the patients

Parameters	Value

Data presented as number (%)	

DISCUSSION

In the current study mean age of the patients was 52.9 ± 10.1 years, which is in agreement with Kensler et al with mean age 57.1 ± 10.1 years [7], and with Hu et al (50 years) [8], but younger that Elebro et al with median 65 years at diagnosis [9], in meta-analysis of 19 studies median age were between 49 – 61 years [10], these studies agree with findings of the current study about age at presentation of breast cancer.

In the current ER positive reported in 73.4% and PR positive reported in 70.9%, Kensler et al. reported higher ER+ that current study with 89.2% of the cases [7], ER+ was higher in Hu et al study with 88.7% but PR+ expression was similar to the current study with 72.2% of the cases [8], Elebro et al reported similar findings to Hu et al [9], In Honma et al PR+ expressed in 208/403 (51.6%) of the cases [11], in Park et al study 78.4% had ER+ status and 69.8% had PR+ status [12], in Castellano et al 680/938 (72.5%) had PR+ [13], these variability in the distribution

of ER and PR in different studies can be attributed to different criteria in these studies and specific population that the study examined, the result of the current study fall within the range of the reported studies.

In the current study T-staging was 13.9%, 57.0%, 25.3% and 3.8% (T1 to T4 respectively) while N-staging was 32.9%, 39.2%, 10.1% and 17.7% (N0 to N3 respectively), the following studies reported similar findings in Carreño et al T-stage of the tumor (T1, T2, T3, and T4) was 45.5%, 42.3%, 6.6% and 6.6% respectively, while node positive disease reported in 34.9% [14], In Honma et al node positive presented in 186/403 (46.2%) of the cases [11, 15], Park et al T-staging was 15.9%, 62.1%, 21.9% (Tis, T1, and T2-3) while N – staging (0 through 3) was 15.6%, 49.2%, 29.9% and 5.3% [12], Castellano et al T – staging was 57.7%, 28.3%, 2.7%, and 2.9% [13].

In the current study her2+ expressed in 24.1% of the cases, in Honma et al study Her2+ expressed in (5.0%) of the cases [11], Park et al 21.9% of the cases expressed Her2+ [12], Castellano et al Her2+ in 10.8% [13], Hu et al Her2+ in 8.6% [8], Kensler et al Her2+ presented in 20.4%[7].

CONCLUSION

The clinical and molecular profile of Iraqi women patients with breast cancer was similar to reported in the literature, with mean age at diagnosis in the six decade, 73.4% ER positive, 70.9% with PR positive, and 24.1% Her2 positive.

Evaluation of "Sublay" and "Onlay" Mesh Hernioplasty Techniques of Ventral Hernial Repair

Ali Hussein Al-Tai

Department of Maxillofacial Surgery, College of Dentistry, Kerbala University, Iraq

ABSTRACT

Ventral abdominal hernias are common surgical conditions that can be presented as emergency and elective cases. Repairing ventral hernias have always been a huge challenge to the surgeons. Mesh hernioplasty was considered as a gold standard to prevent or minimize the incidence of recurrence, but a question arises where should the the mesh sublay or onlay be placed? This research compares the procedures and outcomes of both onlay and sublay techniques in ventral hernia repair. A prospective study of was conducted at the surgical unit of Al-Imam Al-Hussein Medical City on 120 patients submitted for ventral hernias repair. Cases were registered in a year starting from 1st January 2015 to 1st January 2016) and followed up till January 2017. Study population was divided into two groups: 60 patients under group A that included patients who had undergone onlay mesh repair and another 60 patients as group B who were treated with sublay mesh repair. Data collected from both the groups included operation time, placement, and duration needed for drain removal, wound infection, and recurrence rate. Quarterly follow-up for 2 years was performed. Data were analyzed using SPSS 18.0 software; Fisher's exact test was considered as appropriate for analyzing statistical significance; $p < 0.05$ was considered to be statistically significant. The research outcomes indicated postoperative complications such as seroma formation in two patients (3.33%) from the sublay group, whereas 12 (20%) from the onlay group. Wound infection was found in one patient (1.66%) in the sublay group whereas in 6 (10%) patients in the onlay group. No septic mesh was removed in the sublay treated group, whereas one mesh was removed in the onlay type. In the onlay group recurrence was found in 4 patients (6.66%), whereas there was no recurrence in the sublay group. To conclude the sublay mesh hernioplasty is a better alternative to onlay mesh hernioplasty for all forms of ventral hernia cases.

Key words: *sublay; onlay; mesh repair; ventral hernia; umbilical hernia.*

INTRODUCTION

Protrusion of the abdominal contents through the fascia of the anterior abdominal wall is called a ventral hernia. Such defects are categorized as congenital, spontaneous, or acquired or based on their abdominal wall location. For example, hernias occurring from the xiphoid process to the umbilicus are the epigastric; those at the umbilicus are termed as umbilical; hernias that are highly uncommon and spontaneous hernias that occur in the midline below the umbilicus are paraumbilical and hypogastria hernias. Acquired hernias typically occur after surgical incisions, and are therefore termed incisional hernias. Although not a true hernia, diastasis recti can present as a midline bulge. In such a condition, the linea alba is stretched that leads to bulging at the medial margins of the rectus muscles. Abdominal wall diastasis may occur at other sites other than the midline. There is no facial ring or hernial sac, and surgical correction is avoided, unless it is significantly symptomatic.

According to the national operative statistics, 15–20% of all abdominal wall hernias were incisional hernias. Epigastric and umbilical hernias constitute 10% of all hernias. In women, incisional hernias are twice more common than in men. Clear evidence demonstrating that the suture type at the primary operation affects the formation of hernia is lacking [1]. The formation of ventral hernia is linked with many factors including gender,

Corresponding author:
Dr. Ali Hussein Al-Tai,
E-mail: taeeali24@yahoo.com

age, obesity, sleep apnea, emphysema, and prostatism. Other factors associated with collagen destruction in the lung increased hernia formation. The use of a suture to wound length ratio of 4: 1 has been shown to reduce the formation of incisional hernia significantly as compared with the 1 cm bites and 1 cm advanced suturing technique typically used by most surgeons [2].

Whether the incisional hernia rate is influenced by the type of initial abdominal incision remains controversial. As noted, the incidence of ventral herniation post-midline laparotomy ranges from 3% to 20% and doubles in case of a surgical site infection. A meta-analysis of many cases shows that the incidence of ventral hernia formation post different types of abdominal incisions are 2.5% for paramedian incisions, 7.5% in transverse incisions, and 10.5% in case of midline incisions. [3].

AIM OF THE STUDY

To compare onlay and sublay techniques of ventral hernia repair in terms of procedures and outcomes.

Patients and methods

This prospective comparative study was carried out on 120 patients of abdominal hernias admitted in the general surgical unit of Al-Imam Al-Hussein Medical City. Cases were registered in one year starting from 1st January 2015 till the 1st of January 2016) and followed up continued till January 2017. The majority of the cases were registered at the beginning of the year 2015, wherein the average follow-up was 1–2 years with quarterly visits, followed by clinical examination and confirmation by way of ultrasound.

In this study, 60 cases of ventral hernias were managed by onlay (group A) mesh repair and 60 others by sublay (group B) mesh repair. A similar type of mesh (polypropylene) in both the groups was used, and whether onlay or sublay technique was to be followed was left to the surgeon's preference and experience. Follow up of patients of both the groups was performed by checking the following parameters: operative time; drain placement time, which is one drain placed subcutaneously; wound complications; and recurrence rate.

Inclusion criteria

All patients of both genders with the following criteria were included in the study:

1. Post-laparotomy midline incisional hernias and recurrent hernias.
2. Primary hernias (umbilical, paraumbilical, or epigastric), diagnosed on clinical examination and confirmed by ultrasound.

Exclusion criteria

The following groups of patients who had different comorbidities with different degrees of influence on the outcome of the surgery, based on the degree of severity of these comorbidities were excluded from this study to make the procedure the most probable cause of complications:

1. Morbidly obese patients with BMI>40 kg\m^2.
2. Patients with diabetes mellitus.
3. Patients with abdominal malignancy and cirrhosis with end-stage liver disease.
4. All patients with chronic obstructive pulmonary disease (COPD) such as asthma.
5. Patients with obstructive uropathy such as benign prostatic hypertrophy (BPH).
6. Patients presented as emergency cases such as strangulated hernia with signs of obstruction (abdominal distention, vomiting, and absolute constipation) and those who lacked follow-up.
7. Preexisting skin infection at the site of hernia with local signs of inflammation (redness, hotness, and tenderness).

Operative Technique

A/Sublay mesh repair

The principles of the retrorectus or sublay mesh repair included two main steps: mesh placement deep into the recti muscles and mesh extension well beyond the hernial defect. The medial edge of each rectus muscle was identified by palpation, and the extreme medial edge of each rectus sheath was incised along its length to reach the submuscular space. This relatively bloodless plane could be created to the lateral edges of the rectus muscle on each side. Primary "peritoneal" closure was obtained using posterior rectus sheath above the arcuate line, the peritoneum itself, or excess sac below the arcuate line. The posterior rectus sheath along with the peritoneum

is closed with zero proline sutures. Then, the mesh is fastened around and well beyond the defect (about at least 5 cm). The center point of the mesh was assigned by a stitch to avoid malpositioning of the mesh and edges of the mesh were fixed to the posterior rectus sheath by way of multiple stitches. Organs within the abdomen are isolated from injury using the mesh along with a layer of posterior rectus sheath and peritoneum. Adhesions are thereby prevented due to the high viscosity of the mesh. The edges of the muscular sheath were sutured over the mesh by nonabsorbable nylon sutures [4-5].

B/Onlay Mesh Repair

Onlay repair was performed with skin incision over the bulge or the defect. Both the rectus sheath and the defect containing the hernia contents were identified using sharp and blunt dissection. The hernial sac was clearly dissected and the contents were dealt with while the margins of the defect were held by Kocher forceps. The sac's was treated by reducing its contents into the abdominal cavity. With nonabsorbable sutures, the defect in the linea alba was closed and a proline mesh of adequate size was placed on the rectus sheath and fixed with stiches. Redivac suction drains were used for all cases of the two groups with mean time periods of 5 and 7 days for sublay and onlay techniques, respectively, and removed when drainage was observed to less than 20 ml in 24 hours. All surgeries were performed under general anesthesia, and all patients were administered 1 gm 3rd-generation cephalosporin antibiotic preoperatively at the time of induction and continued till the 2nd postoperative day (1 gm) daily. Data were analyzed using SPSS 18.0 software; Fisher's exact test was considered as appropriate for analyzing statistical significance; $p < 0.05$ was considered to be statistically significant.

RESULTS

A total of 120 patients of ventral hernias were managed by both sublay mesh and onlay mesh repair techniques. The youngest patient was 22 year old and the oldest 77 year old; the mean age of the patients was 48 ±5 years. The majority of the patients were female, that is, 90 patients, which represented 75%, and 30 male patients represented 25% of the sample. The majority of the patients were between 51 and 60 years totaling to 40 patients who represented 33.33% of all patients studied. The second age group was 41–50 years, which constituted 25% of the patients (i.e., about 58% or more than half of patients from age 40–60 years as shown in Table 1.

Table 1. Age and gender distribution.

Age in years	Male (30)	Female (90)	Total	Percent (%)
20-30	4	5	9	7.5
31-40	8	12	20	16.66
41-50	6	24	30	25
51-60	8	32	40	33.33
61-70	3	12	15	12.5
71-80	1	5	6	5
Total	30	90	120	100

In this study, most hernias repaired were of spontaneous type (60%), whereas those of incisional type were less and represented 40% of the sample

Seroma formation was observed in 2 patients (3.33%) in the sublay group, whereas in 12 patients (20%) of the onlay group. Wound infection was seen in one patient (1.66%) of the sublay technique group, whereas in in 6 (10%) patients of the onlay group. One patient (1.66%) of the second group suffered from mesh infection and needed its removal, whereas none was observed in the sublay group. Wound edge necrosis occurred in one of the patients (1.66%) of the onlay repair, which was managed by excision of the necrotic edge and primary suturing, and no such case of flap edge necrosis occurred in the sublay group. Paralytic ileus as a complication was observed equally in both studied groups, with one such case (1.66%) in each group. Regarding recurrence rate in the duration of 2 years, follow-up in the sublay group exhibited in no recurrence (0%), whereas that in the onlay group it was observed in 4 patients (6.66%).

The tests of significance were assessed by *p* value, and it was discovered that it was statistically significant in three postoperative complications that are still the main problems in the surgical management of hernias which are as follows:

1. Seroma Formation
2. Wound Infections
3. Recurrence rate

Otherwise, there were no significant differences (statistically) in other variables in the study, as shown in Table 2.

Table 2. Postoperative complications

Postoperative complications	Sublay group n = 60 (%)	Onlay group n = 60 (%) (%)	*p* value
Seroma	2 (3.33)	12 (20)	<0.05
Wound infection	1 (1.66)	6 (10)	<0.05
Mesh removal	0 (0)	1 (1.66)	>0.05
Recurrence	0 (0)	4 (6.66)	<0.05
Flap necrosis	0 (0)	1 (1.66)	>0.05
Paralytic ileus	1(1.66)	1(1.66)	1.000

DISCUSSION

Ventral abdominal wall hernias are a common surgical problem encountered in clinical practice. The outcome of the surgery is based not only on the technique used but also on the experience of the operator, meticulous dissection, tension-free repair, and so on [6]. Many methods are available to deal with these hernias. Commonly practiced techniques for hernial repair use mesh, which is placed either in a sublay or onlay position [7]. The refinement of the sublay technique decreased the recurrence rates and resulted in an overall better outcome that renders it suitable to be declared the gold standard care of ventral hernias. Primary tissue repair is associated with higher unacceptable recurrence rate. Nowadays tension-free mesh repair is an ideal hernia repair technique [8].

