DISCUSSION

In the current study the main inhaler used was MDI with mainly used error than other types, and this type lead to critical error which is mentioned by Price D et al, [11] as fallowing (Failure to remove the cap, not holding the inhaler upright, actuation not corresponding to inhalation; actuation before inhalation, actuation not corresponding to inhalation; actuation is too late (Puff 1), failure to actuate, failure to inhale, inhale too fast, inhalation through the nose). Westerik JA et al, [12] found that errors in Diskus inhaler technique are common among patients with asthma, with over half of patients in this study making ≥1 serious errors. [13, 14]. Before inhalation, do not rinse mouth with water after inhalation and Failure to hold breath after inhalation)

Which is in agreement with Westerik JA et al,[12] when the two errors most frequently reported in our study (failure to exhale before inhalation and insufficient [or absent] breath-hold at the end of inhalation) are in agreement with previously published reports of the most frequently observed errors with the Diskus being ‘‘no exhalation before inhalation’’ and ‘‘no breath holding after inhalation’’. But the third most common error in former study (inhalation that was not forceful from the start), which in agreement with that also been reported by other previous studies [15-17].

CONCLUSION

There is error in using the asthmatic inhalers treatment technique and the most common error were do not rinse mouth with water after inhalation then failure to exhale before inhalation.

ABSTRACT

Background: Studies were carried out at Qadisiyah district, Iraq to study certain aphid species infestation and their associated predators on wheat plants during season 2016-2017. Methods: Survey and population density of piercing sucking pests and their predators on wheat plants were investigated. Results: The dominant aphids were wheat, *Schizaphis graminum* (Rondani), *Sitobion avenae* (Fabricius), *Rhopalosiphum maidis* (Fitch), *Rhopalosiphum padi* (Linnaeus) and *Diuraphis noxia* (Mordvilko). Whereas, the prevailing associated predators were *Coccinella undecimpunctata*(L.), *Coccinella septempunctata*(L.), *Chrysoperla carnea* (Steph.) *Metasyrphus corollae* F., and a few number of true spiders. Obtained results showed that The infestation with *S. graminum* was much higher wheat plantations than other aphids in 2016-2017 season . *Schizaphis graminum* had three peaks of activity were recorded on the last week of January, March and April (455.1,3250.7 and 907.6 individuals/100 tillers, resp.) in 2016-2017 season. Meanwhile, *S. avenae* had two peaks of activity were recorded on the last week of, March and April (2010.9 and 570.2 individuals/100 tillers, resp.).Also, *C. septempunctata* had two peaks of activity were recorded on the last week of, March and Second week of May (35.7 and 25.0 individuals/100 tillers, resp.) on the same period of study.

Keywords: *Cereal aphid, Predators, wheat.*

INTRODUCTION

Aphid are one of the insect groups whose economic importance increases with the development of agriculture[1,2]. Cereal aphid are the serious pests attacking cereal crops, particularly wheat , barley and corn not only in Iraq[3,4] but also in many other countries ; i.e. Egypt , Souther Russia, Iran, Afghanistan, and countries bordering the Mediterranean Sea[2,5]. The species that are capable of causing substantial yield reductions are *Schizaphis graminum* (Rondan), bird cherry oat aphid , *Rhopalosiphum Padi* L., *R. maidis.* F., *Sitibion avenae* F. and *Diuraphis noxia*[2,6]. The use of insecticides in controlling aphids generally, leads to many problems, not only increasing resistant strains of aphids to these chemical substances, but also in induction of pollution to man and beneficial insects such as bees and other pollinators, insect parasitoids and predators[7,8]. Numerous publications documented the supperession of cereal aphid population by natural enemies[2,9,10]. Therefore , this investigation aims to study the role of aphids phagous insects in reducing aphid population on wheat crop in Qadisiyah district, Iraq. Study the effect temperature and relative humidity on the population density of wheat aphid and associated predators on field.

MATERIALS AND METHOD

The present investigation was carried out at fields of Qadisiyah district. Iraq during 2016- 2017 season.

Survey and Population Density of Piercing Sucking Pests and Their Predators on wheat Plants: Surveying of major piercing sucking pests and their predators took place during successive growing season 2016-2017 on wheat plant. The cultivated area was one donum(2500sq.m) ,the sowing date was in the 1st November in 2016-2017 season. Sapling started after about three weeks from planting and continued to the harvesting time. The sample size was 100 wheat tillers and chosed randomly from plants. Direct count of adults

of injurious insects and predators on wheat plant was undertaken. Since the predators under investigation differed in their living habits, activities, and distributions on the host plants infested with different prey and host insects the it was necessary to use one sampling method for all groups such as leaves sampling plant method in order to explain the relationship between pests and their associated predators. Sample of 100 tillers of wheat plants were biweekly in some few cases, picked up randomly and placed in paper bags to be examined carefully under microscope. The number of insect pestes and predators (immature stages and adults) in most cases were directly counted. The collected specimens were kept in vials containing 75% ethyl alcohol with some drops of glycerin to keep their tissues soft, and labeled for date. Identification according to key of Aphididae, described by (Helmi, 2011) and department of classification in plant protection Research Institute, Agriculure Research Center, Egypt.

Study the Effect of Certain weather factors of the Sucking Pests (Aphid species) and Their Predator on Wheat: Daily recorded of minimum temperature, maximum temperature and relative humidity were obtained from Agrometerological station at AL Qadisiyah region during the period of study. The relationship between the biweekly mean number of aphids and predators individuals and the corresponding biweekly means of the previously mentioned weather factors were statistically analyzed. The simple correlation coefficient between weather parameters and the number of pests and their associated predators were studied according to[11,12].

RESULTS AND DISCUSSION

Survey of certain aphid species and their associated predators in wheat plant: The seasonal abundance of the dominant aphid species infesting wheat plants were Green cereal- bug aphid *Schizaphis graminum* (Rondani), English grain aphid *Sitobion avenae* (Fabricius), Coron leaf aphid *Rhopalosiphum maidis*(Fitch), Bird cherry oat aphid *Rhopalosiphum padi* (Linnaeus) and Russian wheat aphid *Diuraphis noxia* (Mordvilko). As seen from Table 1. the percentage in fertation of *R. padi*, *R. maidis*, *S. avenae*, *S. graminum* ,and *D. noxia* were 14.77%, 12.48%, 26.91%, 41.63 and 4.21%, respectively during season 2016- 2017. Similar result were obtained by Alhag *et al* ., 1996 and Abd el – Aziz 2014, who mentioned that five species of cereal aphid found infesting wheat (*R. padi, R. maidis, S. graminum, S. avenae and D. noxia*). Meanwhile, the dominant aphid species were *Coccinella undecimpunctata* (L.), *Coccinella septempunctata* (L.), *Chrysoperla carnea* (Stephens) and *Metasyrphus corollae* (Fab.). The percentage in fertation of *C. undecimpunctata* , *C. septempunctata* , *C. carnea* and *M. corallae* were 25.98%, 38.93%, 20.85%, and 14.24%, respectively during season 2016-2017 (Table 2) . These result agree with Abd El- Aziz 2014, who surveyed that *C. undecimpunctata* , *C. carnea* and *M. corollae* on cereal aphid in wheat plant.

Table 1. Number of aphid insect species and their percentages to total catch related to their orders at wheat plants at Qadisiyah district in the growing season 2016 - 2017.

Aphid species	**2016- 2017**	
Order Homoptera	**Total individuals**	**%**
R. padi	4252.95	14.77
R. maidis	3592.2	12.48
S. avenae	7746.6	26.91
S. graminum	11985.76	41.63
D. noxia	1211.6	4.21
total	28789.11	100

Table 2. Number of beneficial insect species and their percntages to total catch related to their orders in wheat fields at Qadisiyah district in the growing season 2016 - 2017.

Beneficial insect species	**2016- 2017**	
Order Coleoptera	**Total individuals**	**%**
C. undecimpunctata	119.5	25.98
C. septempunctata	179.1	38.93
Order: Neuroptera *C. carnea*	95.9	20.85
Order : Diptera *M. corolla*	65.5	14.24
Total	460	100

Population density of certain aphid species infested wheat plants during the period of study: Five species of aphids were recorded during 2016-2017 season these aphid species were *S. graminum*, *S. avenae*

R. padi, R. maidis, and *D. noxia*.

A.1.*Schizaphis graminum:* Data in (figer1) showed initial number of *S. graminum* occurred in last week of November with a total number of 15.6 nymph/ 100 tiller. Three peaks of activity were recorded at last week of January, March and April (455.1 , 3250.7 and 907.6 individuals).

A.2.*Sitobion avenae:* *S. avenae* began to appear on wheat in 4th week of November. Two peaks of activity were recorded at 4th week of March and April (2010.9 and 570.2 individuals). (Fig 1)

A.3. *Rhopalosiphum maidis* and *R. padi*: Data fig 1 showed initial number of *R. maidis* and *R. padi* occurred in 4th week of November with a total number of (3.7 and 5.3 individuals). One peaks of activity was recorded at last week of February (960.6 and 1050.7 individuals) for *R. maidis* and *R. padi* respectively.

A.4. *Diuraphis noxia*: Numbers of *D. noxia* associated with wheat plant during 2016-2017 season are tabulated in (Fig 1) initial number were stated on last week of December(10.2 individuals / 100 tillers) and gradually increased to reach the maximum (310.2 individuals / 100 tillers) .On the other hand Darwish and Ali ., 1991 found the aphids *S. graminum* and *R. maidis* reached their maximum abundance (406 and 518 / plant) in upper Egypt. These results in agreement with those of Slman., 2006 and Sabbour., 2007 in Egypt, they found that the wheat plants were infested by four cereal aphid, *R. padi, R. maidis, S. graminum*, and *S. avenae.* They reported also that, the population of aphid peaked on fourth week of March. and coincided with the highest number of *C. undecimpunctata.* Tabasum *et al.,* 2012 observed a maximum aphid population on wheat during February 24 and then a decline observed up to march 8. again on march 8 up to march 17.

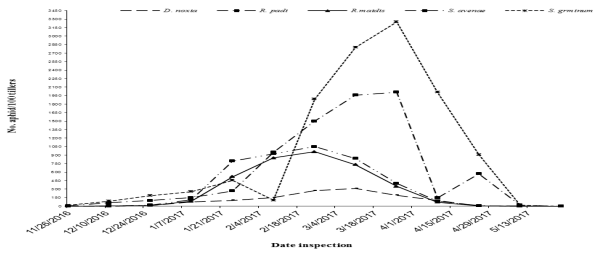

Fig. 1. Seasonal abundances of certain aphid species on wheat plants in 2016 /2017 season at Qadisiyah district.

Seasonal Abundance of Predators Associated with Certain Aphid Species infesting wheat at Qadisiyah District: Catches of predatory species revealed the following species *Coccinella undecimpunctata*, *Coccinella septempunctata*, *Chrysoperla carnea* and *Metasyrphus corollae* and few number of true spiders.

***B.1 .C. septempunctata*:** The *C. septempunctata* began to appear on wheat plants at low density during second week of December (1.2 individuals). Two peaks of activity were attained on 4th of March and 2nd of May (35.7 and 25.0 individuals).

***B.2.C. undecimpunctata*:** The number of *C. undecimpunctata*, took place in the 2nd week of December (1.5 individuals). Its increased to reach their maximum in 4th week of March (31.5 individuals) .

***B.3.C. carnea* :** The *C. carnea*, began to appear on wheat plants at low density during 2nd of December(1.3 individuals). It's increased to reach their maximum in 4th week of March (20.2 individuals) .

B.4. *M. corolla:* Initial number of *M. corollae* , were stated on last week of December(1.5 individuals / 100 tillers) and gradually increased to reach their maximum (15.3 individuals). However , El- Heneidy and Rizk,2004, Slman and Ahmed, 2005 and Yigit *et al* , 2007 , recorded that *C. undecimpunctata*, and *C. carnea* the most specific aphid predator of cereal aphid in wheat fields. Also, Samad, 2004 and El- Heneidy and Rizk, 2004 , recoded that *Metasyrphus corollae* in the third predators position after *C. undecimpunctata*, and *C. carnea.*

Fig. 2. Seasonal abundances of certain predators species on wheat plants in season 2016 /2017 at Qadisiyah district.

Effect of wheather factros on the population density of certain aphid species and their predators on wheat plants

1- aphid

On *R. padi:* The obtain results indicated that the (minimum, maximum and mean) temperatures cleared a negative significant correlation with population of *R. padi* on wheat during 2016- 2017 (-0.5088, - 0.4574 and -0.4833). Meanwhile the mean relative humidity showed a negative slight correlation in the same season.

On *R. maidis:* The (minimum and mean) temperature cleared a negative significant correlation with population of *R. maidis* (-0.4870 and -0.4611) on wheat . However, max., temperature showed slight negative correlation (-0.4349) and the relative humidity showed a slight positive correlation with population *R. maidis* on wheat during season 2016-2017(table 3).

On *S. avenae* and *D. noxia:* The temperature (minimum, maximum and mean) and relative humidity cleared a slight a negative correlation with population of *S .avenae* (-0.1646, -0.1458, -0. 1552 and -0.1402) while, were (-0.335, -0.3036, -0. 3198 and -0.0016) during 2016-2017 season (table 3).

On *S. grminum:* The temperature (minimum, maximum and mean) showed a slight positive correlation with population of *S. grminum* while, the relative humidity cleared a slight negative correlation during season 2016-2017(table 3). These agree with Abd El-Aziz, A.A. A. 2014 who reported that the temperature had a great effect on biology of *S. grminum.* Powell 1986 in United Kingdom mentioned that the low abundance of cereal aphid population infesting wheat may due to the combined action of natural enemies as well as the a variability of climatic conditions from year to another.

Table (3)Simple correlation between certain aphid species and climatic factors on wheat during 2016-2017 season at Qadisiyah district .

Variable		Insect Pests			
Source	*R.padi*	*R. maidis*	*S. avenae*	*S.grminum*	*D. noxia*
Min.Temp.	-0.5088*	-0.4870*	-0.1646	0.0330	-0.3355
Max. Temp.	-0.4574*	-0.4349	-0.1458	0.0258	-0.3036
Mean Temp.	-0.4833*	-0.4611*	-0.1552	0.2932	-0.3198
R.H	-0.0535	-0.0535	-0.1428	-.01857	-0.0016

CONCLUSION

Obtained results showed that the infestation with *S. graminum* was much higher wheat plantations than other aphids in 2016-2017 season. *C. undecimpunctata,* and *C. carnea* the most specific aphid predator of cereal aphid in wheat fields. Statistical analysis showed that temperature and relative humidity were significant with some insects and insignificant with the others.

Influence bacterial inoculant of local isolates of azotobacter vinelandii and irrigation water quality on growth and yield of wheat *(Triticum aestivum* L.)

Ghanem Bahlool Nooni[1], Abdualla Kreem Jbar[1], Sofia Jabbar Jasim Al-Rikabi[1]

[1]Agriculture College, Al-Muthanna University, Iraq

ABSTRACT

The present study deals with the isolation and characterization of *Azotobacter vinelandii* and A pots experiment was conducted at the canopy wood of Agriculture - University of Al-Muthanna (station 2) during winter season of 2016-2017 to study the effect of inoculant bacterial and irrigation water quality and their interactions on yield and growth of wheat. Treatments included four levels of inoculant bacterial (without inoculation A_0 and inoculation with three locally *Azotobacter vinelandii* coded A_1,A_2A_3 and three water qualities river water (0.752 ds.m^{-1} W_0), mixed water (3.6 ds.m^{-1} W_1) and drainage water (6.5 ds.m^{-1} W_2). The results showed, generally bacterial inoculant treatments was superior to the un-inoculant treatment A0 in most character studied and A_2 treatment achieved best result compared with other isolation locally, in height plant, dry weight plant, weight of 1000 seeds, yield and nitrogen uptake) was recorded (99.10 cm, 15.50 g plant^{-1}, 29.29 g, 32.95 g plant^{-1}, 73.56 mg plant^{-1}) sequentially. Generally increasing salinity in irrigation water significantly decreased growth characters, yield, and yield components of plant. Interaction between biofertilizer treatments and salinity had a significant effect on plant growth and yield and yield components of plant and the best result were had been gave by A2W0 in all traits studied (height plant, dry weight plant, weight of 1000 seeds, yield and nitrogen uptake) which was recorded (106.88cm, 17.97g plant^{-1}, 30.34g, 39.34g plant^{-1}, 97.43mg plant^{-1}) respectively.

Key words: *Azotobacter vinelandii, water salinity, inoculant.*

INTRODUCTION

Bio-fertilizers are cheap sources for plants nutrient and alternative mineral fertilizers using. They also reduce soil and water pollution as well as Bio-fertilizers different benefits forms by reducing the of chemical fertilizers quantities[1]. Agricultural development Sustainable is requires optimal use of microorganisms effectiveness and their biological activity in agricultural soils, which is an environmentally safe alternative to the availability of plant nutrients compared to chemical fertilizers[2]. Azotobacter most important for plant growth due to their role of nitrogen supply for plants and it is have been high efficiency of nitrogen fixation and hormones growth production[3]. Many studies refereed that Iraq's soils have been an overabundance of bacteria but there is many factors are inhibit growth and its existence such as drought and salinity of soil[4].Water Quality of irrigation are one of most important of basic natural resources for many centauries of the world particularly that located in semi-dry and dry area which use water irrigation in agricultural production so that are limit factor to development of agriculture in many countries. quality of water irrigation consider when using of water have a salt, the water irrigation quality can be using to expended area which use for agriculture production by mixing it with fresh water and use bacterial inoculants, to reduce harmful of water salt. The study aim is to investigate three isolates, which use inoculants of local bacteria and three levels of water irrigation salinity to determine best level can be suitable for inoculant bacterial and plant growth of wheat plant.

MATERIALS AND METHOD

Isolation and bacteria diagnosis

Three soil rhizosphere samples were collected from geographical local of Al Muthanna province shown in table 1.. Sucrose mineral-salts broth media was used to soil inoculation by *Azotobacter vinelandii* isolates. Soil dilution prepared Take 1 ml to test tubes inoculation by above medium, which was making and sterilized by autoclave for 20 min at 121 °C and 15 lb.by. Tubes incubated at 30 ° C for 7 days and were testing a thin white membrane observation on the surface, which is an indicator of *Azotobacter* spp. Growth taking 0.1 ml of the tubes, which gave a growth indication and spread on a Petri dish surface containing the medium Sucrose mineral-salts agar. Dishes Incubate at 28 ° C for 2-3 days were re streak to obtain pure colonies of bacteria, White colonies were then extracted, a brownish dye was given to the medium.

Table 1. Numbers of soil samples and names of areas and fields collected from them.

Sample number	Geographical	Plant in soil
1	Rumaitha istrict	Wheat
2	Warka district	Alfalfa
3	Samawah district	Barley

Field experience A field experiment was designed to study the effect three *A. vinelandii* isolates and three levels of water irrigation quality. CRD was designed using two factors, as shown below:-

The first factor:-

Bacterial inoculants by four levels symbols taken : -

A0 = without inoculant, A1 = local isolate of Rumaitha district -Muthanna province, A2 = local isolate of Warka district -Muthanna province and A3 = local isolate of Samawah district -Muthanna province

The second factor:-

Water irrigation quality by three levels the symbols taken : -

W0 = 0.750 ds. m^{-1} (river water), W1 = 3.6 ds.m^{-1} (mixed water) and W2= 6.5 ds.m^{-1} (well water). Experiment was carried out by three replicates: Experimental units number = 4× 3 × 3 = 36 units.

Soil preparation

The experiment was conducted in lath-house at the College of Agric., University of AL-Muthanna season 2016-2017. The wheat seeds were cultivated Aba 99 variety in 15/11/2017. Nitrogen fertilizer was added in the form of urea (46% N) at 20 kg N 1 ha^{-1}. a stimulant for the action of the bacteria. The phosphate fertilizer was added as a superphosphate fertilizer (48% P_2O_5) by 60 kg. ha^{-1} potassium was added by 120 kg ha^{-1} in the form of potassium sulfate K_2SO_4 (43% K)., when the wheat arrived to maturity at the end of the winter season of 2017. the wheat crop was harvested by cutting the plants from the area near the surface of the soil, also recorded the following measurements:Plant height, plant dry weight, grain yield and nitrogen uptake of plant.

Table 2. The following table shows chemical, physical and biological characteristics.

pH 1:1	Ece ds.m^{-1}	OM%	Available% N	Available% P	Availabe% K	Sand gm kg^{-1}	Silt gm kg^{-1}	Clay gm kg^{-1}	Total bacteria
7.75	4.25	0.65	24.3	12.5	275	232	388	379	$2.8x10^7$
						Silty clay			

RESULTS AND DISCUSSION

The colonies of the isolated were smooth, convex, glistening and opaque on media. The isolate was Gram-negative, motile rods, positive for catalase and oxidase test. The biochemical characterization (QTS-24 miniaturized identification tests) based on carbon/ nitrogen source utilization pattern revealed that the isolate can utilize more carbon sources than that of nitrogen and indicated highest (98%) similarity to the genus *Azotobacter* when compared with Bergey's Manual of Determinative Bacteriology[5]. The isolate was positive

for tryptophan deaminase, sodium citrate, sodium melonate, ornithine decarboxylase, H2S production, urea hydrolysis, indole acid from glucose, acid from maltose, acid from sucrose, acid from rhamnose, acid from sorbitol and acid from raffinose. The comparison of this biochemistry characteristic depicted 98% similarity *A. vinelandii.* Height Plant cm. The results showed in table (3) the inoculant bacterial effected in the height plant. A treatment A2 was best which recorded a mean 99.10cm with an increase reached 28.83% compared control relative, we can explain to inoculation with *Azotobacter vinelandii* is an ideal tool to supply the soil with a high density of beneficial microorganisms[6]. An increase of the height plant average may be due to the inoculant's characteristics. A researchers Abd El-Gawad et al, 2009 and Zaied, 2009 referred that the secretions of bacteria conduce an important role in the elongation of plant cells, and increased division of plant cells, as well as their activity in the nitrogen fixation, which provided some of the nitrogen in Different stages of growth. The impacts positive are may be due to the effect of environmental factors in the isolates of bacteria isolated from salt environmental zones whereas it is did not adaptation to the new environment[8].

Table 3. Effect of inoculant bacterial and different level of water quality in plant height (cm)

Mean A	W2	W1	W0	
76.58	72.88	77.22	79.66	A0
87.55	83.55	89.88	89.22	A1
99.10	87.88	102.55	106.88	A2
89.33	84.22	89.55	94.22	A3
	83.13	89.80	91.74	Mean W
	A*W	W	A	L.S.D
	6.08	2.31	4.51	

A data of analysis statics revealed a water quality factor influenced on plant height so W_0 treatment was superior which recorded 91.74 cm compared with other treatment $W_1$and W_2 which that reached 89.80, 83.13 cm respectively. A decreases of height plant due to water quality are bad because salinity of water particular in$W_1$and W_2 treatment. The positive response of yield as a result of inoculation may be due to the high ability of these microbes in N2-fixation and the secretion of several compounds that increase soil fertility and decomposition of organic materials that increase the plant's ability to grow and increase productivity.

Dry weight

The results showed in table (4) the inoculant bacterial effect in the dry weight of vegetable plant. for *Azotobacter vinelandii* locally isolated treatment A2 was superior recorded a mean increase of 15.50 gm plant^{-1} with an increase of 29.81% compared control relative, An increase explain to inoculation bacterial with *Azotobacter vinelandii* which is have many characteristics such is provide macro elements as N,P,K and micro elements and secretion some hormones which is promoting plant growth. The results agreed with many researchers[2,7].

Table 4. Effect of inoculant bacterial and different level of water quality in dry weight of the plant (g plant^{-1}).

	W2	W1	W0	
11.94	9.50	11.58	14.75	A0
14.44	12.45	14.69	16.19	A1
15.50	13.41	15.11	17.97	A2
14.74	12.95	14.41	16.87	A3
	12.08	13.95	16.45	Mean A
	A*W	W	A	L.S.D
	0.53	0.33	0.38	

The results in table 4 referred that using water irrigation quality are possibility influence on dry weight of plant. The river water (W0) was used recorded high values reached 16.45 gm plant^{-1} than compared with W1,W2 treatments which gave (13.95, 12.08) gm plant^{-1} respectively. The interaction dual of bio-fertilizer and water irrigation quality in the dry weight of the plant A2W0 was recorded 17.97 g plant^{-1} . A percentage increase was 33.33% maybe that cause of Water irrigation quality effect and inoculant which has the ability to release nitrogen-fixing bacteria through growing season and It has already been shown that the use of nitrogen fixing bacteria with high effective ability in solubilizing organic and inorganic phosphates (Rahim et al, 2016) .

Grain yield (g plant$^{-1)}$

The results of the statistical analysis shown in table

5, which refer effect of inoculant bacterial type and water quality in the grain yield. The locally bacteria A2 were superior to the other treatments regardless the water quality type it recorded 32.95 g plant^{-1}. This is refer to bacteria ability to produce a growth stimulated such as Indol Acitic Acid.This is confirmed by Samurai et al, (2006) as well as it Sidrophorses secretions, which is a sticking to micro elements such as iron and zinc and availability increase its as well as its enzymatic activity and nitrogen fixation[7]. This can supply sufficient N2 and assist the hydrolysis of a wide range of P compounds leading to increased crop production[11]. These results confirmed by the works were carried out by[12,13,14].

Table 5. Effect of inoculant bacterial and different level of water quality in grain yield (g plant^{-1}).

	W2	W1	W0	
26.93	23.59	26.80	30.39	A0
29.57	24.52	28.26	35.92	A1
32.95	28.99	30.53	39.34	A2
28.64	24.68	27.59	33.66	A3
	25.45	28.30	34.83	Mean A
	A*W	W	A	L.S.D
	2.11	1.007	1.162	

The results showed that water irrigation W0 was superior in yield trait which recording 34.83 g plant^{-1} compared with mixed water (W1) and drainage water (W2). This refer to water irrigation efficiency decreased when salinity of water had been increased, which is osmotic pressure was increased, also there is many harmful effective of water saline of inoculant and yield plant. These results are in agreement with those obtained by[15]. The statically analysis showed a treatment had coded A2W0 was superior to the rest of the treatments which recorded 39.34 g plant^{-1}, In general it can be said that the use of biofertilizers with wheat plant at all levels of salinity of irrigation water gave positive results as compared to the control. This is due to the high ability of these microbes in N2-fixating atmosphere and the secretion of several compounds that increase soil fertility and decomposition of organic materials that increase the plant's ability to grow and increase productivity under those levels of salinity of irrigation water[16,17].

Nitrogen uptake (mg plant^{-1})

Data presented in table 6. indicated that inoculant bacterial treatments significantly increased the Nitrogen uptake in dry weight of vegetable plant of Wheat compared with inoculated plants. The treatment (A2) was superior to the other treatments it recorded 73.56 mg plant^{-1}. This result is compatible with the finding of Mahmoud *et al*. (2012) and Paritosh *et al.* (2013).

Table 6. Effect of inoculant bacterial and different level of water quality in nitrogen uptake (mg plant^{-1})

	W2	W1	W0	
55.31	39.37	53.46	73.11	A0
63.88	50.40	59.20	82.04	A1
73.56	56.96	66.28	97.43	A2
68.33	53.65	61.48	89.87	A3
	50.10	60.11	85.61	Mean A
	A*W	W	A	L.S.D
	3.11	2.007	3.162	

The results showed increasing salinity irrigation water caused decreasing nitrogen uptake, compared with River water. W0 treatment had gave the highest values of nitrogen uptake in vegetable plant, It's had been reached 85.61 mg plant^{-1}. The gradual depression occurred in all the growth characters of plant due to the irrigation with saline water. Thus, as salinity is a condition of excess salts in soil solution, it affects plant by increasing the osmotic pressure of the soil solution. These results are in agreement with those obtained by Ebrahim *et al.* (2010). They found that increasing salinity in irrigation water decreased growth characters of plant. The interaction between Biofertilizer and irrigation water salinity had a significant effect on nitrogen uptake of wheat plants. The highest value of nitrogen uptake by plants were recorded 97.43 mg plant^{-1}when inoculated with *Azotobacter* and, irrigated by river water (A2W0).

ABSTRACT

The trial was designed to evaluate the addition of zinc methionine to the diet on some productive and carcasses performance of broiler, the study was conducted in the poultry field, Animal Production Department, Agriculture Faculty, Al-Muthanna University, from 1/4/2018 to 15/5/2018. A total of 400 broiler, one day, unsexed Ross308 strain were randomly distributed to four treatments (100 chick / treatment), each treatment included four replicates (25 chick per replicate), The chickens were reared in four-floor batteries with a measuring 2 x 1.5 meters per floor. The treatments of the experiment were as follows: First treatment (T1): a control treatment, zinc methionine was added at levels 400, 500 and 600 g per ton of feed for T2, T3 and T4 treatments respectively. The results showed that the T4 resulted in a significant improvement ($p \leq 0.05$) in body weight, body gain, feed consumption, feed conversion and mortality compare with other treatments.

Keywords: *zinc methionine, broilers, productive.*

INTRODUCTION

Rare metals are important in feeding poultry, as it affects the speed of growth and metabolic rate, which is reflected in their production performance such as eggs or meat, because it has an important role in vital processes[1.] As well as necessary for the permanence of life, it is an enzyme-stimulating agent involved in the construction of its systems[2]. Zinc is a rare mineral and contributes to the synthesis of more than 300 enzymes[3], formation of blood cells red increased thyroid hormone secretion[4]. Many researchers point to the benefits of zinc as it has the role of manufacturing RNA and DNA, restoring tissue growth and contributing to bone mineral deposition, increases the production of eggs, increases the shell thickness and improves the conversion coefficient of broilers[5,6,7]. The lack of zinc in the diet will affect the growth rate as well as the irregularity of bone formation, decrease in feathering and the decrease of the body's immunity against many diseases[8]. There are many studies on the use of zinc in poultry diets that its addition affects the productive qualities, the addition of high-grade zinc to the diet was given the highest increase in weight gain[9], the same results followed with addition of zinc as well as improved food conversion coefficient[10]. The addition of zinc to broiler broilers led to increased feed consumption and improved food conversion coefficient, and a significant decrease in the mortality, this improvement in body weight, weight gain and feed conversion was positively reflected on the measure of the production index[6,11], this was found by Abbas (2018), observed a significant improvement in body weight, weight gain, feed conversion, production index, significant decrease in mortality and significant improvement of thigh, wing and neck when adding organic zinc to 80 mg / kg feed[13]. Conducted a study on the addition of zinc at levels of 120,90,60,30,0 mg / kg stock feed in improving growth rate as well as good consumption of daily feed. Ezzat et al. (2013) noted that the addition of zinc at different levels of chicken broilers contributed to a higher than normal high body weight. Kwiecień et al. (2016) fed meat broilers on zinc-containing diets that led to a positive increase in chest and femoral weight. Jahanian et al. (2008) reported that the addition of zinc Methionine (Zn Met) to the diets improved the proportion of reflux and the proportion of breast meat and increased liver weight. Al-Daraji et al. (2012) noted that the intake of zinc in

Corresponding author:

Email : Abbasalmachi@gmail.com

large quantities more than the need of the body will prevent the absorption of copper from the bowel, leading to the emergence of anemia. Zinc is poorly absorbed by the intestines so we increase its concentration more than the required requirement of 40 mg / kg feed, as indicated by NRC (1994) to absorb what is needed by the bird and the rest is thrown out of the body and this leads to obstruction absorption of copper from the intestine, The idea of adding zinc methionine (Zn Met) to the diet to know its effect on some of the productive and carcasses qualities of broilers.

MATERIALS AND METHOD

A TOTAL OF 400 CHICKS ONE DAY, ROSS BROILER, were randomized disterbuted to four treatments (100 chick/ treatment), Each treatment consisted of four replicates (25 chick per replicate), experiment treatments were as follows: The first treatment (T1): a control treatment in which the birds fed on a diet without addition. The second treatment (T2): In which the birds were fed on a diet, 400 g / t of zinc methionine was added. The third treatment (T3): in which the birds were fed on a diet, 500 g / t of zinc methionine was added. The fourth treatment (T4): In which the birds were fed on a diet, 600 g / t of zinc methionine was added. The chicks were fed by starter for 1-21 days and Grower for 22-35 days. The ratios were calculated according to table 1. The water and diet were provide ad libitum. Studied traits were weekly body weight, weight gain, feed consumption, feed conversion, mortality and production index[17].

Table 1. Basal diet

Contents	**Starter(1-21 days)**	**Finisher(22-35 days)**
Corn	60	66
Soya bean meal[1]	35	28
Primex[2]	2.5	2.5

Fats (%)	2.80	3.00

1. The soybeans used by an Argentine source contained 48% crude protein and energy representing 2,400 kcal / kg.

2.Premix Max Care contains 16% protein, 900 kilocalorie energy, 10% lysine, 9.5% methionine and 9.5% sodium, 2% fat, 1% fiber, 12% calcium, phosphoric 13% Sodium, 5%. Calcium phosphate was (21.8% calcium and 18% phosphorus).