However, the optimal technique for mesh placement has not been established and remains controversial. The prosthetic mesh can be placed either between the subcutaneous tissues of the abdominal wall and the anterior rectus sheath (onlay mesh repair) on in the preperitoneal or retromuscular (sublay mesh repair). The latter technique has several advantages, one of them being not transmitting the infection from subcutaneous tissues down to the mesh as it lies quite deep inside the subcutaneous tissues [9]. Increased intraabdominal pressure that acts anteriorly on the margins of the mesh tends to push it toward the abdominal wall rather than distracting it away from it. Some studies suggest that the use of the sublay technique as a treatment option for ventral hernias appears to be less complicated than the onlay technique [10, 11, 12].

Ethical Clearance- taken from the scientific committee in Department of Maxillofacial Surgery, College of Dentistry, Kerbala University, Iraq. In their reference no.89 at 2nd. October 2017.

Source of Funding- Self-funding research.

Conflict of Interest – None

CONCLUSIONS

The sublay mesh hernioplasty is a better alternative to onlay mesh hernioplasty for all forms of ventral hernia cases.

Minimal complications and better outcome with sublay mesh hernioplasty in comparison with the onlay technique.

RECOMMENDATIONS

Because of less complications of infections, seroma formation and low recurrence rate in sublay mesh repair during 2 years follow up in which most of the recurrence happens, the use of this method for the repair of ventral hernias is encouraged.

We recommend increasing the number of the patients in the study groups and prolongation of follow-up time to obtain more reliable results.

Estimated Analysis on Environmental Health Risk of 2.5 Micron Particulate Matter to Urban Communities in South Jakarta

Alvia Hamastia[1], Ema Hermawati[2], Rina Marina[1] , Ridcho Andrian[1]

[1]Bachelor and Magister Program of Public Health, [2]Lecture of Master Program in Public Health Faculty, Universitas Indonesia, Depok, Indonesia

ABSTRACT

Background : Urban areas with their numerous activities including transportation, industrial and building construction activities are places that may potentially become the sources of pollution for human health, especially in areas with high population density. $PM_{2.5}$ potentially causes health problems to humans because inhaled pollution remains in alveoli. This may trigger respiratory diseases to cardiovascular diseases.

Objective : The study was to determine the risk level of $PM_{2.5}$ exposure in Jakarta on people living in areas around the *ready-mix* industry

Material & Method : The analysis carried out in this study is an environmental Health Risk Analysis (HRA) conducted to associated with pattern of activities, anthropometric data, and PM 2.5 concentration. This study involved 92 respondents with 10 study area points.

Result: The result of study reveals that there is 1 point having the risk of experiencing health problems with the Hazard Quotient HQ> 1. Although, overall, the people who reside in the study area are on average still relatively safe up to the present, when the health risk in the environment has exceeded the safe limit as at point 1 there must be a risk estimation at 9 other points to identify the safe limit in future.

Keywords *: Air Pollutant, Particulate Matter, Health Risk Analysis, Urban Area.*

INTRODUCTION

Particulate matter of less than 2.5 micron in size is in the form of gas and condensation from the activity of construction and demolition works, and mining operations. $PM_{2.5}$ particle matter is formed from gas and condensation of high temperature vapors during combustion and industrial activities [1]. $PM_{2.5}$ can remain in the air for a long time and may fly to areas hundreds of miles in distance [2] and can easily penetrate through buildings [3]. Consequently, air pollution can affect human health.

Quoted from *Greenpeace* based on the air quality monitoring conducted by the American Embassy in South Jakarta and Central Jakarta, the air quality of $PM_{2.5}$ parameter is very hazardous for the health. The results of monitoring on $PM_{2.5}$ air quality by *Greenpeace* also showed results which are not different from the US Embassy's monitoring with the air pollution index value of AQI 153 in Central Jakarta, and 169 in South Jakarta. The air quality monitoring carried out since January 2017 in 21 locations in the Jakarta Metropolitan Area indicates that the last six months shows an unhealthy air level for humans and will cause more serious health impacts to sensitive groups, such as children, pregnant women, and elderly people [4].

The $PM_{2.5}$ mass concentration in Ahmedabad, India ranged from 0.032 to 0.106 mg/m^3, and Yokohama, Japan 0.363 – 0.04778 mg/m^3, while the PM 2.5 concentration in Beijing ranged between 0.07 and 0.1 mg/m^3 [5]. The

particulate air pollution mostly comprises $PM_{2.5}$ which size is smaller than 1/30rd part of human hair with a diameter of 70 μm consisting of sulfate, nitrate, organic compounds, ammonium compounds, metals, acidic material [6]. Five specific sources of $PM_{2.5}$ namely sulfate, residual oil, traffic, metal industry and ground steel [7].

METHOD

Sampling Site

Jakarta, based on Indonesian Statistics in 2017, is one of the largest cities in Indonesia with the population density of 15,663 people / km^2 where a number of medium and large-scale industries operate reaching 1,410. South Jakarta hosted 68 medium and large-scale industries in 2012. Analysis on the health risk of $PM_{2.5}$ was performed in two districts in South Jakarta, namely in Jagakarsa District with a population density of 15,148 people/km^2 and Pasar Minggu District which has a population density of 14,029 people/km^2.

Sampling Methods

High Volume Air Sampler (HVAS) is a device that is used to collect particles through filtration that can collect particles up to 0.1 μm in size with an efficiency of 99.95% for a particle size 0.3 μm. The total number of particles accumulated in the filter for 1 hour is analyzed gravimetrically during which the flow rate is monitored. The results were displayed in the form of particulate mass units collected per volume unit of air samples taken as μg/m^3. This method is adjusted to the Indonesian National Standard (SNI) method 19-7119.3-2005 with normative references following the United States Environmental Protection Agency (USEPA) method IO-2.1 1999. Sampling of ambient air for Total Suspended Particulate Matter (SPM) and PM_{10} use the method reference from the Third Edition 501 of high volume measurement of size classified as Particulate Matter and Government Regulation of the Republic of Indonesia Number 41 of 1999 concerning air pollution control. Measurement of $PM_{2.5}$ concentration, temperature, humidity, and wind direction were carried out at 10 points.

Health Risk Analysis Methods

Health Risk Assessment (HRA) can be observed by knowing the characteristics of effects that potentially harm human health by pollutant exposure [8]. HRA is the process to estimate the nature and possible adverse health effects to humans who may be exposed to hazardous substances. Its four basic steps are hazard identification, exposure analysis, dose-response assessment, and risk characterization. Hazard identification aims to recognize various hazards that adversely affect the health, while exposure analysis has the purpose to identify exposure pathways of risk agent so that the total intakes received by individuals in the risky population can be determined. Dose-response assessment is to estimate the amount of substances needed to cause varying degrees of adverse health effects. Health risk level is expressed as Risk Quotient (RQ) or Hazard Quotient (HQ). HQ is calculated by comparing the intake value and the Reference Concentration (RfC) [9].

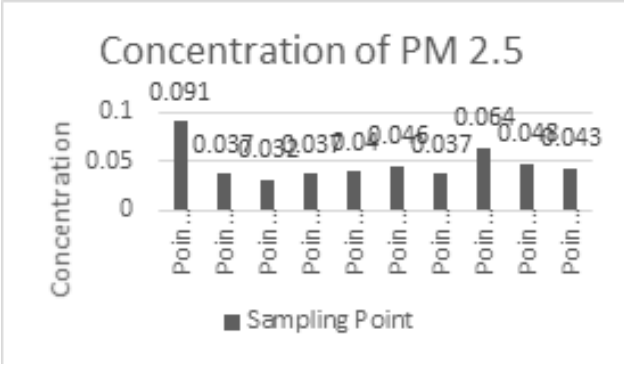
The risk level for non-carcinogenic contaminants is determined by calculating the HQ. If the HQ equals to or exceeds one, there is a risk that may endanger the health.

$$HQ = Intake/RfC$$

Where intake indicates the average daily intake of non-carcinogenic substances during the exposure period. RfC indicates reference concentration [10] The intake of risk agent must be calculated for all exposure pathways in accordance with the anthropometric characteristics and the activity pattern of the population at risk with the following equation,

$$Intake = \frac{CA \times IR \times ET \times EF \times ED}{BW \times AT}$$

Where CA indicates the concentration of $PM_{2.5}$ (mg/m^3) in the air, IR indicates the inhalation rate (m^3/hour), ET indicates the exposure time (hours/day), EF indicates the exposure frequency (days/year), ED indicates the exposure duration, BW indicates the body weight (Kg), and AT indicates the average time (days), 30 (years) x 365 (days/year).



RESULTS AND DISCUSSION

$PM_{2.5}$ Concentration

Table 1. Climatological Factor of Exposure

Parameter	Point 1	Point 2	Point 3	Point 4	Point 5	Point 6	Point 7	Point 8	Point 9	Point 10
C(mg/m3)	0.091	0.037	0.032	0.037	0.040	0.046	0.037	0.064	0.048	0.043
T (℃)	28.6	30.8	30.8	31.1	28.8	29.5	30.3	32.6	31.8	32
RH (%)	74	68	68	64	64	59	56	50	53	52
Wind	North	North	North	North	West	North	West	East	South	East

The highest PM2.5 concentration is at point 1 (Table 1), namely 0.091 mg/m3. This graphic (Graphic 1) exceeds the threshold value set by the National Air Ambient Quality Standard (NAAQS) namely 0.035 mg/m^3. Air humidity at point 1 is also at the highest value among other points which is 74%, which is contrary to the temperature. The temperature at point 1 is at the lowest 28.6%. Low temperature air will pose more risk to the health because the cold air will be trapped and is difficult to exit the area [11].

Graphic 1. $PM_{2,5}$ Concentration

Risky Assignment

The reference concentration (RfC) is the reference dose obtained from the US EPA. As RfC has not been determined for $PM_{2.5}$, the RfC value in this study refers the safe limit that was proposed by the US-EPA National Ambient Air Quality Standard (NAAQS) in 2006 for $PM_{2.5}$ namely 0.035 mg/m^3. To equalize the intake with the RfC, the concentration of risk agent is reduced using the EPA default value, namely IR = 0.83 m^3/hour, ET = 24 hours/day, EF = 350 days/year, BW = 70 kg, AT = 365 days/year, ED = 30 years, then obtained:

RfC = 0.035 mg/m^3 x 0.83 m^3/h x 24 hours/day x 350 hours/year x 30 years

70 kg x 30 x 365 hours/year

RfC = 0.009 mg/kg/day

Hence, the safe limit based on the reference concentration is 0.009 mg per kilogram of body weight per day. This value is used to determine the risk of $PM_{2.5}$ exposure in calculating the risk level (Table 2).

Table 2. Risk level of $PM_{2.5}$ concentration at the study points

Site point	$PM_{2.5}$Concentration (mg/m^3)	LADD (mg/kg/day)	HQ Value	HQ
1	0.091	0.01576	1.7511	HQ ≥ 1
2	0.037	0.00535	0.5948	HQ < 1
3	0.032	0.00653	0.7254	HQ < 1
4	0.037	0.00798	0.8861	HQ < 1
5	0.04	0.00567	0.6296	HQ < 1
6	0.046	0.00403	0.4473	HQ < 1
7	0.037	0.00610	0.6775	HQ < 1
8	0.064	0.00199	0.2212	HQ < 1
9	0.048	0.00697	0.7749	HQ < 1
10	0.043	0.00703	0.7807	HQ < 1
Average	0.041	0.00512	0.5690	HQ < 1

Estimating Risk

Each point has different time spans to experience risks. The range of risky time for each point is determined based on the community condition and environment condition.

Table 3. Average of anthropometry and $PM_{2.5}$ concentration

Point	Concentration (mg/Nm^3)	Weight (Kg)	Exposure Time (hours/day)	Exposure Frequency (days/year)	Duration (years)

In year 2018 (at present) only point 1 has risk. Point 1 is located 200 meters from a readymix industry, to the northwest direction the same direction as the dominant wind direction in May 2018. This causes the PM2.5 concentration to be at the highest point 1 compared to other points. Risk estimation which also involves anthropometric data and patterns of community activity (Table 3) indicates that currently the people who reside at point 1 may be at the risk of experiencing health problems. 4 years later in 2022, the HQ value at point 4 will already have risks exceeding 1 (HQ≤. 2 years afterward points 9 and 10 will be in risky areas, and 4 years later point 7 will be in a risky area, then each point will have risk with an interval of 1 year. Up to 15 years thereafter, in 2033, 10 points in the study area will be at risk of experiencing health problems if the concentration value, anthropometric data and activity patterns do not change (Table 4).

Safe Limit

Inhaled $PM_{2.5}$ can deposit deep in alveoli and may cause inflammation and oxidative stress and alter the cardiac work system. Earlier studies on primarily respiratory health effects, mentioned that $PM_{2.5}$ is one of factors that cause cardiovascular diseases (CVD) including hypertension, increased visits to hospitals, and cardiovascular mortality [12]. High plaque deposit in arteries causes sudden cardiac arrest and other cardiovascular diseases [13].

Estimating safe concentration as the highest limit of PM 2.5 concentration value in an area is calculated using the formula to find safe concentration,

$$CA = \frac{RfC \times BW \times AT}{IR \times ET \times EF \times ED}$$

Of the 10 research points (Table 4), point 1 is the location currently at risk based on the value of HQ. Determination of safe concentration at point 1 with PM2.5 concentration is 0.091 mg/m^3 with the exposure duration of 20.5 years. In calculating safe concentration, the highest concentration that can be tolerated with the activity pattern and anthropometric data at point 1 is 0.052 mg/m^3. If the concentration under the same condition exceeds 0.052 mg/m^3 there will be a health impact on the community particularly in the respiratory system.

The researchers observed that $PM_{2.5}$ exposure is related to dementia [12]. Weuve et al showed that older US women (70 years or older) living in areas with higher levels of $PM_{2.5}$ have more rapid cognitive decline over a 2 year period [14]. They concluded that long-term exposure (7-14 years) for particulate matters at the level typically experienced by many individuals in the United States is associated with significantly worse cognitive decline in older women.

Increased $PM_{2.5}$ concentration also increases risk of inpatient treatment for myocardial infarction, dysrhythmias, heart failure and cardiac arrest [15]. With regard to non-fatal effects, the risk of myocardial infarction has been estimated to be 1.48 times greater in increased PM2.5 concentration (0.025 mg/m^3 in two hours) [16]. Increased $PM_{2.5}$ in humans corresponds with the incidence of atherosclerosis and carotid inima-media thickening [17]. Some studies suggest that each decrease by 0.01 mg/m^3 of long-term exposure to $PM_{2.5}$ can increase by up to 22 months of life expectancy for persons 30 years of age or older. Based on a research in 2004, an increase of $PM_{2.5}$ by 0.01 mg/m^{3}s is associated with an increased risk of mortality by 8% to 18% [13].

CONCLUSION

Health risks can be seen from the risk level of $PM_{2.5}$ exposure in areas around a readymix industry. The level of health risk is determined not only by exposure to pollutant concentration, but involves anthropometric data and patterns of the community's activities that affect the high rate of public health risk in certain areas. Health risks can be viewed from the risk level of $PM_{2.5}$ exposure in the environment around a readymix industry.

ABSTRACT

Background: The beneficial effects of MMN and Iron Folic Acid (IFA) supplementation on pregnancy outcomes is still debatable. The objective of this study is to know the effect of IFA and MMN supplementation since preconception period on pregnancy outcomes. Multimicronutrient deficiencies may contribute to low birth weight and birth length which is associated with increased risk of infant morbidity and mortality in developing countries.

Method: The research was conducted in three sub-districts of Banggai district, namely, Luwuk, North Luwuk, and South Luwuk. This was a double blind study, randomized controlled trial, providing multimicronutrient for women from preconception period using prospective design with saturated sampling technique. A total of 19 preconception women followed until pregnancy and look at the pregnancy outcomes were enrolled from September 2016 to Januari 2018.

Results: The mean birth weight of infants born to pregnant women in the MMN group was heavier at 3142.5 g with a value (p= 0.001). LBW percentage of pregnant women MMN group was smaller, equal to 8.3% with value (p=0,863). The average length of infant born to pregnant women in MMN group was longer, 49,5 cm with value (p=0,001). Short birth length (<48 cm) of pregnant mother MMN group smaller, equal to 41,7% with value (p=0,515).

Conclusions: Pregnant women who get MMN intervention produce better pregnancy outcomes.The nutritional status of women before pregnancy is very important to achieve mother and fetal welfare and also considered as the most important thing for governing fetal growth.

Keywords: *Preconception period, multimicronutrient, birth weight, birth length*

INTRODUCTION

Low birth weight (LBW) is associated with the increasing risk of infant morbidity and mortality in developing countries[1]. It has been estimated that infants weighing 2000–2500 and 2500–3000 g at birth are four- and two-times higher risk of post neonatal mortality than those weighing 3000–3500 g, respectively. Through its impact on fetal growth and micronutrient stores, nutrition of the pregnant woman contributes to infant morbidity and mortality[2,3,4].

Epidemiological studies suggest that the interaction between maternal nutritional intake, hormonal disorders, and placental development is a determinant of stunting. Stunting events begin in the womb and continue until at least 24 months of age; so that the preconception period

Presenting author:
Lucy Widasari,
E-mail:drlucywidasari@.gmail.com
0812-19533645

up to 2 years is a critical period for the occurrence of stunting and a priority for intervention. Babies born less than 2500 grams are classified as premature and small during pregnancy (small for gestational age) a high risk for stunting.

Maternal Mortality Rate in Banggai district in 2014 is relatively high, (279/100.000) compare to the national target 2015 (102/100.000). To overcome these problems, innovative efforts as a breakthrough to accelerate improvement of the nutritional and health status of Preconception Women (PcW) has been started in Integrated Health Post (Posyandu) for PcW. The services to pregnant women or antenatal care have been hampered by the delay of first contact (K1) of pregnant women, and the big number of cases of anemia in pre-pregnant women (preconception). Therefore, preconception women services supposed to be a very important action, which is part of Maternal and Child Health Service (MCH) in Banggai District. Preconception health services are health services for women of reproductive age, before the first pregnancy which is a public health strategy to improve women's health and reduce maternal and child mortality. By following the preconception health service, the mother to-be are able to get early identification of pregnancy risk factors such as anemia before pregnancy, identifying and managing maternal conditions and behaviors during pregnancy which may pose a risk to both mother and newborn.

UNICEF/WHO/UNU proposed a multimicronutrient (MMN) prenatal supplement to replace the existing iron folic acid (IFA) supplement, which has been recommended for decades as a means of preventing maternal anaemia[5,6]. Multimicronutrient supplementation since preconcepcetion period is considered a feasible public health strategy in areas with micronutrient deficiencies and can potentially benefit both mothers and their infants[7,8]. Still, the evidence for benefits of MMN supplementation on pregnancy outcome is sparse[1]. We conducted a randomised, double blind controlled trial in which the effects on birth weight and birth length multimicronutrient supplementation with RDA of 15 multimicronutrients were compared with the conventional iron folic acid (IFA) supplement containing ferro sulfate / ferro fumarate or ferro gluconate and 0.25 mg folic acid.

Multimicronutrient (MMN) supplementation

Maternal micronutrients deficiency during pregnancy is an outstanding public health issue worldwide. Due to the increased nutritional requirement, pregnant women are vulnerable to micronutrients deficiency. However, the beneficial effect of MMN supplementation on preconception women and during pregnancy and on postnatal growth of children are still unclear. There has been a scarse studied on the prevention of MMN deficiencies as a strategy to reduce the risk of prenatal anaemia and attention has tended to focus instead on iron supplementation during pregnancy, with conflicting results.

MMN supplementation should be considered as a strategy for improving the micronutrient and haematological status of preconception women of reproductive age. MMN supplementation using the United Nations International Multiple Micronutrient Preparation (UNIMMAP) is a balanced preparation of 15 vitamins and minerals formulated by an Expert Committee of the United Nations Children's Fund, primarily for using by pregnant and lactating women. The MMN tablet consist of vitamin A (retinyl acetat) 800 RE, vitamin E 10 mg, selenium 65 microgram, vitamin D3 (Colecalciferol) 200 IU, vitamin B1 (Thiamin) 1.4 mg, vitamin B2 (Riboflavin) 1.4 mg, vitamin B3 (Niacin) 18 mg, vitamin B6 1.9 mg, vitamin B12 (cyanocobalamin) 2.6 microgram, asam folat 400 microgram, vitamin C 70 mg, iron 30 mg *(iron sulphate),* zinc 15 mg *(zinc sulphate)*, iodium 150 microgram and cuprum *(cooper sulfat)* 2 mg.

MATERIAL AND METHOD

A randomized, double blind controlled Trial

To fulfill a double-blind requirement, MMN from UNICEF in the form of tablets was processed into capsules. The MMN tablet and IFA tablet is crushed and then put into a combination of pink and white capsules. MMN capsules and control capsules are both made with similar weight and color. Subjects, data collectors and researchers did not know whether the capsules contained MMN or iron folate, so the parties involved in the field did not know whether the subjects were in the MMN group or iron folate group.

Randomisation and intervention

The women enrolled in the study were individually randomized with iron folic acid and multimicronutrient supplements. MMN supplementation using the United

Nations International Multiple Micronutrient Preparation (UNIMMAP) is a balanced preparation of 15 vitamins and minerals formulated by an Expert Committee of the United Nations Children's Fund, primarily for using by pregnant and lactating women. One group received a daily multimicronutrient tablet containing of 15 micronutrients as recommended in the future prenatal supplement. The control group received the conventional prenatal iron folic acid (IFA) supplement. Preconception women were instructed to take one tablet weekly if not in menstruating period, and to take one tablet daily if in menstruating periode and during pregnancy preferably together with breakfast.

The manufacturer provided the tablets in containers with a colour code for each intervention group. This code was kept secret from study participants, study personnel, and data analysts until data cleaning and preliminary data analysis had been carried out. For managing of administration in the field, randomization by excel randomization six block program AABB, ABAB, ABBA, BBAA, BABA, and BAAB was done. However, the health workers who collected outcome data after delivery did not have any knowledge of intervention group of the women.

Android gate way

There has been conducted a 24-hour consultation and monitoring of capsules consumption through android. The team of the first 1000 days of life provides 24-hour consultation services through android to ensure the consumption of capsule and question – answer of daily emerging issues during preconception period–positive pregnancy test up to the delivery.

Study area and population

The study was carried out from September 2016 to Januari 2018 in three sub-districts of Banggai district, namely, Luwuk, North Luwuk, and South Luwuk Central Sulawesi.

Infant Measurements

Newborn weight were measured to the nearest 1 mm with a TANITA digital scale. To measure the infant's body length using a length board. All measurements were made in the health centers. To ensure reliability, all anthropometric variables were measured twice, by regional public hospital or clinic staff who have been trained and under the supervision of researcher. The average of the 2 measures was used for analysis. The weighing scales were calibrated monthly.

Statistical analyses

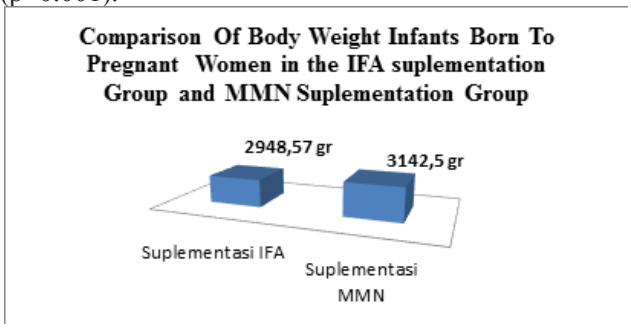
The type of statistical test used is adjusted to the type of variable being tested, if there is a test of the relationship between categorical data and categorical data then using the chi-square test, the average difference test depends on the normality of the data (Anova or Kruskal Wallis) when testing the relationship of categorical data and numerical data. Meanwhile the confidence interval used was 95% with p-values < 0.05 were considered significant. All statistical analyses were performed with SPSS 23.0 (SPSS® Inc.)

RESULTS

Homogeneity Test

Homogeneity between groups before treatment is very important in an experimental study, to ensure that differences in conditions after treatment between groups is indeed an effect of treatment (Meneinert, 1986). In table 1 it can be seen that in both IFA and MMN supplementation groups all variables were homogeneous with p value> 0.005 by testing the homogeneity of variance with Anova test.

Table 1. Homogeneity Test for Preconception Women in IFA Supplementation Group and MMN Supplementation Group



No	Variable	P value*
1	Residential area	0,633
2	Mother's age	0,989
3	Education mother	0,321
4	Father's education	0,648
5	Mother's work	0,499
6	Father's work	0,102
7	Systolic blood pressure at preconception periode	0,079
8	Diastolic blood pressure at preconception periode	0,189
9	Maternal weight at preconception periode	0,086
10	Maternal height at preconception periode	0,848
11	Body mass index at preconception periode	0,818

Cont... **Table 1. Homogeneity Test for Preconception Women in IFA Supplementation Group and MMN Supplementation Group**

12	Mid Upper Arm Circumference at preconception periode	0,601
13	Maternal Haemoglobin level at preconception periode	0,467
14	Maternal Sflt-1 value at preconception periode	0,661
15	Maternal VEGF value at preconception periode	0,766

**Anova test (test homogenity of variance)*

From graph 1, it can be seen that the comparison of the average body weight of infants born in the IFA Suplementation group was lower (2948 g ± SD 344.40) compared to the average body weight of infants born in the MMN supplementation group (3142.5 g±SD 464.48) and the results of statistical tests showed that there were significant differences in the average of body weight infants born to pregnant women in both groups (p=0.001).