3. Chemical composition of the components of diet was calculate according to NRC (1994).

Statistical analysis

The data were analyzed in a one-way analysis using the statistical program[20], The averages were compared using the Duncan Multiple Test[21].

RESULTS AND DISCUSSIONS

BODY WEIGHT

Significant increase (P≤0.05) for the treatment (T4) in the body weight at the 5 weeks age, the body was 1995 g for T4 and 1968, 2939 and 1873 g, the other treatments T3, T2 and T1 respectively, These results were consistent with Kucuk et al. (2003): Ezzati et al. (2013): Abbas (2018) who observed a significant superiority of the final body weight when adding organic zinc to broilers, this improvement in body weight may be due to the zinc as an enzyme, important for metabolism, thus improved body weight[2]. The modern broiler breeds were characterized by rapid growth and therefore need zinc to become larger. This increases the body weight by increasing the level of zinc in the diets, but does not reach the excessive limit that allows it to bind with copper and impede its absorption and the incidence of anemia.

(N.S) No significant differences between mean values. * There were significant differences between the mean values at the probability level (P≤0.05).

Body gain

Table 3. shows a significant increased (P≤0.05) in for the cumulative body gain weight. The fourth treatment (T4) recorded the highest value of this trait at 1955 g on the rest of the experiment, which recorded the lowest values significantly and reached 1833 g. These results were consistent with the findings of Innoconti et al. (2004): Ao et al., (2006): Abbas, (2018), which showed that the addition of zinc to the broiler chicks resulted in a significant improvement in body gain.

T1: A control treatment in which birds are fed on a diet without additives. T2: fed the birds on a diet supplemented with 400 g / t of zinc methionine. T3: fed the birds on a diet supplemented with 500 g / t of zinc methionine. T4: fed birds on a diet supplemented with 600 g / t of zinc methionine. (Mean ±S.E) means ± standard error. (N.S) No significant differences between mean values. * There were significant differences between the mean values at the probability level (P≤0.05).

Feed Consumption

Table 4. shows that there is a significant superiority (P≤0.05) for birds of the fourth treatment (T4) for the consumption of the cumulative feed, recorded a value of 3400 g / bird at the age of 5 week for the other of the experimental birds, which recorded values less 3381, 3358 and 3308 g / bird for treatments T1, T2 and T3 respectively. The reason may be that nutrition at high levels of zinc leads to an increase in microscopic microbes that enter the zinc in their diet, which have a major role in the digestion of fiber, especially the secum, which works to increase the speed of food passage in the intestines, Which increases the need for birds to consume large amounts of feed[23].

T1: A control treatment in which birds are fed on a diet without additives. T2: fed the birds on a diet supplemented with 400 g / t of zinc methionine. T3: fed the birds on a diet supplemented with 500 g / t of zinc methionine. T4: fed birds on a diet supplemented with 600 g / t of zinc methionine. (Mean ±S.E) means ± standard error. (N.S) No significant differences between mean values. * There were significant differences between the mean values at the probability level (P≤0.05).

Feed conversion

Table 5. indicates a significant improvement (P≤0.05) for the feed conversion of T3 and T4 and recorded the best improvement of the feed conversion of 1.75 and 1.74 respectively, compared to T1 (control), which recorded the worst feed conversion was reached 1.80. while T2 did not differ significantly with the treatment of T1 (control), and T3 and T4 were not different. The improvement in the feed conversion may be due to the introduction of zinc in the synthesis of fatty acids, which contribute significantly to the improvement of the general health of birds and thus improve the conversion coefficient of food[24].

Table 5. Effect of Addition of Different Levels of Zinc Methionine (Zn Met) on feed conversion (g diet/ g weight gain) of broiler (± S.E.).

CONCLUSION

The high levels of zinc methionine (600 mg per ton of feed) resulted in improved all productive traits of broilers compared with other treatments.

Topical Combination of Nifedipine with Lidocaine for Anal Fissure Treatment

Rasha Kadim Albayati[1], Adel Musa Al-Rekabi[2], Nahedh R. Alammar[2], Hayder Adnan Fawzi[3]

[1]Department of Surgery, Al-Diwaniyah Teaching Hospital, Al-Diwaniyah, Iraq, [2]Department of Surgery, College of Medicine, University of Al-Qadisiyah, Al-Diwaniyah, Iraq, [3]Clinical Pharmacy Departments, Baghdad Medical City Hospitals Campus

ABSTRACT

Background: A fissure consist of crack or tear in the vertical axis of the anal canal between the anal verge and the dentate line. Anal fissure is treated by two ways either medical or surgical treatment or both.

Objective: evaluate the healing response of topical application of nifedipine with lidocaine in acute and chronic anal fissure

Material and method: A prospective study of one hundred patients presented with anal fissure to outpatient surgical clinic in Al-Diwaniyah teaching hospital, the patients divided into two groups, 40 patients (15 males and 25 females) with acute anal fissure, and 60 patients (25 males and 35 females) with chronic anal fissure.

Results: There was no statistically significant difference in the healing rate between acute and chronic lesion, however the rate of healed lesion in acute setting is higher than that of chronic setting (80% vs. 56%)

Conclusion: Topical application nifedipine and lidocaine effective in treating acute anal fissures with the healing response of 85%, and prevent evolution of acute anal fissures to chronic anal fissure.

Keywords: *acute, chronic, anal fissure, Medical treatment.*

INTRODUCTION

Anal fissure is the most common cause of severe anal pain and bleeding [1]. Anal fissure is an elongated ulcer in anoderm below dentate line, more common posteriorly due to more adherent of anoderm to underlying tissue in posterior midline so the blood supply is significantly low as shown by the Doppler flow-metry study [2]. It is estimated that 25% of a women and 8% of a men have anterior fissure [3]. Constipation and passing of hard faces lead to tearing of the mucosa causing pain and bleeding[4].

The pain of anal fissure is severe and always disproportionate to the severity of physical lesion, it may be so severe that patients may avoid defecation for days until it becomes inevitable, this lead to harden of a stools, which farther tear the anoderm during defecation [5]. This ulcer is ischemic ulcer and due to hypertonicity of internal anal sphincter due to pain and spasm of sphincter, this causing a vicious cycle and this can lead to chronic anal fissure [6].

Chronic anal fissure have traditionally managed with lateral internal sphincterotomy or anal dilatation sphincterotomy, however it has been associated with incontinence in up to 35% of patients. Furthermore, this does not take into account normal weakening of the sphincter with age as well as the possibility of future anorectal surgery or obstetrical trauma. Dilatation of the anal canal has also been associated with sphincteric tears and subsequent incontinence [7]. Controlled pneumatic dilatation, however is a variation to the technique that may reduce the risk of sphincter in jury [7].

More recently, less invasive strategies have been adopted to induce sphincter relaxation topical agents including nifedipine reduce internal sphincter pressure

Corresponding author:
Hayder Adnan Fawzi
Email: hayder.adnan2010@gmail.com

and increase blood supply to ischemic ulcer by decreasing the internal anal sphincter tone, and topical agents nifedipine also have anti-inflammatory action. As lidocaine, is the most common topical anaesthetic for anal fissure, which break the vicious cycle of pain [8, 9].

During pregnancy and following childbirth the fissures occur as a superficial split in anterior anoderm may progress to a chronic anal fissure [10]. A typical fissure may be multiple, off the midline, large and irregular, these may be caused by inflammatory bowel disease, local or systemic malignant, venereal infection (syphilis, HIV) trauma, tuberculosis, and chemotherapy [11]. The aim of the current study to evaluate the healing response of the anal fissure to topical application of nifedipine with lidocaine gel, and prevent evolution of acute anal fissure to chronic anal fissure.

MATERIAL AND METHOD

A prospective study carried out in the surgical outpatient clinic of AL-Diwaniyah teaching hospital from January 2017 to January 2018. The study included one hundred patients, each patients were followed up during the admission period, examination of the anal fissure and its signs, like puckered or spatulated anus, anal sphincter tone by doing per rectum examination (subjective feeling) for the chronic fissure to decided wither its tight or relax, examination for the skin tag (present or absent), and also examination for pressure which indicate the chronicity of anal fissures.

After that the patients were given the formula (cream Nifedipine (0.3%) – lignocaine (1.5%) Combination) [12] and explain to them who to use the formula, the frequency of visit every two weeks to evaluate the response to the formula.

According to the signs and symptoms, the patients were divided into two groups, the first group with acute anal fissure (15 males and 25 females) and second group with chronic anal fissure (25 males and 35 females). In Both groups patients were instructed to apply cream locally into the anal canal twice daily for 3 weeks after defecation [12].

Anal fissure was defined as acute when its symptoms (moderate to severe pain during defecation, bleeding per rectum) is within 3 to 6 weeks of onset, the patients were assessed with history and physical examination [13]. Chronic anal fissure defined by duration of symptoms longer than 3 months, the presence of induration at fissure edges, sentinel pile, hypertrophied anal papillae, and circular muscle fibres at the base of the cutaneous defect [14]. The response was shown as stopping or decreasing the bleeding, decreasing the pain, the relaxation of internal anal sphincter and disappearance the induration.

STATISTICAL ANALYSIS

Analysis of our data done using the software program: SPSS 21 (Statistical Package for Social Sciences). Numeric data were represented by the mean ± standard error, while the categorical data represented by numbers and percentages. Independent t-test was used to study the difference between two. For the study of the association between categorical data, the Chi-Square test used. The significant level considered when the P value < 0.05 [9, 15].

RESULTS

There was no statistically significant difference in the healing rate between acute and chronic lesion, however the rate of healed lesion in acute setting is higher than that of chronic setting (80% vs. 56%)

Table 1: healing of lesions in male after 6 weeks

	Healed	Not healed	P value
Acute (15)	12 (80%)	3 (20%)	0.123
Chronic (25)	14 (56%)	11 (44%)	

There was no statistically significant difference in the healing rate between acute and chronic lesion.

Table 2: healing of lesions in male after 8 weeks

	Healed	Not healed	P value
Acute (15)	13 (86.7%)	2 (13.3%)	0.591
Chronic (25)	20 (80%)	5 (20%)	

There was no statistically significant difference in the healing rate between acute and chronic lesion, however the rate of healed lesion in acute setting is higher than that of chronic setting (80% vs. 57.1%)

Table 3: healing of lesions in female after 6 weeks

	Healed	Not healed	P value
Acute (25)	20 (80%)	5 (20%)	0.064
Chronic (35)	20 (57.1%)	15(42.9%)	

There was no statistically significant difference in the healing rate between acute and chronic lesion.

Table 4: healing of lesions in female after 8 weeks

	Healed	Not healed	P value
Acute (25)	23 (92%)	2 (8%)	0.455
Chronic (35)	30 (85.7%)	5 (14.3%)	

DISCUSSION

Today, the treatment of chronic anal fissure has become challenging because of irreversible damage and deformation of the internal anal sphincter. Additionally, given that most patients with anal fissure are young and worried about non-voluntary faeces excretion and the consequences after surgery, the use of alternative medicines for treating patients with anal fissure has been of recent concern [16].

In the current study the healing response of acute anal fissure (AF) after (6 weeks) for both females were 80%, and after extended therapy (8 weeks) the healing response of acute anal fissure for females was 92% and for males were 86.7%, our findings were in agreement with Antropoli et al in which 141 patients treated with nifedipine topically (0.2% nifedipine gel) every 12 hours for three weeks they reported a total remission from acute anal fissure after 21 days of therapy to be 95% [17]. Our findings were in agreement with Digennaro et al in which 171 patients with acute AF treated with Diltiazem gel applied every 12 h for 40 days the rate of efficacy was 89.4 % (complete healing: 64.3 %, improvement: 25.1 %) [18], also in agreement with Katsinelos et al The effect of topical nifedipine in treatment of acute anal fissure showed that a course of (8 weeks) nifedipine achieved 85.2% remission indicated by resolution of symptoms and healing of fissure and the unhealed 14.8% that 50% undergo lateral internal sphincterotomy and 50% of them continue therapy for four additional weeks that resulting in healing the fissure [19].

In the current study chronic anal fissure the healing response after (6 weeks) for females were 57.1% (20 patients) and for males were 80% (20 patients), but after extended therapy (8 weeks) the healing response of chronic anal fissure for females were 85.7%% (30 patients) and for males were 80% (20 patients). Our findings were in agreement with Digennaro et al in which 171 patients with acute AF treated with Diltiazem gel applied every 12 h for 40 days with chronic fissure the rate of efficacy was 62.8 % (complete healing: 23 %, improvement: 39.8 %) [18]. In a study conducted by Golfam et al, 110 individuals were studied with chronic anal fissure, out of whom 60 were treated with nifedipine and 50 were controls (conventional treatment). In the nifedipine group, 70% of patients achieved recovery (which is in agreement with our findings), and in controls, 12% recovery was observed after four weeks. In the Golfam et al. study, recovery and healing of the pain in the nifedipine group were significantly different from that of the control group [20].

Oral and topical calcium channel blockers (CCBs) have recently been shown to lower the anal resting pressure by relaxing the internal anal sphincter [21-23]. The transport of calcium through the L-type calcium channels is important for the maintenance of internal anal sphincter tone [24]. As opposed to glyceryl trinitrate, which reduces resting anal tone by releasing nitric oxide, nifedipine (a calcium channel blocker) reduces the tone and spontaneous activity of the sphincter by decreasing the intracellular availability of calcium [24].

CONCLUSION

Topical application nifedipine and lidocaine effective in treating acute anal fissures with the healing response of 85%, and prevent evolution of acute anal fissures to chronic anal fissure.

Relationship between Diabetes Mellitus and Tuberculosis in Indonesia

Indriya Wardhani[1], Mondastri Korib Sudaryo[2]

[1]Master of Epidemiology, School of public Health, University Indonesia,
[2]Departement of Epidemiology, School of public Health, University Indonesia

ABSTRACT

Backgrounds: Tuberculosis was one of the 10 caused of death in the world. Tuberculosis was caused by *mycobacterium tuberculosis* which was transmitted through droplets. One risk factor for tuberculosis was diabetes mellitus. The risk of death due to tuberculosis in people who had diabetes would be higher than whom did not have tuberculosis. This study was aimed to determine the relationship between diabetes mellitus and tuberculosis.

Method: This study used a cross sectional study design. The data analyzed were 34,257 people who participated in the Indonesia Family Life Survey 5 in 2013-2014. Prevalence Odds Ratio crude, Prevalence of adjusted odds ratios and 95% CI were calculated using the chi-square and the multivariate binary logistic.

Result: The prevalence of tuberculosis in this study was 6.6%. From the chi-square results there was a significant relationship between diabetes mellitus and tuberculosis with POR 3.88 (2.49-6.05). Multivariate binary logistic result was a significant relationship between diabetes mellitus and tuberculosis with POR 4.93 (3.01-8.1) after being adjusted by confounder variables.

Conclusions: There was a significant relationship between diabetes mellitus and tuberculosis.

Keywords: *Diabetes Mellitus, Tuberculosis, Indonesia*

INTRODUCTION

Tuberculosis was one of the top 10 caused of death in the world[(1).] Tuberculosis caused by *mycobacterium tuberculosis* which was transmitted through droplets. Every one positive smear would transmit 10-15 people or 17% probability of infected each contact[(2)]. About a quarter of the people in the world had latent tuberculosis where the person had been infected with *mycobacterium tuberculosis* but they were not sick and could not transmit it. In 2017, 10 million people suffered from tuberculosis and 1.6 million people died. Two-thirds tuberculosis cases in the world were India, China, Indonesia, Philippines, Pakistan, Nigeria, Bangladesh and South Africa. The prevalence of Tuberculosis at Indonesia in 2016 was 361,893 residents[(1)].

WHO had set a target for ending TB endemic by 2030 by reducing the mortality rate by 95% and the incidence rate by 90% by 2035[(1)]. The success rate of treatment for all tuberculosis cases in 2017 was 85%, this number had increased from the previous year. To achieve it, we must take preventive actions besides success rate of treatment targets. People of productive age, malnutrition or diabetes, HIV, and smoker had high risk of tuberculosis. People with weak immunity due to chronic diseases such as diabetes mellitus had a high risk of getting tuberculosis. 15% of cases of tuberculosis in the world was probably related to diabetes mellitus. The risk of death due to tuberculosis in people who had diabetes would be higher than those who did not have tuberculosis. 7.9% of cases of tuberculosis in the world were caused by smoking[(1)]. Based on research in China by Zhang et al., smoking could increase the risk of tuberculosis by 1.28 times[(3)]. The largest proportion of tuberculosis cases in Indonesia in 2016 at the age of 25-34 years was 18.07% followed by age 45-54 at 17.25%[(4)].

Based on a retrospective cohort study in Taiwan in 2011-2012 by Yen et al., underweight could increase the risk of death from tuberculosis by 2,14[5]. Poor ventilation could facilitate the spread of *mycobacterium tuberculosis* by air. Based on research conducted by Halim, Naning and Satrio poor ventilation could increase the risk of tuberculosis by 2.21 times[6].

Based on the explanation above, the researcher wanted to know the relationship between diabetes mellitus and tuberculosis.

METHOD

This research used cross sectional study design. This study used Indonesian Family Life Survey (IFLS) data 5. The survey was conducted by the University of Southern California and RAND in 13 provinces in 2014 to 2015[7]. The survey was carried out by observation, interviews, and measurements on weight and height. The sample used in this study amounted to 34,256 people. In this study using all respondents aged ≥15 years who took the IFLS survey 5. In this study the exposure was diabetes mellitus and its outcome was tuberculosis. Determination of tuberculosis status by interviewing whether the respondent had or had not been diagnosed with tuberculosis by a doctor. Determination of DM status by interviewing whether the respondent had or had not been diagnosed with DM by a doctor.

Measurements of body weight and height were carried out by trained interviewers. Variable BMI (Body Mass Index) uses the category by Ministry of Health there were[8]:

Skinny category : BMI <18.5

Normal category : BMI ≥18,5 - <24,9

Fat category : BMI ≥25.0 - <27.0

Category of obesity : BMI ≥27.0

For smoking behavior variables, education was also obtained by interview method. Whereas the variable of house ventilation and the type of house floor were obtained by observation by the interviewer. Age variables used the age category by statistics Canada there were[9]:

Children : 0-14

Youth : 15-24 years

Adult : 25-64 years

Elderly : >65 years old

Data processing was started by merge data so it became a data set that matches the selected variable. Then re-coding and categorizing the variables of age, BMI, education, smoking behavior, number of cigarettes consumed, type of floor, and cooking fuel. Data analyzed were descriptive analysis, bivariate analysis, and cox regression analysis.

RESULTS

This study with a total sample of 34,257 after the data cleaning process contained missing data were on sex variables (6 respondents), age variables (7 respondents), education variables (93 respondents), BMI variables (2,035 respondents), cooking fuel variables (50 respondents), ventilation variables and type of floor (1 respondent). Table 1 was the characteristics of the respondents there were gender, age, education, smoking behavior, cigarette consumption per day, body mass index, ventilation conditions, type of house floor and cooking fuel for tuberculosis. Table 1 also provided potential confounders. Variables that had the potential as confounders were gender, age, education, smoking behavior, body mass index, type of house floor and cooking fuel.

In this study physicians who had been diagnosed with tuberculosis by 2,260 (6.6%) people, and those who had never been diagnosed with tuberculosis were 31,998 (93.4%) people. In sex variable, the highest was woman with 17,919 (52.3%) people, while the largest age group was in the 25-64 year age group with 24,399 (71.2%) people. The most moderate education variable was 17,550 (51.2%) people, while the most body mass index (BMI) with the normal category was 17,990 (52.5%) people. In the smoking variable the largest proportion of non-smoking was 21,671 (63.3%) people, and cigarette consumption was ≤18 cigarettes per day amounting to 32,223 (94.1%) people. A total of 29,405 (85.8%) respondent had good house ventilation, while the most variable type of house floor was a type of non-soil floor of 32,940 people (96.2%). Variable non-risk cooking fuels was 27,106 (79.1%) people. In table 1, it can be seen that there were a lot of tuberculosis in women of 1,385 (7.7%), and in age group of >65 years was 322 (12.4%). High education amounted to 626 (13.5%) people with normal category BMI of 833 (8.3%) people and had a smoking behavior of 196 (11.7%) people with consumption of cigarettes > 18 cigarettes per day of 150 (7.4%) people were have higher prevalence of

tuberculosis than others. Subjects with high prevalence of tuberculosis had good house ventilation amounted to 1,971 (6.7%) people, and non-soil type of floor house were 2,221 (6.7%) people. Subjects with high prevalence of tuberculosis using non risk cooking fuels were 2,018 (7.4%) people.

Table 2. Analysis of bivariate and multivariate mellitus diabetes and tuberculosis.

Variable	Tuberculosis (N=34.257)				POR crude	95% CI	Pvalue	POR adj	95% CI	Pvalue
	Yes		No							
	N	%	N	%						
DM										
Yes	25	1,1	92	0,3	3,88	2,49-6,05	0,000	4,93	3,01-8,1	0,000
No	2.235	98,9	31.906	99,7						

In table 2 it can be seen that there was a relationship between diabetes mellitus and tuberculosis. People with diabetes mellitus had a risk of 3.88 (95%CI 2.49-6.05) times for tuberculosis rather than whom did not have diabetes mellitus. Multivariate analysis is done by entering all variables suspected of being confounders. The POR after adjusted variables of sex, age, education, smoking behavior, body mass index, type of house floor and cooking fuel was 4.93 (95%CI 3.01-8,1).

DISCUSSION

The prevalence of tuberculosis in this study was 6.6% (2,260) of 34,257 respondents. Tuberculosis was common in women, age groups> 65 years, higher education, fat BMI, ever smoking behavior, type of floor of the house that was not soil, and non-risk cooking fuel. There was a significant relationship between diabetes mellitus and tuberculosis (POR 3.88 95%CI 2.49-6.05). After being controlled by the confounder variable there was a significant relationship between diabetes mellitus and tuberculosis (POR 4.93 95%CI 3.01-8,1).

In case-control research conducted by Alisjahbana et al., diabetes mellitus was increase the risk of OR 4.7 (95%CI 2.7–8.1) tuberculosis. After adjusted variable confounders (such as socioeconomics, environmental factors, contact with patients, and history of tuberculosis) the result did not reduce the strength of the association between diabetes mellitus and tuberculosis[10]. This was consistent with a systematic review of 13 observational studies conducted by Jeon and Murray that diabetes mellitus increases the risk of RR 3.11 (95%CI 2.27-4.26) in the occurrence of tuberculosis[11]. This was consistent with the systematic review conducted by Al-Rifai et al., that diabetes mellitus patients had 3.59 times (95%CI 2.25–5.73), 1.55 times (95%CI 1.39–1.72), and 2.09 times (95%CI 1.71–2.55) increased risk of active prospective in four TB, 16 retrospective, and 17 case-control studies. Diabetes mellitus with uncontrolled blood sugar had a higher risk of developing tuberculosis compared to diabetes mellitus with controlled blood sugar[12]. In a cohort study in Australia conducted by Dobler, Flack and Marks diabetes mellitus increases the risk of tuberculosis 1.48 (95%CI 1.04-2.10) in people with diabetes mellitus and 2.27 (95%CI 1.41 -3.66) in people with diabetes mellitus who use insulin. In this study also states that the attributable risk was small, so that if the incidence of diabetes mellitus in the population was high, screening and treatment of diabetes mellitus patients was necessary[13]. According to Harries et al., and Dooley and Chaisson it was more reliable to screening tuberculosis patients when patients undergo treatment compared to the start of treatment. Tuberculosis was a chronic disease that is likely to increase blood sugar due to cytokine stimulus, causing false positive diabetes mellitus if screening is too early[14][15].

In a study conducted by Workneh, Bjune and Yimer in ethiophia, stated that the risk of tuberculosis with diabetes mellitus dying increased 3.96 (1.76–8.89) times compared with no diabetes mellitus. This may be due to poor glycemic control and impaired immune cells in patients with diabetes mellitus[16]. This is according to what was done in a study conducted by Martens et al., in mice, that mice have acute diabetes mellitus will be exposed to tuberculosis after 4 weeks of infection[17]. According to Dooley and Chaisson, diabetes mellitus

increased sensitivity to *mycobacterium tuberculosis* through multiple mechanisms. The mechanisms directly related were hyperglycemia and cellular insulinopenia, and indirect effects on the macrophage and lymphocyte function. Most important cells in prevented tuberculosis infection were phagocytes (alveolar macrophages and their precursor monocytes) and lymphocytes[15].

The limitations of this study was the use of interview methods for smoking behavior variables so that the results are likely to be underestimated. The use of interviews with tuberculosis and diabetes mellitus status can result in underestimated results. While the variable of home ventilation was only done by observation by the interviewer without any measurement. The results of this study had controlled confounder variables, but there were potential confounder who had not been controlled such as social economy and contact with tuberculosis patients.

CONCLUSION

The results of this study there was a relation between diabetes mellitus and tuberculosis. This study was present information for tuberculosis prevention and further research.

Funding: This study was supported by the International Indexed Publication for Student Final Projects Grant 2018 from the Research and Community Development Center of the University of Indonesia.

Conflict of Interest: None declared

Acknowledgment: We are grateful for the data provided by the Indonesian Family Life Survey. We are thankful to the Research and Community Development Center of the University of Indonesia for the financial support.

Ethical Clearance: The IFLS surveys and their procedures were properly reviewed and approved by IRBs (Institutional Review Boards) in the United States (at RAND) and in Indonesia at the University of Gadjah Mada (UGM) for IFLS5. Ethical clearance taken from IRB (institutional Review Boards) committee Thus all requirements for consent for adults and children were met and approved by those IRBs before fieldwork could begin.

A Cross-secsional Study: Analysis Risk Factors Against Pulmonary TB AFB Positive in Indonesia

Ira Aminah Padang[1], Mondastri Korib Sudaryo[2]

[1]Master of Epidemiology, School of Public Health, University of Indonesia,
[2]Departement of Epidemiology, School of Public Health, University of Indonesia

ABSTRACT

Background: Indonesia is a third rank in TB cases worldwide. TB is a disease caused by multifactors where the environment interacts with host-related factors. So, the study was conducted to identify the multifactors and to get the main risk factor of pulmonary TB AFB positive in Indonesia.

Methods: A cross-sectional study, Subjects were the age group ≥15 years who were followed by the interview and had complete data. Pvalue <0,025 was considered statistically significant and included to final model by screening the factors which able to predict the prevalence of pulmonary TB.

Results: The prevalence of pulmonary TB AFB positive was 1.72%. Chi square test showed statistically significant association against pulmonary TB were gender OR=1.42(1.26-1.60), Diabetes Mellitus history OR=3(2.35-3.82), Contact with active TB patients OR=3.49(2.90-4.20). Multivariate analysis showed, Active smoker, gender, age category, contact with active TB patients, and diabetes mellitus history had role against pulomonary TB AFB positive in Indonesia. The main risk factor was active smoker OR=3.71.

Conclusion: Age, gender, diabetes mellitus, active smoker, and contact with active TB patients were significantly risk factors to predict pulmonary TB. Active smoker had 3.71 greater risk of having pulmonary TB compared with non pulmonary TB.

Keywords: *Risk factors, pulmonary TB AFB positive, Indonesia*

INTRODUCTION

Globally, it was estimated 10.0 million people (9.0–11.1 million) developed TB disease in 2017. The highest cases countries: India (27%), China (9%), Indonesia (8%), the Philippines (6%), Pakistan (5%), Nigeria (4%), Bangladesh (4%) and South Africa (3%)[(1)]. Earlier in the 20th century, the discipline of pulmonology had been driven by epidemic levels of TB in the USA (the rate of PTB in New York City was 247 per 100 000) [(2)]. In 2017, the global incidence for TB was 48.9 per 100 000 males and 39.7 per 100 000 females [(3)]. In 2014, the World Health Assembly embraced an ambitious resolution to reduce deaths from TB by 95% by 2035 [(4)].

Indonesia is the third rank in TB worldwide. The management of *M. tuberculosis* infection was a new priority action for "End Tuberculosis Strategy". Hence, identifying the significant risk factors of TB in Indonesia is essential effort to do. The SDG and End TB Strategy targets set for 2030 cannot be achieved without intensified research/study and development. The main reason, we use this survey to identify risk factors to predict pulmonary TB AFB positive and to get the main risk factor against pulmonary TB in Indonesia.

Study Design and Data Collection

Design was a cross-sectional using Prevalence Survey TB 2013-2014 data. It collected information on individual, household and community level data using multistage cluster stratified random sampling on≥15 years old[(5)]. Selected cluster was 156 district from 33 provinces in Indonesia.Field supervision during data collection was carried out regularly by the Balitbangkes research team and partners (WHO, KOMLI Tuberculosis, Directorate of Tuberculosis and TORG). Supervised activities included pre-survey, data collection, panel

team activities, and data analysis.

Measures

The quality of surveys was guaranteed at all stages by recruiting qualified teams, compliance with standard operating procedures for all activities, trials, team training and regular supervision. Socio-Demographic Characteristics and Risk Factors; age , gender, level of education, DM history, tuberculosis history, active smoker, passive smoker, and contact with active tuberculosis patients. Pulmonary TB was difined by the result of microscopic test from respondents' sputum.

Statistical Analysis

Logistic regression was performed to calculate the risk factors and to get the final model of pulmonary TB AFB postive.

RESULTS

Table 1. Assosiation of pulmonary TB AFB positive

Characteristics	Tuberculosis		Non Tuberculosis		Total	OR	95%CI	p
	n =1,091	%	n = 62,190	%

Contact with active tuberculosis patients								
No	957	1.6	59,794	98.3	60,751	1		
Yes	134	5.3	2,396	94.7	2,530	3.49	(2.90-4.20)	0.0001

The prevalence of pulmonary TB AFB positive in Indonesia was 1.72%. The highest proportion of TB was ≥ 55 years group 2.7%. The proportion of TB in male was 2.1% higher but non TB female was 98.5% higher.

Table 2. Final Model Prediction

Risk Factors	B	df	p	OR	95%CI
Gender	0.837	1	0.000	2.31	1.99-2.67
Education	0.162	1	0.014	1.17	1.03-1.34
DM history	1.027	1	0.000	2.79	2.18-3.57
Active smoker	-0.773	1	0.000	0.46	0.39-0.54
Contact with active tuberculosis patients	1.277	1	0.000	3.58	2.97-4.32
Constanta	-4.454	1	0.000	0.012	

The final model to predict of pulmonary TB BFA positive in Indonesia;

Pulmonary TB = -4.454+0.837(Gender)+0.162(Education)+1.027(DM History)-0.773(Active Smoker)+1.277(Contact with Active Tuberculosis Patients)

Probability to suffer TB:

$$\frac{1}{1 + e^{\text{Pulmonary TB}}}$$

No difference of education level between TB and non TB. Respondents had DM history and suffered TB 4.8% higher than non TB only 1.6 %. Almost non TB had no tuberculosis history (100%). The proportion of TB and no TB between active smoker and passive smoker were the same. In respondents with contact active TB patients, the proportion of TB was 5.3% and non TB was 94.7% while the proportion of no contact with active TB, TB was 1.6% and non TB was 98.3%.

Male have risk 1.42 greater of pulmonary TB. Education level has no significant risk of TB. DM has risk 3 greater of pulmonary. Active smoker and passive smoker were a protective to pulmonary TB. Respondents contact with active TB patients has risk 3.49 greater than those who have no contact.

DISCUSSION

Risk of pulmonary TB AFB positive could be accurately predicted by gender, education, DM, active smoker, and contact with active tuberculosis patients. Study in Ambo Hospital, the risk of one or more family member with history of TB (OR=4.4;95%CI1.5–12.9) [6]. Study in Vietnam found RR of smear-positive disease among household contacts was 6.4 (95%CI,4.5-9.0;P<0.001)[7]. Quoted from Ambo Hospital study,45% of TB cases had a family history of TB compared with 11% of the controls (OR=7.55; P< 0.001). The risk appears to increase when the contact is with a close family member[5]. Study in China identified the cumulative risk of active TB among close contacts 1.48% (95%CI 1.15%–1.88%)[6].

Study of Ojha Institute, living with TB AFB positive patients are at high risk[8].Although TB control programmes have averted millions of deaths, their effects on transmission and incidence rates are not yet widely detectable[36].The second risk factor is DM. It risks 2.79 times to pulmonary TB. WHO collaborative framework for TB-DM recommends bidirectional screening[9]. The global diabetes epidemic is steadily increasing in every country[10,11]. High prevalence, severe clinical characteristics and poor outcomes of pulmonary TB patients with DM highlight the necessity of early bidirectional screening and comanagement in Shanghai, China[12].

TB-DM comorbidity is characterized by increase inflammation with elevated circulating levels of inflammatory cytokines and other factors[37]. Cohort study by Kim found risk of DM RR=3.57 (95% CI 3.07-5.16) [38]. Prevalence of DM progressively increased 27.9%. Patients age 55-64 years had the highest association of DM (OR=3.53) compared with those under 45 years [13]. Adults with DM had significantly higher odds of TB (aOR 1.90; 95%CI 1.15–3.14) compared to adults

without DM after adjusting for age, sex, smoking status, history of active TB, and foreign born status[14].

DM were seven times represented in TB patient population (OR=6.6;95%CI=3.788–11.60) in comparison to the general population[15]. In Maryland, severity of DM affects the risk of developing TB adjusting for HIV status, age, weight, and foreign birth (OR=6.5 95%CI 1.1–38,P=0.039)[16]. TB infection prevalence among patients with DM type 2 was 51.3%[17]. In Asian population, DM is an independent risk factor for all cause mortality with HRs 1.17-1.27[13].The peak prevalence of DM observed in countries of Asia, North America, and Oceania[18].DM increased risk of developing and dying from an infectious disease[19].TB is the leading killer among global infectious diseases[35].

The third risk factor is gender.Male have risk 2.31 greater suffer pulmonary TB. Epidemiological information shows the differences between men and women in prevalence of infection, rate of progression from infection to disease, incidence of clinical disease, and mortality due to TB[20].Study from Iran, The incidence of TB in males and females was 62% and 38%[21]. Study populations in China, Male was significantly associated with increased risk of TB HR 2.36 (95% CI 1.30–4.30) [22].

South Nigeria; 2625 TB patient, 61.4% were males while 38.6% were females with ratio of 1.59[23].Male predominance in TB incidence which has been previously explained[24]. Investigation of TB Prevalence in Nigera Delta, male 63% of the prevalence while females 37%[25]. Kaplan–Meier survival analysis demonstrated significantly higher mortality in the men (p=0.005). Multivariate analysis, male was an independent risk factor (OR=1.96; 95% CI, 1.12–3.41)[26].

The fifth, education was the risk factor to TB. Study in US shown under High school graduate had risk 3.23 (95%CI 2.16–4.83) greater to latent tuberculosis infection[27]. Cross-sectional study in Semarang, Indonesia in 2012 found low education was 56.7% and high education was 43.3%[28].

Finding from this study active smoker is a protective factor (OR=0.46) to prevent pulmonary TB. It is needed continued study to examine the relationship of active smoker on patophisiology of pulmonary TB to determine the consistency of the effects of active smoker of pulmonary TB AFB positive. Using another design of study which is able to evaluate association between active smoker and tuberculosis correctly. Finding of active smoker in this study shows opposite result from another study. Smoking is causally associated with active tuberculosis[29]. Smoking is significantly associated with pulmonary TB in India (OR for mild, moderate and heavy were 2.28, 2.51 and 2.74)[30].

CONCLUSION

Ministry of health launched “find and treat until healing” program in 2016. One of indicator is case detection rate by investigation contact by health worker with population around index cases. A guideline on investigation among close contacts of infectious cases exist in regulation “Minister of health Number 67 year 2016” mentioned about investigation contact strategy[31]. WHO also has recommended contact investigation. Household contact investigation strategies can bring case detection in community. This strategies are particularly effective in high TB burden regions[32].

TB is a major cause illness and death worldwide especially in Asia and Africa. DOTS has lead to significant increase in the treat ment success (82.7%) (WHO target 85%) and decrease in the default and failure rates [40]. Continued program collaboration between TB and DM programs will help to integrate public health programs. DM is risk factor for the development of pulmonary TB and both disease present endocrine alterations likely to play in certain immune-endocrine-metabolic associated disorders[39].

Screening for active tuberculosis in DM should lead to earlier detection of TB[33]. Monitoring, recording and reporting on case numbers and outcomes are responsibility of collaborative framework between TB and DM programs.TB control in low and middle income countries are isoniazid preventive therapy for preventing TB among HIV and household contacts of infectious TB patients, clinical algorithms for diagnosing smear-negative TB disease in patients seeking care, screening algorithms for excluding TB-HIV-infected individuals eligible for preventive therapy, and programmatic provision of second-line treatment for multidrug-resistant TB[34].

Ethical Considerations: Ethics testing conducted by the Balitbangkes ethics committee. Written informed consent was obtained from all respondents before data collection was carried out.

Limitations

This study is a secondary data analysis, not all covariate variables were examined.

Conflict of Interest: Both author declared that no competing interest exist.

Acknowledgement: We thank to the Research and Community Development Center of University of Indonesia for the financial support and to Indonesian Ministry of Health who provided the data survey.

The Achievement of Ministry of Health Polytechnic Semarang as an Excellent Service University Upon Implementing A Decade of Internal Quality Assurance System

Lanny Sunarjo[1], Enik Sulistyowati[2], Triana Sri Hardjanti[3], Supriyadi[4]

[1]Ministry of Health Polytechnic, Semarang, Indonesia

ABSTRACT

Background: Since 2007 the head of the Semarang Health Ministry Polytechnic has established and implemented an Internal Quality Assurance System to guarantee the quality of services and graduates as well as to oversee the implementation of higher education regulations as a form of public accountability. The research objective was to examine trends in the level of student satisfaction with lecturer performance and education administration services since the quality assurance was implemented for a decade.

Method: The number of samples ranged from 10-20% with a random sampling technique from the population of Semarang Health Ministry Polytechnic students ranging from 5000 to 7,000 people spread across 7 campuses in 5 different cities in Central Java. Student satisfaction with lecturer performance and educational administration services is measured by giving questionnaires to students and then the data are analyzed by statistical correlation test of Pearson Product Moment.

Results: The results showed that for a decade the level of student satisfaction with lecturer performance and educational administration services continued to increase. There is a significant relationship between student satisfaction with education administration services.

Conclusion: Further research is qualitatively needed to assess the level of student satisfaction in a holistic manner related to matters that are considered important by students on lecturer performance and educational administration services.

***Keywords**: : Excellent Service, Quality Assurance, Health Polytechnic, A Decade.*

INTRODUCTION

Ministry of Health Polytechnic Semarang (MHPS) as one of the government-owned educational institutions that provide health education services in Indonesia is a community service institution that is an integral part of the national education system. Students are users of educational services, and administrative services are the essential resources for educational institutions [(1)]. Research on the level of student satisfaction with MHPS services shows that the level of student satisfaction is highest in aspects of lecturer performance, administrative and laboratory services [(2)]. Measuring the level of student satisfaction with lecturers' performance and administrative services in 1 decade (consecutive time) is very necessary for educational institutions as the primary capital in developing strategies to improve the quality of teaching, learning, various supporting services, and infrastructure. Improper strategy formulation can have a severe impact on institutions regarding improving the quality of education, design and curriculum development and institutional reputation [(3)]. On the other hand, if the strategy is formulated appropriately can have a significant impact on these matters above.

To improve and guarantee the quality of services and graduates, since 2007 PKS has implemented an ISO 9001-based Internal Quality Assurance System (SPMI) and obtained an ISO 9001 certificate in 2009 and obtained recertification every 3 years until June 2018. Based on the Decree of the National Accreditation Board of Universities High No. 0365 / SK / BAN-PT / Accredited / PT / I / 2017, MCC institutions have been

accredited with Good status. The accreditation of study programs is carried out by the Independent Accreditation Institution of Health Higher Education resulting in almost 50% of the 14 study programs with the A status accreditation (Excellent).

The level of student satisfaction with educational administration services is essential for higher education providers. The service is categorized as quality if the service received is following the expected service. The quality of higher education services is divided into 3 (three) dimensions, namely service to students, lecturers' abilities/performance and the physical environment of universities. The mission of MHPS is to organize a professional learning and teaching process. To support the implementation of the mission, it is necessary to analyze the extent to which the institution has provided services to its customers. Besides that, this is also an effort to support MHPS to maintain the certificate of ISO 9001 (*Quality Management System*) and improve the results of study program accreditation.

Since 2009 MHPS has been measuring and evaluating customer satisfaction every year, especially in the academic process which is the primary process of the education services business provided, based on the things mentioned above, the author wishes to examine the trend of the level of student satisfaction on the performance of lecturers and educational administration services from 2009 to 2017.

METHODOLOGY

This study included descriptive analytic research. The research data used were primary data from 2009 - 2017. Data collection techniques were used through observation, questionnaires, documents, and literature. The population is students spread across 7 campuses in 5 different cities in Central Java (Semarang, Magelang, Blora, Pekalongan, and Purwokerto) with an average of 5000-7000 students per year. Sampling is done by random sampling technique. The number of samples is calculated according to the formula [4] as below:

$$n = \frac{Z^2_{1-\alpha/2}\, P\,(1-P)\, N}{d^2\,(N-1) + Z^2_{1-\alpha/2}\, P\,(1-P)}$$

P = proportion of students not satisfied

d = precision = 5%

N = the number of students PKS

Z = 1.96

Based on this formula, each year the number of samples is obtained as follows:

Table 1. Sample Distribution

Year	Number of Samples (People)
2009	556
2010	624
2011	601
2012	512
2013	860
2014	850
2015	850
2016	850
2017	1150

Measurement of perceptions held students on lecturer performance and institutional administration services by giving questionnaires answered with Likert scale [5] ranging from Excellent (5), Good (4), Satisfactory (3), Poor (2), and Awful (1).

Items used to measure lecturer performance include: timeliness in the teaching and learning process, material mastery, the ability to arouse student attention to the courses given, ability to create student activities in thinking and acting, the ability to connect the lessons provided with the students' knowledge or experiences, the ability to choose the right learning media, providing refreshing on the material taught, giving opportunities for students to play an active role in group work, ability to understand and treat students according to their characteristics, and providing evaluations describing student progress, achievements, as well as shortcomings must be corrected.

The items used to measure educational administration services include the availability of learning physical administration facilities, accessibility and dissemination of learning administration service procedures, availability of building physical facilities, availability of physical media for learning, availability of administrative officers provide services, willingness of administrative officers to help and deliver services quickly, the friendly and trustworthy administrative officers and the attentive administrative officers.

The relationship between lecturer performance and educational administration services with student satisfaction was analyzed by using *Pearson Product Moment* correlation test with $\alpha = 0.05$.

RESULTS

The results of the validity test on lecturer performance variables between 0.508 to 0.698 and educational administration service variables are between 0.545 to 0.75. This shows that item statements to measure the variables of the performance of lecturers and educational administration services are valid. Further, the values of Cronbach's alpha ranged from 0.881 to 0.889. Thus the value of Cronbach's alpha on lecturer performance variables and education administration service variables is above 0.8 indicating that item statements to measure the variable performance of lecturers and educational administration services are reliable [6].

Age of respondents ranged from 18 to 22 years where most of the respondents were female (80%). The average level of student perceptions of the performance of lecturers showed that the highest student perceptions scored > 4 on the item "mastery of material" (4.15) and "giving students the opportunity to play an active role in group work "(4.04) while the lowest on the item "timeliness in the teaching and learning process" (3.64).

The level of student satisfaction with the performance of lecturers fluctuated with the lowest in 2010 (score 3.3) and the highest in 2017 with a score of 3.82. Most students (47.9%) are seen as "satisfied," and 37.6% with the category "dissatisfied" to the performance of lecturers and a small proportion of students felt very dissatisfied (7.8%) and very satisfied (6.8%). The highest score of student perceptions was > 4 on the item "availability of learning administration physical facilities in terms of attendance document, college journal, semester learning plan well "(4.04) and the lowest on the item of " availability of building physical facilities like lecture room, discussion and presentation room"(3.75). The score of student perceptions about the education administration service from 2009 to 2017 increased by 20% from 3.07 to 3.77. Most students (51.6%) were satisfied, and 34% of students felt dissatisfied with the educational administration services that had been done, while 7.5% of students felt very dissatisfied and 6.9% of students felt very satisfied. The results of the correlation analysis between lecturer performance and educational administration services with student satisfaction are shown in Table 2.

Table 2. Correlation between Lecturer Performance and Educational Administration Services to Student Satisfaction

No	Variable	Pearson Correlation	Coefficient of Determination (%)	p- Value
1	Lecturer Performance	0.579	33.50	0.102
2	Educational Administration Services	0.954	90.90	0,000

Table 2 shows a significant correlation (p-value <0.001) between educational administration services and student satisfaction levels while lecturer performance is not correlated with the level of student satisfaction.

DISCUSSIONS

The score of the level of student satisfaction towards the education administration service of the Ministry of Health Polytechnic Semarang (MHPS) from 2009 - 2017 has increased from year to year ranging from 20% from 3.07 to 3.77, approaching score 4 with satisfying categories. Continuous improvement is in line with the principle of the Internal Quality Assurance System which has been implemented by the Semarang Ministry of Health Polytechnic since 2007 to ensure the quality of services and graduates, oversee the ongoing implementation of higher education and as a form of public accountability, and education administration services begin 2 years later (2019). Improving the quality of education administration services continuously plays an essential role in maintaining and enhancing

the quality of education management [7]. In 2017, the Ministry of Health Polytechnic Semarang received an award certificate from the Ministry of Research and Higher Education , the Directorate General of Learning and Student Affairs for their earnest efforts in realizing a quality culture through the application of the Internal Quality Assurance System or in Indonesia is known as *Satuan Pengawas Mutu Internal* (SPMI). The use of internal quality assurance is an effort to improve the internal performance of educational institutions, especially teaching and learning methods and processes [8]. Since 2007 the MHPS has implemented SPMI based on ISO 9001, over time SPMI has been determined to follow government regulations and refer to the National Standards for Higher Education. The results of the application of SPMI have a significant impact on the results of accreditation, especially the accreditation of study programs, nearly 50% of the total 14 study programs have resulted in A (Excellent) accreditation status, the highest level in Indonesian educational accreditation system.

The results of this study indicate that better education administration services the higher the level of student satisfaction. The highest student perception scores > 4 are found on the item "availability of learning physical administration facilities (attendance document, college journal, semester learning plan) and functioning well." This result is consistent with the research conducted at the Nusa Dua Tourism College of Bali where academic service quality has a positive and significant effect on student satisfaction by 89.5% [9]. Student satisfaction can be increased by improving the quality of educational services through physical evidence variables, reliability, responsiveness, assurance, and empathy [10].

Educational administration services are positively correlated with student satisfaction. The quality of service dramatically influences customer satisfaction — services provided by service providers in proving something that is not really so that consumers can feel the services provided to consumers. Customer satisfaction is determined by various types of services customers get as long as they use several stages of the service. Satisfaction obtained in the early stages of service can lead to perceptions of excellent service quality for the next step so that customers feel satisfied with the overall service. The service situation is related to the internal conditions of the customer so that it affects service performance. Service performance can be determined by function, service process and the physical environment where service is provided. Customer perception of a service is determined by the three things above. Therefore, service providers must provide services beyond what is expected by consumers so that these service providers become the best from other service providers [11].

CONCLUSION

Although students of the Semarang Ministry of Health Health Polytechnic have been satisfied with the performance of lecturers and educational administration services, these institutions must continue to improve and improve SPMI continuously in line with the needs of stakeholders including students. To maintain lecturer performance and educational administration services, institutions need to allocate monetary resources to focus on developing human resources, especially discipline and expanding learning facilities on campus. Further research is qualitatively are necessary to assess the level of student satisfaction in a holistic manner related to matters that are considered important by students on lecturer performance and educational administration services.

Ethical Clearance: Ethical clearance was obtained from The Ministry of Health Polytechnic Semarang, Indonesia. We also wish to thank all the participants who contributed to this study.

Snakehead Fish (*Chana striata*) Powder Formulation for Increasing Calorie and Protein Intake in Malnourished Children

Magdalena[1], Mahpolah[1], Ismi Rajiani[2]

[1]Ministry of Health Polytechnic Banjarmasin, Indonesia, [2]Department of Business Administration, STIAMAK Barunawati Surabaya, Indonesia

ABSTRACT

Background: The cases of malnutrition in South Kalimantan are still high, and two districts which are included in the prevalence of undernourishment are South Hulu Sungai District and Batola District. This study aims to increase protein intake in children with malnutrition by giving additional input in the form of snakehead fish powder.

Method: The method of this study was quasi-experimental. This study used two groups with one treatment. The study was conducted at Berangas Health Center, Alalak Sub-District, Barito Kuala District, South Kalimantan. The research subjects were 50 people, with criteria for malnourished children under five who did not increase their weight scales in rows twice. The analysis used the t-test with the significance level used was $p < 0.05$.

Results: There was no difference in calorie intake between the group who received conventional toddler formula and the group who received the fish formula, and there was a difference in protein intake between the group who received conventional toddler formula and the group that received the recommended fish formula.

Conclusion:. The formula of snakehead fish is perfect for sufferers of malnutrition because the high protein in snakehead fish contains high levels of albumin that can improve cells and body tissues and help to boost growth in toddlers.

Keywords: *Malnutrition, toddlers, snakehead fish, South Kalimantan*

INTRODUCTION

Indonesia as a developing country still faces considerable nutritional problems. Malnutrition in children under five occurs because at that age more nutritional needs and toddlers are stages of maturity that are prone to nutrition. Lack of energy and protein is malnutrition due to low consumption of energy and protein in daily food, so it does not meet the nutrition adequacy rate.

Corresponding Author:
Magdalena
Ministry of Health Polytechnic Banjarmasin, Indonesia
email: lenarere@yahoo.co.id

Protein deficiency is one of the leading nutritional problems that is often found in toddlers in Indonesia and other developing countries. Protein deficiency has an impact on growth, intellectual development, and productivity between 20 - 30%, while also having a direct effect on morbidity and mortality [(1)].

Based on Research data in 2013 cases of under nutrition in South Kalimantan were 8.2%, malnutrition 19.2% and tends to continue in recent years. This figure shows that cases of malnutrition in South Kalimantan are still high mainly in two districts: South Hulu Sungai District and Batola District. Malnutrition data in the Berangas Health Center in Alalak Subdistrict, Barito Kuala Regency up to June 2016 were: 1 malnutrition (0.045%), toddler (under the red line) 73 toddlers (3.3%)

and those treated in TFC (Therapeutic Feeding Center) as many as six people. This case increased compared to data in 2015, cases of malnutrition were one person (0.045%), toddlers 53 people (2.31%) and none were treated at TFC. In 2017, malnutrition continued to increase in Alalak District as many as 374 children under five (30.6%) with the highest nutritional status, namely in Beringin Village as many as 57 toddlers (16%) [2].

Nutritional therapy in malnourished children has a significant role in accelerating the healing of diseases. Errors in feeding will slow the healing of the disease. Excess or lack of nutrition can worsen the condition of the child, and can even cause death. Therefore, parents should be informed about the patient's rights in the care and feeding of malnourished children. Nutritional therapy for sufferers of malnutrition is applied in several phases, namely: the stabilization phase, the transition phase and the rehabilitation phase [3].

Various studies to improve nutritional status in sufferers of malnutrition including by providing snakehead fish extract which has a high albumin content can help increase albumin levels in patients with poor nutrition with low albumin levels below 2.5 mg%. Other studies also reported that the use of snakehead fish as a source of protein turned out to maintain the albumin value of patients hospitalized in the hospital so that it can help speed up the healing process of patients [4]. This study aims to determine the formula for fragrant fish to increase calorie intake and protein in children with malnutrition.

RESEARCH METHOD

This study was a quasi-experimental study, and this study used two groups with one treatment.. The research location was carried out at Berangas Health Center, Alalak District, Barito Kuala District, South Kalimantan. The subjects of the study were 25 control groups and 25 treatment groups with the criteria of malnourished children who did not increase their weight scales twice — respondent data consisting of name, age, gender. The data was collected by interviewing and filling out the questionnaire. Food intake data (formula of potatoes with snakehead fish) were obtained by talking the subject directly by using a 2x24 hour food recall form for two times a day. 2x24 hour food recall results were analyzed using *Nutri2008* — a different test using t-test. Toddler formula is a modification of the formula F 100 plus a special biscuit for toddlers. Snakehead Fish Formula is a modified formula for sufferers of malnutrition consisting of food ingredients: snakehead fish, potatoes, carrots, milk, vegetable oil, sugar, and salt.

RESULTS

The difference in calorie intake in the group of malnourished children under five who received formula toddler compared to the group of malnourished children under five who received the formula for snakehead fish was p = 0.079, which means there was no difference in calorie intake in the two groups. Differences in protein intake in the group of malnourished children under five who received formula toddler compared to the group of malnourished children under five who received snakehead fish formula was p = 0, 016 which means there is a difference in calorie intake in both groups.

Table 1. Calorie Intake Rate of Malnutrition Patients

Calorie Intake Rate Category	Toddler Formula Group		Snakehead Formula Fish Group		p-value
	n	%	n	%	
a. Over	17	68	7	28	
b. Good	5	20	5	20	
c. Mild Deficit	1	2	4	16	0.079
d. Moderate Deficit	0	0	2	10	
e. Severe Deficit	2	10	7	26	
Total	25	100	25	100	

Table 1 shows most levels of caloric intake in the group that received toddler formula were in over categories, namely 68% while in the group that received the formula for snakehead fish the biggest category was also over (28%) with p-value = 0.079.

Table 2. Protein Intake Under Nutrition Patients

Calorie Intake Rate Category	Toddler Formula Group		Snakehead Formula Fish Group		p-value
	n	%	n	%	
a. Over	11	44	14	64	
b. Good	12	48	6	16	
c. Mild Deficit	1	4	1	4	0.016
d. Moderate Deficit	0	0	2	8	
e. Severe Deficit	1	4	2	8	
Total	25	100	25	100	

Table 2 shows the level of protein intake in the group that received formula toddlers is mostly in the over category, which is 44%, while the group that gets the formula for snakehead the biggest category is also over (64%) with p-value = 0.016.

DISCUSSION

Optimizing the handling of nutritional problems in children under five can be done through diversifying the development of additional food formulas by considering the nutritional aspects, health benefits, acceptability, endurance and local food resource advantages —local food material, among others, in the form of snakehead fish (*Chana striat*) [5].

The advantages of snakehead fish include the womb protein is higher than other food ingredients such as eggs, chicken, and beef. Besides, collagen protein of snakehead fish is also lower than livestock meat, which ranges from 3-5% of total protein. Low collagen causes snakehead fish meat becomes easier to be digested by babies, elderly groups, and also people who just recovered from illness. [8]. Besides the snakehead fish is known as a fish that can heal wounds, reduce pain, and postoperative discomfort [9]. Many snakehead fish are caught in the area the waters of Kalimantan that are not far away from the community living area , and the processing is still limited to being dried fish or sold freshly. Potential of snakehead fish development for other purpose is big but if consumed directly there are still people who don't feel willing to consume because of the original head shape snakehead fish resembles a snake. If consumed fresh, it requires more seasoning because snakehead fish tastes plain. Processing of fish snakehead into flour can be an alternative in decreasing fishy aroma and enhancing acceptance and consumption of snakehead fish [10].

The level of caloric intake in toddlers who get formulas in the form of biscuits and milk, is more in the over intake category (68%), because the calorie content of cookies every 100 grams is 458 kcal, and in milk powder skim every 100 grams is 362 kcal. The form of food in the form of biscuits which are packaged in dry form becomes small portions, but the calorific value is high. The level of caloric intake in the group that received the formula for snakehead fish was much the same in the category of more consumption (28%) and the level of heavy deficit intake (28%). For comparison, 100 grams of potato contain 83 kcal, skim milk every 100 grams is 362 kcal and fragrant fish every 100 gram is 74 Kcal.

The level of protein intake in group I which received formula for toddlers was at most good intake categories (48%), and protein intake in group II who received the formula for the most type was 64%. The calorific value of fresh fish in 100 grams is 25.2 grams. Herring protein is also high in albumin. The high albumin content in snakehead fish causes this fish is used to overcome hypoalbumin [6].

Based on statistical tests (p = 0.079), there was no difference between group I calorie intake (toddler formula) and group II calorie intake (snakehead fish formula), and there was a difference between group I protein intake (formula toddler) with group II (fish formula snakehead) with a value of p = 0.016.

Calories in toddler formulas are given according to the condition and condition of toddlers' weight of malnutrition, formula F 100 containing 1000 kcal, protein 29 grams plus 30-gram biscuits at 137.4 kcal, protein 6.9 grams so that it amounts to 1137.4 kcal and 35, 9 grams of protein. This can increase calorie and protein intake for all malnourished toddlers. The formula, F 100 consists of 50 grams of sugar, 60 grams of vegetable oil, 80 grams of skim milk, added mineral mix and water could be in the form of a gel, so that it is diluted plus water and stirred until homogeneous, making it easy to consume. The number of Calories in a fragrant fish formula with a composition of 200 grams of potatoes, 10 grams of sugar, 20 grams of skim milk, 50 grams of harp fish, 30 grams of carrots, and 10 grams of vegetable oil for two recipes are 1142 Kcal and 36.6 grams of protein.

The value of calories and protein that are not different in the two formulas can be a reference for giving formulas to better sufferers of malnutrition. The difference in protein intake is more significant in the group that gets the formula for snakehead fish can be provided more often for sufferers of malnutrition. Snakehead fish that have high protein values also contain high albumin, and its function is to maintain fluid balance in the body that can prevent edema [7]. Another feature of albumin is to help the formation and repair of cell tissue in the body for the development and growth of thermal children [8].

Snakehead fish has a very high protein content of albumin, the results of the study revealed that in the nutritional content of snakehead fish there was 6.2% albumin. Albumin is a type of protein that is found in 60% of human blood plasma whose function is to maintain and improve tissue and improve health in patients with malnutrition and poor nutrition [4].

CONCLUSION

There is no difference in calorie intake in the group that received formula toddlers with a group of toddlers who received formula of fragrant fish. There was a difference in protein intake in the group that received formula toddlers with a group of toddlers who received formula of fragrant fish. The formula of snakehead fish is perfect for sufferers of malnutrition because high protein snakehead fish also contains high levels of albumin that can improve cells and body tissues and help to enhance the growth of toddlers.

Spatial Analysis of Hypertension Risk Factors Incidence in South Kalimantan Province

Suroto[1], Mahdalena[1], Ismi Rajiani[2]

[1]Ministry of Health Polytechnic Banjarmasin, Indonesia, [2]Department of Business Administration, STIAMAK Barunawati Surabaya, Indonesia

ABSTRACT

Background: This study aims to identify spatial effects on risk variables that influence the incidence of hypertension in South Kalimantan Province because the region has specific geographical variations.

Method: The research method used is cross-sectional with a population of all households in the province, city districts in Indonesia. The data to be analyzed in this study is the incidence of hypertension data in 13 regencies of South Kalimantan Province.

Results: It is identified 5 groups of districts/cities in South Kalimantan Province that have similarities regarding risk factors affecting the incidence of hypertension.

Conclusion: The results obtained can be used by the relevant leaders as a consideration in determining policies to suppress and control the incidence of hypertension in the province of South Kalimantan by considering factors related to specific hypertension disease in the regency/city area of each group.

Keywords: *Spatial, Hypertension, South Kalimantan, Indonesia*

INTRODUCTION

Hypertension is one of the non-communicable diseases that become public health problem [(1)]. Uncontrolled hypertension can lead to degenerative diseases, such as congestive heart failure, kidney failure and vascular disease [(2)]. Hypertension is called the silent killer because it is asymptomatic and can cause fatal strokes. Although it cannot be treated, prevention and management can reduce the incidence of hypertension and accompanying diseases. Hypertension is the number 3 cause of death after stroke and tuberculosis, reaching 6.7% of the death population in all ages in Indonesia [(3)].

According to the guidelines of the World Health Organization (WHO) in 2011, one billion people in the world suffer from hypertension, two-thirds of whom are in developing countries that are low-middle income [(4)]. The prevalence of hypertension will continue to increase sharply, predicted in 2025 later, around 29% of adults worldwide suffer from hypertension. Hypertension has resulted in the deaths of approximately 8 million people each year, 1.5 million deaths occur in Southeast Asia, of which a third of the population suffers from hypertension [(5)].

Based on basic health research in 2013, the prevalence of hypertension in Indonesia obtained through measurements at ≥ 18 years of age was 25.8% revealed the highest in Bangka Belitung 30.9%, followed by South Kalimantan 30.8%, East Kalimantan 29.6% and West Java 29.4% [(6)]. The prevalence of hypertension in Indonesia obtained through a questionnaire diagnosed by health personnel was 9.4%, diagnosed by health personnel or taking medication at 9.5%. So there are 0.1% who make their own medicine — respondents who have normal blood but are taking hypertension medication at 0.7%. Thus the prevalence of hypertension in Indonesia is 26.5%.

The aim to be achieved in this study is to identify spatial effects on risk variables that influence the incidence of hypertension in the province of South Kalimantan.

METHOD

This research is a secondary data-based documentation study. To complete the information contained in the research objectives required primary data collection through observational research with a survey approach. The data used were data from the 2013 Basic Health Research (Riskesdas) and BPS. The data is the result of a descriptive cross-sectional survey with a population of all households in the province, city districts in Indonesia. Primary data was also taken through a questionnaire on the respondents include knowledge, attitudes, self-concept, and family support — the location of this research in Banjarmasin Kalimantan Selatan. The research period was 2015 to 2016.

The data to be analyzed in this study is the incidence of hypertension in 13 regencies of South Kalimantan Province.

Table 1: Description of Research Variables

Variables	**Description of Variables**	**Types of Variables**
Y	Percentage of residents who have been diagnosed with hypertension / high blood pressure by health personnel	Response
Variables	Description of Variables	
X_1	Percentage of male population	Predictor
X_2	Percentage of population with primary education	Predictor
X_3	Percentage of population with smoking habits every day	Predictor
X_4	Percentage of people who have moderate physical activity habits.	Predictor
X_5	Percentage of population who have fruit consumption habits seven times a week	Predictor
X_6	Percentage of people who have a habit of consuming vegetables seven times a week	Predictor
X_7	Percentage of people who have a habit of consuming salty food more than one time per day	predictor
X_8	Percentage of people who have the habit of eating food fat/cholesterol / fried more than one time per day	predictors
X_9	Percentage of population with medical assurance / veteran / retired	predictors

RESULTS

The full Geographical Weighted Regression (GWR) model for each location is presented in the Appendix. Districts in South Kalimantan Province have different models of the prevalence of hypertension. Based on the variables that are significant for each area, a grouping of districts/cities is formed that has similar variables which significantly influence the prevalence of hypertension. The cluster of districts/cities that have related variables that have a significant effect on the incidence of hypertension is presented in Table 4

Table 2: District / City Grouping Based on Significance

Spatial Groups	Variables significance	Variables Description of Variables
Tanah Laut	X3, X4, X6	Percentage of hypertensive patients diagnosed (Y) Percentage of the population of male sex (X_1) Percentage of population with basic education (X_2) Percentage of population with daily smoking habits (X_3) Percentage of people with physical activity (X_4) Percentage of the population consuming fruit - ingredients seven times in 1 week (X_5) Percentage of people who consume vegetables seven times in 1 week (X_6) Percentage of people who drink salty food more than 1 time per day (X_7) Percentage of the population consuming fatty food consumption/cholesterol / fried food more than one time per day (X_8) Percentage of population with health insurance ownership (X_9)
Tanah Bumbu	X3, X4, X6	
Kota Baru	X4, X8	
Banjar	X4, X5, X6, X7	
Kota Banjarmasin	X4, X5, X6, X7	
Banjar Baru	X4, X5, X6, X7	
Barito Kuala	X3, X4, X9	
Tapin	X1, X5	
Hulu Sungai Selatan	X1, X5	
Hulu Sungai Tengah	X1, X5	
Hulu Utara River	X1, X5	
Tabalong	X1, X5	
Balangan	X1, X5	

Grouping based on significant variables is divided into five groups. There are districts/cities that have similar variables that have a significant effect on the surrounding areas, but there are districts/cities that have their uniqueness because the variables that are having a significant impact are not the same.

Based on the results of spatial regression, there are five groups. Districts/cities that have similar variables that have a significant effect on the surrounding districts/cities. The results of the above study indicate that group 1 consists of Tanah Laut and Tanah Bumbu Districts with characteristics Percentage of population with daily smoking habits (X_3), Percentage of people with physical activity (X_4), Percentage of the population consuming vegetables seven times in 1 week (X_6). Group 2, Kota Baru Regency with the characteristics of the percentage of the population having physical activity (X_4), Percentage of the population consuming consumption of fatty/cholesterol / fried foods more than once per day (X_8). Group 3 consists of Banjar Regency, Banjarbaru City, Banjarmasin City, with characteristics Percentage of population who have physical activity (X_4), Percentage of people who consume fruits 7 times in 1 week (X_5), Percentage of population consuming vegetables 7 times in 1 week (X_6), the percentage of people who drink salty food more than 1 time per day (X_7). Group 4 in Barito Kuala Regency with characteristics Percentage of population with smoking habits every day (X_3), Percentage of people with physical activity (X_4), Percentage of population with Askes / JPK PNS / Veteran / Pension ownership (X_9). Group 5 consists of Tapin Regency, Hulu Sungai Selatan, Hulu Sungai Tengah, Hulu Sungai Utara, Tabalong, Balangan with characteristics Percentage of the population of male sex (X_1), Percentage of the population consuming fruits seven times in 1 week (X_5).