Graph 1. Comparison Of Body Weight Infants Born To Pregnant Women in the IFA Supplementation Group and MMN Supplementation Group

Table 2. Comparison of Body length Infants Born To Pregnant Women in the IFA and MMN Suplementation Group

Body length of Infant Born	**IFA Suplementation Group (n=7)**			**MMN Suplementation Group (n=12)**		
	Mean ± SD	**Median**	**Min± Max**	**Mean ± SD**	**Median**	**Min± Max**
	47,86 cm ± 2,41	**48 cm**	**50 cm ± 43 cm**	**49,5 cm ± 2,54**	**49 cm**	**55 cm ± 46 cm**
Mean difference body length of Infant Born To Pregnant Women in the IFA and MMN supplementation group						
Difference	1,64 cm					
95% CI	47,66 – 50,13					
P value	0,001					

From table 2 shows that in the IFA supplementation group the average body length of infants born to pregnant women was 47.86 cm±2.41 median value of 48 cm and the average body length of infants born to pregnant women in MMN supplementation group was 49.5 cm±2.54 and median value was 49 cm. The difference in body length of the IFA and MMN supplementation groups was 1.64 cm. The mean birth weight of infants born to pregnant women in the MMN group was heavier at 3142.5 g with a value (p = 0.001). The average length of infant born to pregnant women in MMN group was longer, 49,5 cm with value (p = 0,001).

Table 3. Category Body Length of Infant Born to Pregnant Women in the IFA and MMN Supplementation Group

Supplementation Group	Short birth length (<48 cm)		Normal birth length (≥48 cm)		Total		P value
	n	%	n	%	n	%	
IFA	4	57,1	3	42,9	7	100	0,515
MMN	5	41,7	7	58,3	12	100	
Total	**2**	**47,4**	**17**	**52,6**	**19**	**100**	

**Chi Square Test*

From table 3 shows that short birth length (<48 cm) of pregnant mother MMN group smaller, equal to 41,7% with value (p = 0,515).

DISCUSSION

The effect of MMN supplementation on infants' birth weight

Birth weight is a simultaneous effect of energy and protein intake factors that play a dominant role, as well as the role of MMN in determining nutritional status since the preconception period. The meta-analysis of MMN administration and pregnancy outcomes conducted[9] explains that the exact mechanism of how MMN supplementation can affect pregnancy outcomes is not yet understood, but MMN can improve immune function thereby reducing the risk of infection in the mother, improving maternal energy metabolism, improve response to stress, and increase the volume of plasma and erythrocytes circulating in the body.

The effect of MMN supplementation on infants' birth length

Between the metaphysics and epiphyses lies the growth plate, where bone growth occurs, so that the bones can become long. The increase in height occurs because of the increasing number of cells in the modified growth plate by MMN supplementation, wherein the content of vitamin D which is a steroid prohormon plays an important role in calcium absorption by regulating calcium absorption in the small intestine. Vitamin D stimulates the synthesis of calcium binding proteins and phosphorus binding proteins in the small intestinal mucosa.

Bone mineralization is positively associated with bone mineral density (BMD). Vitamin D deficiency causes a decrease in calcium absorption which causes the release of calcium from the bone to maintain circulating calcium concentration[10]. Vitamin D also plays a role in stimulating the differentiation and proliferation of chondrocytes so that the growth of the bone growth plate is better, resulting in more body length addition compared to the IFA supplementation group. The more nutrient content, the better absorption of vitamins so that its utilization is more effective for bone growth.

There are a number of biological pathways that explain the role of vitamin D that can affect maternal health, placental and fetal growth during pregnancy. In vitro research shows that vitamin D plays an important role in the metabolism of glucose and insulin which can affect the availability of energy for the fetus.

Vitamin D modulates the immune system that can help shape the right maternal immune response to the placenta which also regulates the key target genes associated with proper placental implantation. Vitamin D plays a direct role in the production of antimicrobial peptides such as katelicidin, which are produced after activation regulated by vitamin D receptors where the production requires 25 (OH)-D which plays an important role in preventing infection during pregnancy. Vitamin D also affects bone and muscle growth[11].

Recent studies have suggested a direct role of vitamin D in the regulation of Hoxa-10 in human endometrial stromal cells. Overall, the study shows that endometrial expression of Hoxa-10 plays an important role in controlling uterine reception, implantation, and desidualization[12] and will further influence fetoplacental

blood flow.

CONCLUSION

Pregnant women who get multimicronutrien (MMN) intervention since preconception period produce better pregnancy outcomes. Posyandu for PcW in Banggai District has became an innovative intervention to increase the health status of PcW starting from preconception period. Preconception period is the best time for women to modify their dietary habits and select healthy nutritional patterns that associated with better birth outcomes.

Ethical Clarance: The study was approved by the Hasanuddin University with the number 1578/ H4.8.4.5.31/31/PP.36-Kometik/2016. All women received an anti-helminthes prophylaxis with albendazole (400 mg base) before receiving the supplementation.

Ineffective Regulation of Narcotics Crime Prevention (Criminology Perspective)

Amir Ilyas[1], Rini Anggraeni[2], Yuyun Widaningsih[3]

[1]Department of Criminal Law, [2] Public Health Faculty, [3]Medical Faculty, Hasanuddin University Makassar

ABSTRACT

The reality is that it should be a reason for us to worry because it threatens the future of the young generation who are the holders and successors of the nation's relay. That said because the impact caused by drugs is so tragic. The impact of drugs includes physical, psychological, social and economic impacts. This study aims to find out the causes of the increasing number of crime narcotics in the perspective of criminology. This type of research is an empirical research. Police officials, advocates, and narcotics abusers were taken as samples in this study. Data collection is done through interviews and documentation. The results showed that the regulation of narcotics crime prevention has not been effective in practice. Narcotics crime should have been reduced to the lowest in the presence of Act Number 35 the Year 2009 on Narcotics, but in reality, tend to increase every year. In the perspective of criminology with the observation of the age, sex, education, and work of narcotics perpetrators, it is found that multiple factors are interrelated, including psychological factors, sociological factors, and economic factors as criminal etiologies that trigger an increase in narcotics crime.

Keywords: *Narcotics crime, Criminology, Crime etiology.*

INTRODUCTION

The danger of drugs is no doubt. However, drug abuse is increasingly prevalent in various countries around the world, including Indonesia. When someone starts taking drugs, there is a high chance of experiencing addiction. The longer, the user will need a higher dose in order to feel the same effect. When the effects of drugs begin to disappear, users will feel uncomfortable due to the appearance of withdrawal symptoms and will want to use them again [1].

Drugs that dissolve in the body will be channeled through blood throughout the body, including the brain. The effects of drugs depend on the type consumed, dosage, duration of use, and body size of the person who consumed them. In addition to influencing the body, the danger of drugs can also cause things that interfere with a person's quality of life. An addict is also more susceptible to sexually transmitted infections, accidents, and suicide attempts due to being under the influence of drugs[2]

According to data quoted from the Provincial National Narcotics Agency (BNNP) of South Sulawesi, the impact of drugs includes physical, psychological, social and economic impacts. Physical effects such as nervous system disorders (neurological): convulsions, hallucinations, and disturbances of consciousness. The psychological impact is not the normal ability to think, feeling anxious. Dependence/always need medicine. Socio-economic impacts, for example, always harm the community, both economic, social, health and legal.[3]

Drug distribution and use at this time are very worrying. In a sign that Indonesia is a transit place for drug trafficking by the international kingpin. We should be concerned and alert to the dangers of drugs that threaten the young generation of this nation. Drugs have a very broad impact and can damage the joints of the nation's life. The danger of drugs is actually very massive, even less destructive than the dangers of corruption itself.[4.] The crime data cited above is the result of the national scale collection of the Republic of Indonesia case. In the local scale, it is also found that crime statistics tend to increase every year. In Makassar City in the period of 2012 till. In 2015 the crime rate was: in 2012 there were 288 people, in 2013 there were

255 people, in 2014 there were 323 people, and in 2015 there were 429 people data from Polrestabes Makassar, 2016. Only in 2013 did the number of Narcotics crimes experience a decline, which is 33 people decreased, and in 2015 again increased to 106 people.

Subjective approach is to look at individual factors as determinants of the occurrence of crime, wrong because of your own fault (SS). In essence, this approach is influenced by indeterministic theory [5]. While the objective approach is to look at factors outside individual conditions as the cause of crime, wrong because the Environment is Wrong (LS). This approach is influenced by deterministic theory.

MATERIAL AND METHOD

Research sites

This research was carried out in Makassar City, namely at the Makassar Polrestabes. The researcher took this location, considering that at that location, it was the first time that narcotics crime cases were examined by police law enforcement officers.

Type of Research

The type of research in this study is empirical research. The goal is to reveal the etiology of narcotics crime with the aim of providing legal solutions to the increase in crimes from a criminological perspective.

Data Collection Techniques

In this study interview and documentation, techniques were used. The interview technique was carried out on police law enforcement officers, advocates, narcotics abusers including users, dealers and narcotics dealers in the city of Makassar. While documentation is carried out through the collection of statistical data on crimes found in the Makassar Police

Data analysis

The data analysis method used is qualitative analysis, by analyzing and describing the data obtained both from primary data and secondary data, the results of research through a criminological approach to the etiology of narcotics crime and its countermeasures.

RESULTS AND DISCUSSION

Criminology as the science of various knowledge, the body of knowledge, is dominantly defined as the science that seeks to investigate the causes of the symptoms of evil in ways that exist in it. By conducting an investigation into the causes of these crimes, this is then the scope of the study of criminal etiology which is none other than one of the main branches of criminology [6]. Related to the increasing number of narcotics crimes with a view to revealing their criminal etiology, four variables will be used which consist of the age of the perpetrator, the sex of the perpetrator, the education of the perpetrator and the work of the perpetrator.

As stated above, that because criminology uses various sciences, then to measure all four variables, it cannot be separated from anthropological approaches, psychological approaches, and sociological approaches as well as in the applied field of criminology: criminal anthropology, criminal psychology, and sociology criminal.

Age of Narcotics Crime Actors

Formulation of different criminal responsibilities between children (12 to 18 years) with adults is a further consequence of a person's cognitive phase to be able to think fully or not be able to think fully

In a psychology perspective, especially developmental psychology, adulthood should be one of the physical variables that can prevent a person from committing a crime. Ansem of developmental psychology if connected with statistics of narcotics criminals based on one's adult age, it does not support the reduction in the number of narcotics criminals. This can be noted through the following table 1:

Table 1: Number of Narcotics Crimes in Makassar City Based on the Age of the Perpetrators (2012 to 2015)

Years 10-17	Age (year)				
	18-20	21-25	26-30	> 31	
2012	15	36	59	70	122
2013	18	27	63	42	105
2014	20	39	61	75	131
2015	19	44	103	85	178
Total	72	146	286	272	536

The interesting thing from the presentation in Table 1 above is that the increase in the age of narcotics criminals is directly proportional to the increase in narcotics criminals. Physical and biological development of the stage of perfection, but perfectly cognitive is unable to hold the offender acting based on the norms of goodness contained in him as a reflection of his social environment. According to National Police Headquarters data contained in the book Population Perspective of Islam written by M Cholil Nafis, from 2004 to March 2009, there were 98,614 cases (97% more) teenage children were drug users[1].

Narcotics perpetrators from 10 to 17 years of age and 18 to 21 years of age are essentially unable to live independently. He has not been able to make a living on his own, has not been able to earn money independently, even if there is money in his hand it is usually obtained from his close relatives. He was most likely to get close to giving his mother's father. Therefore if you want to use or consume narcotics that are expensive, you will certainly be constrained from the financial aspect to buying narcotics ingredients.

Crime is learned through interaction with other people by learning techniques of crime, distinctive motivation, encouragement, rationalization, and attitude6. While narcotics crimes committed by adults are not influenced by totality alone. The country of Indonesia as a developing country with a poverty rate is still high, and at the same time more and more demands to live in luxury 7 cause social consequences of irregularities. The deviation is by becoming a narcotics dealer so that the finances are sufficient to meet all needs that can increase its prestige.

Gender of Narcotics Crimes

Comparing the quantity of crime based on sex, the perpetrator is still a series of individual factors as their physical and psychological state. Although in examining narcotics crime by looking at the sex of the perpetrator, it cannot be separated from environmental factors. The combination of these individual factors and environmental factors is then referred to as the bio-sociological approach[3]. The quantity of narcotics criminals who are always dominated by male-sex offenders rather than a female can be considered in the following Table 2:

Table 2: Number of Narcotics Crimes in the City of Makassar Based on Gender Actors

(2012 to 2015)

YEAR	Gender	
	Male	Female
2012	259	17
2013	243	21
2014	269	39
2015	369	45
TOTAL	1.140	122

Based on Table 2 above, there are two things that need to be explained further, namely: (1) Why are the number of narcotics perpetrators dominated by male sex offenders? (2) Why do narcotics perpetrators, both male and female, tend to increase every year? Although in 2013, male sex offenders experienced a decline. The opportunity is that men who are more demanding work to be outside the home, than women are more at home taking care of their children, family, and husband's eating needs, of course, the opportunity for men to become narcotics abusers is more open than with women [8]

It is different from narcotics abusers who are female, the cause they commit crimes is not because of economic problems which are the main reason. They become more abused by their association with the workplace. In some cases the average woman is also a narcotics abuser because the family conditions are broken (broken home), so by becoming a drug user, her family's problems for a moment do not burden her mind again [9].

Education Status of Narcotics Crime Actors

The purpose of education for everyone is essential to form their personality with integrity, responsibility, and agility in differentiating a good and right decision. The analogy is that the higher the level of education a person means the more his experience goes through the process of internalization of a shared value so that the output is easier to avoid all actions that have been criticized by the community in their environment.