DISCUSSION

Spatial analysis is a set of methods for finding and describing the level/pattern of a spatial phenomenon so that it can be better understood. By conducting spatial analysis, new information is expected to emerge which can be used as a basis for decision making in the area under study. The methods used are very varied, from visual observation to the use of mathematics / applied statistics [7].

As a method, spatial analysis seeks to assist planners in analyzing the condition of the problem based on data from the target area. And the concepts that underlie a spatial analysis are distance, direction, and relationships. The combination of the three regarding a region will vary to form a significant difference that distinguishes one location from another. Thus distance, direction, and the relationship between the position of an object in an area with objects in another region will have a clear difference. And these three things are things that are always present in spatial analysis with certain stages depending on the planner's perspective in looking at a problem of spatial analysis [8].

The analysis using the Geographic Weighted Regression (GWR) method aims to determine the variables that influence the prevalence of hypertension at each observation location, namely the sub-district in the province of South Kalimantan. The result described is the prevalence of hypertension modeling using the Geographic Weighted Regression (GWR) method.

CONCLUSION

The results obtained can be used by the relevant leaders as a material consideration in determining policies to suppress and control the incidence of hypertension in the province of South Kalimantan. By considering factors related to specific hypertension disease in the regency/city area of each group.

Health Improvement after Childbirth with Traditional Snack Consumption

Serilaila[1], Betty Yosephin Simanjuntak[2], Lela Hartini [3], Mahpolah [4]

[1]Department of Midwifery, Ministry of Health Polytechnic Banjarmasin, Indonesia, [2]Department of Nutrition, Ministry of Health Polytechnic Bengkulu, Indonesia, [3]Department of Midwifery, Ministry of Health Polytechnic Bengkulu, Indonesia, [4]Department of Nutrition, Ministry of Health Polytechnic Banjarmasin, Indonesia

ABSTRACT

Background:. After giving birth, most mothers complain of pain, so they are not fit. Traditional ingredients is usually consumed by postpartum mothers to restore health, but no research has been carried out to find the effectiveness. The study aimed to determine the effect of consuming traditional food called *kekerit* on fitness by using rats before applied further to human beings.

Method: The study was conducted using *randomized pre-post test control group design* on female, white rats that were made pregnant and waited until delivery. The sample was 18 rats consisting of 9 treatment groups and nine control groups. The study was conducted at the Laboratory of the Faculty of Veterinary Medicine, Bogor Agricultural University of Indonesia by assessing fitness through swimming three times on days 1, 5 and 11, and then the data were analyzed by employing *t-test.*

Results: The mean swimming pool of intervention rats 101.00 ± 6.65 seconds compared to controls 68.65 ± 6.58 seconds on the first day and there was a significant difference in the fitness of rats with p= 0.039 .

Conclusion: Upon successful completion test on rats, the health of postpartum mothers may be accelerated to recover after consuming *kekeri*t, but further research is needed to examine the feasibility.

Keywords*: Fitness, Strength, Post-Partum, traditional snack*

INTRODUCTION

After giving birth as many as 76% of women experience at least one health problem within eight weeks after giving birth. Feeling discomfort in the form of pain after childbirth, excessive sweating, breast swelling, constipation, hemorrhoids and perineal pain [(1)]. Overcoming this problem some people believe in doing taboos [(2)]. Perform rituals or drink concoctions so that they can improve health and strengthen the body [(3)].

The culture of drinking potions, usually herbs, especially Javanese people in Indonesia, is believed to be efficacious as a traditional treatment that is safer and cheaper compared to modern medicine. Mothers do this during pregnancy, childbirth, childbirth, and breastfeeding by 80.5% every day to drink it as an effort to maintain health [(4)]. This habit occurs in postpartum mothers, especially the Sundanese in the Permu Immigration Village, Kepahiang District, Bengkulu Province, in the form of consuming *kekerit* as a snack that is believed to be able to restore health during the postpartum.

Kekerits snack is a traditional powdered food consumed during childbirth consisting of grains, discoveries, cooking spices and leaves, roots or stems. Ingredients consist of the keratin grain the form of: *Oryza sativa, Arachis hypogaea L, Phaseolus radiatus L, Glycine max*, and a little *Zea mays* ssp. Mays. The herbs and spices: *Zingher officinale rocs*, *Kaempferia galangal L*, *Curcuma domestica Val,* as well as Various spices: *Myristica fragrans Hout, Ammonium cardamom*

Corresponding Author: Serilaila
Department of Midwifery,
Ministry of Health Polytechnic Banjarmasin, Indonesia
E-mail: serilaila11@yahoo.co.id

and other leaves such as medicinal plants [5].

Kekerit Snacks have been prepared and made by parents or family since the age of pregnancy over seven months. The way to make it is still simple using all the dried ingredients (the results of drying) are roasted and after being cold pounded until smooth and stored in a jar to be ready to be served. This habit has been passed down from generation to generation, originally from the Sundanese but because of its efficacy, other tribes such as Java, and the Serawai or Rejang tribes from the Bengkulu province also followed, thus becoming the local wisdom of this village [6].

The paradigm that develops in today's society, consuming *kekerit* as a traditional herb is felt to be beneficial which is harmless and has no side effects. This assumption is not entirely correct, for that there needs to be scientific proof through clinical trials using experimental animals such as a rat. The existence of these tests is expected to be able to find out the benefits of creaking in improving health, especially fitness. The purpose of this study was to determine the effect of consumption of snacks *kekerit* by a rat on physical fitness after childbirth.

METHOD

This research was conducted by *randomized pre-post test control group design,* which is to perform fitness tests in the treatment group by giving extra food *kekerit* while the control consumed only food standard ration from the Food and Drug Supervisory Board of the Republic of Indonesia (BPOM RI). The research was carried out at the Laboratory of the Faculty of Veterinary Medicine, Bogor Agricultural University, from April to September 2016. Samples were used by rat *Striped Sprague Dawley* female who had given birth to 18 children, aged 2.5-3 months, weighing 150-300grams.

Each experimental group was divided into 3 for observation of fitness on days 1, 5 and 11 in the control group or treatment through swimming test. The fitness test is carried out using rat swimming in a rectangular tub filled with water. Each mouse swims three times and counts in seconds from starting to swim to being unable to swim.

Before the treatment, rats were acclimatized for two weeks, and then rats were synchronized lust by using prostaglandin preparations with the double injection method. After that, the rats have been mated together using a 1: 3 comparison stud. Then the pregnant rat has waited until they give birth within 22-25 days.

Each rat was given a food ration based on the Indonesian Supervisory Food and Drink Board standard and placed in groups with the same environment and treatment, and the room temperature was set with a range of 20-28ºC, 50 + 10% humidity and a 12-hour dark-light cycle (RSPCA, 2011). Shortly after giving birth, the rats were weighed and then the treated rats were fed snacks *kekerit* with through the stomach every day with a dose of 0.370 gr/kg body weight as much as one administration at 9-10 is.

RESULTS

The content of substances Nutritional *Kekerit* Snacks

Kekerit snacks laboratory tests have been conducted at Bogor Agricultural Biochemistry at the content of nutrients contained in these foods are as follows:

Table 1. Substance Nutrient Content

No.	Component	%
1.	Macro Nutrient	
	a. Substances.Water	4.3% gr
	b. Ash	0.5% gr
	c. Protein	18.7% gr
	d. Fat	38.4% gr
	e. Rough Fiber	0.5% gr
	f. Carbohydrate g. Energy	5.6% gr 443 Kcal
2	Vitamins	
	Vitamin A	2.5 mcg / g
3	Analysis of minerals	
	a. Ferum	3.94 mg / g
	b.Zinc	0.22 mg / g
	c. Magnesium	0.02mg / g

Source: Biochemical Laboratory, 2016

Examination of bioactive components is analyzed to see whether there is nothing (qualitative) does not assess how much. Qualitative analysis results detected were flavonoids, triterpenoids, phenol and tannin (Table 2).

Table 2. Qualitative Analysis of Bioactive Components

	Qualitative Analysis	Indicators
	a.Alkaloid	Negative
	b.Flavonoids	Positive
	c.Triterpenoid	Positive
	d. Phenol	Positive
	e.Hydroquinone	Negative
	f.Saponin	Negative
	g. Tannins	Positive

Kekerit Snacks Effect Against Rat Physical Activity

Physical healthiness assessment of rats can be seen from the ability to swim and judged by the length of time that can be carried by rats to swim.

Table 3. Effect of Giving *Kekerit* Snacks Based on Swimming Time

Day	Parameters	Control	Treatment	*p-value*
1	Second	68.65 ± 6.58 101.00	± 6.65	0.039 *
5	Seconds	87.15 ± 18.17	129.50 ± 52, 04	0.391
11	Seconds	67.30 ± 9.90	173.15 ± 36.98	0.06

*Note: test paired sample t-test * <0.05 = significant*

DISCUSSION

Health for every human being is something important for activities. Fitness, especially from the first day after giving birth can support health, primarily due to pain and fatigue after childbirth [7]. Previous research has shown that postpartum mothers are physically active characterized by higher health awareness and can reduce the risk of postpartum depression [8].

The results showed that, the swimming ability of rat given snacks *kekerit* was longer. On the first day of, the control rats were only able to survive swimming for 68.65 seconds while the rats that received *kekerit* snacks were able to survive for 101 seconds. This situation shows that these rats are more fit than control rat, because swimming means being able to do activities and of course in a fit condition [9].

The ability to engage in energy needs, *kekerit* snacks contain 443 calories of energy derived from food in the form of 70% grain. The food is from black sticky rice, peanuts, soybeans, corn which is an energy source. High energy content in this substance can meet the additional food requirements during childbirth and breastfeeding. In the first six months it takes 330 calories of energy, 20 g of protein, 11 g of fat, 45 g of carbohydrate [10]. Based on Table.1 *Kekerit* snacks can meet these needs in 100 grams containing 18.7 grams of protein, 38.4 grams of fat, 5.6 grams of carbohydrates and 443 calories. The content of this nutrient can be an additional source of daily nutrients for nursing mothers. Nursing mothers generally feel hungry faster because at the same time the mother must fulfill her nutritional needs and produce milk. *Postpart*um mothers often consume *kekerit* snacks until 40 days postpartum. This high enough energy is good for supporting breastfeeding for babies and preventing supplementary feeding which is usually the reason for mothers not to breastfeed exclusively [11].

The presence of protein in *kekerit* snacks is beneficial in the postpartum period which functions as improving aerobic performance (endurance), increasing anaerobic capacity to increase strength and energy [12]. Also, protein is an essential substance for the structure and function of the body and the recovery of reproductive organs during postpartum [13].

The results of previous studies reported that, herbal medicine *Galohgor* contained Fe 0.221 mg, and Zinc 0.34 mg. While this study obtained a higher Fe content,

ie 3.94 mg and Zinc lower than 0.22 mg (Table.1). The need for Fe is 26 mg for breastfeeding mothers with an addition of 6 mg. Iron in food is in the form of iron-hem as in hemoglobin and myoglobin animal foods, and iron-them in plant foods. Iron can be absorbed by the body up to 25%, while ironnonhem can be absorbed by the body only 5%. 100% *kekerit* snack in plant foods, then 0.197 mg is absorbed and if the mother consumes 50 gram *kekerit* snacks per day, about 31% can be fulfilled from *kekerit* and can prevent the occurrence of anemia due to Fe deficiency and such cases often occur in postpartum mothers as much as 50-60% [14].

Flavonoids are beneficial for health as an anti-inflammatory, anti-oxidant and antiproliferative and anticancer activity [15]. Flavonoid food sources in kekerit snacks come from nuts which are as anti-oxidant [14]. In *kekerit* snacks contain spices such as kencur, ginger, turmeric. Ginger and turmeric contain flavonoids and *triterpenoids* (Table 2) can be used as a source of antioxidants and treatment of chronic diseases and mineral deficiencies [10]. *Triterpenoid* is a component found in plants that have an odor and can be isolated from plant material which functions to capture free radicals in the human body. One of the ingredients of *kekerit* is *Centella Asiatica* which contains *triterpenoids* which can improve the body's immune system, which contributes to the fitness of post-partum mothers [16].

CONCLUSION

Kekerit snacks tested at the rat can be beneficial to the health of postpartum mothers, supported from existing content in the form of macro-nutrients, vitamins and minerals, and antioxidants. Further testing needs to be done to humans or postpartum mothers so that the immediate effects and benefits are known that *kekerit* is a healthy traditional snack.

Ethical Clearance: This research has been carried out and obtained ethical approval from the Health Ministry Polytechnic Research Ethics Commission in Bengkulu (Approval Number: DM.01.04 / 007/3 / V / 2016). The authors would like to thank the laboratory of the Faculty of Veterinary Medicine and the laboratory IPB Biochemistry that has helped in the research process. The assistance provided is meaningful for the completion of this study.

Conflict of Interest: The author states that in this study there were no conflicts of interest.

Source of funding: We thank you especially to the Bengkulu Health Ministry of Health Polytechnic Indonesia for financing and supporting this research with the Decree of the Head of the Health Resources Education Center No: HK.02.04 / III.1 / 03234/2016.

Evaluation of Apelin, Periostin and Tartrate-resistant Acid Phosphatase-5B in Ankylosing Spondylitis Male Patients According to their Disease Activity

Israa Abdelmalik Salem[1], Adnan F. Al-Najar[1], Abbas Toma Joda[2]

[1]Department of Chemistry and Biochemistry, College of Medicine, Al-Mustansiriyah University, Baghdad, Iraq,
[2]Department of Medicine, College of Medicine, Al-Mustansiriyah University, Baghdad, Iraq.

ABSTRACT

Introduction: Apelin is a proinflammatory adipokine that can be induced by other inflammatory mediators. Periostin is produced by different types of tissue under the influence of inflammation and mechanical stress.

Aim: The aim of this study was to evaluate serum (Apelin, Periostin (POSTN), and Tartrate-resistant acid phosphates (TRACP)-5b among ankylosing spondylitis (AS) male patients with active and inactive disease and find the correlation between disease activity and the studied parameters.

Material and Methods: Fifty-eight male Ankylosing spondylitis (AS) patients were included in this study. Serum Apelin, Periostin (POSTN), and tartrate-resistant acid phosphates (TRACP)-5b were measured using commercial enzyme-linked immunosorbent assay (ELISA) kits. Disease activity was determined by using a BASDAI score.

Results: Ankylosing spondylitis (AS) male patients with active disease had a significantly high serum level of serum TRACP-5b (P-value <0.001) while serum of (Apelin and Periostin) levels shows no significant differences (P-value > 0.05) when to AS males with inactive disease.

Conclusion: The results of this study suggest that serum Apelin and periostin levels show no differences among AS male patients with active when compared to AS male patients with the inactive disease, but serum TRACP-5b was elevated in AS male patients with active disease.Correlations between disease activity (BASDAI score), and serum POSTN and with serum TRACP-5b have been found.

Keywords: *Ankylosing spondylitis, Apelin, Periostin, TRACP-5b, and BASDAI.*

INTRODUCTION

Ankylosing spondylitis (AS) is a chronic, systemic rheumatic disease with long-term inflammation that affects mostly the joints of axial skeleton (sacroiliac and other joints in the spine (vertebra) and less commonly peripheral joints[1]. AS influence the quality of life, the newly formed bones (at vertebral sides) is the main factor to determine the disease's outcome[2]. Morningstiffness of more than one hour, fatigue and the pain in the lower back at the night and in the morning arethe mainsymptoms of AS[3]. The pathogenesis of AS consist of a number of different inter-related processes, each of which is controlled by different pathways and factors[4]. There is a combination of genetic and nongenetic factors leads to clinical disease[5]. Ankylosing spondylitis is mostly affecting young people[6]. AS is seen in male more than female, the ratio of 2:1, and the familial occurrence is common[3,7]. The diagnosis of AS before the occurrence of permanent damage is not easy, the diagnosis usually delays between 5 to 10 years from the onset of disease symptoms due to missed diagnose of young men with

inflammatory back pain (IBP) and the radiographic changes in the sacroiliac joints (a late feature of the disease) needed many years to appear by conventional radiology[1,8,9]. The diagnosis of AS is made by a mixture of radiological changes, clinical features, and laboratory results, however, classification criteria are available for patient categorization[3]. Apelin is a one of adipokines, is an endogenous peptide that has the ability to bind to the apelin receptor (APJ or AR) which is also known as an orphan G protein-coupled receptor (GPCR)[10]. Apelin can act as pro-inflammatory adipokines, in addition to that other inflammatory mediators such as (TNF-α and IL6) can induce it is an expression[11]. It has been found that apelin increases in obesity, cardiovascular disease, cancer[12-15].

Periostin (POSTN) is a 90 KD, secretory matricellular protein consisting of 836 amino acids in human [16]. POSTN is a multi-functional proteinsince it can express by a wide range of human tissue due to mechanical stress or injury[17]. It is involved in the bone anbolism via regulation of Wnt-β-catenin signaling. It also plays a major role in the pathogenic mechanisms of syndesmophyte formation in ankylosing spondylitis[36]. TRACP-5b is specifically from osteoclast thus TRACP-5b considered as a new, sensitive important biomarker of bone resorption, and data show that it is the only marker reflecting osteoclasts number and metabolic activity of osteoclast[18]. Various techniques are available for the measurement of AS. However, Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) is a self-administrating tool that composed of six formulated questions, each of which has ten scores that assess fatigue, spinal pain, joint pain, and the duration and the severity of morning stiffness use to determine the activity of the disease[19]. With this background, the aim of the present study is to compare serum apelin, periostin, and TRACP-5b levels among AS male patients according to their disease activity (BASDAI Score). Also to find the correlation between disease activity and the studied parameter in the ankylosing spondylitis.

MATERIALS AND METHOD

Patient enrollment

Fifty -eight male patients with ankylosing spondylitis under the age of 50 were involved in this study. Oral consent was taken before enrolled the patients in the study.

Blood biochemistry

The blood samples were taken from both healthy males and AS male patients in fasting condition to determine serum (Apelin, Periostin and TRACP-5b) levels using commercial ELISA Kits and according to the manufacturer's instructions (the kits were manufactured by My BioSource Inc., USA). Patients with diseases other than AS have been excluded from the study. All patients were subjected to Bath ankylosing spondylitis disease activity index (BASDAI) questionnaire to determine disease activity. Patient with Scores of 4 or greater suggest active disease, and patients with scores below 4 refer to the inactive disease[20].

Statistical analysis

Statistical analysis was done using SPSS version 23 computer software.

RESULTS

Table 1 represents the variation of apelin, periostin and tartrate-resistant acid phosphatase in active and inactive BASDAI condisions. Statistically non-significant (P=0.51) difference in serum apelin level (Mean±SD) were found in the inactive AS disease (2556.9±439.2pg/ml) as compared to the active AS disease (2488.0±351.6pg/ml). Similar results were obtained with the serum periostin levels. While, a significant increase (P<0.001) in serum TRACP-5b level (Mean±SD) was found in with active disease (7.4±1.9mlU/ml) when compared to the inactive disease (5.5±1.8mlU/ml). Scatter diagram with the fitted regression line showing the linear correlation between disease activity (BASDAI score) and serum periostin among patients with ankylosing spondylitis (AS) is depicted in the Figure 1.

Table 1: The comparison of the studied parameter according to disease activity in ankylosing spondylitis (AS) male patients.

	Disease activity		
Parameter	**Inactive (BASDAI score <4) No= 28**	**Active (BASDAI >= 4) No=30**	**P-value**
Apelin (pg/ml)	2556.9 ±439.2	2488 ±351.6	0.51 [NS]
Periostin (ng/ml)	3.3 ±0.7	3.0 ±0.6	0.06 [NS]
Tartrate-resistant acid phosphatase (mlU/ml)	5.5 ±1.8	7.4 ±1.9	<0.001 [S]

[S]= significant differences between two independent means using student-t-test at 0.05 level. Mean±SD

The Correlation coefficient (r) and significance between the studied parameters in ankylosing spondylitis (AS) male patients and disease activity were depicted in Table 2. There was a significant weak positive correlation between disease activity and serum TRACP-5b (r=0.371, P=0.004) and a significant weak negative correlation between disease activity and serum POSTN (r=-0.34, P=0.009), while no correlation has been found between disease activity and serum Apelin.

Table 2: The Correlation coefficient (r) and the significance between the studied parameters in ankylosing spondylitis (AS) male patients and disease activity.

	Serum Apelin (pg/ml)	**Serum Periostin (ng/ml)**	**Serum Tartrate resistant acid phosphatase (mlU/ml)**
Disease activity (BASDAI score)	r= -0.03 P=0.82[NS]	r= -0.34** P=0.009	r= 0.371** P=0.004

[NS] =no significant difference between two independent means using students-t-test at

0.05 level.

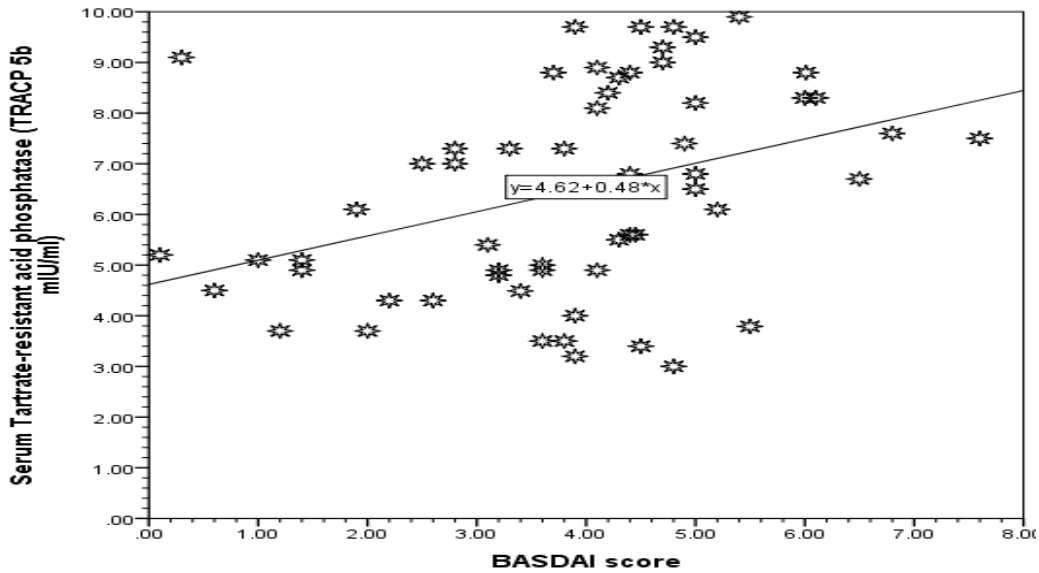

Figure 2: Scatter diagram with the fitted regression line showing the linear correlation between disease activity (BASDAI score) and serum Tartrate-resistant acid phosphatase (mlU/ml) among male with ankylosing spondylitis (AS).

DISCUSSION

Ankylosing spondylitis (AS) is a long-term inflammation of the spine in addition to other joints; it affects men more than women usually in young age and associated with significant alterations in the bone metabolism[21,22]. Hence, in the present study only male individuals are considered. Apelin, adipokines can promote inflammation in obese person through playing the key role in the communication between the adipose tissue and the immune system but the mechanism is not totally known[23,24]. The ample amount of literature reported the correlation of apelin with obesity[25-30]. Periostin as a molecule is expressed in a wide variety of tissues; it has the ability to act as a structural and signaling molecule[16].

This study shows no significant change in serum apelin, and periostin levels but there is a significant increase in TRACP-5b serum level of AS male patients with active disease (Table 1). In addition to that, it shows a positive correlation between disease activity and serum TRACP-5b (r = 0.371, p=0.004) (Table 2, Figure 1) which agrees with the previous studies[2,31]. A positively correlated between serum TRACP-5b level and disease activity were reported in previous studies[2,31] which inturn indicated the reduction in bone formation and the elevation in bone loss are the manifestations of bone metabolism of AS patients as a result of the inflammatory process[27,28]**. High disease activity associated with an increase and related to bone resorption process in patients with AS[32,33,38]. While the finding of this study disagrees with Éric** et al[34] that found no correlation between disease activity and TRACP-5b possibly due to differences in sample size.

This study also shows a negative correlation between disease activity and serum POSTN level (r=-0.340, p=0.009) (Table 2 and Figure 2). The results are agree with the previous studies[35]. Solmaz et al[35] that suggested the suppression of periostin expression in AS patients occurred with high disease activity and related to the progression of radiological damage. While, another study[36] reported lower activity in initial stages which elevated in advanced disease activity, systemic inflammation simultaneously less extensive radiographic damage due to the role of IL-13.

In the present study, serum Apelin level shows no correlation to disease activity (Table 2). Our results are in accordance with previous reports[32,34]. The accumulation of adipocytes there by increased in apelin occurring under obesity condition can be closely linked with functional ability and structural integraty of lymphatic vessels but no bone structure and function. Apelin signaling leads to enhanced lymphatic and blood vessel integrity[26,35-37]. However, Hartavi et al[39] showed a negative correlation between serum apelin and disease activity. Is worth to mention that the association between the activity of the disease and bone turnover markers has not been fully studied[35].

CONCLUSION

In the present study, no correlation has been found between serum apelin and disease activity. A weak negative correlation was found between disease activity and serum POSTN. A weak positive correlation was found between disease activity and serum TRACP-5b.

Ethical Clearance: The ethical clearance was taken from College of Medicine, Al-Mustansiriyah University, Baghdad, Iraq. Oral consent was taken before enrolled the patients in the study.

Sleep Disturbances and Self-Management among Adolescents with Nocturnal Asthma in Al- Najaf City

Doaa Ghaleb Hadi Al- Abayechi[1], Fatima Wanas Khudair [2], Arafat Hussain AL-Dujaili[3]

[1]Department of Pediatric Nursing, Faculty of Nursing , University of Kufa, Iraq, [2]Assistant Prof. Faculty of Nursing , University of Kufa, Iraq, [3]Asst. Prof .Dr. Arafat Hussain AL-Dujaili, University of Kufa, Iraq

ABSTRACT

Self-management improves quality of life among adolescents with nocturnal asthma. This study aimed to identify sleep disturbances and self-managements regarding asthmatic attack among adolescents with nocturnal asthma. Therefore, a cross sectional study was conducted at the Emergency Department in Al-Najaf, during the period October 15th 2017 to September 18th 2018. The study included 100 adolescents with nocturnal asthma who met the inclusion criteria, a pre-structured validated questionnaire was used, including demographic information, sleep disturbances variables and self-managements questionnaire. Data were managed and analyzed using the statistical package for social sciences software version 25 and appropriate statistical tests were applied accordingly. The findings revealed that (66.6%) of patients had moderate and (30%) had severe sleep disturbances. Also, (77.7%) of patients had a poor and (22.2%) had fair self-management. It had been significantly found that females were less aware for self-management, ($P<0.05$), other characteristics showed no significant association, ($P>0.05$). In conclusion, an evidence of sleep disturbances among the adolescents that result from asthmatic attack during the night. Deficit knowledge regarding self-management of asthmatic attack and other female gender can contributed to such attacks.

INTRODUCTION

Asthma is a chronic inflammatory disease complex that occurs in the airways(bronchi) in the lungs. Being widespread globally, asthma kills one person in every 250 deaths in the world [1]. According to the World Health Organization(WHO) estimate in 2005 it affects around 300 million people worldwide. Asthma is among the highest twenty chronic conditions for global ranking of disability-adjusted life years in adolescents. Death rates from asthma in children globally range from 1% to 7% of 100 000. The prevalence of asthma has increased in developing countries over the last 30 years but now appears to have stabilized, with about 10–12% of adults, 12-14% of adolescents and 15% of children affected by the disease. In developing countries the prevalence of asthma had been much lower [2].

Asthma is characterized by recurrent attacks of breathlessness and obstruction of airflow causes frequent occurrence of wheezing, shortness of breathing, chest tightness, and cough especially nighttime, or early morning which vary in severity and frequency from person to person. These episodes are usually associated with variable airflow obstruction that is often reversible, either spontaneously or with treatment [3]. Nocturnal asthma usually worsens at night, the systems representing this nocturnal worsening of symptoms are not totally seen but rather might be driven by circadian rhythms of circulating hormones (epinephrine, cortisol, and melatonin and neural instruments). An increase in airway inflammation at night has been reported. This finding may reflect a reduction in endogenous anti inflammatory mechanism [4,5] . It has also been shown that adolescents are more prone to shorter sleep duration and poor sleep habits. Focusing on adolescent youth is critical as many health-related behavioral patterns that are formed during adolescence continue in adulthood and affect adult health outcomes[6] .

Adolescent sleep is important because it might be both a cause and the result of health problems. However, it still remains a neglected topic in adolescent health research, partly because there are widespread misunderstandings about adolescents' needs for sleep. In fact, the sleep needs of teenagers are not very dissimilar to those of primary school aged children. They remain higher than adult needs across the second decade of life; probably because sleep plays a big part in creating the environment for healthy brain development, adolescent brains are still changing and refining across this age period [7].

Patients and Method

This was a cross-sectional study carried out in Al-Najaf city-Iraq at the Center for Allergy and Asthma in Al-Sadr teaching hospital, and the emergency department of Al-Hakim and Al-Zahra teaching hospitals during the period 15th October 2017 to 18th September 2018. Included 100 adolescents with nocturnal asthma

Study Instrument included the following parts:

Part I: Patients' Demographic Data and Clinical Data

Part II: Patients' Sleep disturbances in asthmatic adolescent scale

Part III: Asthma self-management questionnaire .

Data were collected through a structured interview technique with the subjects and the statistical analysis performed using the statistical package for social sciences and appropriate statistical tests and procedures applied accordingly with level of significance of < 0.05.

FINDINGS

Sleep disturbances were mild in 4%, moderate in 66% and severe in 30% of the studied group, (Table 1). Responses of the study participants towards Self-management items were poor in most of these items giving poor overall self-management evaluation , (Table 2). No statistically significant association had been found between self- management and sleep disturbances from one side and demographic characteristics of the studied group from the other side except one correlation was significant which was between female gender and poor Self-Management, (P<0.05), (Table 3), furthermore, females had significantly lower mean score of self-management, 3.91 ± 1.97 compared to males (mean score: 4.94 ± 2.41), (P<0.05), (Table 4)

Table 1. Distribution of sleep disturbances among the studied group

Sleep disturbance	No.	%
Mild	4	4.00
Moderate	66	66.0
Sever	30	30.0
Total	100	100.0

Table 2: Responses and evaluation of the study participants toward the self-management questionnaire items (N = 100).

Male	53	4.94	2.41
Female	47	3.91	1.97
t-test=2.318, P. value = 0.023			

DISCUSSION

Adolescents have suffer from moderate sleep disturbances of nocturnal asthma. Adolescents have difficulty sleeping on a daily almost, the highest rate (66%), this is due to asthmatic attack lead to sleep disturbances during night, this study agrees with the study conducted by Levin et al [8]. Overall, patients responses to the items of asthma self-management questionnaire

ASMQ revealed wide gaps in knowledge of asthmatic patients about the disease, the role of different medication and method of prevention of asthma attack and 77% of adolescents have poor self-management about asthmatic attack during night time such as the recruited adolescents had poor knowledge of the technique of using the inhaler with regard to the steps taken during the use of the device. Where linked the improper use of inhaler among asthmatic patients with poor control of the disease with a lack of health education and irregularity of follow up visits as significant predictors of improper use [9,10] .

In this study asthmatic patients were correlation sleep disturbance and self-management in gender that the male more knowledge than female (53%), the low level of knowledge about the most important items that help the patient to self-manage asthma can be attributed to the absence of formal health education [11]

CONCLUSION

Based on the study results the study, there was an evidence of sleep disturbances among the adolescents due to asthmatic attack during the night. Deficit knowledge regarding self-management of asthmatic attack , gender, residency, and levels of education could play a role in these attacks. The intensity of sleep disturbance at night could contributed to difficult sleep, drowsiness during the day, and early morning awakening. There were very wide gaps in the adolescent's knowledge of the most essential items about the disease, medications and preventive measures and how to use the inhaler that decreases asthma exacerbations. Therefore, it is recommended to create voluntary courses to raise awareness among adolescents and educate parents in cooperation with specialized medical staff. An educational programs targeting asthmatic adolescents and parents could improve self-management and commitment to self-care as an important part of reducing the risk of asthma and morbidity, using standard health care guidelines, and get benefit of the social media, posters educational publications to educate about self-management and risk factors that increase attacks of asthma.

Ethical Permission : The study protocol was approved by the council of the college of nursing , university of Kufa and the ethical committee of researches . Verbal informed consents were obtained from all participants and their parents, Data were collected according to the World Medical Association Declaration of Helsinki 2013

Conflict of Interest : None.

Source of Funding : Self-Funded.