One research in the United States also shows that prison inmates at the "Richland Parish Detention Center," Louisiana, generally only have education in

grade 2 elementary school to grade 1 junior high school (second grade to seven grade). Those with low education are always wrong in having perceptions about life and law[10]. Some of the results of the above research, in fact, contradict the results of research found on the number of narcotics crimes in the city of Makassar, when viewed from the education status of each perpetrator. It is precisely at the level of high school education, the perpetrators are more compared to narcotics criminals who are in junior and elementary education levels. More details about the conflict can be noted in the following table 3:

Table 3: Number of Narcotics Crimes in Makassar City Based on the Level of Education Actors (2012 to 2015)

Years	Education			
Elementary School	Junior High School	Senior High School	College	
2012	15	36	195	42
2013	41	55	152	7
2014	66	90	147	20
2015	68	127	216	18
Total	190	308	755	87

Based on Table 3 above shows that the highest number of narcotics abusers occurs at the level of high school education compared to the level of elementary and junior high school education. Only the narcotics abusers with higher education status then the number of perpetrators, suddenly shows a decrease.

Apart from that which is a striking difference, so that narcotics criminals with higher education status suddenly decline, none other than because the population in Makassar city is far more high school educated than college graduates.

Job Status of Narcotics Crime Actors

A person's work will certainly be a reflection if the economic situation becomes sufficient to meet his life's needs. If many people crave a profession as a civil servant, actually they are craving for a more established economy. A person's job status that is directly proportional to the economic situation, associated with the potential or not to become a narcotics abuser is very difficult to measure. Someone who has financial supplies, in the sense of an established economy, has the potential to become a narcotics abuser. For those in the group, even though the price of narcotics is expensive, it is definitely affordable, at least as a user.

The criminologist's conclusions about the close relationship between work and crime will be supported by the results of this study. The highest number of narcotics perpetrators is in fact played by those who are unemployed. This can be noted through the following table,

Table 4: Number of Narcotics Crimes Based on the Workers' Acts (2012 to 2015)

Occupation	Year (person)			
	2012	2013	2014	2015
Student	12	5	13	6
Collage Student	20	23	23	13
Government Employee	5	10	3	5
Private Employee	92	54	68	79
Police	5	-	1	-
Entrepreneur	59	58	67	108
Farmer/ Fisherman	-	2	1	2
Daily Labour	40	46	63	95
Unemployment	71	57	84	121
Total	304	225	323	429

Based on Table 4 above shows that the highest number of narcotics abusers occupy the first position in each year (other than 2013), namely those who are only unemployed. Then followed by those who work as entrepreneurs, day laborers, and private employees. It was found in this study that narcotics criminals with unemployment status, the main factor causing them to be involved in these crimes, are mostly caused by economic motives compared to other reasons, such as severe

stress so that narcotics are considered as life escape. This grouping is more dominant, the perpetrators act as dealers or bookies.

For narcotics abusers who come from the daily labor profession, the same situation applies to the entrepreneurial profession, which is only as a user, but not used during breaks. Daily laborers actually use narcotics with the aim to boost adrenaline work while eliminating fatigue after a full day's work. While narcotics offenders who come from the entrepreneurial profession and private employees are caused by their orientation in a social class. One experiences a shift from one choice to another because it is faced with different social activities[11,12]. Then the narcotics offenders who come from the profession of daily labor, are mostly caused by ecological and physical factors, each of these factors intertwines, narcotics cannot be separated from their parts of life and work.

CONCLUSIONS AND SUGGESTIONS

The results of this study indicate that the regulation of narcotics crime prevention has not been effective in practice. The narcotics crime rate should have been reduced as low as possible, but in reality, it tends to increase every year. In a criminology perspective with observations of age, sex, education, and occupations of narcotics criminals, it was found that multiple factors are interrelated, including psychological factors, sociological factors, and economic factors as criminal etiologies that trigger an increase in narcotics crime rates.

Reaction to the breaking law against these crimes is by eliminating the criminogenic factor which is the cause of the crime (abolitionist system). Priority should be given to increasing employment opportunities, then counseling and education of narcotics hazards in all lines regardless of the age and profession of each person. Police and BNN must prioritize capturing narcotics dealers because these are the main causes of the emergence of dealers in the narcotics business with very promising benefits.

ABSTRACT

The lungs are exposed to $PM_{2.5}$ via inhalation; $PM_{2.5}$ then settles in the alveoli and circulates via the blood system, causing chronic obstructive pulmonary disease and cardiovascular issues. $PM_{2.5}$ triggers the formation of superoxide anions and provide signals for the formation of superoxide dismutase . Workers at ready-mix concrete factories had long-term exposure to high doses of $PM_{2.5}$. This study investigates the effects of $PM_{2.5}$ on the blood SOD concentration of workers.

This cross-sectional study involved 53 subjects chosen with random sampling and interviewed to obtain individual characteristic data. $PM_{2.5}$ value was measured by gravimetric analysis using High Volume Air Sampler and EPAM-5000. The SOD value was tested with the RanSOD-Kit and read using RX-Monza. Data were analyzed with chi-square and multiple logistic regression.

It was determined that the workers exposed to $PM_{2.5}$ ^{3}65 mg/m^3 had a 10x higher risk of obtaining a SOD concentration of <84.40 U/mL than the workers exposed to $PM_{2.5}$ <65 mg/m^3.

There is a significant relationship between $PM_{2.5}$ exposure and SOD concentration. Working status and length of employment were identified as contributing variables (p-value 0.029; OR 10.165; CI 1.276–90.994). This study suggests that $PM_{2.5}$ exposure leads to a decrease in SOD concentration. It is necessary to take preventive measures for workers.

Keywords: *superoxide dismutase, antioxidant, oxidative stress, $PM_{2.5}$*

INTRODUCTION

The total population of Indonesia in 2010 was 237.641.326, including the urban population of 118.3 million (49.7%) and the rural population of 119.3 million (50.2%) [1]. Such a large population increases the need for building construction and transportation facilities; thus, ready-mix concrete plays an important role in the building material industry. Batching plants in the ready-mix concrete industry increase the concentration of particulate matter ($PM_{2.5}$) with a diameter of 2.5 mm, impacting the health of workers. The real-time risk calculation shows that 21.4% of batching plant workers are in the at risk category [2]. The safest area that can be inhabited by members of a nearby community is more than 2.5 km from the center of the cement industry and has a $PM_{2.5}$ concentration of about 28 mg/m^3 [3]. In the presence of fine particles ($PM_{2.5}$), neutrophils from asthmatic patients showed an increasing tendency to generate reactive oxygen species (ROS) [4].

Silica and iron comprise the majority of PM_{10} and $PM_{2.5}$ in dwellings between a 500 m and 3000 m radius

from the cement factory [5]. $PM_{2.5}$ is the external factor that triggers the formation of ROS in the body [6]. $PM_{2.5}$ with an aerodynamic diameter of <10 μm has a greater impact on human health [7].

The $PM_{2.5}$ surface is rich in transition elements that can increase free radicals. $PM_{2.5}$ triggers chronic obstructive pulmonary disease (COPD); causes inflammation, impaired lung function, and immunity dysfunction; and can change the structure of respiratory epithelium [8]. ROS will damage molecules, such as proteins, carbohydrates, and even DNA[9], through the lipid peroxidation reaction [10]. ROS plays several physiological roles, such as cell signaling. ROS are normally generated as by-products of oxygen metabolism, environmental stressors (i.e., ultraviolet, ionizing radiation, pollutants, heavy metals), and xenobiotics [11].

At certain levels, free radicals give signals to the body to establish the superoxide dismutase (SOD) enzyme. The human body provides antioxidants to convert the oxidants into less harmful substances [12]. This SOD enzyme converts superoxide anion radicals into oxygen molecules and hydrogen peroxide which are less reactive. SOD is the first line of defense affected by free radicals. The decrease of total antioxidant capacity is significantly related to the increase of lipid peroxidation[13]. In the blood assays of patients with COPD, the oxidative markers are higher, while antioxidants (catalase, copper, and SOD) are significantly reduced [14].

The purpose of this research is to study the effect of $PM_{2.5}$ exposure on workers' SOD enzymatic blood concentration at the ready-mix concrete factory in Jakarta.

MATERIALS AND METHOD

a. Study Design

This research is a cross-sectional design study using simple random sampling from 125 workers. Blood samples were taken from 53 subjects and assayed at the Health Laboratory of Jakarta. The subjects were the workers of a concrete ready mix factory in batching plants; all subjects signed informed consent and were neither ill nor taking special medication.

b. $PM_{2.5}$ measurement

Fine particles (<2.5 mm $PM_{2.5}$) were collected from ambient by Tisch high volume air sampler in temperature 28.29±2.15°C and 74.34±8.13%RH. The concentration of indoor $PM_{2.5}$ was measured by 2.5mm-impactor gravimetric HazDust EPAM-5000.

c. Superoxide dismutase (SOD) measurement

Blood SOD enzyme concentration was assayed by RanSOD^{O} Kit and read by RX-Monza. The role of this measurement is to get the dismutation of the toxic superoxide anion to hydrogen peroxide and oxygen. This method employs xanthine and xanthine oxidase to generate superoxide anion radicals. It will react with 2-(4-iodophenyl)-3-(4-nitrophenol)-5-phenyltetrazolium chloride (I.N.T) to create a red formazan dye. The SOD activity is then measured by the degree of inhibition of this reaction. One unit of the SOD is the one which causes a 50% inhibition of the rate of reduction of INT. The INT reduction rate is linearly associated with the inhibitory activity by SOD [15]. The INT method is easy and inexpensive, which can be used in routine erythrocyte and serum analyses for SOD [16].

d. Body Mass Index

Characteristics of subjects were obtained by interviewing them using questionnaires. The body weight obtained by calibrated scale and the body height obtained by microtoise.

e. Statistical Analysis

We analyzed these data by chi-square, while the final model was analyzed by multiple regression.

f. Ethics

This study has passed the ethical clearance by the Research Ethics and Community Service Commission, Public Health Faculty, Universitas Indonesia (282/UN2/F10/ PPM/00.02/2018 dated 17 April 2018).

RESULTS

This research was performed in a batching plant. The subjects were mostly outdoor workers, such as mixer truck drivers, technicians, central mixer unit operators, and waste operators; while only 12 people were administrative employees. The production process is determined as a wet batching plant type where materials are mixed with water in a central mixer and directly poured into the mixer truck [17]. The determination of sample points referred to the National Standard SNI 19-7719.6-2005.

Table 1. Distribution of $PM_{2.5}$ Concentration Based on Sampling Points

Sampling point	Sampling location	$PM_{2.5}$ (μg/m³)
1	Stockpile	129.05
2	Central mixer & silo	117.45
3	Laboratory, workshop & waste treatment	113.35
4	Outdoor gate & parking lot	120.30
5	Office	46.75

The distribution of $PM_{2.5}$ concentration can be seen in Table 1. The highest amount of $PM_{2.5}$ concentration was found in the stockpile area (129.05 mg/m³) where material loading and unloading activities are carried out using trucks. The lowest amount of $PM_{2.5}$ exposure was found in the office (46.75 mg/m³), the distance of this workspace is relatively far from the center of $PM_{2.5}$ exposure.

Table 2. Statistic Overview of $PM_{2.5}$ SOD Concentration and Characteristics of Subjects

Variables	Mean	Median	Standard deviation	Min-max
$PM_{2.5}$ (μg/m³)	101.65	113.35	30.47	46.75–129.05
SOD concentration (U/mL)	99.46	84.40	58.03	30.60–398.40
Age (year)	34.40	34.00	8.58	20–53
Length of employment (year)	4.64	3.00	4.53	1–22
Vegetables &fruits consumption (portion/week)	33.88	28.00	17.08	2–70
Body mass index (kg/m²)	24.16	23.51	6.01	15.72–33.35

As shown in Table 2, the average $PM_{2.5}$ concentration is 101.65 μm/m³. This value exceeds the maximum limit of 65 μm/m³ as regulated in the Government Regulation No. 41 of 1999. According to this value, we classified subjects into two groups: those who were exposed to $PM_{2.5}$ above 65 μm/m³ and below 65 μm/m³.

Table 3. Subject Characteristics

Variables	n	%
Number of subjects exposed to $PM_{2.5}$		
<65 mg/m³	12	22.60%
≥65 mg/m³	41	77.40%
SOD enzymatic concentration		
≥84.40 U/mL	26	49.10%
<84.40 U/mL	27	50.90%
Age		
< 28 years	15	28.22%
≥ 28 years	38	71.78%
Working status		
Group 1 (not in contact with the mixer truck)	23	43.40%
Group 2 (in contact with the mixer truck)	30	56.60%
Length of employment		
<3 years	19	35.80%
≥3 years	34	64.20%
Smoking		
No	11	20.80%

Cont... **Table 3. Subject Characteristics**

Yes	42	79.20%
Vegetables and fruit consumption		
enough (≥35 portion/week)	24	45.30%
less (<35 portion/week)	29	54.70%
BMI		
Normal (18.5 ≤ BMI < 25)	26	49.10%
Not normal (BMI<18.5 or BMI≥25)	27	50.90%

Based on Table 3, the number of subjects that received $PM_{2.5}$ exposure ³65 mg/m³ is 77.40%. Furthermore, the percentage of subjects who had SOD value below 84.4 U/mL is about 49.10%. There were 38% of the subjects who were 28 years of age or older. The SOD level in human blood starts to decrease with age at 28 years old [18]. The percentage of subjects who consumed approximately 35 portions of vegetables and fruit in a week was 54.70%.