Factors Associated with the Occurrence of Anemia in Pregnant Women in the Work Area of Baraka Public Health Center, Enrekang District, South Sulawesi Indonesia

Kalma

Health Polytechnic of Ministry of Health in Makassar, Indonesia

ABSTRACT

Study of factors related to anemia in pregnant women in the work areas of Baraka Public Health Facility of Enrekang District aimed to know the parity, mother's age, and inter-pregnancy interval with anemia in pregnant women was conducted. The method used in this study is a laboratory observation method with a descriptive approach, where each respondent was examined for hemoglobin (Hb) levels as a dependent variable and data about independent variables. The study was conducted from June to October 2017. The results showed that the parity factor and age of pregnant women had a relationship with the incidence of anemia, where the p-value <ά (0.05), the distance of pregnancy did not have a significant relationship with the incidence of anemia, where the value of p> ά (0.05). From the results of the study concluded that the age of pregnant women is the most influential factor in the incidence of anemia in pregnant women in Baraka Public Health Center, Enrekang District.

INTRODUCTION

Public health development in Indonesia is mainly aiming to increase life expectancy, improve the quality of life of human resources, and improve the quality of life in order to improve family welfare so that it can deliver optimal levels of public health. Health is one of the basic human needs, so it needs to endeavor so that every citizen is increasingly aware of the importance of health for himself and his environment, and can increasingly behave good healthy life.

Undermutrition is one of the main problems of public health in Indonesia. Especially in poor pupulation[9]. Nutrition problem, especially in pregnant women, is a big problem because it is a supporting factor for anemia in pregnant women. Anemia during pregnancy is a significant health problem in order to improve public health. Regarding maternal and child health, anemia is a major nutritional problem in developing countries including Indonesia.

Anemia is one of the factors that become an indicator of the success of a nation's health development that describes socio-economic capabilities in meeting the needs of quality and quantity of people's nutrition [1].

Anemia during pregnancy is a significant health problem to improve the degree of public health related to public health. Regarding maternal and child health, anemia is a major nutritional problem in developing countries, including Indonesia.

Data from the World Health Organization (WHO) in 2010 showed that anemia in pregnant women ranged from 20-85% with hemoglobin levels (Hb ≤ 11 g/dL). In developing countries including Indonesia, the infant mortality rate and the percentage of anemia during pregnancy are the most sensitive indicators to describe health status, especially maternal health in infants. The Indonesian Health Demographic Survey (SKDI) in 2012 showed that maternal mortality (MMR) in Indonesia was 228/100,000 live births. The causes of maternal

Corresponding Author:
Kalma
Health Polytechnic of Ministry of Health in Makassar, Indonesia, Wijaya Kusuma Raya Street 56 Makassar, Indonesia, Email: kalmaanalis@gmail.com

deaths due to bleeding were 29.67%, infections 5.51%, abortion 1.77%, prolonged labor 1.65%, and others 34.35%. Maternal mortality is one indicator of the success of health services in a country. The direct cause of maternal death is bleeding, eclampsia and indirect causes are anemia [4].

Pregnancy is a natural process and not a pathological process. Pregnancy usually develops and results in the birth of a term healthy baby through the birth canal, but this is not always as expected, normal conditions can be pathological/abnormal. From the medical record data of Baraka Health Center in 2015 showed the number of pregnant women who had their pregnancies examined in 2015 as many as 196 people with some cases of anemia as many as 72 pregnant women. Nowadays, researchers interested to do research to determine factors related to the incidence of anemia in pregnant women in the working area of Baraka District Enrekang Health Center. The factors studied included: parity, age, and inter-pregnancy interval [2].

Anemia is a decrease in the number of red blood cells or the concentration of hemoglobin in the blood circulation. Causes of anemia include malnutrition, lack of iron, malabsorption, massive blood loss such as labor, abnormal menstruation, chronic infectious diseases such as pulmonary tuberculosis, intestinal worms, malaria, and others. According to World Health Organization, anemia in pregnant women is classified based on Hb levels of pregnant women into three categories as follows: normal (Hb ≥ 11 g/dL), mild anemia (Hb 8-10 g/dL), and severe anemia severe (Hb <8.0 g/dL) [10].

MATERIAL AND METHOD

The type of research used in this study was observational with a descriptive cross-sectional study approach. Pregnant women who examined themselves at the Baraka Public Health Center in Enrekang District included in this study were examined their hemoglobin (Hb) levels. Data on dependent and independent variables are collected simultaneously, to obtain information about the relationship of several factors to the incidence of anemia in pregnant women in the working area of the Baraka Public Health Center in Enrekang District.

This study was carried out from June to October 2017. The populations in this study were pregnant women who were in the working area of the Baraka Health Center in Enrekang Regency who came to have their pregnancies examined during the study period. The samples in this study were pregnant women who had their pregnancies examined at Baraka Health Center in Enrekang Regency. The sample size in this study was 65 people. The sampling technique in this study is the total sampling technique.

The independent variables in this study were factors related to the incidence of anemia in pregnant women: parity, the age of pregnant women, and inter-pregnancy interval. The dependent variable in this study was anemia in pregnant women.

The data obtained in this study include primary data, namely hemoglobin levels examined directly in pregnant women with the Sahli method. Also, other primary data obtained in this research is filling in questionnaires distributed to pregnant women to identify data relating to knowledge, education, age, parity, and inter-pregnancy interval. Other than that, secondary data also obtained including a profile of the Department of Health of Enrekang District and the medical record of the patients from Baraka Public Health Center in Enrekang District.

Materials and tools used in this study are 3 mL syringe, tourniquet, cotton, lancet, a reaction tube, 20 µl micropipette, Sahli hemometer, alcohol 70%, and HCl 0.1 N solution.

DATA ANALYSIS

The analysis used in this study is regression analysis which aims to determine the relationship of each independent variable to the dependent variable. Regression analysis also used to know which variable, from the three independent variables, is the most dominant relationship with the incidence of anemia in pregnant women.

FINDING

Hemoglobin level of pregnant women in the working area of Baraka Public Health Center displayed in Table 1. Twenty-six of respondents (40%) suffered from anemia based on their hemoglobin level while the other 39 pregnant women (60%) not. Table 2 displayed that as much as 84.6 % (55 pregnant women) are low-risk parity while 15.4 others are high-risk parity.

Table 1 Distribution of Respondents Based on Occurrence of Anemia in Pregnant Women in Baraka Health Center in Enrekang District in 2017

Hemoglobin level	**(n)**	**(%)**
Anemia	26	40
Normal	39	60
Total	65	100

Table 3 Distribution of pregnant women who check their pregnancies according to the age of pregnant women at the Baraka Health Center in Enrekang Regency in 2017

Age	**(n)**	**(%)**
High Risk	11	16,9
Low Risk	54	83,1
Total	65	100

Source: Primary Data 2017

Based on the age, it is shown in Table 3 that 11 of respondents (16.9%) are high risk, while the majority of them (83.1% or 54 people) are low risk. It is displayed in Table 4 that all (100%) of women included in this study were at low risk based on the inter-pregnancy interval.

Table 4 Distribution of pregnant women who check their pregnancies according to the inter-pregnancy interval at the Baraka Public Health Center, Enrekang District in 2017

Inter-pregnancy interval	**(n)**	**(%)**
High Risk	0	0
Low Risk	65	100
Total	65	100

Source: Primary Data 2017

DISCUSSION

Anemia in pregnancy is a condition where the hemoglobin (Hb) level is lower than the standard value which is less than 11.0 g/dL. Pregnant women whose hemoglobin levels 8.1-10 g/dL, 6.5-8 g/dL, and < 6.5 g/dL were classified as suffering mild, moderate, and severe anemia, respectively (Tabrizi and Barjasteh

2015). Anemia in Indonesia is still considered a public health problem since its high prevalence, especially for pregnant women. Anemia in adults can cause fatigue and weakness which resulting in lowering productivity and the declining of work capacity[3].

Anemia can be caused by malnutrition, lack of iron, malabsorption, massive blood loss (such as labor and abnormal menstruation), and chronic infectious diseases (including pulmonary tuberculosis, intestinal worms, malaria, and others)[6][7].

Parity is the number of deliveries performed or experienced by a woman with live births or stillbirths. The number of births can affect the body's metabolic process. The present data of prevalence of anemia in pregnant women (40%) was higher compared to national health survey conducted by Ministry of Health [5] .

The analysis using chi-squared with ά 0.05 showed that that there is strong association between parity and the incidence of anemia among pregnant women in Baraka Public Health Center of Enrekang District (p-*value* = 0.000). The result means that high risk parity (or pregnancy more than 3 times) has a higher chance of anemia compared to low risk parity. High risk parity in pregnant women usually relates to the level of knowledge that the mother lacks in the impact of the number of pregnancies. There is still lack of dissemination of information through counseling about the normal number of pregnancies by every woman.

Age is one factor that cannot be changed. Epidemiological attention is made to certain age groups because it has its own important problems. Age grouping is usually based on the presence of a problem and is specifically associated with other health factors. The age referred to in this study is the age of pregnant women with high risk i.e. less than 20 years and more than 35 years. Mother's age is very influential on the development of reproductive organs. This relates to the physiological state of the mother's body in accepting presence and supporting the development of the fetus. A woman entering the age of marriage will experience a certain phase in her life where healthy reproductive age is between 20-35 years. There was a significant relationship (p *value*= 0.000) between the age of pregnant women with the incidence of anemia among pregnant women in Baraka Public Health Center of Enrekang District based on chi-squared test.

Inter-pregnancy interval is the interval between two consecutive births of a woman. Setting the interval between pregnancies has an impact on the health of the mother and her baby, the inter-pregnancy interval that is too tight (<2 years) is more risky than the longer inter-pregnancy interval (> 2 years). This is because the anatomy of a woman needs time to restore her health and adequate nutritional intake. Based on this research, there is no association between interpregnancy interval and the incidence of anemia in pregnant women in Baraka Public Health Center of Enrekang District based on chi-square test (p-*value* = 0.40).

CONCLUSION

there is a significant association between parity and the incidence of anemia in pregnant women in Baraka Public Health Center of Enrekang District

there is significant association between the age of pregnant women and the incidence of anemia in pregnant women in Baraka Public Health Center of Enrekang District

there is no association between the inter-pregnancy interval with the incidence of anemia in pregnant women in Baraka Public Health Center of Enrekang District

the age of pregnant women is the most factor that associated with anemia in pregnant women in Baraka Public Health Center of Enrekang District.

Conflict-Of-Interest Statement : In this study between researchers and research, subjects did not have a conflict of interest, because subjects did not have personal or informal relationships with researchers.

Source of Funding : The source of funds in this study came from the Research of Health Workforce Development of the Ministry of Health of the Republic of Indonesia.

Ethical Clearance : The ethics of this study were obtained from the Ethics Commission for Health Research, Poltekkes Kemenkes Makassar.

ABSTRACT

Streptococcus pyogenes one cause of respiratory tract infections including pharyngitis. Seventy-three percent of doctors prescribe antibiotics for pharyngitis. In developing countries, antibiotics are prescribed for 44-97% of hospitalized patients, sometimes with inappropriate doses. Improper antibiotic use can cause side effects such as allergies or diarrhea, increase health care costs, and increase the possibility of selection for antibiotic resistance. Research needs to be done on natural antibiotics found in natural ingredients. One of the natural ingredients empirically has many properties and is relatively safe is honey from bees. Honey has substances that are bactericidal and bacteriostatic like antibiotics. This study aimed Minimum inhibitory concentration (MIC) and minimum bactericidal concentration (MBC) honey bee *Trigona spp* against *Streptococcus pyogenes* in vitro. In concentration of 2.5%, 5%, 7.5%, 10%, and 12 , 5% and knowing the effect of honey bee *Trigona spp* with a concentration of 2.5%, 5%, 7.5%, 10%, and 12.5% against *Streptococcus pyogenes* in vitro. Type of research is the experiment with the Posttest-Only Control Group Design, the research material of honey from *Trigona spp* independent variable is the concentration of honeybees *Trigona spp*. The dependent variable is the level of turbidity produced in a tube to measure MIC and the number of colonies *Streptococcus pyogenes* on Blood Agar Plate media to measure MBC. The results of the MIC determination showed that all concentrations showed clear, MBC results the largest number of colonies occurred at a concentration of 2.5% of the total colony colonies and colonies growth the smallest occurred at a concentration of 10% of the number of colonies 0 colonies, Conclusions of MIC cone honey bee *Trigona spp* against bacteria *Streptococcus pyogenes* occurred at a concentration of 2.5%., MBC moth honey *Trigona spp* against bacteria *Streptococcus pyogenes* occurred at a concentration of 10% . There is an influence of the honey *Trigona spp* on the bacteria *Streptococcus pyogenes*, which is indicated by the value of p <0.05, which is 0,000 using the Linear Regression test.

Keywords: *MIC, MBC, Streptococcus pyogenes.*

INTRODUCTION

Streptococcus pyogenes (Streptococcus group A) is one of the causes of respiratory tract infections including pharyngitis. In Indonesia every year ± 40 million people visit health care centers because of pharyngitis[1]. In the United States, 15−30% of cases of pharyngitis are in school-age children and 5-15% of cases of pharyngitis in adults. Usually occurs in the winter, which is a result of infection with Streptococcus, hemolytic, group pharyngitis is rare in children less than three years[2].

Seventy-three percent of doctors prescribe antibiotics for pharyngitis, most of which are caused by bacteria. In developing countries, antibiotics are prescribed for 44-97% of hospitalized patients, sometimes with inappropriate doses. Incorrect antibiotic use (indications, selection, length of administration, and improper doses) can cause side effects such as allergies or diarrhea, increase health care costs, and increase the likelihood of selection for antibiotic resistance[3]. Antibiotic resistance in Indonesia has been found, such as staphylococcus

aureus which is resistant to methicilin[4] and vancomicin[5].

Indonesia is rich in natural ingredients that can be used as an antibacterial, anti-fungal or anti-larvae. As Anredera cordifolia[6], lime[7] for antibacterial, Cananga odorata (Lamk). Hook[8], Carica papaya Linn[9], Syzygium polyanthum[10] for anti-larvae and Kaempferia galanga L.[11], Jatropha curcas[12] as antifungal. Another natural material that is widely used is honey. Bee honey empirically has many properties and is relatively safe, Research Wineri et al. (2013) proved that honey has an active effect against and inhibits pathogenic bacteria that cause infection, such as *Streptococcus pyogenes* which can cause pharyngitis[13]. Honey has substances that are bactericidal and bacteriostatic like antibiotics. Bacteria cannot live and develop in honey because honey has antibiotic substances such as anti-viral interferon, and inhibin which can inhibit bacterial growth[14].

MATERIALS AND METHOD

This type of research is the experiment the form of a Posttest-Only Control Group Design.

The research was carried out at the Bacteriology Laboratory of the Health Analyst Department of the Health Ministry of Health Banjarmasin January 2018. The research material was honey from the honeycomb (*Trigona spp*).

The independent variable was the concentration of honeybees *Trigona spp*. The dependent variable is the level of turbidity produced in the tube to see MIC and the number of colonies *Streptococcus pyogenes* on BAP (Blood Agar Plate) media to see MIC.

Research steps include bee determination at the Entomology Laboratory of the Faculty of Biology, Gadjah Mada University, Yogyakarta. The sampling of honey bee honey and sterility testing. Making suspense of bacteria. *Streptococcus pyogenes* Making a series of bee honey concentration in each sterile test tube as in the following table. :

Table 1.Honey Dilution

SterileTube	Concentration of	Honey (ml)	Aquades Solution (ml)
1	5%	0.25 ml	4.75 ml
2	10%	0.50 ml	4.50 ml
3	15%	0.75 ml	4, 25 ml
4	20%	1.00 ml	4.00 ml
5	25%	1.25 ml	3.75 ml

Treatment of Research: Determination of MIC :: Preparing a sterile test tube and labeled according to variations in the concentration made of 2.5%, 5%, 7.5%, 10%, 12.5%, PC (positive control), NC (negative control) and HC (honey control). From each concentration, 1ml was taken and added 1 ml of bacterial suspense. The positive control tube filled with 1 ml of 5 µg of Levofloxacin antibiotics and 1 ml of bacterial suspension. The negative control tube was filled with 1 ml of sterile TSB and added with 1 ml of bacterial suspension. The honey control tube was filled with 1 ml of bee honey plus 1 ml of sterile TSB. Mix well and incubated for 24 hours at 37ºC in the incubator. The results were read by finding a tube containing the lowest honey content but still being able to inhibit bacteria (clear solution) which was declared as MIC. After obtaining the results of Minimum inhibitory concentration, the examination continued with the determination of MIC[11].

Determination of MIC: The tube that was determined MIC was taken as much as 50 µl then leveled on the surface of Nutrient Agar (NA) media using a spreading rod. Incubated for 24 hours at 35ºC in an incubator[15]. Read the results by counting the number of colonies growing on the surface of the media using the colony counter and then looking for concentrations that do not show bacterial growth at all. Five repetitions.

RESULTS AND DISCUSSION

Table 2: Results of Minimum Inhibitory Concentration (MIC)

Level of clarity of repetition of	Concentration of honey beetle					Control	
	2.5%	5%	7.5%	10%	12.5%	Negative (KN)	Positive (KP)
1	Clear	Clear	Clear	Clear	Clear	Cloudy	Clear
2	Clear	Clear	Clear	Clear	Clear	Cloudy	Clear
3	Clear	Clear	Clear	Clear	Clear	Cloudy	Clear
4	Clear	Clear	Clear	Clear	Clear	Cloudy	Clear
5	Clear	Clear	Clear	Clear	Clear	Cloudy	Clear
average	Clear	Clear	Clear	Clear	Clear	Cloudy	Clear

Table .3: Results of Minimum Bactericidal Concentration (MBC)

Clarity level of repetition of	Concentration of honey beetle					Control	
	2.5%	5%	7.5%	10%	12.5%	Negative (KN)	Positive (KP)
1	40	8	1	0	0	4416	0
2	35	25	5	0	0	3888	0
3	31	8	2	0	0	4304	0
4	31	14	1	0	0	4112	0
5	38	20	0	0	0	3984	0
Average	35	15	2	0	0	4141	0

The average number of colonies *Streptococcus pyogenes for* each concentration in determining the minimum Bactericidal concentration is presented as in Figure 1.1.

Fig. 1 Average Number of colonies *Streptococcus pyogenes* on Determination of Minimum Bactericidal Concentration (MBC)

Based on the results of normality data testing using Shapiro-Wilk, it is known the asymp value. Sig = 0.365; 0,408; 0,223; 0.782. Asymp value. Sig> 0.05, it can be stated that MIC data is normally distributed.

Table. 4 Normality Test Results for the Number of colonies *Streptococcus pyogenes* on Determination of Minimum Bactericidal Concentration (MBC)

	Minimum Bactericidal Concentration	Kolmogorov-Smirnov[a]			Shapiro-Wilk		
		Statistics	Df	Sig.	Statistics	Df	Sig.
Number of Colonies *Streptococcus Pyogenes*	2.5%	.238	5	.200*	.892	5	.365
	5%	.225	5	.200*	.900	5	.408
	10%	.261	5	.200*	.859	5	.223
	KN.	172	5	. 200*	.956	5	.782 The

The test continued with the ANOVA test to assess the quality of the regression equation obtained. Based on the ANOVA test results obtained a significant value of 0,000 so that the equation obtained is not used.

Regression test results obtained a significance value of 0,000. The value of significance <α = 0.05 can be stated treatment of different concentrations of honey bees effect on the growth of *Streptococcus pyogenes* in vitro.

The results of the determination coefficient test, the R square value is 0.420. This value is to conclude that the effect of bee honey on the growth of *Streptococcus pyogenes* is 42% (obtained from 0.420 x 100%), which means that honey bee has a weak influence on the growth of *Streptococcus pyogenes*.

The results showed that the higher the level of concentration of honey bee honey added, the greater the ability of inhibitory power and killing power on the growth of *Streptococcus pyogenes*. This is characterized by the occurrence of clarity in TSB media tube dilution test (table 2) and a decrease in the number of colonies *Streptococcus pyogenes* that grow on the surface of the nutrient agar media (table 3). Based on the results of the regression test obtained a significance value <α = 0.05, it can be stated that the treatment of different concentrations of bee honey affects the growth of *Streptococcus pyogenes*.

Based on Erywiyatno's (2014) research on the minimum concentration of honey which can inhibit the growth of Group A beta-hemolytic Streptococcus by diluting honey at concentrations of 10%, 20%, 40%, 60%, 80%, and 100%, it shows that the minimum inhibitory concentration (MIC) on packaged honey against the growth of Group A beta Streptococcus hemolyticus is positive (+) at a concentration of 90% and Minimum Bactericidal Concentration (MBC) is at a concentration of 95%[16].

According to Wineri (2013) based on the origin of manufacture, honey is divided into natural honey and packaged honey. Physically packaged honey has similarities with natural honey, but there are differences in nutritional content. Natural honey has high sugar content in the form of fructose 38.19%, glucose 31%, and sucrose 1.31%. The sugar content found in natural honey causes the viscosity of natural honey to be thicker compared to packaged honey, this is due to the process of making packaged honey there is a stage of giving water and other mixtures so that the volume of honey packs becomes more. Also, packaged honey does not contain enzymes, vitamins, and minerals as found in natural honey. Therefore, the results of the study of Minimum Inhibitory Concentration (MIC) and Minimum Bactericidal Concentration (MBC) in the honey bee honey (*Trigona spp*) occur at low concentrations compared to the results of Erywiyatno's research using packaged honey.

Honey has substances that are bactericidal and

bacteriostatic like antibiotics. Bacteria cannot live and develop in honey because honey contains an element of potassium which is an element that prevents moisture so that it can inhibit bacterial growth. Based on the results of research it has been known that honey has the broad spectrum antibiotic activity to fight pathogenic bacteria. Honey also contains phenol, peroxide and non-peroxide components, has a thick viscosity, and a low pH that can inhibit bacterial growth. The hygroscopic properties of honey can attract water from the living environment of bacteria which results in dehydrated bacteria. Honey is also an immunomodulator by triggering macrophages to produce cytokines involved in killing bacteria and repairing tissues. These antibacterial properties are effective in inhibiting the growth of *Salmonella typhi, Escherichia coli, Enterobacter aerogenes, Staphylococcus aureus* and *Pseudomonas aeruginosa*[13].

Non-sting honey bee *Trigona spp* has been shown to contain high phenolic levels. Phenolic benefits for health include functioning as antioxidants, antibacterial and anti-inflammatory. The research examined the phenolic content in honey produced by Apismellifera, A. dorsata, A. cerana, and two types of Trigona sp. The results showed that the phenolic content of honey was Trigona superior to honey from the genus Apis bee. The values of the phenolic content of honey studied were 602.4 mg EAG (Galatea Acid Equivalent) per kg of honey; 589.2 mg; 510.4 mg; 791.5 mg; and 1,058.8 mg[17].

The mechanism of action of phenol compounds in killing bacterial cells is three ways, namely denaturing bacterial cell proteins, inhibiting cell wall synthesis, and damaging bacterial cell membranes. Phenol compounds denature bacterial cell proteins by forming hydrogen bonds with bacterial proteins. Results in the structure of bacterial proteins damaged and enzymes were becoming inactive. In addition, the mechanism of phenol in inhibiting bacterial cell wall synthesis by poisoning the protoplasm and breaking peptidoglycan bonds[18].

Flavonoids contained in honey bee which also functions as antibacterial Flavonoids can damage cell membranes by inhibiting the synthesis of macromolecules, depolarizing cell membranes and inhibiting DNA, RNA and protein synthesis. inhibits the function of the cytoplasmic membrane and inhibits energy metabolism in bacteria[19].

The antibacterial activity of honey is also related to its osmotic condition. Honey is a supersaturation solution of sugar that has an osmotic ability. Water molecules react strongly with sugar in honey; there is only a small amount of free water left for the growth of microorganisms. The enzyme activity of glucose oxidase will produce hydrogen peroxidase. Decomposition of hydrogen peroxidase will increase reactive free radicals. These free radicals will react to organisms resulting in death. Osmotic pressure can cause microorganisms to dehydrate and die[20].

CONCLUSION

MIC honey *Trigona spp* against bacteria *Streptococcus pyogenes* occurs at a concentration of 2.5%. MBC bee honey *Trigona spp* against bacteria *Streptococcus pyogenes* occurs at a concentration of 10%. There are an influence of honey *Trigona spp* bacteria *Streptococcus pyogenes*,

ABSTRACT

In this work, lipopolysaccharides of *Klebsiella pneumonia* and extract of Glycyrrhiza glabra were used to investigate the humoral immunity in mice Balb/c (in vivo). In contrast, little is known about humeral immunity induced by LPS and Glycyrrhiza glabra. Some parameters were used to achieve this study, are WBC and differential count, Concentration of antibodies IgA, IgM, IgG and Concentration of complement proteins type C3 and C4 / mg / 100. The results showed there are a significant change in a parameters values in IgA, IgM, IgG and Concentration of complement proteins type C3 and C4 ,also in CBC and differentiated WBC.

Keywords: *LPS, immunology, extract of Glycyrrhiza glabra, in vivo, Klebsiella pneumoniae.*

INTRODUCTION

The Glycyrrhiza glabra (licorice) plant has a long and storied his Tory of utilization in both Eastern and Western societies pre-dating the Babylonian and Egyptian realms, The antiquated Greeks and Romans are known to have cultivated the plants in the third century, Licorice was a prescriptive specialist of Hippocrates in the treatment of asthma dry hack and other "pectoral diseases[1,2,4]. The licorice (Radix Glycyrrhizae or Liquiritiae radix), which is comprehensively utilized as a part of prescription and business, is gotten from the sweet foundation of different types of Glycyrrhiza. Licorice is local to southern Europe and parts of Asia; it is a standout amongst the most usually utilized homegrown [3,5]. *Klebsiella pneumoniae* is a Gram-negative bacterium that colonizes the skin, mouth, gut mucosa, and oropharynx, is likewise a crafty pathogen causing an assortment of contaminations, including bacteremia, urinary tract diseases also, liver abscesses [6,7]. The Glycyrrhiza glabra extricates were additionally found to Fortify humoral resistance in chickens tentatively tainted with the Newcastle infection (NDV), The talked about plant conveys various medical advantages what's more, applies mitigating, antibacterial, antifungal what's more, hostile to cancer-causing impacts because of the nearness of an- Anthraquinones, saccharides and cell reinforcement vitamins (A, C and E). [8,9,10,11,12]

METHODOLOGY

Identification of K.pneumoniae

Microscopical examination (Gram staining film)

Smears were prepared by taking a small amount of isolated colony from a bacterial culture on a glass slide by mixing a colony of the testing bacterium with a drop of distilled water, stained with Gram stain and examined using an oil immersion objective lens under 100X power.

Cultural characteristics

The morphological characteristics of isolated colonies were carefully studied with the aid of a lens 10X lens. Depending on the above two criteria the cultures were primarily classified as pure or mixed cultures.

The growth of the bacterial isolates

The bacterium *K.pneumoniae* was obtained from the College of Science, University of Iraq. This isolate

was a subculture in 10 ml Nutrient broth and incubated for 48 hr at 37 ºC. Then the insulation of bacteria was achieved by taking 4 ml of the culture broth in 1000 ml of sterilized nutrient broth and incubated in the same conditions in a shaker incubator at 100 cycles/ min for 48 hours, then Centrifugation of culture broth at 3000 cycles/min for 15 min at 4 ºC and the sediment was suspended in Phosphate buffer saline (pH 7.2) and centrifugated by same condition three times until getting the pure sediment and stored in 4 ºC.

Extraction and purification of LPS

LPS of *K.pneumoniae* was extracted using a reference [13,14], and purified using the modified Vogel's method [15,16].

Extraction of licorice

Licorice was extracted according to a papers [17,18,19.20,21.22].

Laboratory animals

Males of Swiss white mice Balb/c with old 6-7 weeks in this study which obtained from Medicative Control Center, Ministry of Health, Baghdad, Iraq

DISCUSSIONS

Firstly ,the effect of the immunization by using lipopolysaccharides (LPS) of *K. Pneumonia* and *Glycyrrhiza glabra extract* on IgG, IgM, IgA antibody level is reported in table 1. The results of the effect of LPS antigen injections of *K. Pneumonia* at IgG, IgM, IgA antibody level. The results showed significantly higher levels of antibodies in the treatment using LPS antigen, *Glycyrrhiza glabra extract* and LPS antigen as compared with the control groups and the treatment in which the extract was used For the unit. The antigen (LPS) with *Glycyrrhiza glabra extract* showed the highest difference of antibodies IgA, IgM, IgG, 187.3, 121.8 and 1115.3, respectively, compared with the Control group and the treatment of the *Glycyrrhiza glabra extract*, which did not register any significant difference. The results of the present study agree with [23,24,25,26.27]. that *K. Pneumonia* infection leads to an increase in antibody production. Elevation in antibody levels in treating mice may be due to the ability of the *K. Pneumonia* antigen to stimulate lymphocyte reproduction. The results of the current study were also agreed with [27,28]. There was a significant increase in antibody levels of IgG, IgM, and IgA since the increase in the concentration of these antibodies is indicative of the development of humoral immunity.

Secondly , the effect of the immunization by using lipopolysaccharides (LPS) of *K. Pneumonia* and Glycyrrhiza glabra extract in a concentration of the complement proteins type C3 and C4 are reported in table 2. The results showed an increase in the concentration of complement proteins type C3 and C4 which the treat by LPS antigen, Glycyrrhiza glabra extract compared with the control groups. The antigen (LPS) with *Glycyrrhiza glabra* extract showed the highest difference in the concentration of C3 and C4 complemental proteins at 132.68, 48.23 respectively, compared with the control group and the treatment with the Glycyrrhiza glabra extract, which showed no significant difference. Łukawska, Polcyn-Adamczak, and Niemir, (2018) were found that the concentration of C3 and C4 complemental proteins was significantly higher in mice which the immunization by using lipopolysaccharides (LPS) compared with the control group.

Finally, The effect of the immunization by using lipopolysaccharides (LPS) of *K. Pneumonia* and Glycyrrhiza glabra extract in a WBC and differential WBC count are reported in table 3. The results of the present study showed significant differences towards increasing the total number of white blood cells in the treatment in which the LPS antigen with the Glycyrrhiza glabra extract where it gave the highest significant difference. In the differential count of white blood cells, the results showed significant differences in the number of Neutrophils compared to the control groups and the treatment in which the extract was used alone. The results also showed that there were significant

differences in the reduction of the number of white blood cells lymphocytes compared to control groups. The highest value of total white blood cells in the group was treated with LPS antibody with the Glycyrrhiza glabra extract 16130 compare of control group 5667. The differential count was the highest number of treated cells with LPS with Glycyrrhiza glabra extract, where it was 54.07 % compared to the control. The results of the total number of white blood cells in our study are consistent with Khaertynov *et al*.,(2018) showing that the injection of Swedish white mice with *K. Pneumonia* leads to an increase in the total number of white blood cells compared with the control group.

CONCLUSION

The results showed there are a significant change in a parameters values in IgA, IgM, IgG and Concentration of complement proteins type C3 and C4 ,also in CBC and differentiated WBC comparative with others parameters.

ABSTRACT

Honey can be contaminated with microorganisms, especially spore-forming bacteria. Bacteria that can survive in honey are *Bacillus sp* and *Clostridium sp*. This study aimed to determine the presence of *Bacillus sp.* and *Clostridium sp.* on Trigona and Apis bee honey and honey packs after 1 year of storage. *Trigona sp.* honey, *Apis sp.* honey was taken directly from the honeycomb located in Hulu Sungai Tengah and Tanah Laut, South Kalimantan. Honey packs were 2 types of honey supplements for children taken randomly as much as 6 packs, at a drugstore in the Banjarbaru market. Honey packs were examined in laboratory before and after storage for 1 year at room temperature. Laboratory tests were performed on samples with parameters of TPC (Total Plate Count), *Bacillus sp.*, *Clostridium sp*., pH and moisture content. Results of research on Trigona honey found 50% of *Bacillus sp*., 10% of *Clostridium sp.*. Apis honey contained bacillus 50%, clostridium 5%. Honey packs before storage contained 83% bacillus, 33% clostridium, after 1 year storage bacillus 50%, clostridium 50%. It is recommended to research the germination inhibition factor of bacterial spores in honey.

Keywords: *Spore-forming bacteria, honey, Trigona sp., Apis sp.*

INTRODUCTION

Microorganisms contained in honey can affect the quality and safety of honey. Microbes found in honey are bacteria and fungi. These microbes can come from nectar, bees, humans and dust. The bee intestine contains 70% Gram negative bacteria such as *Achromobacter*, *Citrobacter*, *Enterobacter*, *Erwinia*, *Escherichia coli*, *Flavobacterium*, *Klebsiella*, *Proteus*, and *Pseudomonas*. Gram negative bacteria such as coliform have commonly contaminated food ingredients. They can contaminate sauces[1], dumplings[2], even water sources such as wells[3]. It also contain 27% of Gram-positive bacteria such as *Bacillus*, *Bacteridium*, *Streptococcus* and *Clostridium spp* and 1% fungi[4].

Most bacteria could not grow and multiply in honey, but some bacteria are found in honey[5]. Spore-forming bacteria such as *Bacillus sp*., *Clostridium perfringens*, and *Clostridium botulinum* can survive in honey at 25°C.

Clostridium botulinum is presented in studies of honey samples in Argentina and Brazil. Honey containing *Clostridium botulinum* even becomes the cause of botulism in infants in California[6]. *Clostridium botulinum* spores contaminated honey is one source of botulism[7].

Bacillus sp is a bacterium that is widely found in the environment. can contaminate water, soil, air and even the air of the laboratory space[8]. *Bacillus cereus* is a bacteria caused food poisoning that can occur at infective dose of at least 10^3 bacteria per gram of food. These bacteria contaminate many foods including infant formula[9], baby rice cereal[10], cooked rice[11]. The heat resistance character of Bacillus spores cause them to persist in food. This diarrhea is caused by the enterotoxins produced during the growth of bacteria in the small intestine[12].

Methods and materials

This type of research was descriptive observation. Research samples are *Trigona sp*. honey, *Apis sp*. honey, and honey packs in the form of children supplement honey. *Trigona sp*. honey and *Apis sp.* honey were taken

directly from the honeycomb located in Hulu Sungai Tengah and Tanah Laut, South Kalimantan. Honey packs were 2 types of honey supplements for children taken randomly as much as 6 packs, at a drugstore in the Banjarbaru market. Honey packs were examined in laboratory before and after storage for 1 year at room temperature. Laboratory tests were performed on samples with parameters of TPC (Total Plate Count), *Bacillus sp.*, *Clostridium sp*., pH and moisture content.

Bacterial isolation used thioglycholate media (Merck) and blood agar plate (Merck). Incubation of blood agar plate for aerobic and anaerobic used Oxoid Anaerobic Gas Generating Kit (Anaerobene TM 2.5L AN0025A) and Oxoid Anaerobic Indicator (BR0055B). Suspect colonies of *Bacillus sp*. on the blood agar plate have characteristics of 4 - 5 mm colony diameter, pieces, rough, grey, uneven edges, slightly wavy, an-hemolytic. Suspect colonies of *Clostridium sp*. on blood agar plate have characteristics of 5 - 10 mm colony diameter, clear, smooth, shiny, creeping, darker colored in the middle of the colony, keeping, hemolytic. Colonies that grew on media were colored with Gram stain and produced images of Gram-positive bacteria with spored-bacil form. Media for biochemical tests were Simon citrate (Merck), SIM (Merck), TSIA (Merck), glucose, lactose, mannose, maltose, saccharose. Biochemical test results for *Bacillus sp.* were glucose +, lactose -, mannose +/-, maltose +/-, sakarosa +, indol -, motility +, citrate -, TSIA: slope -, base +, H2S -, gas -. Biochemical test results for *Clostridium sp.* were glucose +, lactose - / +, mannose -, maltose +, sakarosa +, indol -, motility +, citrate -, TSIA: slope -, base +, H2S -, gas -.

Measurement of honey pH used pH meter (Lutron PH-209), moisture content was calculated by gravimetric method.

Bacterial contamination in honey bee might also come from soil containing bacterial spores. Bacteria could live on moist and humid soils and environments where many livestock lived[13]. The spore-forming bacteria found in honey in this study were *Clostridium sp* and *Bacillus sp*. This study was in line with research on honey samples in Argentina found *Clostridium botulinum* as much as 1.1% and in brazil as much as 7.06%[6]. *Bacillus cereus* was found as much as 42% in baby food in Isfahan, Iran[14]. *Clostridium sp*. and *Bacillus sp*. form the metabolically inactive endospores but are resistant to adverse environmental conditions including heat. Spores could germinate under favorable conditions and could cause food spoilage and food poisoning after consumption[15].

The genera *Clostridium* and *Bacillus* are commonly found in soil, water, and gastrointestinal tracts of insects and animals, as well as humans. Both genera grow in low oxygen environments. Clostridia require more anaerobic atmosphere, but some species is aero-tolerance. *Clostridium* and *Bacillus* pathogen species can survive in and out of various host species. The disease is often associated with toxins and protein spores that include gangrene gas, food poisoning, diarrhea, pseudomembranous colitis, and enterotoxemia[16]. The pH values of all honey samples in this study were acidic (pH 3.01-6.4). The lowest acidity was detected in *Trigona sp*. (3.30 ± 0.246), followed by *Apis sp*. honey (4.91 ± 0.856), and honey packs (5.70 ± 0.19). There was a significant difference of honey pH between *Trigona sp.* with *Apis sp.* honey ($P < 0.05$). The pH of honey in this study was close to the pH value of honey in the previous study, ie Yemen, Egypt, Saudi, Kashmir (pH 4,114-4,637)[17]. Other studies have also shown that the pH of honey is close to similar values, ie in Indian, Algerian, Brazilian, Spanish and Turkish honey (pH 3.49-4.70)[18]. Honey with acidic pH is not a good medium for microbial growth. The pH 7.4 media supports better spore growth than pH 5.5[19]. Spores were inactivated at lower pH values of the media[20].

The degree of honey acidity correlates with the fermentation of sugars in honey into organic acids. The acidity of honey causes honey to stabilize against microbial decay Bogdanov et al. (2008). The acidity of honey may also indicate that the honey sample has a high mineral content[21].

The results showed that after 1 year storage at room temperature honey packs tend to show increased number of germs, such as *Bacillus sp.* and *Clostridium sp*. The food composition and storage conditions determine germination and development of living spores[22]. The composition of honey that contained more than 180 substances, including amino acids, enzymes, proteins, vitamins, minerals, ash, organic acids and phenol compounds[18] can be a good growth medium for microbes.

The color of honey varies like dark yellow, blackish brown or black. The most important aspect that affect the marketing value of honey is the color of honey. Color

change may be associated with mineral content, heavy metal contamination, and high temperature or light exposure[23]. The results showed the honey color were bright yellow to brown. *Trigona sp*. honey tend to have more brown color, a more acidic pH and a more watery texture. The color of honey is affected by the mineral content in it[24]. This is because *Trigona sp* bees consume more minerals. The amount of *Trigona sp.* Honey production is much less because these bees produce more propolis[25].

CONCLUSION

Trigona honey contained bacillus sp 50%, clostridium 10%. Apis honey contains bacillus 50%, clostridium 5%. Honey packs before storage contains 83% bacillus and 33% clostridium. After 1 year storage honey packs contains bacillus 50% and clostridium 50%.

Comparison of CT, MRI, and Diffusion–Weight MRI in Differentiation Cystic Brain Tumors (Prospective Study)

Hassan Falah Al-Khafaji[1], Kassim A. H. Taj-Aldean[2]

[1]Babylon Health directorate, Babylon province, Hilla, IRAQ,
[2]Dept. of Surgery/ College of Medicine / University of Babylon, Hilla, Iraq

ABSTRACT

Objective: To determine the ability of MRI, diffusion–weight MRI images and ADC (apparent diffusion coefficient) in comparison to CT scan to differentiation cystic brain tumors.

Method: From January 2017 to October 2018, this prospective study included 60 patients (age range 20 to 85 years, mean age 55 years) diagnosed clinically as having cystic brain tumor. A conventional MRI was done on Philips MRI a 1.5T using T2, T1 and fat-suppressed technique and echo-planar spin-echo sequence diffusion weight and ADC is carried for all patients with CT scan.

Results: All CT scan and MR imaging features were categorized brain lesion as cystic brain tumor according to the features of imaging which were compared the result with histopathological findings. Sixty patients, 34 male and 26 female the diagnosis was confirmed with pathological findings which included Primary malignant cystic brain tumors 16 (20%) Primary benign cystic brain tumor 24 (26%) and Metastatic tumor 20 (32%). The sensitivity for diagnosis primary malignant cystic tumor 60%, Primary benign cystic brain tumor 100% and the sensitivity of DWI for diagnosis metastasis tumor 81%. Diffusion–weight MRI and ADC is good modality for differentiation cystic necrotic tumor.

Conclusion: According to our results we concluded that MRI has more accuracy than CT scan for diagnosis brain tumors and biopsy correlation. Both CT scan and MRI reports for diagnosis of benign or malignant tumor compared with pathologic findings and they were not significant.

Keywords: *Brain Neoplasms, Computerized Tomography, Magnetic Resonance Imaging, Diffusion–Weight, ADC (apparent diffusion coefficient) .*

INTRODUCTION

There is MRI protocol for preoperative cystic brain tumor assessing include T1 weighted with gadolinium enhanced, T2 weighted and diffusion weighted to evaluate the lesion, vascularity and blood brain barrier integrity these sequence result in correct diagnosis in majority of cases[1].

all primary benign tumor can be diagnosis by DWI. The sensitivity of DWI for diagnosis of primary benign cystic brain tumor is 100% [2,3].

computed tomography CT) and magnetic resonance image (MRI) are being routinely used to screen the neonate for plausible intracranial problems [4-7].

Diffusion –weighted MR has an establish role in the differential diagnosis between brain abscess, cystic tumor and between epidremoid cyst and arachnoid cyst[8].

CT scan remains a good choice in diagnosis of some conditions like bone or vascular involvement and metastases to the skull base [9].

There is protocol for typical MRI in preoperative assessing tumor of brain include T2 and T1 weighted, diffusion weighted to evaluate the lesion T1 weighted with gadolinium enhanced, blood brain barrier integrity, irregularity and vascularity these sequence result in correct diagnosis in majority of cases [10,11].

The aim of this study was to investigate whether the different cystic brain tumors can be differentiated

on CT scan, MRI and diffusion –weight (MRI) and apparent diffusion coefficient (ADC) on the basis of their appearance and characterization of signal intensity.

PATIENTS AND METHOD

In this cross-sectional study, 60 patients aged 20–85 years (mean age 50 years) with clinically suspected brain tumor were included. The patients were having different clinical presentations; headache 42 (70%), Dizziness 12 (20%), and Confusion 6 (10%).

For all patients, CT scan, conventional MRI preoperative and diffusion–weighted MRI were done to show characterization of brain tumor by CT appearance whether cystic or solid. All solid tumors were excluded from this study, then MRI signal intensity was done.

This study was carried out in department of surgery, Hilla teaching hospital, Iraq, in the period extended from January 2017 to October 2018. Chief complains of all patients documented from their medical record. Pathologists evaluated the lesions as benign or malignant, without any information about CT scan or MRI reports. CT scan reported cystic or solid lesion, with or without calcification and edema, shifting and enhancement. CT scan or MRI reports were concluded lesions as benign or malignant. The MRI pictures had been seen and confirmed by two radiologists to differentiate the brain tumor whether followed by operative exploration in the same hospital, the median time between initial MRI and surgery 31 days (range 5 days to 76 days).

CT scan by Philips 64 slice then Magnetic resonance imaging (MRI) was carried out on a Philips 1.5T system using multiplanar sequence T2, T1 and fat-saturation and sequence diffusion weight is carried for all subjects. All MR imaging features were categorized according to the features of imaging as malignant or benign without clinical details.

MRI Protocol

In this study Philips MRI 1.5 T units was used, with different planes (coronal, sagittal and axial) see the brain lesion whether cystic or solid, site, texture, extension, and intensity. Used multiplanar sequence diffusion weight with ADC do for all patients. In this study, the thickness of slice was 5 mm and the slices numbers averaged 14, which decrease the effects of eventual motion and volume partial between diffusion-weighted imaging and conventional MR.

RESULTS

Sixty subjects admitted in teaching hospital in Babylon in Iraq have different symptom and signs. In this study, age of patients included ranged from 25-85 years mean age (55 year), 34 male and 26 female, then routine CT scan and conventional MRI examination was done, in conventional MRI examination show the patient normal or abnormal, if there is mass in brain or not, the abnormal patient who have cystic mass in brain do DW MRI in department of radiology in the same hospital to determine the mass, appearance of mass, nature and side then do ADC (apparent diffusion coefficient), the appearance of MRI are read by two radiologist without known history of patient to determine the diagnosis and mention the report, then all patient do surgery in in the same hospital. In all 60 patients the diagnosis was confirmed with histological evaluation which include primary benign cystic tumor 24 (40%), have primary malignant brain tumor (cystic glioma) 16 (26%) and patients have metastatic tumors 20 (34 %).

All primary benign cystic brain tumors (arachnoid cyst and epidermoid cyst) can diagnosed by CT scan show hypodense area fluid density (Figure 1), DWI and ADC show high signal on DW MRI and low signal on ADC, so the sensitivity for diagnosis arachnoid cyst and epidermoid cyst on DW MRI are 100%. (Figures 2). The pattern of enhancement on CT scan and MRI can be shown in (Table 2).

Sixty patients by using CT scan, which 13 (54%) were diagnosed benign from 24 benign tumor, 10 (62.5%) malignant from 16 malignant tumor and 9 (45%) were diagnosed metastasis from 20 metastasis tumor. Sensitivity, specificity, positive predictive value and negative predictive value of CT scan were 83%, 10%, 93% and 3% respectively. The accuracy of this method was 78%.

While by MRI Sensitivity, specificity, positive predictive value, negative predictive value and accuracy of MRI were 94%, 27%, 93%, 3% and 88% respectively.

The sensitivity for diagnosis primary cystic malignant brain tumor only 6 from 16 primary malignant cystic brain tumor (Figure 3) show hyper intense on DWI and hypo intense on ADC while the remain primary cystic tumor 6 show hypo intense on DWI and hyper intense on ADC Table 1) make the sensitivity of DWI foe diagnosis primary malignant cystic tumor 60%, in

metastatic tumors 4 out of 20 metastatic tumors showed hyper intense on DWI and hypo intense on ADC while the remain showed hypo intense on DWI and hyper intense on ADC make the sensitivity of DWI for diagnosis metastasis tumor 81%. as shown in (Figure 4).

Table 1: Signal intensity of cystic cerebral tumor on DWI and ADC

Type of cerebral lesions	**Number**	**DWI**	**ADC**
Primary malignant cystic brain tumors	N=16 N=0	High signal Low signal	Low signal High signal
Metastatic tumors	N=15 N=5	Low signal High signal	High signal Low signal
Arachnoid cyst	N=14 N=0	Low signal	High signal
Epidermoid	N=10 N=0	High signal	Low signal
Total	60		

Table 2: Pattern of enhancement on CT scan and MRI

D/D	**CT scan**	**MRI**						**PET**
		T1	**T2**	**Gad enhanced**	**DWI**	**ADC**	**MRS**	
Primary cystic neoplasm	Hypodense with rim enhancement	Hypointense	Hyperintense	Thick rim or nodular	variable	high	Suppressed NAA and Creatinine. Elevated choline and lactate in high grade glioma	Increased Metabolic Uptake
Metastasis	Hypodense lesions with rim enhancement	Hypointense	Hyperintense	Thick rim or nodular	Dark	high	Suppressed NAA and Creatinine. Elevated choline and lacate variable.	Increased Metabolic Uptake
Primary benign cystic tumor	Ring enhancing lesions with surrounding edema. multilobulated lesions may be seen s/o daughter abscesses	Core hyperintense, surrounding hypointense edema	Cavity hypointense, surrounding hyperintense edema	Ring enhancement	Bright	low	Lactate, lipids, amino acids, acetate and succinate peaks	Increased Metabolic Uptake

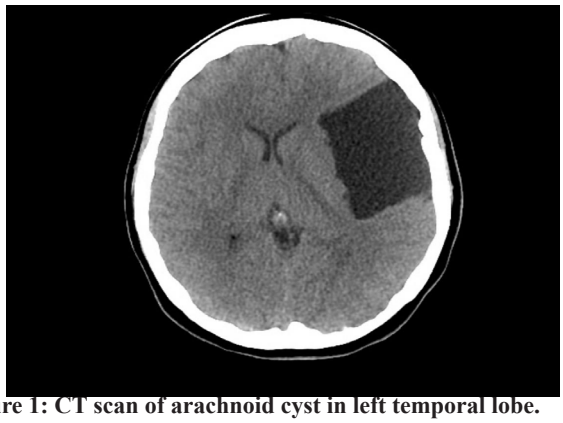

Figure 1: CT scan of arachnoid cyst in left temporal lobe.

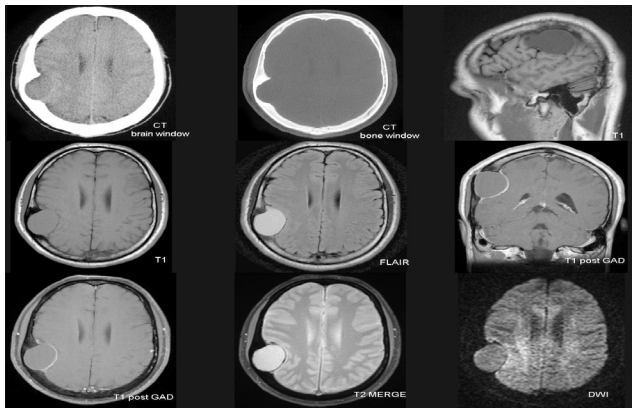

Figure 2: Arachnoid cyst in right parietal lobe

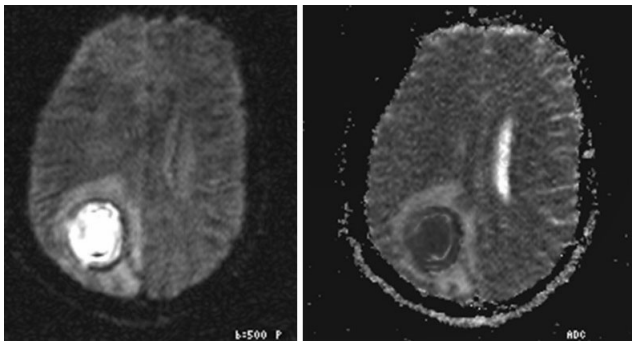

Figure 3: Cystic glioma in right occipital lobe.

Figure 4: Metastatic tumor from lung cancer in left occipital lobe on DWI shows low signal surrounding by high signal edema

DISCUSSION

According to our result, CT scan and MRI were sensitive imaging in intra cranial tumors but they are not specific. Their high positive predictive value and low negative predictive value also made them reliable diagnostic procedures when it is difficult to access mass directly.

In this study relation between CT scan findings and pathologic findings surveyed and concluded that some findings like cystic or solid lesions, calcification, shifting, edema and enhancement did not predispose biopsy reports, but hydrocephaly found as a predictive finding in CT scan reports for determining malignant tumors.

MRI is a good module using multiple relaxation properties seen in tissue types to provide information on content of masses of soft tissue, the result of this information show the character of masses of soft tissue [12,13]. Diffusion-weighted MR imaging is found to be highly specific and sensitive for the diagnosis of cerebral infarction in acute stage [14].

In this study, the sensitivity of DWI 90% for diagnosis of primary brain tumor. This result goes with finding of Bukte [15]. DWI (diffusion–weight MR imaging) has shown promise in differentiating malignant neoplasm and brain abscess the ability of DWI to diagnosed brain abscess enables a neurosurgeon to change planning of management, all brain abscess restricted water diffusion as indicated by hyper intense on DWI and diminished on ADC this finding similar to finding by Leuthardt [16].

In this study we focused on ability of DWI and ADC to characterize necrotic tissue from water content of brain mass that DAI restricted all water in abscess causing the abscess high signal on it and low signal on ADC this finding similar to finding by several reports[4,11].

In this study relation between CT scan findings and pathologic findings surveyed and concluded that some findings like cystic or solid lesions, calcification, shifting, edema and enhancement did not predispose biopsy reports, but hydrocephaly found as a predictive finding in CT scan reports for determining malignant tumors.

In this study the sensitivity of DWI for diagnosis abscess are 100 %, for diagnosis primary benign cystic brain tumor (arachnoid and epidermoid cyst) are 100 %

this result goes with finding of several reports [13].

In tumor lesion presence large areas of necrosis can be well detected on the elevated ADC [17]. One of the early reported applications of diffusion imaging in brain tumors diagnosis was the differentiation between primary benign epidermoid and extra-axial cysts[18]. In our study found Diffusion-weighted imaging is good modality for distinguishing brain abscess from cystic or necrotic tumor lesions, is more best than performing conventional MRI alone the finding similar to finding by Chang [19].

In this study, patients were classified into three main groups; first group: the patients with cystic or necrotic malignant brain tumors of high grade necrotic glioma (16 cases); second group: is benign cystic masses, arachnoid and epidermiod cysts (24 cases); and third group: metastatic cystic tumor (20 cases).

On visual assessment, all brain abscesses showed ring enhancement at post contrast T1 weighted images and brain abscesses are hyper intense on DWI and hypo intense on ADC maps (restricted diffusion) make the sensitivity of diffusion weighted for diagnosis brain abscess 100% this result similar to finding by Leuthardt[20].

CONCLUSION

According to our results we concluded that MRI has more accuracy than CT scan for diagnosis brain tumors and biopsy correlation. Both CT scan and MRI reports for diagnosis of benign or malignant tumor compared with pathologic findings and they were not significant. There is widely applied of Diffusion-weighted MRI imaging for diagnosis of various diseases including the detection of cystic brain tumors from abscess, and distinguishing arachnoid from epidermoid cysts.

Health Literacy as a Risk Predictor of Cardiovascular Diseases among Informal Sector Worker in Makassar City

Novita Medyati[1], Ridwan Amiruddin[2], Arsunan, A.A[2], Muhammad Syafar[3], Saifuddin Sirajuddin[4], Risnah[5]

[1]Doctor Program, Faculty of Public Health, UNHAS Makassar, [1]Department of Occupational Health Sciences, Faculty of Public Health, UNCEN, Papua, [2]Department of Epidemiology, Faculty of Public Health, UNHAS Makassar, [4]Department of Behavioral Sciences at thePublic Health Faculty, UNHAS Makassar, [5]Department of Nutrition at the Public Health Faculty, UNHAS Makassar, [6]Department of Nurse, Faculty of Medicine and Health Sciences, State Islamic Universityof Alauddin, Makassar

ABSTRACT

Background: Health literacy is a concept that can influence a person's health status. The purpose of this study was to determine the relationship between health literacy and the risk of cardiovascular disease in informal sector cooks in Makassar City. **Method**: The quantitative study method with cross sectional design was carried out in the working area of the Tamalanrea Health Center in 80 informal sector cooks determined by purposive sampling. Data collection uses HLS-EU prevention of cardiovascular disease, and the form of the Jakarta Cardiovascular Score. Processing data with SPSS version 20 for Windows, analyzing data with Chi Square test on 95% CI and $\rho<0.05$. The results showed that more than half of the informal sector cooks had a low literacy level (63.7%) and were in the high risk category of cardiovascular disease (52.5%). **Result:**There is a significant relationship between low health literacy and the risk of cardiovascular disease ($p = 0,006$). **Conclusion:** low health literacy is very influential on the risk of cardiovascular disease. It is recommended to use a preventive health based literacy model for informal sector workers to be able to be independent in seeking their health.

Keywords: *Health literacy, Risk of cardiovascular disease*

INTRODUCTION

According to WHO (2016), deaths from cardiovascular disease have affected more than 75% of the population in low and middle income countries.[1] This condition is caused due to the fact that integrated primary health care programs for early detection and treatment for people who have risk factors are often not utilized properly, so the disease is slowly detected and eventually experiences death.[2]

Indonesia is one country that has a high risk of premature death. According to WHO (2016), non-communicable diseases are estimated at 75% as a cause of death from all deaths, as much as 35% of the proportion of deaths caused by cardiovascular disease and predicted to continue to increase.[3]

The international world continues to try to reduce the incidence of non-communicable diseases. World Heart Federation (WHF) has initiated a cardiovascular disease prevention and control program called 25 by 25 Global Target. This program was created with the aim of reducing the premature mortality rate due to CVD by 25% in 2025.[4]

On national scale, Indonesia has taken several control measures against the risk of cardiovascular disease, such as making guidelines for controlling heart and blood vessel disease[5], GERMAS programs (Healthy Life Society Movement), and CERDIK appeal (regular health checks, eliminate cigarette smoke, diligently exercise physically, healthy and balanced diet, adequate rest, and manage stress), but the results are not maximal. The results of the Basic Health Research (Riskesda)

prove the increase in cases of cardiovascular disease in 2018 compared to 2013. [6,7]

Research conducted by Kurniawidjaja (2007) in several companies in Indonesia, found that 40% - 58.3% were caused by cardiovascular disease.[8] Informal sector cooks are workers with a high prevalence rate of the incidence of hypertension. Research conducted by Bosu (2015) found the highest prevalence of hypertension in cooks in the West African region at 68.9% compared to other types of work.[9] Factors causing cardiovascular disease in workers, can be caused by the work environment such as noise,[10-13] work stress,[14-16] chemicals in the form of pollutants,[17,18] workloads,[19,20] and healthy lifestyle.[8,14] Kurniawidjaja reported thatcase identification results of cardiovascular disease in workers at an automotive factory and found 23% of workers at high risk, 50% at risk of developing cardiovascular disease, where the dominant risk factors for health problems were factors that could be intervened with healthy life behaviors.[8]

The results of a study conducted by Won et al. (2013) found that knowledge is a significant predictor of cardiovascular events in workers.[21] According to Setyawaty, the lack of knowledge and skills regarding occupational health and safety in the workplace has resulted in workers being at risk of getting accidents due to work and work-related illnesses and diseases due to work relations.[22]

Health literacy is what underlies good health knowledge and is very influential on the healthy behavior of individuals.[23] Research conducted by Andrade et al (2017), to characterize specific knowledge of cardiovascular disease, especially stroke and myocardial infarction (MI), and its relationship with sociodemography factors, health knowledge and clinical history, in 1624 Portuguese residents, found important gaps in knowledge related to cardiovascular health in Portuguese society. Andrade et al (2017), suggested the need for a strategy and practice of health education to improve knowledge of cardiovascular health among the Portuguese population.[24]

METHOD

This study used a cross sectional study from January to February 2018 on 80 informal sector cooks determined by purposive sampling technique. Data collection used the HLS-EU cardiovascular disease questionnaire, consisting of 15 questions for disease prevention for workers.[23] Health literacy questionnaire is a standard questionnaire but researchers modified the questionnaire so that it was easier to understand by respondents without changing the purpose of each question.

The results of the validity test by comparing the r value of the table with r count obtained by the value of r count (0.635 - 0.853)> r table, so the questionnaire was declared valid. The instrumental reliability test results are using the Cronbach's Alpha formula, obtained by the reliable coefficient value of 0.943> 0.60 then the statement is said to be reliable. Determination of the risk of cardiovascular disease using the form of the Jakarta Cardiovascular Score. Jakarta Cardiovascular Score is a standard questionnaire so that validity and reliability tests are not carried out. Obtained from the risk value for gender, age, blood pressure measured using a Sphygmomanometer, body mass index (height measured by microtoise which has a precision of 0.1 cm; body weight was measured by tread scales), smoking, diabetes based on the statement of respondent has ever been diagnosed by a health worker and physical activity based on the statement of respondents who refer to the criteria in the Jakarta Cardiovascular Score, with a sensitivity level of 77.9% and high specificity of 90%, against the Framingham study scoring.[25] Processing data with SPSS version 20 for Windows, analyzing data with Chi Square test on 95% CI and $\rho < 0.05$.

RESULT

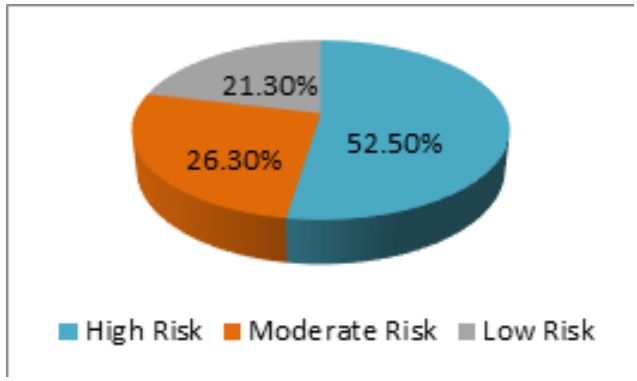

Figure 1. Distribution of Risk of Cardiovascular Disease to Respondents

In Figure 1, the data collection results show that the highest percentage of cardiovascular disease risk in respondents is in the high risk category (52.5%).

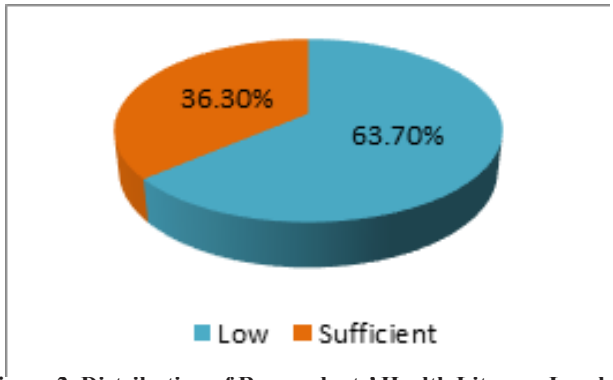

Figure 2. Distribution of Respondents' Health Literacy Levels

Figure 2 shows the identification of respondents' Health Literacy using the HLS-EU questionnaire, where the largest percentage of respondents was in the category of low Health Literacy (63.8%).

Table 1: Relationship between Health Literacy and the Risk of Cardiovascular Disease in Respondents

Health Literacy	Risk of cardiovascular disease			Total	ρ - Value
	High	Moderate	Low		
Low	33(64,7%)	12(23,5%)	6(11,8%)	51 (100%)	0,006
Sufficient	9(31,0%)	9(31,0%)	29(100%)	29(100%)	
Total	42(52,5%)	21(26,3%)	17(21,3%)	80 (100%)	

p value < 0,05

Table 1 shows a high percentage of respondents with low literacy, had a high risk of cardiovascular disease (64.7%). There is a trend of an increased risk of cardiovascular disease in respondents who have low health literacy. Table 1 also shows a significant correlation between the level of health literacy and the risk of cardiovascular disease.

DISCUSSION

Health literacy is a process carried out by a person related to his health condition in terms of making appropriate decisions so that he is always in a healthy condition.[26-28] The results of this study indicate the level of health literacy of respondents in the less category (63.7%).

The level of health literacy that is lacking is a condition that must receive attention from the government because it involves a basic understanding of the risk of an illness. The level of health literacy can be influenced by several determinants, the first is a personal determinant that includes age, gender, race, socio-economic status, education, employment and income, and the second is the determinants of society and the environment including demographic conditions, culture, language and community systems) and social determinants (family support and relations).[28,29]

In addition, access to health information also affects a person's ability to obtain health information and education from health care providers.[30] Especially for informal sector workers, inherent characteristics such as low education levels, lack of access to health information and health services, will ultimately lead to poor workers' health. The results of a survey conducted by the ILO in collaboration with Jamsostek (Workers' Social Security), found that 80% of informal sector workers do not have health insurance other than expecting guarantees from their families.[31]

Regarding the risk of cardiovascular disease, the results of this study prove a significant relationship between the level of health literacy and the risk of cardiovascular disease. There is aincreasing trend risk of cardiovascular disease in workers with low health literacy than workers with sufficient health literacy.

Research conducted by Ko et al (2013), corroborates the results of this study. Ko et al. conducted a study of

the relationship between health literacy and knowledge and control of disease in patients with hypertension in Singapore, found a significant relationship between health literacy of patients with hypertension and knowledge of hypertension.[32]

Relationship between health literacy with different cases of disease is carried out by several researchers, namely Kalichman and Rompa (2000) and Giselle et al (2006). This study provides evidence that health literacy is a factor that has a significant relationship with the health and treatment of patients with HIV AIDS.[26,33] According to Nutbeam, health literacy is the goal of the concept of behavioral-based health and communication education that aims not only at lifestyle changes but also to achieve awareness of the effects of health and encourage individuals and communities to act in dealing with health problems.[27]

This study proves that informal sector workers with a low level of health literacy have the potential to experience the risk of cardiovascular disease, so a model of preventive action based on health literacy needs to be made to

CONCLUSIONS

this study shown that health literacy greatly influences cardiovascular disease. informal sector workers with a low level of health literacy have the potential to experience the risk of cardiovascular disease.

RECOMMENDATIONS

Health literacy model are a recommended to prevent cardiovascular disease in informal sector workers in order to be independent in seeking their health.