Not sufficient	15	51.7	14	48.3	29	100		
BMI ratio								
Normal	14	50.0	12	50.0	26	100	1.26 (0.43–3.70)	0.89
Not normal	13	48.1	14	51.9	27	100		

By chi-square test, as shown in Table 4, we obtained the p-value of 0.03 for the correlation between $PM_{2.5}$ exposure and SOD concentration. Statistically, there is a significant difference in SOD concentration in workers exposed to $PM_{2.5}$ ³65 mg/m³ and <65 mg/m³.

Table 5. Model for the Correlation between SOD Concentration and $PM_{2.5}$ Exposure

Variables	Coeff.B	p-value	Odd ratio	95%CI	
				Lower	Upper
$PM_{2.5}$	2.319	0.029	10.165	1.276	80.994
Working status	-0.714	0.373	0.490	0.102	2.359
Length of employment	-1.074	0.095	0.342	0.097	1.204
Constant	-0.769	0.401	0.463		

Multivariate regression was conducted as shown in Table 5, it can be concluded that workers who received $PM_{2.5}$ exposure of more than 65 mg/m³ in the batching plant were at ten times higher risk of having the SOD concentration below 84.4 U/mL than those who received $PM_{2.5}$ exposure below 65 mg/m³.

DISCUSSION

The deposition of particulate matter in human respiratory tract depends on the size of the particles: larger particles are deposited in the upper respiratory tract, while smaller particles penetrate deep into the alveolar spaces [19]. $PM_{2.5}$ as an external factor produces free radicals in the body and brings about the oxidative stress. They trigger the forming of free radicals, such as superoxide anion. The metal content of $PM_{2.5}$ acts as an electron donor. Superoxide anion creates a signal to the body to produce a large amount of SOD enzymatic antioxidants. If there is an imbalance between prooxidants and antioxidants due to increased ROS (from chronic exposure), pathological reactions appear and cause various diseases, such as chronic obstructive pulmonary disease [20].

Daily workplaces are related to the decrease of SOD concentration. The percentage of workers in Group 2 who had SOD concentration below 84.4 U/mL was 60%, and these people were technicians, waste operators, and drivers. Stockpile area was the highest concentration place that may be caused by some ready-mix concrete activities, such as material unloading, material reversal, and mobilization of back-haw vehicles.

The workers need to consume a sufficient amount of vegetables and fruits to provide themselves with exogenous nutritional sources which can improve health by controlling free radicals. Some research found that changes in moisture content during storage, cooking, and processing stages can misrepresent changes in nutrient content [21]. Steamed vegetables have better texture quality than boiled ones, whereas boiled vegetables show limited discoloration [22].

Increased physical activity is believed to increase energy expenditure beyond dietary intake that results in weight loss. In view of this, workers can be directed to adjust their BMI ratio to the normal category by performing a healthier lifestyle, such as doing physical activity, consuming more vegetables and fruits, and checking their health regularly [23].

A long-term exposure of $PM_{2.5}$ forms a ROS accumulation that triggers the DNA signal to initiate the production of SOD enzymes, which leads to a lower level of SOD concentration than that in humans who are slightly exposed to $PM_{2.5}$. Long-term exposure of $PM_{2.5}$ with a ten times higher dose leads to a decrease in SOD and glutathione peroxide concentration and an increase in malondialdehyde concentration in blood [24].

Good technologies and management systems are the best ways to resolve the dust problem in stockpile, central mixer, conveyor, and workshop areas [25]. Relevant organizations should establish their hazard identification procedures and prepare a work plan by applying the hierarchy of controls.

CONCLUSION

There is a significant correlation between $PM_{2.5}$ exposure and SOD concentration in blood, so it is

necessary to take preventive actions in a ready-mix concrete plant to prevent diseases in workers. This research specifically deals with the issue of $PM_{2.5}$ pollution and SOD enzymes antioxidant in workers at a ready-mix concrete plant that can serve as an early detection signal for the workers.

ABSTRACT

Background: Severe air pollution has affected the health of individuals both nationally and globally. The dangerous pollutant $PM_{2.5}$ could trigger oxidative damage, which has been widely studied in relation to health problems, such as lung cancer, chronic obstructive pulmonary, and cardiovascular diseases. Malondialdehyde (MDA), which is a secondary product of the lipid peroxidation of polyunsaturated fatty acids, is a marker of oxidative stress.

Objective: This study aims to analyze the association between $PM_{2.5}$ and MDA concentration in concrete batching plant workers as a population at risk of dust pollution.

Material & Method: This research was conducted in April–May 2018 with a cross-sectional method involving 53 samples of workers chosen by simple random sampling. Beside $PM_{2.5}$ and MDA concentration, other variables including smoking status, supplement consumption, age, physical activity, body mass index, years of work, and rotational shift working were also studied.

Results: The results indicated a significant correlation of $PM_{2.5}$ and age with MDA concentrations in concrete batching plant workers. P value between $PM_{2.5}$ and MDA concentration was 0.025 with OR 15,791 CI (1,410-176,833). These findings suggest that exposure to $PM_{2.5}$ leads to oxidative stress as evidenced by MDA concentration. These findings suggest that exposure to $PM_{2.5}$ leads to oxidative stress as evidenced by MDA concentration.

Keywords: *$PM_{2.5}$, oxidative stress, malondialdehyde (MDA), concrete batching plant, industry, age.*

INTRODUCTION

Ambient air quality is one of the major factors affecting human health at both the global and the national level. An estimated 72 percent of premature deaths are caused by ischemic heart disease, 14 percent by chronic obstructive pulmonary disease or lower respiratory tract infections, and 14 percent by lung cancer related to air pollution.[1] Compared to other pollutants, particulate meters (PM) are the most dangerous for human health. The toxicity characteristics of $PM_{2.5}$ are related to metal and organic components that are absorbed into the particles or constitute the $PM_{2.5}$ formers themselves as well as the biological components, sulfates, nitrates, acidity, and reactive gases absorbed by the surface of particles such as O_3.[2] Research has shown associations between health effects and $PM_{2.5}$-forming components, such as iron, nickel, zinc, ammonium nitrate, carbon elements, organic carbon, nitrates, and sulfates.[3]

Air pollution due to high $PM_{2.5}$ levels has been associated with increasing incidences of

respiratory diseases, such as lung cancer, chronic obstructive pulmonary disease (COPD), and cardiovascular disease.[1, 4 – 7] In animal experiments, air pollution has been shown to induce oxidative stress. Epidemiological studies have also indicated an association between exposure to air pollution in urban areas and oxidative stress in bus drivers.[8] Malondialdehyde (MDA) is a secondary product of polyunsaturated fatty acid (PUFA) oxidation, which determines the degree of lipid peroxidation used as an oxidative stress biomarker.[6, 8, 9] Research showed an association between particulate dust levels and the incidence of oxidative stress in school students in China, as evidenced by MDA levels in urine. Another study also proved that MDA levels in children living in industrialized areas were higher than those of children living in non-industrial areas. Weiwei Lin et al. in Beijing identified associations between pollutant concentrations of CO_2, $PM_{2.5}$, SO_2, NO_2, and CH with MDA concentrations in the urine of schoolchildren.[4, 8, 10]

Research has shown that workers are the population at risk of COPD or cardiovascular diseases due to exposure to $PM_{2.5}$ in their working environment.[11–14] Concrete batching plants and ready mix plants produce concrete for large-scale construction. Concrete batching plants with poor settings and controls can pollute the surrounding environment with wastewater, dust, and noise.[15] This study aims to analyze the association between $PM_{2.5}$ exposure and oxidative stress using the MDA biomarker among workers in a concrete batching plant. In addition, this study also investigates other factors of MDA concentration variables including smoking status, supplement consumption, age, physical activity, body mass index, years of work, and rotational shift working.

MATERIALS AND METHOD

a. Study Design

This research was carried out in a concrete or ready mix batching plant in Jakarta, Indonesia with cross-sectional study on April 2018. A total of 53 workers were selected using simple random sampling and calculated based on the average difference hypothesis test formula.[16] The inclusion criteria were that each participant must be 18–55 years old, one who worked in the position as his or her main job, and a willing research respondent who signed an informed consent.

b. Sample Collection and Analysis

Blood samples were collected by certified phlebotomy nurses from a certified laboratory, using anti-coagulant EDTA in the batching plant before being carried to laboratory for analysis. The plasmas were then separated from other parts of blood and reacted using *thiobarbituric acid* (TBA) as a catalyst which brought in pink-color substance that could be read by spectrophotometry 532 nm wavelength.[17, 18]

c. $PM_{2.5}$ Exposure and Other Variables

The concentration of $PM_{2.5}$ was measured in the ambient air of the working environment. There are five air sampling points consisting of point 1 (stockpile), point 2 (central mixer and silo), point 3 (lab, workshop, and waste treatment), point 4 (gate and parking lot), and point 5 (the office). *High Volume Air Sampler* (HVAS) was used for the measurement of outdoor-based air samples and Haz Dust EPAM 5000 for indoor-based air samples. Calculation of $PM_{2.5}$ concentration was performed using the gravimetry method for HVAS and direct reading for Haz Dust EPAM 5000. Air sampling was carried out twice at every point for one hour on the day and one hour at night. Other factors of MDA concentration consisting of smoking status, supplement consumption, age, physical activity, body mass index, years of work, and rotational shift working were assessed using questionnaires.

d. **Statistical Analysis**

We analyzed the concentration of $PM_{2.5}$ in μg/m^3. The comparison of MDA concentration between workers who worked in the high and low levels of $PM_{2.5}$ was shown. The final model of analysis involving multivariate logistic regression and using SPSS 22nd version was conducted to understand the association between $PM_{2.5}$, MDA concentration and other factors consisting of smoking status, supplement consumption, age, physical activity, body mass index, years of work, and rotational shift.

RESULTS

Based on the respondents' distribution, the concentration of $PM_{2.5}$ was not normally distributed with the median value of 113.35 μg/m^3 and the standard

deviation of 30.27. The minimum value of $PM_{2.5}$ inhaled by respondents was 46.75 μg/m^3, while the maximum was 129.05 or 95%. 95% CI assumed that the concentration of $PM_{2.5}$ dust in the batching plant of PT X was 93.01–109.70 μg/m^3. The average concentration of MDA was 0.264 nmol/mL with the variation of 0.048 nmol/mL. The lowest concentration of MDA was 0.176 nmol/mL, while the highest was 0.351 nmol/mL. These results showed that 95% of respondents had MDA concentrations in blood of 0.251 to 0.277 nmol/mL (Table 1).

Table 1 Distribution of Respondents by $PM_{2.5}$ and MDA Concentration in Concrete Batching Plant

Variable	Average	Standard Deviation	Min-Max	95% CI
$PM_{2.5}$ Concentration	113.35 μg/m^3	30.27	46.75–129.05	93.01–109.70
MDA Concentration	0.264 nmol/mL	.048	0.176–0.351	0.251–0.277

For further analysis, $PM_{2.5}$ concentrations were categorized based on the Indonesian regulation concerning air pollution which sets the maximum concentration of $PM_{2.5}$ at 65 μg/m^3. MDA concentrations were to be categorized according to the mean into two groups consisting of below average and above average. MDA was below average if the concentration is 0–0.263 and above average if the concentration is 0.264 or more (Table 2).

Chi-square test was performed to see the relationship between MDA variables and various independent variables including $PM_{2.5}$ concentrations, smoking status, supplement consumption, age, physical activity, body mass index, years of work, and rotational shift. This analysis shows that only $PM_{2.5}$ concentration and age were significantly related to MDA concentration with p-value of under 0.05.

Table 2 MDA Concentration in Respondents by $PM_{2.5}$ Concentration and Age

Variables		MDA Concentration						OR	95% CI
		<0.264 nmol/ML		≥0.264 nmol/ML		Total			
		N	%	N	%	N	%		
$PM_{2.5}$ concentration									
	> 65 μg/m3	24	58.5	17	41.5	41	100	7.06	**1.37-36.40***
	≤ 65 μg/m^3	2	16.7	10	83.3	12	100		
Age									
	≥ 28 years old	22	57.9	16	42.1	38	100	3.78	**1.02-14.06***
	< 28 years old	4	26.7	11	73.3	15	100		

The last analysis was done in multivariate logistic regression. This modeling aims to validate the relationship of one major variable with the dependent variable by controlling some confounding variables.[19] It can be explained that workers who breathe $PM_{2.5}$ air at work points that do not meet the quality standard are 15.791 times more likely to have MDA concentrations above average after being controlled by age, body mass index, and work shift (Table 3).

Table 3 Multivariate Analysis

Variables	β	p-value	OR	95% CI	
				Lower	*Upper*
$PM_{2.5}$ concentration	2.759	0.025	15.791	1.410	176.833
Age	1.629	0.032	5.096	1.149	22.603
Shift rotation	-0.399	0,706	0.671	0.084	5.333
Body mass index	0.541	0,407	1.771	0.458	6.839
Constant	-3.355				

DISCUSSION

This study, whose design involves twofold measurement of $PM_{2.5}$, found a high level of $PM_{2.5}$. Referring to the Indonesian regulation concerning air pollution, the maximum concentration of $PM_{2.5}$ was set at 65 μg/m^3 for outdoor areas. There was a significant concentration difference between indoor-based and outdoor-based areas. Indoor-based concentration of $PM_{2.5}$ was below the maximum value. $PM_{2.5}$ concentration becomes the most determining factor in MDA concentration. However, the relationship between $PM_{2.5}$ and MDA concentration is also controlled by age.

Age is one of the factors associated with oxidative stress. Some studies with biomarkers like MDA, isoPGF2α, GPx, GSH-Px showed a significant association between age and concentration of biomarkers in either the blood or urine. [20-22] In line with the research by Bolzani et al., this study showed there is a significant relationship between MDA and respondents' age. The presence of higher MDA concentrations in individuals aged 28 years or more may be associated with a decline in SOD that is used as an antioxidant. Biologically, age is a complex concept that basically refers to the physiological capacity and physiological reserves of organs and systems within an individual. This physiological capacity decreases with age.[22] According to the Environment Protection Authority of Australia, several potential sources of air pollution from the concrete batching plant are the delivery of raw materials in trucks, trailers and tankers, storage of raw materials in bunkers and stockpiles, raw material transfer at the front end of loaders, conveyors, wagons, and agitators as well as leakage or spillage of raw materials from silos, inspection cover and channel wor.[23] Concrete raw material consisting of aggregate, cement, and fly ashes is the main cause of the high-level $PM_{2.5}$. A study by Ayse Orman et al. conducted at a cement plant showed that field workers exposed to cement dust directly had higher MDA concentrations than office workers.[24] Other studies also showed that $PM_{2.5}$ concentrations are related to MDA concentrations in the urine or in the blood both in children and in adults. [4, 8, 25, 26]

Higher MDA concentration in workers exposed to $PM_{2.5}$ may be due to the presence of metals which are the components of the $PM_{2.5}$ themselves in the batching plant. The metal compositions present in the particulates Cr, Co, Ni, Mn, Zn, V, Cu, and especially Fe and Aromatic Poly Hydrocarbons (PAHs) which are the main compositions of particulates and may lead to additive or synergetic interactions with the particle surface area. Either stand-alone or together, the chemical and physical characteristics of PAH and metals can produce reactive oxygen species (ROS) and oxidative stress.[27-29] Research suggests that silica particles derived from cement or fly ash in the batching plant can induce ROS that controls antioxidant defenses in the lungs and causes lipid peroxidation and cell damage. Among the different aldehydes that can be formed as a secondary product of fat destruction, Malondialdehyde (MDA) is one of the most mutagenic products of toxic fat peroxidation.[9] The higher the MDA in a person, the worse the oxidative stress is found in the person. This is related to the adverse health consequences for that person.[29]

CONCLUSION

This study proves that the concentration of $PM_{2.5}$ is the biggest risk factor associated with MDA concentration of workers in the concrete batching plant.

Teachers as Promoters of Sex Education Among Adolescents with Mental Retardation

Hestilia Nurul Ma'rifah[1], Evi Martha[1]

[1]Faculty of Public Health, Universitas Indonesia

ABSTRACT

Adolescents with mental retardation have the right to receive health information including sex education. This study aims to obtain information about the sex education practices implemented by teachers at Special School-C Dharma Asih in Depok 2018. The study used a qualitative approach with Rapid Assessment Procedure (RAP) design. The research participant consisted of eight teachers, the headmaster, parents of student, a health promotion officer at the Depok Jaya Primary Health Care, and staff at Regional 2 Education Branch Office of West Java Province. The results showed that sex education was provided classically and incidentally at Special School-C Dharma Asih. The teachers not only had adequate knowledge of sex education but also believed that sex education should be given to adolescent with mental retardation as early as possible. The constraints faced by the teacher included the lack of a sex education module and educational tools that support sex education in schools. Schools do not have specific policies related to sex education of adolescents with mental retardation. Cooperation between teachers, parents, primary health care workers, and education offices has not been optimal for encouraging sex education. This study suggests that the involvement of all stakeholders in the development of special policies related to sex education for adolescents with mental retardation should be encouraged.

Keywords : *Sexuality education, adolescents, mental retardation, teachers.*

INTRODUCTION

The prevalence of mild, moderate and severe mental retardation world wise is estimated to be 2%, 1.5% and 0.3%, respectively. In Indonesia, the prevalence of mental retardation is 13.68%, amounting to 290,837 people.[1]

Adolescents with mental retardation have a below-average intelligence level (IQ <70) that causes impairments in cognitive, language, motoric and social functions.[2,3] However, they have same sexual drive as adolescents with normal development.[4]

Teachers can be promoters of sex education for adolescents with mental retardation. However, a lack of self-confidence in teaching about sex and the perceptions of sex education as a taboo can hamper the provision of comprehensive sex education.[5,6]

No special curriculum for sex education exists in Indonesia. The provision of sex education in school is still integrated with several subjects, such as natural sciences, religion, citizenship, and physical, sports and health.[7,8] Sex education is also incidentally delivered because teachers do not have sex education-related modules or special guidelines.[9]

Training for teachers on sex education is still very limited, whereas training on pre-education can improve a teacher's initiative in providing sex education.[10,11]

Based on this background, this study aims to obtain extensive information on the sex education practices that have been carried out by teachers at the school for the disabled, Special School-C Dharma Asih, in Depok.

MATERIALS AND METHOD

This qualitative study applied a Rapid Assessment Procedure (RAP) design at Special School-C Dharma Asih in Depok, in May-June 2018. Data collected through in-depth interviews and observation. The analysis method used was thematic analysis. Data validity was assessed by triangulation of the source, method, and data.

RESULTS

Knowledge

Results of study indicated that almost all teachers had adequate knowledge of sex education. Only one teacher considered sex education to be related to sexual intercourse.

Several aims of sex education were conveyed by teachers, such as protecting children from sexual abuse, guiding children based on norms, and enhancing children's skills of taking care of and maintaining their reproductive health.

The teachers were also aware that children with mental retardation enter the adolescent period at the age of 13-15 years. In female adolescents, some of the physical changes that occur are menstruation, breast growth and hip enlargement. Male adolescents, on the other hand, experience physical changes, such as wet dreams, voice change, moustache growth, and the emergence of Adam's apple. Children with mental retardation who begin to enter puberty often show aggressive behaviour at school, such as demonstrating emotions that are difficult to control, gazing at someone for a prolonged period, getting physically close to someone, poking, hugging Someone suddenly, and masturbating in public.

Perception

Almost all teachers thought that adolescents with mental retardation need sex education because parents do not necessarily provide sex education at home. Almost all teachers felt confident when delivering sex education.

Nevertheless, one teacher thought that sex education does not need to be delivered comprehensively because it is considered taboo and would encourage the adolescents to exhibit deviant behaviours.

Supporting Facilities

Supporting facilities are important for enhancing the effective provision of sex education for adolescents with mental retardation. The tools often used by teachers are pictures, both printed and digital, displayed through InFocus or accessed directly through mobile phones. In this study, one teacher taught certain sex education materials through direct demonstrations. This approach is considered to be more casual, allowing the children to feel more open and less shy.

The teachers did not have sex education modules available for use. All teachers thought that module provision is important for facilitating the systemic provision of sex education.

This study observed that Special School-C Dharma Asih had no supporting facilities like banner, posters or leaflets related to sex education. The walls in the school's hallway were only used to display announcements, documents concerning the school's activities, and some of the students' crafts.

Sex Education-Related Program and Policy

Sex education-related program and policy are used to guarantee the continuity of sex education practices at schools. Unfortunately, the Education Office, schools, and Depok Jaya Primary Health Care have not developed any sex education-related programs and policies. The Education Office only deals with general curriculum-related programs, while sex education is under the responsibility of Social Affairs Office. Schools do not provide special programs because sex education is already integrated in the instruction of several related subjects, such as religion, citizenship, the natural sciences, and physical, sports and health. The Depok Jaya Primary Health Care's reason for not implementing sex education programs is due to limited human resources, time, and funds.

Seminar and Training

Seminar and training are useful to improving the knowledge and skills of teachers in sex education. Some of the teachers said they had participated at a seminar on sex education in 2006 held by one of universities in Bandung. Other teachers said that they had not yet participated in sex education-related seminars and trainings. The teachers thought that the regular provision of trainings and seminars on sex education is required

to increase their insight into sex related issues among adolescents with mental retardation.

According to the information given by the Primary Health Care in Depok, there was in fact a routine training held by the Education Office for the teachers responsible for teaching the health-related curriculum. Unfortunately, Special School-C Dharma Asih has not yet received the curriculum materials. As the Primary Health Care Centre has not yet proposed that special school for the disabled should participate in the training.

Sex Education Practice

Sex education was classically and incidentally delivered by the teachers based on the needs. Classically delivered sex education is integrated in the teaching several subjects. By contrast, incidentally delivered sex education was conducted on a case-by-case basis when adolescents behaved in sexually deviant ways, such as suddenly hugging someone, watching porn or masturbating at school.

The contents often taught in sex education involved an introduction to sexual organs and functions, sexual abuse prevention, sex hygiene, reproductive rights and the ways to making friends with the same and opposite sex. One exemplary aim was to ensure that the adolescents understood that they should not be engaged in a romantic relationship during their education and that they may get married later after graduation and get a job.

The methods often applied by the teachers while providing sex education were lectures and personal briefing given to the children. The use of these methods was adjusted according to the children's needs. The lecture method was applied during class teaching, while the personal approach was applied when certain children exhibited deviant sexual behaviours.

Evaluation of the delivered materials was conducted by asking the adolescents about the information delivered and directly observing the changes in the adolescents' attitudes and behaviours. In addition, several of the teachers performed the evaluation by asking parents about the adolescents' behaviours at home.

DISCUSSION

Almost all teachers had adequate knowledge of sex education and the sexual development processes of adolescents with mental retardation. Sufficient knowledge will encourage a comprehensive sex education practice. Travers, Tincani, Whitby and Booutot stated that before delivering sex education, the caregiver should have a good knowledge of the definitions and objectives of sex education, the concept of human development, the child's personal ability, and sexual behaviours, and culture in the greater society.[12]

Nevertheless, there are still teachers who have misleading perceptions that sex education means the teaching of sexual intercourse. Sex education-related training for teachers at special schools for the disabled is still minimal. The results of this study showed that none of the teachers had participated in a sex education-related seminar or training within the last five years. This result was further corroborated by the statement of the officer at the Education Office that no sex education-related seminars or trainings for teachers at special schools for the disabled have been held by the office.

The lack of education and training for teachers at special schools for the disabled shows the low level of attention given by the government to the sex-related issues among adolescents with mental retardation. According to Nurse, training will improve the knowledge and ability to identify sexual problems, such as sexual abuse.[11] Byrne, Rietdijk and Pickett mentioned that training on pre-education for teachers can elevate the teachers' knowledge of sexual concepts, improve their pedagogical skills and enhance their comprehension of the methods of delivery.[10]

Despite the fact that the teachers consider sex education to be important for adolescents with mental retardation, no specific policy related to sex education in schools exists. Byrne, Rietdijk, and Pickett stated in their study that school policy is important for influencing the response and behaviour of teachers toward the practice of sex education.[10]

According to the United Nations Educational, Scientific and Cultural Organization, a teacher may experience some conflicts while delivering sex education. Some teachers may not be confident and may feel confused when handling sex-related issues. Therefore, teachers need guidelines that give a clear picture of what to teach and how to teach it.[13]

Sex education can be carried out classically, namely by integrating sex education materials into the teaching of several subjects. A study by Pakasi and Reni

showed that sex education-related materials in schools are provided especially in natural sciences, religious and physical, sports, and health classes.[5] Tjasmini discussed an integrated sex education model, in which self-development programs teach several skills, such as bathing, teeth brushing, vulva hygiene during menstruation, toilet use, getting dressed, communication, and makeup application.[14] A special curriculum for sex education is needed to make sex education more systematic.

Sex education can also be applied incidentally when adolescents show deviant sexual behaviors, such as suddenly hugging someone, watching porn videos or masturbating in class. According to Aziz, the teaching of sex education can be performed directly when the child is exhibiting a certain condition.[15]

The contents taught in sex education at the school under study included an introduction to sexual functions and organs, the prevention of sexual abuse, sex hygiene, reproductive rights and ways to establish relationships with friends of the same and opposite sex. These materials were quite comprehensive. However, according to Aziz, some topics have not been taught by teachers, such as risky sexual behaviours, sexually transmitted infections (STIs) and human immunodeficiency virus and acquired immune deficiency syndrome (HIV/AIDS), abortion and contraception,[15] even though they are also important for adolescents with mental retardation. Rosdami, Djaswadi and Sumarni asserted that the adolescents with less knowledge of reproductive health, STIs and HIV/AIDS, abortion, and contraception are susceptible to risky sexual behaviours.[16]

Sex education materials are delivered gradually based on the needs and the ability of adolescents in receiving information. Tutar Güven and İşler thought that sex education must be adjusted according to the ability level of the adolescents with mental retardation.[17] As it difficult for them to receive information, the sex education provided must be in an understandable language.