Anxiety Level of Dental Care among Adolescents in Kepulauan Selayar District

Lilies Anggarwati Astuti[1,2], Nurnaeni1[3], Faiqah Umar[1,4], Hasanuddin Tahir[5], Asmawati Amin[6]

[1] Post Graduate Program of Medical Science, Faculty of Medicine, University of Hasanuddin, Makassar, Indonesia, [2]Department of Periodontology, Faculty of Dentistry, University of Muslim Indonesia, Makassar, Indonesia, [3]Gunung Sari Makassar Midwifery Academy, Makassar, Indonesia, [4]Makassar Medical State Laboratory, Indonesian Ministry of Health, Makassar, Indonesia, [5]Department of Periodontology, Faculty of Dentistry, University of Hasanuddin, Makassar, Indonesia, [6]Department of Oral Biology, Faculty of Dentistry,University of Hasanuddin, Makassar, Indonesia

ABSTRACT

Introduction: Dental health has not seen any tangible results that needs an attention and require cooperation from various parties. One of the contributing factors is the lack of data on the level of community dental and oral health care needs that owned by the local government so that efforts to actualize healthy communities including dental and oral health are less than optimal. The objective of the study is to identify the level of anxiety of dental services among adolescents in Kecamatan Benteng, Kepulauan Selayar Distict. **Subjects and Methods:** The present study is a purposive-sampling study, adolescents between the age of 17 to 21 years old in state senior high school. This study obtained 511 students from three different schools and processed with SPSS Version 16. **Discussion:** A total of 511 students showed four level of anxiety— Not Anxious, Less Anxious, Anxious and Very Anxious. Most student experienced a not anxious level (56,8%), while only 2,3% students showed a very anxious level. In addition, the respondent was divided into two groups, based on visiting dentist in the last two years. Respondents who have had last visit to the dentist more than 2 years witnessed more anxiety than they who are visiting dentist in the last two years. **Conclusions:** The cause of anxiety to dental treatment is influenced by many factors, which relate closely to the pain history on dental treatment both in the adult and children.

Keywords: *Anxiety, Dentist Care, Adolescents, Kepulauan Selayar District.*

INTRODUCTION

Kepulauan Selayar is a district in South Sulawesi Province , Indonesia, which Benteng city is the capital city. This district has an area of 903.35 km² and a population of ± 100,000 inhabitants. This area is the only regency in South Sulawesi that its entire territory separated from the mainland of South Sulawesi and more than that region Kepulauan Selayar District consists of a group of islands so that is the archipelago region. This place consists of 123 islands, both large islands and small islands extending from North to South which has a stable number of schools each year. Those are elementary school 139 units (16,207 students), junior high school 52 units (5,232 students), senior high school 8 units (2,343 students) , and vocational school 7 units (1,481 students).

In addition, it has variety of health facilities. There are one general hospital, 13 public health centre and 61 units supporting community health centre. On the other hand, oral and dental health problems are found in Kepulauan Selayar which need to get attention and require cooperation from various parties. Moreover, efforts to overcome have not seen any tangible results when

measured with public dental health indicators. One of the contributing factors is the lack of data on the level of community dental and oral health care needs that owned by the local government so that efforts to actualize healthy communities including dental and oral health are less than optimal. If this continues, obviously dental and oral health especially in the community will continue to decline. And ultimately affect their quality of life[1,2].

Anxiety is a vague feeling of discomfort, with a shadow that something undesirable will happen (Kargan & Haveman, 1976). Surveys generally showed that most of the general population avoid regular visits to dentists because they are afraid to do so. In recent studies, anxiety about dental care is associated with the length of time since the last visit to dental care and the greatest frequency of cancellation visits. Anxiety about dental care restricts partial, or prevents all oral health care services. An anxious person shows more damage or missing teeth and less restored teeth [4.5]. The level of anxiety is closely related to the method of oral and dental treatment that will be given to the patient. Patients with high levels of anxiety will find it more difficult to receive dental and oral care as well[3, 13].

SUBJECTS AND METHOD

The present study was a purposive-sampling study among adolescents between the ages of 17 to 21 years old in state senior high school. This study obtained 511 students from three different schools. Those schools were Benteng Senior High school, Muhammadiyah Senior High school and Benteng Vocational High school. Examination of survey was based on questionnaires/survey forms. Researchers attend all senior state high school and vocational schools in each location then explained the purpose of visits, followed by the distribution of a questionnaire /survey form and filling the questionnaire/survey form. Eventually, the data collected was processed with SPSS Version 16.

DISCUSSION

Results showed that the characteristics of respondents consists of age, sex, class grade, parental education level , last visit to dentist and anxiety of dental services. Majority respondents was in 16-17 years old (75.5%) and the least age was in 20-21 years old (0.8%). In addition, most of respondents were women (58.1%), while another was only 41.9%. The respondents was generally second grade (57,9%) and most of them had parents with bachelor education level (51,1%). In the last two years, it had 52,4% who had visited the dentist. Furthermore, most of the respondents do not feel anxious about dental services (56.8%). The data result is shown in Table 1 below:

Table 1. Characteristics of respondents

Respondents Characteristics	n	%
Age Group (year)		
16 - 17	386	75 , 5
18 - 19	121	23 , 7
20 - 21	4	0, 8
Gender		
Man	214	41 , 9
Women	297	58 , 1
Grade		
1	12	2 , 3
2	296	57 , 9
3	203	39 , 7
Parents' Education		
High school	250	48 , 9
Bachelor	261	51 , 1
Last Visit To Dentist > 2th		
Yes	268	52 , 4
No	243	47 , 6
Anxiety Level of dental services		
Not Anxious	290	56 , 8
Less Anxious	149	29 , 2
Anxious	60	11 , 7
Very Anxious	12	2 , 3

Source: Primary Data

Table 1 showed that most of adolescences were not anxious of dental services. Even thought it showed a not anxious level, there were other anxiety levels which almost a half of the results. This sums that anxiety of dental services was still an issue in Kepualaun Selayar District. Moreover, the correlation of anxiety level and last dentist visiting is shown in table 2.

Table 2. Correlation of anxiety level to dental services and last dentist visit.

Anxiety	Last visit to the dentist > 2 years				Amount	
	Yes		No			
	n	%	n	%	n	%
Not Anxious	145	54,1	145	59,7	290	56 , 8
Less Anxious	82	30,6	67	27,6	149	29 ,2
Anxious	33	12,3	27	11, 1	60	11 , 7
Very Anxious	8	3,0	4	1 , 6	12	2 , 3
Amount	268	100	243	100	511	100

Source: Primary Data

Table 2 shows that in the last two years visiting the dentist had almost the same number in all level of anxiety. Respondents who've had last visit to the dentist more than two years mostly felt not anxious (54,1%). This number has slightly lower than them who were not visiting the dentist, which were 59,4%. In contrast, other anxiety levels on respondents who visited the dentist experienced a little more percentage compare to them who had not visited.

Different types of anxiety components are interconnected with one another, but it is important to repeat here that there is no one-on-one relation between the components. Some people are actually very anxious about dental treatment but regularly and fairly cooperatively examined while others may actually avoid visiting dentists.[6,14]

Approach through education alone is not enough, because it only gives partial impact on behaviour change. Although humans need information and skills, they have no motivation to implement the newly-given information[15]. The idea that research alone is not enough, supported by research conducted by Todd et al (1982). Although 91% of the sample size is large enough to agree that regular visits to dentists are important to maintain dental health, 43% say they go to the dentist only when experiencing symptoms. The imbalance between knowledge and the actual behaviour may related to the motivation factor, especially the consequences seen from its actions.[6]

A review of the literature estimates that 9% of the world population suffer from a sense of fear/anxiety to dental treatment, with a reduction in prevalence as age increase. The cause of anxiety to dental treatment is influenced by many factors, which relate closely to the pain history on dental treatment both in the adult and children. The prevalence of fear to dental care is considered high (24.3 %), but lowers than fear of snakes, heights or injured physically.

Surprisingly, among all the phobias, the most common is dental phobia (3.7 %). These findings should be on alert by both researchers and dental care practitioners as a very real problem with the aim to finding ways to improve the conditions. [12] Fear to dental care usually begins in childhood with a negative experience, commonly expressed as a painful experience and/or being treated by a rough dentist.

Although it tends to decrease with age increasing, anxiety of dental care can last until adolescence and continue into adulthood. This is important. Therefore, the dentist should be able to identify these patients, with the aim to plan dental interventions that can reduce an individual's anxiety level. [12]

CONCLUSIONS

The cause of anxiety to dental treatment is influenced by many factors, which relate closely to the pain history on dental treatment both in the adult and children.

ABSTRACT

Essentially, kids world are identic with playing activities, mainly in early age kids. Through games, children are experiencing the learning process. This study aims to evaluate and provide recommendations to reduce the risk of accidents at Kindergarten. The result shows that there were several accidents experienced by children when playing in a playground such as bumping into a friend, crashing into a game device, stumbling, and falling from the playground. The playground in Immanuel Kindergarten generally has a relatively narrow and hollow place but has a clear guardrail so that children remain within reach. Some students play not according to how to play the tool, which increases the risk of falling. In general, there are differences between playgrounds at Immanuel Kindergarten and playground standards (p value 0.03<0.05), which is caused by several factors that influence human, method, equipment and environment. The improvements suggestions are referred to the strategy that is most likely to be implemented, namely the SO strategy to provide prior knowledge to children before playing and manage to play facilities.

Keywords: *playground, evaluation, t-test, fishbone, SWOT*

INTRODUCTION

Children are unique individuals and have all the potential that can be developed. Children naturally have the ability to develop their potential. This ability is obtained by children through the experience of associating with people in their environment, whether parents, siblings, peers, or other adults. Early experiences of hanging out with their environment can be obtained by children from an early age. Early childhood is a child who is in the age range of 0 years from birth to the age of 6 years.[1,2]

The early period (0-6 years) becomes a sensitive period that is the period of physical and psychological maturation functions that are ready to respond to the stimulation provided by the environment. This period is a time to study physical, cognitive, language, social-emotional, self-concept, discipline, independence, art, morals, and religious values[8]. Basically, the world of children is identical with playing, especially at an early time. Through games, children experience the learning processes.[3]

One place for children's education or kindergarten (TK) which has a children's play area as a means of learning is Immanuel Kindergarten Batu City. This kindergarten has an outdoor children's play area with various playground equipment such as swings, slides, and globe climbing. During breaks, the children are very active in trying various games that require physical ability in the play area. However, children's playground equipment and the playing environment can pose a great risk if not carefully designed and maintained. Based on preliminary studies conducted at Immanuel Kindergarten Batu City, there were several accidents experienced by children while playing in the playground. The following is data about accidents during play experienced by children recorded within 1 month based on the results of interviews with TK Immanuel teachers, namely 40%

crashing a friend, 33% stumble, 20% crashing into a game tool, 7% falling from a game tool.

Management of children's play area needs to be considered so that it can provide benefits to playing with children. In addition, good management of various aspects such as game tools, playing methods, supervision, and the playing environment can also reduce accidents while playing. Therefore, the design and construction of children's playgrounds in schools, especially kindergartens require emphasis on security and comfort aspects to ensure their level of safety.[4,5]

METHOD

Time and Place

Study about the evaluation of playground in kindergarten takes a place in Immanuel Kindergarten. This study was conducted during June-August 2018.

Data Collection

Data collection was done by collecting primary data and secondary data. Primary data in the study were collected through observation of play activities and children's behavior. Then do an evaluation by filling in the checklist of a good playground. Data related to accidents while playing and safety culture while playing for children were also conducted by interviewing several accompanying teachers who accompanied the children while playing. Secondary data that used in this research is the standard data on a good playground.

Data Processing Method

Based on the results that have been obtained, data processing is carried out through comparative studies with dependent sample t-test by comparing the standards of good playgrounds with observations obtained directly from observations in the field, as well as secondary data obtained through supporting studies. In addition, an analysis was carried out using a causal diagram and formulation of strategies to correct problems with the SWOT method.

RESULT AND DISCUSSION

Physical Conditions of Playground

One of the things that need to be considered in the management of the playground is the condition of the environment where children play. This can be in the form of the physical condition of the land and building play, or the condition of outdoor playground equipment that is in the playground. The playground at Immanuel Kindergarten has an area of approximately 40 m^2 with a variety of game tools namely climbing the globe, swings, seesaw, as well as a number of agility rides where students will face obstacles such as climbing, bowing through holes, and so on.

The children's playground in Immanuel Kindergarten generally has a relatively narrow place so that children who play and run are very likely to collide with other children. In addition, there are several holes on the surface of the playground that cause the possibility of a child falling because of the hole. However, the children's playground has a guardrail made of iron fences and hedgerows so that the children keep playing in the place provided and affordable by the teacher's supervision.

Safety Culture

The culture of child safety when playing is an important thing that must be introduced to children so that children can use the facility to play properly and not to engage themselves or others. During playing, all students of Immanuel Kindergarten were always accompanied by several teachers, so that the children were still under surveillance. Teachers of Immanuel Kindergarten carry out controlling functions so that children keep playing safely and preventing accidents. However, there are still children who have a tendency to endanger themselves while playing. Here are some examples of cases of misuse of play facilities performed by children:

One of the students climbed the stairs not through the steps, but through the ladder barrier which should be used to hold hands so as not to fall. This can endanger the child because with the position of the body as shown below, the child easily loses balance and allows an accident to fall from the playground.

Some students are seen standing in the swings and handrails, so that when a swing moves it can cause children to lose balance.

Based on the results of interviews with the teachers of Immanuel Kindergarten, children are always reminded when using the game but not in accordance with the actual way of use. There is no specific overview for children about the available play facilities and how to

play, so children are free to explore the usefulness of the tool. But every resting hour and the child is free to play in the outdoor area, each teacher has informed students to be careful in playing.

Comparative Study

The comparative study was conducted to evaluate the place of play of observation objects with a good standard of the playground, and analyze the causes of various aspects so that further steps can be identified.

Comparison of Playgrounds Immanuel Kindergarten with the Standards

This comparative study was carried out using the student-t test to compare whether there was a difference between the object's playground and the predetermined standard. The actual situation in Immanuel Kindergarten is perceived value, which is an assessment of the observations perceived by observers. While the standard playground is the expected value. This assessment uses an interval scale of 1-3 with successive provisions that arenot appropriate, appropriate, and very appropriate. After getting perceived and expected values, the gap or difference between the two is calculated by subtracting the expected value from the perceived value.

Table 1. Comparative Value of Playground in Immanuel Kindergarten with Standards

No.	Aspects	Perceived	Expected (Standard)	Gap
1.	Equipment and play areas do not have the following: sharp points or angles; splinters or protrusions that might catch children's clothing; peeling paint; loose or rusty parts; small parts that can be released or present the danger of suffocation, aspiration, or consumption; danger of strangulation; components that can tear the skin, pinch, thin, or destroy body tissues.	1	3	2
2.	To prevent the trap of the head or limbs of children, all openings while playing or other equipment are too large for the child's head or limbs to be trapped or too small to be inserted into the child's body.	2	3	1
3.	To prevent finger traps, openings are smaller than 3/8 inches or larger than 1 inch.	3	3	0
4	Other toys and equipment used in and around the water play area are made of solid plastic or metal. No one uses glass material.	2	3	1
5	Children do not play in areas where there are water bodies including tubs, buckets, washbasins, toilets, swimming pools, pools, irrigation canals, or installed wading pools, unless adults watching are within arms that provide a touch of supervision.	2	3	1
6	There is no danger of tripping	0	3	3
7	There is no danger of being hit by goods	3	3	0
8	Hazardous equipment are not available or cannot be accessed by children using barriers such as fences.	2	3	1
9	Children wear hats or hats in full to protect their faces from the sun if they are not in a shady place.	0	3	3
10	Physical activity / outdoor time is not taken as a punishment.	3	3	0
11	Caregiver / Teacher uses simple rules for behavior that children can understand. They use clear, direct and simple commands, and descriptive praise.	2	3	1
12	Caregivers / Teachers encourage positive behavior, promote self-regulation, and model desired behavior.	3	3	0
13	Caregivers / Teachers support children in learning appropriate social skills and emotional responses as well as providing predictable daily routines and schedules.	3	3	0

In determining whether there is a difference between the object of observation and the standard, the t-test is carried out by setting the significance level or alpha of 5%. H_0 shows that there is no difference between the object of observation and the standard, while H_1 shows the difference between the object of observation and the standard used.

Based on these results, it is known that the sig value is 0.003 <0.05, so H_0 is rejected. This means that overall, there are differences between the object of observation and the standard. This difference can occur, among others, because there are some things that are not in accordance with the standard of the playground.

Improvements can be made by improving aspects that have a large gap between perceived, and expected. The biggest gap is worth 3, namely in the aspect of no tripping danger and aspects of the use of hats in outdoor activities. Here are examples that are suitable for amusement park improvements:[6,7]

The use of pedestal playgrounds that are safe and flat like carpets or fine sand, so there are no holes that can make a child trip.

Use a hat or head protection when children play in an open area so that children are protected.

Cause-Effect Analysis

Generally, there are several factors that cause children's playgrounds, especially those in kindergartens, to still cause potential accidents in children. The following is a causal diagram to explain the root causes of potential accidents when playing:

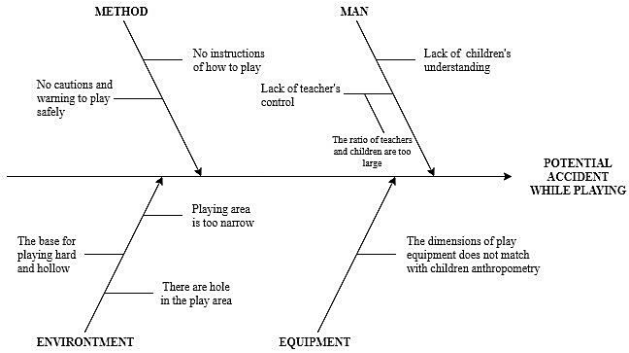

Figure 1. Cause-Effect Diagram

Strategic Planning

Based on the SWOT analysis it can be seen that in developing playgrounds in Immanuel Kindergarten Batu City there are very influential factors, which is internal factors including strengths and weaknesses and external factors including opportunities and threats. The following is an internal factor evaluation (IFE) and external factor evaluation (EFE) table from the playground in Immanuel Kindergarten:

Table 2. Table Matrix IFE and EFE

	Strength			
No.	Information	Weight	Rating	Score
1.	The game facilities that are owned are quite varied, among others, a vehicle for agility, swings, globe climbing and slide.	0,2	4	0,8
2.	There are teachers who accompany children every play.	0,2	3	0,6
	Subtotal	0,4		1,4
	Weakness			
No.	Information	Weight	Rating	Score
1.	Lack of information about how to play	0,2	2	0,4
2.	Lack of debriefing on children regarding safety in playing	0,1	3	0,3
3.	The playing environment is too narrow	0,1	2	0,2
4.	The base for playing hard and hollow	0,2	2	0,4
	Subtotal	0,4		1,3
	TOTAL	1		2,7
	Oportunity			
No.	Information	Weight	Rating	Score
1.	Game facilities that are owned can increase children's agility and motor power	0,5	4	2
	Subtotal	0,5		2

Cont... **Table 2. Table Matrix IFE and EFE**

	Threat			
No.	Information	Weight	Rating	Score
1.	Land degradation	0,2	3	0,6
2.	Facilities that are damaged due to high playing frequency	0,3	3	0,9
	Subtotal	0,5		1,5

Based on the analysis in the IFE matrix, the strength factor has a total score of 1.4, and the weakness factor has a total score of 1.3. The results of the EFE matrix indicate the opportunity factor has a score of 2, while the threat factor has a value of 1.5. Then it is known that the strength value above the weakness value, with the difference (+) 0.1 and the opportunity value above the threat value with the difference (+) 0.5. From the results of the identification of these factors it can be described in the SWOT Cartesian Diagram

From the SWOT diagram, the playground at Immanuel Kindergarten is in quadrant 1, which is aggressive. Being in quadrant I is a very favorable situation, because the Immanuel Kindergarten playground has the opportunity and strength so that it can take advantage of the opportunities that exist. The strategy that must be applied in this condition is to support aggressive growth policies (Growth Oriented Strategy).[6,7,8]

The explanation of strategic planning can be described below:

Strength: The game facilities that are owned are quite varied, among others, a vehicle for agility, swing, globe climbing and slide, there are teachers who accompany children every play.

Weakness: Lack of information about how to play, lack of debriefing on children regarding safety in playing, the playing environment is too narrow, the base for playing hard and hollow.

Opportunity: Game facilities that are owned can increase children's agility and motor power.

SO Strategy: Using strength to utilize opportunity=3.4, manage game facilities to increase children's motor power, the teacher gives play instructions and helps students optimize their physical condition to improve motor skills

WO Strategy: Minimize weakness to utilize opportunity=3.3, provide information about how to play, provide information related to safety in playing, expand the playground so that it can add games that increase child agility, improve the playground so that it doesn't cause accidents.

Threat: Land degradation, facilities that are damaged due to high playing frequency

ST Strategy: Using strength to overcome threats=2.9, maintain the feasibility of playing equipment, give instructions on how to play so as not to damage the game

WT Strategy: Minimize weakness to avoidthreats=2.8, optimize available land and choose a safe place to play.

The strategy that is applied in the development of the playground in Immanuel Kindergarten is to support aggressive growth policies (Growth Oriented Strategy) that is to manage game facilities in order to increase children's motor power, and provide play instructions and help students optimize their physical condition to improve motor skills.[7,8]

CONCLUSIONS

The playing environment tends to be narrow and hollow, causing several accidents, including colliding and tripping. Children do not fully understand the safety of playing so that there are still children who have the potential to cause accidents. In general, there are differences between playgrounds at Immanuel kindergarten and playground standards (sig. 0.03 <0.05). The biggest difference lies in the aspect of no tripping danger and aspects of the use of hats on outdoor activities caused by several factors including human, method, equipment, and environment. Proposed suggested improvements refer to the strategy that is most likely to be implemented, namely the SO strategy to provide prior knowledge to children before playing, and manage play facilities.

Correlation Tuberculosis Drugs Treatment Phase with SGPT/ Bilirubin Total Level and Correlatioan both of the Enzymes from TB Patients

Anny Thuraidah[1], Jihan Rahmah Naily[1], Nadiya Uswatun Hasanah[1], Leka Lutpiatina[1]

[1]Medical Laboratory Technology Poltekkes Kemenkes Banjarmasin, Mistar Cokrokusumo Street 4a Banjarbaru Indonesia,

ABSTRACT

Tuberculosis (TB) is a disease caused by Mycobacterium tuberculosis that can infect some organs of the body such as lungs, kidneys, and bones. Multidrug therapy method using Isoniazid, Rifampicin, Ethambutol, Pyrazinamide, and Streptomycin. Anti Tuberculosis Drugs (ATD) have side effects on the liver, skin, and nerves. Unwanted one is hepatotoxic. This research aims to determine correlation long of ATD administration with total Bilirubin and SGPT level from pulmonary TB patients at Sungai Tabuk 1, and Martapura Barat PHC also determines a correlation between the Total Bilirubin with the SGPT . 25 people as the sample with accidental sampling technique. This research is the analytic survey with cross-sectional study design. The results is 1.36 mg / dL for 0-2 months, 3-4 months were 1.19 mg / dL, and 5-6 months1.13 mg / dL for mean of Total Bilirubin and 30,58 u/l, 19,83 u/l dan 15,16 u/l for mean SGPT level. Spearman test is p 0,001 for Bilirubin ; 0,002 for SGPT with duration ATD administration and 0,000 between those enzymes. A conclusion is there is the significant correlation between duration of administration ATD with total Bilirubin (-0,632) and SGPT (-0,597) While the decrease of level value from both enzymes had the strong correlation (0,972). Recommended for further research to the same respondents with another ATD.

Keywords: *ATD; Treatment Phase; SGPT; Total Bilirubin*

INTRODUCTION

Pulmonary tuberculosis (TB) is a disease caused by the bacteria Mycobacterium tuberculosis which transmitted through the air, usually attacks the lungs but can also attack other organs of the body[1]. Pulmonary tuberculosis is a chronic disease that is still a health problem in the world, including in Indonesia. Six countries accounted for 60% of new tuberculosis cases, namely India, Indonesia, China, Nigeria, Pakistan, and South Africa

According to Indonesian health profile data and information in 2016, the number of new tuberculosis cases was 156,723 cases whereas South Kalimantan ranked 22nd at 2,811 cases consisting of 1,733 men and 1,078 women. The number of tuberculosis cases is possible because of problems in the health center, including patient noncompliance for treatment and low quality of sputum collected by patients for examination[2]. Annual report on Sungai Tabuk 1 and Martapura Barat Health Center in 2016 pulmonary tuberculosis (TB) cases ranked first for infectious disease cases. Since 1995, Indonesia has adopted a WHO-recommended treatment strategy, namely the Directly Observed Treatment Shortcourse (DOTS) strategy. The implementation of the DOTS strategy is proven to reduce tuberculosis mortality[3].

The minimum treatment for tuberculosis for six months with 2 phases namely intensive phase is the initial treatment phase is detected until the second month, and the continuous phase is the treatment phase after the intense period of the 3rd month until the 6th month completed. General therapy is given Isoniazid, Rifampicin, Ethambutol, Pyrazinamide, and Streptomycin. Anti-tuberculosis drugs (ATD) have side effects on the liver, skin, nerves and can cause gastrointestinal. The severe impact that is currently in focus is the effect of anti-tuberculosis drugs on the liver, which causes hepatotoxic, known as Antituberculosis Drug-induced Hepatotoxicity (ATDH)[5].

This is because of the liver functions as the center of a metabolic disposition of all drugs and foreign substances in the body. In the liver, the medication is changed to be more hydrophilic, so it can dissolve in water and can excrete in urine or bile. The resulting liver traces have a direct effect, namely by producing enzyme-drug complexes. This complex will then cause cell dysfunction, membrane dysfunction, and T cell cytotoxic response[6].

Tests that can be done to assess hepatotoxic liver function include measurement of serum bilirubin levels, aminotransferase or transaminase, alkaline phosphatase, Gamma GT, and albumin. The progressive increase in SGPT and Bilirubin levels is very dangerous. Continuous improvement will result in drug-induced hepatitis. When drug-induced hepatitis occurs, the treatment must be stopped, if it occurs in the intensive phase, after the normal SGPT level returns, the treatment is continued with the same drug unless pyrazinamide is replaced with streptomycin. But if it occurs in the advanced phase, after the normal SGPT level returns, the treatment is continued with the same drug, Isoniazid, and Rifampisin[7]. Pyrazinamide should not be given to patients with the abnormal liver function if the patient in the intensive phase has the abnormal liver function.

In the previous study by Pramastuti1 out of 27 patients, there was an increase in SGPT of 22 people[4]. Another supportive study was a study conducted by Khadka[8], out of 114 patients 92 patients had elevated SGPT within normal limits, and 22 patients had elevated SGPT above the normal limit. While the increase in bilirubin levels is used as a specific indicator of hepatic impairment, which can be fatal if not treated early[9]. Besides that, there is an association between the increase in SGPT with Bilirubin in patients with Hepatitis C[10]. From the description of the previous background to find out the hepatotoxic effect of Anti Tuberculosis (ATD) drugs, a study was conducted to determine the relationship of the duration of Anti Tuberculosis (ATD) treatment to SGPT levels and Bilirubin and to determine the relationship of decreased SGPT levels with Bilirubin pulmonary tuberculosis patients.

MATERIALS AND METHOD

The study is an Analytical Survey with a Cross-Sectional design. The study sample was 25 patients with pulmonary tuberculosis category I on intensive phase treatment and advanced phase at Sungai Tabuk 1 Community Health Center and West Martapura Community Health Center. Sampling technique Accidental sampling with criteria for pulmonary TB patients over 18 years with regular treatment. The equipment used by Pharma 08 photometer, Randox RX Monza photometer. Reagents used from the biosystem.

RESULTS AND DISCUSSION

Table 1. Results of measurement of SGPT levels and total bilirubin

Respondents	Giving medicine 0-2 months				Giving medicine 3-4 months				Giving medicine 5-6 months			
	SGPT (u/l)		Bilirubin (mg/dl)		SGPT (u/l)		Bilirubin (mg/dl)		SGPT (u/l)		Bilirubin (mg/dl)	
1	49,5	A	1,77	A	23	N	1,27	A	13	N	1,08	N

5-6 months	44,4	55,6

DATA ANALYSIS RESULTS

Table 5. Results of statistical analysis

Test statistics	Long ATD with SGPT		Long ATD with Bilirubin Total		SGPT with Bilirubin Total	
	p	**Koef korelasi**	**p**	**Koef korelasi**	**p**	**Koef Korelasi**
Normality	0,010	-	0,022	-	-	-
Spearman	0,002	-0,597	0,001	-0,632	0,000	0,972

Single-dose Rifampicin can interfere with excretion of bilirubin so that it can increase unconjugated bilirubin which causes real or subclinical jaundice, without accompanied hepatocellular damage. This can be temporary and will occur early in patients with previous liver abnormalities[11]. Rifampicin also increases INH metabolism into isonicotinic acid and hydrazine, both of which are hepatotoxic. The half-life of plasma AcHz (Acetyl Hydrazine) which is a metabolite of INH shortened by Rifampicin and AcHz rapidly converted into its active metabolite by increasing the rate of oxidative elimination from AcHz, which is related to the high incidence of liver necrosis caused by INH and Rifampicin in combination[12].

On examination of SGPT levels in intensive phase treatment, 5 samples with SGPT levels exceeded normal values because pulmonary tuberculosis patients experienced the highest increase in transaminase enzymes in the fourth week to the sixth week after administration of ATD[13]. This was due to intensive treatment with four types of anti-tuberculosis drugs, namely Isoniazid, Rifampicin, Pyrazinamide and Ethambutol are consumed every day for two months of treatment[14]. And the incidence of hepatotoxicity was higher in patients with latent tuberculosis infection who received combination therapy with Rifampicin and Pyrazinamide compared with patients who only given Isoniazid[15].

Isoniazid inhibits CYP1A2 gene function which functions to detoxify hydrazine, where hydrazine is an isoniazid metabolite which, if further metabolized by cytochrome P450 will produce a product that causes hepatotoxic. While the pyrazinamide toxicity mechanism is unknown, according to case studies in mice, pyrazinamide inhibits the activity of several CYP450.12 And the metabolism of Rifampin starts from acetylated rifampicin to acetylation, then hydrolyzed to 3-formyl rifampicin[11].

In addition to factors from consumption of ATD, SGPT levels exceeding normal values can also be caused by various factors. Based on the results of the questionnaire submitted, all patients on intensive phase treatment who had SGPT levels exceeding normal values were in the age range of 40 to 65 years. This is consistent with Clarasanti's study, with samples with high levels of transaminase enzymes after ATD therapy at most in the 41-50 year age group of 16 people[16].

Also, 2 out of 5 patients who have SGPT levels exceeding normal values are active smokers. Smoking causes lipid peroxidation which causes damage to normal cell membranes from the liver. If liver cell damage occurs, there will be an increase in SGPT and SGOT in smokers compared to nonsmokers[17]. Smoking and shortness of breath also affect the increase in bilirubin levels in line with Lavigne's research results Smoking worsens the condition of pulmonary TB patients. Shortness of breath causes reduced oxygen intake which affects the decrease in oxygen in the body. Lack of oxygen is harmful to the body because it can damage organs such as the liver which plays a very important role in removing toxic substances[24].

Based on the results of examination of SGPT levels in the intensive phase it can be seen that SGPT levels were only 1.5 times higher than normal. Treatment does not need to be stopped if the increase in SGPT levels is less than three times, only to strictly monitor the liver function of the patient while undergoing treatment.7 ATD hepatotoxicity does not occur in every patient but can cause extensive and permanent liver injury and can cause death if not detected at the initial stage[18].

All results in the advanced phase of 3-4 months and eight patients in the advanced phase 5-6 months had normal SGPT levels. Because the type of ATD given in that phase only consists of Isoniazid and Rifampicin and is only consumed three times a week for four months of treatment[14]. And how to administer ATD 3 times per week compared to each day has little impact on the occurrence of hepatotoxicity[15].

In the advanced phase of 5-6 months, there is 1 sample that has SGPT levels exceeding normal values. Hepatic reactions usually appear during the first two months of treatment but can appear at any time during the treatment period[16]. And this can occur due to hypersensitivity reactions in susceptible individuals.

Increased bilirubin levels only occur in the first two and three months of ATD therapy. This is because in the first and second months an intensive phase of ATD administration, giving four treatment regimens at

once for two months. This is due to the inhibition of bile synthesis and excretion of bile acids and bilirubin and cholesterol in bile[20].

Based on the questionnaire submitted the patient worked more than 8 hours and had less than 8 hours of sleep, which caused a lack of rest time. Poor sleep is also the main cause of liver cirrhosis because the body's system requires enough hours for the detoxification process. Like Pramudiantoro's statement that there are several factors that can increase SGPT levels are insufficient rest, too tired and consumption of drugs[24].

Bilirubin is the final breakdown product of heme (hemoglobin), increased in liver cell damage and cholestasis[10]. Increased destruction of erythrocytes that are not matched by the speed of conjugation and secretary of bile flow resulting in increased bilirubin levels, and conjugated bilirubin cannot escape the bile to the intestine so will re-enter and be absorbed into the bloodstream, elimination is less due to the presence of bile duct obstruction or problems in processing bilirubin.[21,22]. Bilirubin levels that are above normal values are also influenced by several factors including hemolytic anemia which is a toxic effect from isoniazid and rifampicin[20,12]. Thuraidah A, et al 2017 states that there is a long relationship between consumption of anti-tuberculosis drugs and anemia[25].