In practicing sex education, the teachers use instructional media in the form of high-quality printed images or digital images displayed through InFocus or directly accessed via tablets or mobile phones. The use of media is considered effective for enhancing the children's comprehension of the information provided. Psychologically, children with mental retardation prefer learning through visual media rather than written media.[15] In addition, Travers, Tincani, Whitby and Boutot pointed out that the use of media such as videos, images and diagrams, is effective for conveying sex-related information to children with special needs.[12] A study by Palupi revealed children's positive responses toward the development of animated videos for sex education, suggesting that children are more interested in watching animated videos of sex education than listening to lectures.[18]

To determine whether the sex-related information has been relayed successfully, teachers conduct an evaluation by directly asking the adolescents with mental retardation about the materials delivered via several questions. Teachers also observe any changes in the adolescents' attitudes and behaviours. Teachers even ask the parents about the adolescent's behaviour at home as part of evaluation.

Teachers consider the parents' involvement in sex education to be important, as the adolescents spend more time at home than at school. According to the International Planned Parenthood Federation, several of key players in the provision of sex education to adolescents with mental retardation include teachers, parents, peer educators, and service providers.[19]

The absence of collaboration between stakeholders is one of the barriers that schools face in the practice of sex education. Collaboration is needed to ensure the delivery of comprehensive sex education. The groups that can effectively encourage the practice of sex education are teachers, parents, health workers, and acedemicians.[20]

CONCLUSION

The teachers at Special School-C Dharma Asih had adequate knowledge of sex education. The teacher considered it important to provide sex education to adolescents with mental retardation as early as possible. The constraints faced by the teachers involved the lack of a sex education-related module and supporting facilities in the form of visual learning media to improve the practice of sex education at school. Schools need specific policies to encourage the sustainable practice of sex education. In addition, collaboration between teachers, the students' parents, the Primary Health Care Centre and the Education Office is needed to establish

the provision of comprehensive sex education.

Improper Use of Inhaler Technique in the Control of Asthma in Adult

Mustafa Neama[1], Hawaa Khalid Alwan[2]

[1] M.B.ch.B, F.I.B.M.S. (Med), F.I.B.M.S. (Res). Department of Medicine-Baghdad Teaching Hospital/University of Baghdad-College of Medicine, [2]MBChB, the Ministry of Health, Iraq, Dyala

ABSTRACT

Background: Asthma is a chronic inflammatory disease of the airways in which they are involved a lot of cells and elements cellular and that in susceptible individuals causes recurrent episodes of wheezing, shortness of breath when breathing, feeling tightness of chest and cough. **Aim of the study:** To assess the asthmatic patient's inhaler use technique, any error if present. **Patients and method:** A cross sectional study conducted in consulting respiratory unit in Baghdad teaching hospital from the 1st of July 2017 to the end of February 2018. **Results:** Device preparing errors was present in 47.2% of asthmatic patients, failure to exhale before inhalation was present in 80.2% of patients, exhalation during inhalation was present in 10% of patients, short inhalation time was present in 51.7% of patients, not rinsing mouth with water after inhalation was present in 85.5% of patients and repetition more than recommended was present in 22.8%. **Conclusions:** There is error in using the asthmatic inhalers treatment technique.

Keyword: *Asthma, inhaler, device*

INTRODUCTION

The concept of asthma has been evolutionary. Until 1975 it is considered that asthma is produced by a contraction of the bronchi; With the advent of fibrobronchoscopy and bronchoalveolar lavage, it was discovered that there is also chronic inflammation of the airway, which generates the symptoms; later, the progress in the techniques of bronchial biopsy with which it will be recognized and created in the 1990s, in the sense that the disease is reversible. Remodeling of the airway secondary to chronic repetitive inflammation, which explains that over time, the uncontrolled asthmatic patient has persistent obstruction.(1)

Due to its multifactorial etiology, respiratory functional alterations and its diverse clinical expressions, according to the age of presentation, there is no definition that completely describes this entity. Therefore, defining asthma is complex, since it is a multifactorial disease (etiology, morphological characteristics, functional changes and clinical manifestations), in which there is an interaction between the immune system and the autonomic nervous system. However, the most complete definition is that which takes into account both the functional and the cellular point of view, that is why the definition that best adapts is that proposed by the Global Initiative for Asthma (GINA 2006), (2) that proposes asthma as a chronic inflammatory disease of the airways, in which many cells and cell products play an important role. Chronic inflammation produces an increase in airway reactivity and recurrent episodes of wheezing, respiratory distress, intercostal retractions, coughing and chest tightness, especially at night and in the morning.(3) These episodes are associated with airflow obstruction, reversible spontaneously or with treatment. Inflammation also causes an increase in the bronchial response to a wide variety of stimuli. Thus, in all cases it is emphasized that asthma is a chronic inflammatory alteration of the airways, which can be associated in an acute or chronic way. with airflow limitation as a result of bronchoconstriction, edema, mucous secretion, inflammation and, in some patients, remodeling of the airways. The remodeling of the airway corresponds to those structural changes characterized by thickening of the reticular lamina with deposits of subepithelial and perivascular fibrin, hyperplasia of the mucous glands, smooth muscle and vascular. This determines the thickening of the wall of

Corresponding author:
Hawaa Khalid Alwan
MBChB, the Ministry of Health, Iraq, Dyala

the bronchi of greater conduction (accessible to their study by mucosal biopsy) and also in the small airway (accessible by bronchoalveolar lavage). [4]

Epidemiology

The prevalence of asthma varies according to the geographical area, climate, lifestyle and economic development of each region. [5] The World Health Organization (WHO) estimates that it affects 300 million people and even today It is the cause of death worldwide, estimating 250 000 asthma deaths per year. [2] In the last four decades, the prevalence increased significantly, mainly in industrialized cities. [6] However, in the last 10 years prevalence has been established. plateau, where despite remaining high, no increases have been reported.

Epidemiological studies are being carried out throughout the world, predominantly cross-sectional, in order to determine the prevalence of asthma and its tendency. Thus, in 1991, the International Study of Asthma and Allergies in Childhood (ISAAC = International Study of Asthma and Allergies in Children) was created, together with the European Community Respiratory Health Survey (ECR-HS = European Community of Respiratory Health), Studying young adult population, have determined that countries such as United States of America, Canada, United Kingdom, New Zealand and Australia have higher prevalences, while the lowest are in China, India, Ethiopia, Indonesia and Eastern Europe. The ISAAC and the ECRHS show a great variability in the spatial distribution of asthma. Epidemiological studies in Latin America have revealed differences in the prevalence of asthma, with figures from 5.7 to 16.5% in the pediatric population. [7]

Industrialized countries and urban areas are among risk factors of the disease. [8] The current reported prevalence in the Middle East region is somewhat lower, varying between 5.6% in Saudi Arabia and 8.5% in Kuwait. In Iraq, approximately 200,000 patients per year with asthma are either hospitalized or treated in an Emergency Room. [8]

Etiology and classification

Attempts have been made to classify asthma according to its causes, intensity and obstruction of the airway valued by the maximum expiratory volume at the end of the first second (FEV1) or peak expiratory peak (PEF) and its response to management. This is not appropriate, since asthma is multifactorial and both genetic and environmental factors contribute.Previously, asthma was classified as extrinsic, which had an allergic component, and in intrinsic asthma, which represented a group of patients where there was no justified cause and with negative allergy laboratory tests. Asthma can be classified by etiological factors, severity or type of airflow limitation. Given that it is a heterogeneous disease, there are multiple causal factors both for its induction and for its exacerbation, from viral infections in childhood to occupational exposure in adults. Severity is estimated by a combined evaluation of symptoms, amount of beta two bronchodilator agonists (β2) to control symptoms and lung function. [9]

Classification based on severity

In this type a series of variables are grouped which include:

a) The frequency of symptoms during the day and night,

b) Its repercussion in the daily activities carried out during the day and night,

c) The use, number of times and the dose in which β2 agonist is used to treat the symptoms and

d) Lung function.

This classification is useful, since it relates the inflammation of the airway with the clinic and with the indexes of severity of symptoms according to the intensity of the asthma. In addition, it links the clinical data with the degree of obstruction of the airway and the variability of the Para clinical parameters that measure this obstruction (FEV 1 or PEF). In this way, chronic asthma has been subdivided into: mild intermittent, mild persistent, moderate persistent and severe persistent. The advantage of this type of classification is that in a practical way it allows to start treatment based on the severity and establish, later, a treatment plan according to the control and stabilization of symptoms. It has been proposed by the National Program of Education for Asthma (NAEPP). Thus, the severity of patients with asthma can be classified in one of these four steps before treatment and during the monitoring of it. If the asthma control is maintained, the degree of asthma is reclassified and another management is installed according to the intensity. [10]

METHOD

Study design and study setting:

A cross sectional study conducted in consulting respiratory unit in Baghdad teaching hospital from the 1st of July 2017 to the end of February 2018.

Patients:

A total of 400 adults with persistent asthma for at least 6 months duration, and agreeing to the Global Initiative for Asthma criteria, the patients within the age ≥18 years old and who had received at least one dose of inhaled corticosteroids and long-acting beta-2 agonists, either in separate or fixed combinations, irrespective of pharmacologic agent(s).

Data Collection

The data were collected by using a specially designed questionnaire form. At first socio-characteristics (age, on age, sex, education, occupation, current therapies, outcome measures of asthmatic patient's treatment and inhaler technique) of the patients were collected

Statistical Analysis

The analyses were conducted with statistical package for social science IBM-software (SPSS 22). Data are expressed as mean ± SD or number and percent.

Results:

A total of 400 adult asthmatic patients with mean age of 42.7±13.3 years.The inhaler types constituted MDI with spacer (2.5%), MDI (79%), Diskus (0.8%), Turbuhaler (5.2%), MDI & Turbuhaler (11.5%) and MDI & Diskus (1%). (Figure 1)

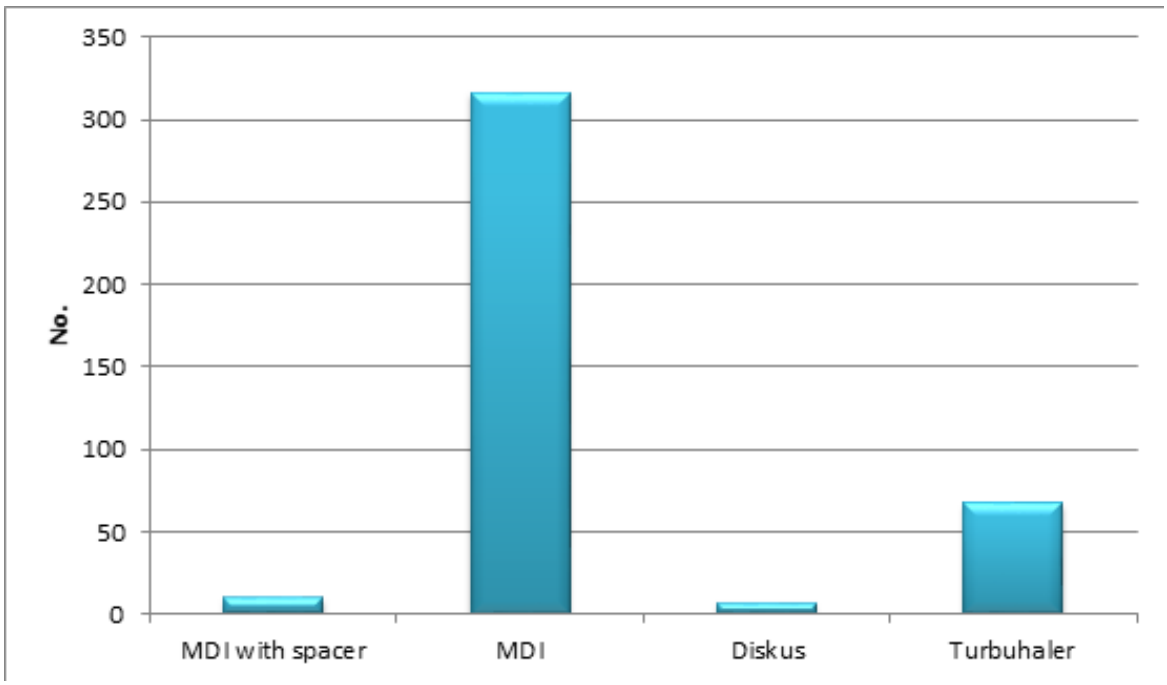

Figure 1: General types of inhalers.

Device preparing errors was present in 47.2% of asthmatic patients, failure to exhale before inhalation was present in 80.2% of patients, exhalation during inhalation was present in 10% of patients, short inhalation time was present in 51.7% of patients, not rinsing mouth with water after inhalation was present in 85.5% of patients and repetition more than recommended was present in 22.8% of asthmatic patients. (Table 1)

There was a highly significant association between daytime symptoms > 2/weeks and Diskus inhaler type ($p<0.001$). A highly significant association was observed between bronchodilator need and MDI with spacer type ($p<0.001$). There was a highly significant association between night waking and Diskus inhaler type ($p<0.001$). A highly significant association was observed between activity limitation and MDI type ($p<0.001$). There was a highly significant association between well controlled

onset and MDI with spacer type (p<0.001). (Table 2)

**Fishers exact test, S=Significant.*

Highly significant association between device preparing errors and MDI inhaler type (p<0.001), between short inhalation time and Diskus inhaler type (p<0.001), Failure to hold breath for 5-10 seconds among patients used MDI inhaler type (p<0.001), Failure to exhale before inhalation was significantly higher among patients used MDI inhaler type (p<0.001). Exhalation during inhalation was significantly higher among patients used MDI inhaler type (p=0.008). (Table 3)

Table 3: Distribution of outcome measures according to inhaler types.

Variable	MDI & spacer		MDI		Diskus		Turbuhaler		P