CONCLUSION

The conclusion of this study is that there is a significant relationship between the duration of use of anti-tuberculosis drugs with total bilirubin levels ($p = 0.001 < \alpha$) and SGPT ($p = 0.002 < \alpha$) with a correlation value of -0.632 for Bilirubin Total and -0.597 for SGPT, which states the relationship is moderately correlated and the longer the use of the drug levels are getting lower. While the significant relationship between the decrease in total bilirubin levels and SGPT has a strong correlation (0.972).

ABSTRACT

Background. Workers in the concrete industry can be negatively affected by exposure to particulate matter. Particulate matter that is 2.5 microns in width or less ($PM_{2.5}$) is one of the most dangerous air pollutants because it can be inhaled into the lungs and enter the bloodstream. **Objective.** This research analyzed workers' health risks due to inhalation exposure to $PM_{2.5}$ in at a concrete batching plant. **Materials & Method.** The risk was calculated using an environmental health risk assessment method to determine the value of the risk quotient (RQ). The RQ was obtained by dividing the body exposure intake by the reference concentration. If the value of RQ>1, then risk management is necessary. This study calculated the risk of $PM_{2.5}$ exposure for 59 workers. Samples were collected at 4 points in the plant for 1 hour using a high-volume air sampler; each point was sampled 2 times, once during the day and once at night. **Results.** The average concentration of $PM_{2.5}$ was 120 mg/m^3 that means the concentration was above the quality standard. The calculation shows that $PM_{2.5}$ is risky to workers in life time duration (25 years) with the average yield at least for the next 9 years because reach RQ=1,096. Thus, risk management is required for the next 25 years by reducing $PM_{2.5}$ concentration.

KEYWORDS: *$PM_{2.5}$, Concrete Batching Plant, Environmental Health Risk Assessment*

BACKGROUND

Fine particle or $PM_{2.5}$ is one indicator of air pollution. Particulate matter consists of a complex mixture of solid and liquid particles of organic and inorganic substances suspended in the air.[20, 23] Tracheobronchial penetration of PM is related to particle size and efficiency of the lung defense mechanism[12, 21] Particles smaller than 10 micron cause larger problem, because these particles can enter the lungs and then enter the alveoli into the bloodstream[7] Exposure of $PM_{2.5}$ can cause acute and chronic effects[11, 18] WHO estimates that around 7 million people die every year from exposure to fine particles in polluted air that penetrate deep into the lungs and cardiovascular system, causing diseases including stroke, heart disease, lung cancer, chronic obstructive pulmonary diseases and respiratory infections, including pneumonia[13, 26] These fine particles can penetrate deep into the lungs and then irritate and damage alveolar wall, it will interfere lung function which clinically causes coughing, shortness of breath, and increased risk of Chronic obstructive pulmonary disease (COPD) associated with impaired lung function[9, 16]

The source of $PM_{2.5}$ pollution from industrial activities are usually comes from mining activities, factory chimneys, burning products and the cement industries[4] Batching Plant is a factory that ready mix concrete in accordance with the mix design that is ordered by the contractor who is doing construction[19] Ready mix concrete basically consists of water, cement, fine aggregate and coarse aggregate. Ready mix concrete components include calcium, silica, aluminum,

magnesium, iron oxide and sulfur dioxide compounds along with fly ash, fine aggregates, coarse aggregates and admixture. These materials are source of $PM_{2.5}$ pollution[5, 15]

The objective of this study was to assess the level of non-carcinogenic health risks caused by workers' inhalation exposure to $PM_{2.5}$ in ambient air at a concrete batching plant. The ultimate goal was to formulate a risk management recommendation. Previous environmental health risk assessments (EHRAs) have been conducted to pinpoint where $PM_{2.5}$ exposure affects people working in the cement industry, and they have said that the most considerable risk is in areas closest to pollutant sources[3]

MATERIALS AND METHOD

The method used in this study is the EHRA, which consists of several steps: (1) hazard identification, (2) exposure assessment, (3) dose-response analysis, and (4) risk characterization[14, 17]. Two kinds of samples were used as variables in the risk assessment. The first sampling technique is interviewed workers to know the activity and antrhopometric chracteristics. The second technique was the use of a high-volume air sampler to measure the $PM_{2.5}$ concentrations in the ambient air at the batching plant. The short-term sampling method was used in which samples are collected for 1 hour. The research sample consisted of 59 workers as respondents while the criteria for including each respondent were as follows: (1) a permanent worker in the plant, (2) 18-55 years old when the samples were taken, and (3) a worker in an outdoor area. $PM_{2.5}$ samples were taken at 4 points in outdoor areas and were collected 2 times at each location, once during the day and once at night. The chronic daily intake (CDI) of $PM_{2.5}$ was calculated using the following equation[14] :

Where:

CDI = Chronic Daily Intake (mg/kg/day),

C = Concentration of risk agent (mg/L for drinking water and mg/kg for food),

R = Rate of intake or consumption (L/day for drinking water and kg/day for food),

t_E = Time of exposure (hours/day),

f_E = Frequency of annual exposure (day/year),

Dt = Duration of exposure, year (real time or projection, 30 years for residential default value),

Wb = Weight (kg),

tavg = Average time period (Dt x 365 days per year for non-carcinogenic substances, 70 years x 365 days per year for carcinogenic substances).

Estimation of the level of health risks derived from calculations using Risk Quotient (RQ) is calculated through the equation[14] :

CDI = Intake (mg/kg/day)

RfC = Reference Concentration (mg/kg/day)

RESULT

Hazard Identification. The risk agent in this study is the exposure of $PM_{2.5}$ toward respiration of human body. The highest concentration location for $PM_{2.5}$ exposure is located in the stockpile area during the morning shift which is 137.2µg/m^3, and the lowest is in the silo and parking lot during the morning shift which is 107.5µg/m^3. The average concentration per day of $PM_{2.5}$ is 120µg/m^3 (Table 1).

Table 1. Concentration of $PM_{2.5}$ on 4 points in Batching Plant

No.	Location	Measurement Time	Concentration (µg/m^3)	Average concentration perday (µg/m^3)
1	*Stockpile* Area	09.15-10.15	137,2	129,05
		21.10-22.10	120.9	
2	Central Mix & Conveyor	14.40-15.40	133,5	117,45
		20.00-21.00	101,4	
3	Lab, Workshop, & Waste Treatment	11.10-12.10	114,4	113,35
		21.10-22.10	112,3	
4	Silo & Parking Lot	15.00-16.00	107,5	120,3
		20.00-21.00	133,1	
Total				**120**

Exposure Assessment. Weight measurement and worker activity patterns aim to determine $PM_{2.5}$ exposure to workers in the Batching Plant. Variables that need to be known from the worker activity to calculate the intake are in Table 3. The Frequency of Exposure (f_E) aims to find out the number of working days of workers for one year. Every worker has a 12-day leave per year. The working day of workers in outdoor is 9 per 10 days, so the working days per year multiplied by 365 days is 329 days/year, then minus the days of leave, so total frequency of exposure is **317 days/year.**

The duration of Real Time Exposure is based on the actual time conditions of all respondents, but workers can work in the Batching Plant until their retirement and are constantly exposed to $PM_{2.5}$ exposure. Therefore, it is necessary to calculate the Duration of Life Time Exposure ($Dt_{lifetime}$) with an EPA default value for industry which is **25 year**[8].

The average time period (t_{avg}) is the average time of year the workers working at the Batching Plant. To find out the value by calculating the duration of exposure multiplied by the number of days per year which is 365 days/year for non-carcinogenic exposure (Dt × 365 days/ years for non-carcinogenic substances). The calculation is:

$$T_{avg} = D_t \times 365 \text{ days/year}$$

$$T_{avg} = 25 \text{ year x } 365 \text{ days/year}$$

$$T_{avg} = \mathbf{9.125 \text{ days/year}}$$

Based on the results of the data retrieval, it was found that these Batching Plants have a concentration of $PM_{2.5}$ of 0.12mg/m^3 with the average body weight of the worker 66.83kg and the inhalation rate 0.64m^3/hour, based on the activity pattern of working for 12 hours per day for 317 days per year with the average worker working for 2 years (Table 2), based on the calculation of the formula for the intake value which is **0.0016 mg/ kg/day**. The calculation is an actual duration of work ($Dt_{real\ time}$) of the workers. Because the company will continue to operate and the workers should work until their retirement, it is also necessary to calculate the life time intake ($Dt_{life\ time}$) which is 25 years for the industry[6] The calculation of lifetime intake produces a value of **0.0124 mg/kg/day**.

Table 2. Distribution of Anthropometry and Activity Patter of Respondent

Variables	Mean	Median	Min	Max	Normality Test
Age (year)	33,83	33	20	53	Normal
	66,83	65,00	41	101	Normal
Weight (Kg)	0,6361	0,63	0,53	0,73	Normal
Inhalation Rate (m^3/day)					
Time of Exposure (hour/day)	12,2669	12,5	9	15	Normal
Duration of Exposure *Real time* (year)	3,3153	2	3 month	16	Abnormal

Dose-Response Analysis. The purpose of the Dose-Response Analysis in this study is to calculate the Reference Concentration (R_fC) with the intake calculation and the value in safe limits that do not cause detrimental effects on workers. The calculation value of R_fC is **.**

Risk Quotient. The Risk characterization is calculated to determine the level of risk for workers exposed to $PM_{2.5}$. If the value is RQ <1 then exposure is not risky, whereas if the value is RQ> 1 it is considered risky exposure. The calculation of the total risk of Batching Plant with real time duration using the same equation produces **RQ = 0.412** meaning that $PM_{2.5}$ exposure is not at risk in the Batching Plant with real time exposure duration. Based on the calculation of the life time duration, the risk has begun since the worker has worked for 9 years because the value of RQ> 1 is equal to 1.096. (Table 3). The result of RQ value shows risk, then the exposure with the life time duration requires risk management.

Table 3. Risk Projection

2 years	5 years	9 years	15 years	20 years	25 years
0,412	0,609	1,096	1,826	2,435	3,044

DISCUSSION

The calculation of environmental health risk assessment of $PM_{2.5}$ exposure to Batching Plant workers shows that $PM_{2.5}$ is not a risk to workers for the duration of real time exposure, but it is risky to workers in the duration of lifetime exposure. Data regarding worker characteristics, anthropometric factors, and activity patterns are required to determine the amount of risk that individuals are exposed to at certain $PM_{2.5}$ concentrations. The results of the univariate analysis regarding the characteristics of respondents show that the average age of workers at the Batching Plant is 34 years old. Based on the research about the association between $PM_{2.5}$ exposure and impaired lung function, the human respiratory system stalls to 80% in late adolescence, which is 18 years old for women and 20 years old for men. During its development, the lungs can experience modification and damage that are at risk for experiencing respiratory diseases during adulthood. After achieving optimal lung function, the advancing age will affect the decline in lung function to reach 28 ml per year. Thus, the advancing age will increase the risk of respiratory health[10]

The average concentration (C) of $PM_{2.5}$ at the Batching Plant in 4 sampling points during days and nights is 120 $\mu g/m^3$. The measurement results show that in every point of sampling the concentration of $PM_{2.5}$ passes the limit value. The permissible concentration of $PM_{2.5}$ within 24 hours according to several regulations such as the Indonesian Government Regulation number 41 of 1999 is 65 $\mu g/m^3$; on the other hand, according to the National Ambient Air Quality Standards - US EPA[8], it is 35 $\mu g/m^3$, and according to WHO air quality guidelines[25], it is 25 $\mu g/m^3$. The measured concentration exceeds the quality standard, meaning that the exposure is dangerous for humans and the environment. The highest concentration is in the stockpile area with the measurements during morning shift of 137.2 $\mu g/m^3$. Stockpile is a place to store coarse aggregate (gravel) and fine aggregate (sand). Much particulate dust spreads when the aggregate is blown away by the wind because it is placed in an open space. The aggregate transfer to the Load-In Hopper uses Wheel Loaders, the movement of Wheel Loader tires and the smoke of the vehicle can also spread particulate dust. These things allow high concentration of $PM_{2.5}$ in the air[2, 22]

This study uses calculation done individually and on the average of RQ value at Batching Plant. The calculation of the Batching Plant area with real time exposure duration does not indicate any risk, but the duration of life time exposure shows that health risk will start from the duration of work for 9 years. Therefore, risk management is necessary. Risk management is carried out on the duration of life time exposure due to RQ > 1. Risk management planning can be done in arithmetic calculation of intake with various modifications. What can be done is to do risk management to reduce $PM_{2.5}$ concentration.

CONCLUSION

The conclusion of this study is that the average concentration of $PM_{2.5}$ at Batching Plant pass the limit value based on The Indonesian Government Regulation number 41 of 1999, The National Ambient Air Quality Standards, and WHO air quality guidelines. The average calculation of risk with real time duration is not treacherous because RQ=0,412. But, the calculation shows that $PM_{2.5}$ is risky to workers in life time duration (25 years) with the average yield at least for the next 9 years because reach RQ=1,096. Therefore, risk management can be done by reducing the $PM_{2.5}$ concentration.

RAPD Identification of Bacteria Isolated from Arm Third Degree Burn Wound

Hanan Sami Nouri

Dept. of Basic Nursing Sciences, College of Nursing / Mosul University, Iraq

ABSTRACT

This study aims to isolate different types of bacteria from the wounds of the third degree burns in the forearm area and to define those types at the morphological level and using the RAPD-PCR technique. And study the sensitivity of isolated species towards certain types of antibiotics traded. 35 swabs of third-degree burns were collected in the forearm area of 35 patients. 12 species of bacteria were isolated and purified from those swabs. The necessary tariff tests were carried out.

The isolated bacteria were identified as morphology and the result was the following: Bacillus sp, Enterobacter sp, E.Coli sp, Klebseilla sp , Pseudomonas aeruginosa and MRStaphylococcus aureus. Seven antibiotics; amoxicillin , Cefaclor, ampicillin , amoxicillin/clavulonic acid , Ciprofloxacin , Imepenim and Vancomycin were tested to identify the isolates of the isolated bacteria. DNA was extracted from isolates. The RAPD-PCR method was applied to DNA extracts according to a standard method using 3 primers. This technique resulted in repeated trip patterns used for genetic differentiation. The phylogeny tree in Figure 2 obtained from statistical analysis of the RAPD-PCR band pattern of 12 bacterial isolates using three RAPD primer shows that there are only two main groups branched from one ancestor at linkage distance 16%. One of these groups contains isolate number 10, while the other group contains isolate no.12 and branched at linkage distance 15% to other two sub groups one of them contains isolates 1, 11 while the other group contains the other remaining 8 isolates. The study showed different types of infectious bacteria according to the age of the injured and the causes of injury, which is worth studying on a larger scale.

Keywords: *third degree burn; infection; bacteria; identification; RAPD-PCR; sensitivity*

INTRODUCTION

The skin is the first line of the immune system of the body as well as containing nerve cells to do the sensory function.[1, 2] Burns are one of the most common home injuries, especially in children. Burns are not limited to the pain and biting sensation, but can cause severe damage to skin and skin, causing skin cells to die in the affected area.[3] Although severe burns may require emergency measures to prevent complications, burns are often recovered without complications, taking into account the degree of incineration and the cause[4, 5]. Burns are divided into three main types depending on the degree of damage to the skin and skin; first-degree burns, mildest damage, second-degree burns and third-degree burns, the most severe type of burns [5] .

The immune response changes after the injury burns, especially the third degree, where the first defense wall of the body drops and inhibits immunity and less efficiency. The burns of the third degree on the largest proportion of the enemy and whenever the destruction of the skin on a large scale, the greater the cases of infection [4, 6] .

RAPD reactions are PCR reactions, using a small-size primer that can be randomly attached to multiple DNA sequences in the bacterial genome and the creation of repeated autopsy patterns that are used in genetic differentiation[7]. If there is a mutation in the DNA template at the site that was previously a supplement to

the paint, a PCR product will not be produced, resulting in a different pattern of the DNA parts that are inflated on the gel. The other difference between this method and ordinary PCR is the use of two different temperatures. Because bacteria are the main cause of nosocomial infection, especially in patients with burns[6].

The aim of this study was to determine the genetic pattern of RAPD from strains of isolated bacteria from burn patients to characterize their genetic diversity.

MATERIALS AND METHOD

The 35 sterile swabs samples were collected from burned arms at ------- hospital after having a signed agreement form of the patient's family.

Samples were properly labeled with patients Name, Age, and Gender. The samples then were processed at the laboratory.

We used 3 different media to cultivate the isolated bacteria; Nutrient agar, Blood agar, and MacConkey's agar with the addition of antifungal agent like azole .The media was autoclaved for 15 minutes at 121°C.

Streaking of the samples on the plate were done in three plates each with one of the previously mentioned media and incubated for 48 hours on 37° C.

The colonies that appeared on the plates were sub cultured and purified. The pure colonies obtained from the sub culturing and purification process were numbered and labeled.

Morphological and biochemical identification of the purified isolates were performed[4]. Table 1 summurize the biochemical tests used to identify the bacterial isolates. Table 2 shows the list of antibodies used in identification of the bacterial shambles.

DNA extraction

. From a bacterial suspension 200 ml was used in genomic DNA extraction using DNA extraction kit (Bio-Rad , USA).

RAPD-PCR reaction

DNA amplification was performed on a thermo cycler (Bio Rad, USA) in a final volume of 25 µL containing 21µL of master mix (thermo, usa), 2.5 µL of 50 mM primer and1.5 µL genomic DNA .list of primers used in this study as following : primer 1 (3 - AGCGGGCCAA-5), primer 2(3-GCGCGATCTGGTTCACTCG-5), primer 3 (3- CAGTGAAAATTCACTGGCAAC-5). [8].

The cycling conditions were as follows: initial denaturation at 96 8C for 2 min followed by 3 cycles of denaturation at 94 8C for 1 min, annealing at 36 8C for 2 min, extension at 72 8C for 2 min and 29 more cycles of denaturation at 94 8C for 1 min, annealing at 58 8C for 1 min, extension at 72 8C for 1 min and a final extension at 72 8C for 5 min[8].

The RAPD-PCR products were loaded on a 1.5% (w/vol) agarose gel with 0.5 mg/ml of Ethidium bromide, and were analyzed by gel electrophoresis and banding patterns were observed in Gel-Documentation system (Uvitec, UK). A 1 kilobase DNA ladder (Fermentas, Canada) was used as a molecular size standard. The RAPD fingerprints were analyzed and genotypes were assigned on the basis of number and weight of band differences. Each reaction was repeated at least three times for reproducibility. The minor non reproducible reactions were excluded from the study.

RESULTS AND DISCUSSION

After infection with third degree burns is a critical condition to affect the immune system. Topical antibiotics are used intravenously to prevent and treat infection. The collected samples were divided into groups according to type and by age and then by isolated bacterial species after their morphological and biochemical identification. This result was recorded in Table 4. The males and females were eliminated 51.5% and 48.5%, respectively. The majority of the studied samples were of the age of 25-45 years by 60.1%. The most common cause of the eye injury was the incidence of burns as a result of edible oil by 42.9%.

Table3. statistical analysis of the patients data

	No	percentage	Types of bacteria isolated
Sex			
male	18	51.5%	Enterobacter, E.Coli, Klebseilla, Bacillus Pseudomonas aeruginosa
Female	17	48.5%	Enterobacter, E.Coli, Klebseilla, Bacillus Pseudomonas aeruginosa
Age			
1-10	5	14.2%	E.Coli, Bacillus, Enterobacter
10-25	9	25.7%	Klebseilla, Enterobacter, Bacillus
25-45	21	60.1%	Staphylococcus, E.Coli, Enterobacter , Pseudomonas aeruginosa Pseudomonas aeruginosa
Couse of burn			
Direct fire	8	22.8%	Klebseilla, Enterobacter, Bacillus
Hot water	10	28.5%	E.Coli, Bacillus, Pseudomonas aeruginosa
Cooking oil	15	42.9%	Staphylococcus, E.Coli, Enterobacter
Electricity	2	5.8%	E.coli , Klebsella

The results of the current study showed the presence of infection in burns of the third degree in the forearm. These results are consistent with the study conducted by[6], which investigated the association of microbes with burn patients . In 2004, isolated a number of different bacterial isolates from post-burn infection, including S. aureus, epidermis and klebsiella [2, 9]. These results are concise with our study, which isolated us by eight different types of bacteria including Pseudomonas aeruginosa, Staphylococcus aureus, klebseilla, E.coli, epidermis, Enterobacter, and bacillus. Adeyemiet al; in 2006, it was reported that most severe burns were due to the association of pseudo-auregenousa, klebseilla, staphylococcus aureus, E. coli and Staphylococcus epidermis. [3, 10]The present study agrees with the previous researcher. It is also in line with research conducted by [10-12]. The results of our study are consistent with the results[7] . The causes of this high frequency of Pseudomonas aeruginosa, Staphylococcus aureus and Klebsella may be present in abundance in the air, and can remain within the waste range of environmental conditions and show resistance against a number of antibiotics. The current research work is also consistent with reports[13, 14]. It is well documented that children 1-15 years of age are more likely to have burns[14]. The results of our study showed that the highest percentage of burn injuries in the age group 25-45 years were recorded 60% followed by age group. These results are consistent with the research work of [13, 15].

The 12 bacterial isolates were tested on molecular levels by DNA fingerprinting with random primers (RAPD) (figure 1). The RAPD analysis data of these bacterial isolates can be used for further molecular identification using 18srRNA sequence. The phylogeny tree in Figure 2 obtained from statistical analysis of the RAPD-PCR band pattern of 12 bacterial isolates using three RAPD primer (Figure 2) shows that there are only two main groups branched from one ancestor at linkage distance 16%. One of these groups contains isolate number 10, while the other group contains isolate no.12 and branched at linkage distance 15% to other two sub groups one of them contains isolates 1, 11 while the other group contains the other remaining 8 isolates.

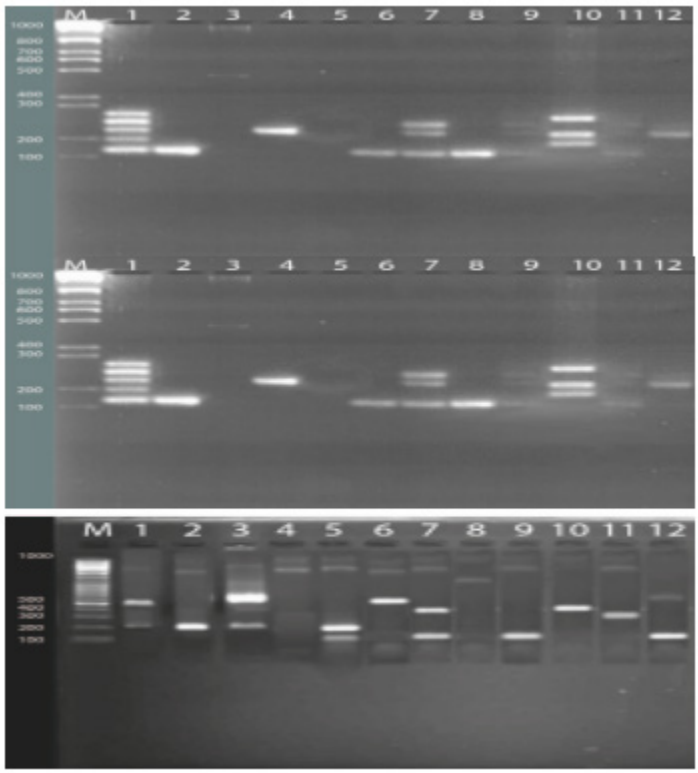

Figure 1 – RAPD-PCR fingerprints of 12 isolates from burn patients A: using primer1 B: using primer2 C: using primer3. M: DNA molecular weight marker (1 kilo base), 1–12: Samples

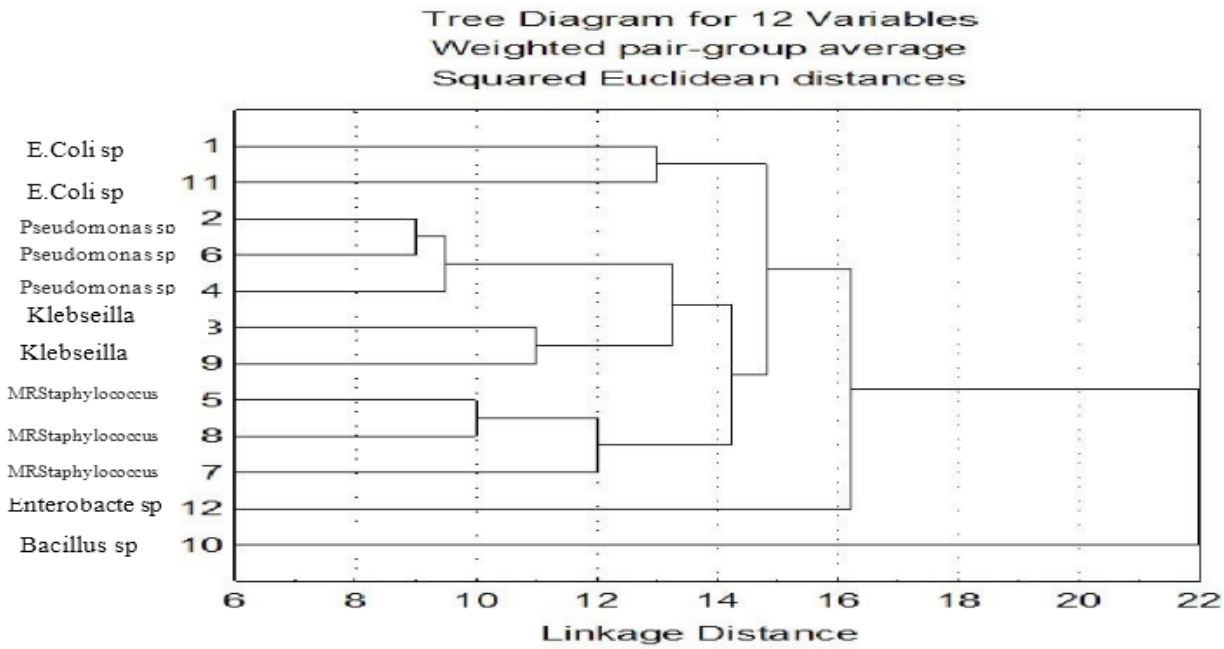

Figure 2. The phylogenetic tree

The gelectrophorasis gel showes some common bands of some bacterial species indicating that those samples are related on moleculer levels. The data of the RAPD analysis with those specific primers previously mentioned in table 4 was enlisted to relate the data obtained from the morphological identification , antibiotic sensitivity test and moleculer analysis of the tested isolates.

The data revealed that isolates 10, 12 were have the most far genetic distance among the twelve bacteria isolates, while isolates 1, 11 were laid in the same group indicating genetic similarity between these two isolates which in turn differ from the 8 remaining bacterial isolates. This results indicates that there were only one species of Enterobacter (sample 12) and Bacillus (sample 10). Isolates 1and 11 represents 2 species of E.Coli while Pseudomonas sps showed to be in 3 different species (samples 2,6,4) . MRStaphylococcuson the other hand represented by 3 subspecies 5,8,7. There were 2 isolates from the morphological identification appeared to by Klebseilla sp while genetically they were not in the Staphylococcus branch on the phylogenetic tree analysis.

The difference in genetics observed in this study is not expected because the result is different depending on the cause of the injury and the difference in the age of the patient. Some researchers in their experiments also reported a wide genetic variation and the appearance of some unexpected bacterial species in cases of burns in different degrees.[16]

CONCLUSION

The study showed genetic differences among the types of bacteria isolated from wounds from burns of the third degree. It also showed the presence of some unknown organisms that show morphology that they will be developed and therefore we recommend completing research on those species to define them molecularly. The study showed different types of infectious bacteria according to the age of the injured and the causes of injury, which is worth studying on a larger scale.

ABSTRACT

The main objective of this study is to identify the impact of social media tools on improving patients' mental image of the healthcare provided by private hospitals (an applied study in Amman city).

An analytical descriptive style was used to achieve this goal because this method was appropriate for the nature of the study. A questionnaire was designed as a tool to collect data. The questionnaire was first presented to a number of experts in the marketing field. The study population consisted patients treated by private hospitals in Amman, Jordan. The study sample was a proper sample of this population: (550) patients received copy of the questionnaire, and (513 copies were returned and deemed suitable analysis.

The study shown that social media had a statistical significant impact on patients' mental image of private hospital, and Facebook shown the greatest effect cognitive and behavioural dimension, whereas Twitter showed the greatest effect on the influence dimension.

Keywords*: Social Media; Mental Image; Healthcare Service; Private Hospital; Amman.*

INTRODUCTION

All animal species have perfected a system of communication, but humans are the only species capable of spoken language [1, 2]. Communications are important for many reasons. For humans in particular, communication a sense of social cohesion. As mankind has evolved over the centuries, our means of communication have followed suit. Communication has existed in different forms since man appeared on Earth [2]. Communication methods have evolved over time, from direct contact to letters to landline phones and now to communication through social media [1].

Mahmod_jasim2000@yahoo.com;
00962788106069

The internet plays an essential and important role in facilitating communication between people and organizations locally on a global and international scale [3]. Business organizations have adopted electronic means to promote their products and take advantage of the benefits offered by these new forms of communication [4].

The information revolution ushered in by the internet leads organizations to seek to adapt these methods of communication to reach their targeted markets and strengthen their relationships with segments of these markets. This is done by circulating and, publishing information about their products [4,5] these promotions may be communicated by the organization itself or through electronic communication methods, especially social media, the goal of building a positive mental image of organization's products or services. Organizations do this to gain popularity, name recognition and good reputation [6].

Like all other organizations, hospitals particularly private hospitals work hard to build a positive mental image of the services they offer to patients. In building this image, they are aware of the importance of communicating and sharing information with patients [7].

This need, requires them to adapt the modern communication methods, including social media and to use these methods to circulate and publish information about their services [8]. These services vary in quality which influences patient thoughts, feelings and behaviours towards the services of these private hospitals [9].

Building a positive mental image is not an easy matter. The adopted strategies must affect the three dimensions of mental image (the cognitive dimension, Influence dimension and behavioural dimension) [10]. This can be done only by providing accurate information, establishing credibility and maintaining continuous communication with patients in a way that creates the best possible mental image and influences patient's future behaviour choosing and trusting a particular hospital [11.8].

Previous studies have indicated that there is, at least, one social media account for every household in the world .This finding clearly demonstrates how far these communication methods spread and how quickly society has accepted them, regardless of the cultural, social, religious, racial and ethnic differences among people [12,13].Social media gathers people from different location and countries under one umbrella called the internet [6].

In the last few years the healthcare economy has further developed as a result of technological developments and the implementation of ideas and principles borrowed from business economic analysis [8,14].

Because of this hospitals and healthcare centers have transitioned from location for patients lodging hygienic system that provide many types of integrated healthcare services, meets patients' their health needs and improve patients' opinions of healthcare [15]. Based on business principles, economic analysis and the concept of the healthcare economy, healthcare marketing has become an essential way for healthcare system to address heavy and increasing market competition [6,16]. Healthcare marketing maintains relationships with exiting patients and attract new patients. Also increases patient satisfaction and improves mental the image of the healthcare services provided by these systems [11].

From this perspective, this study examines the role of social media in proving patients 'mental image of the healthcare services provided by private hospitals.

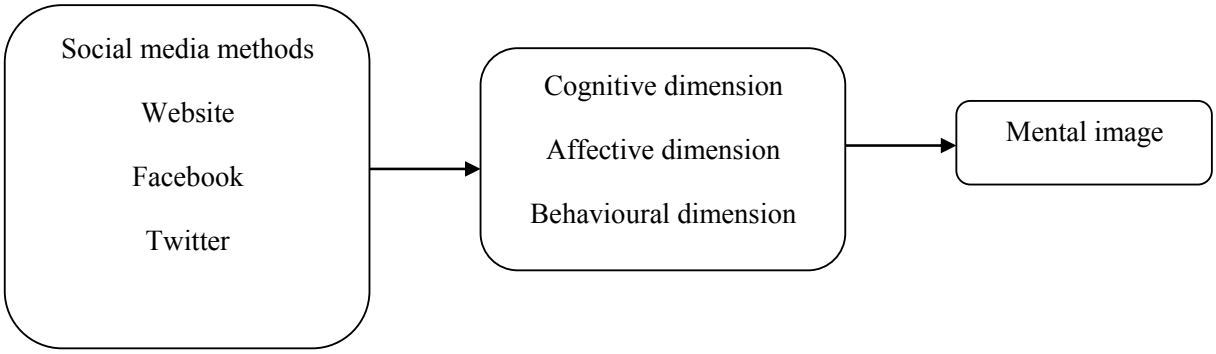
Study questions

Administrators of hospitals and healthcare centers have increasing focused on their presence on social media and its effects on the organization's target audiences. They believe these methods will reach the largest number of patients while incurring low operational costs (i.e. an internet connection ,electronic devices such as computers and mobiles and the salaries of the employees who manage these accounts) It is worthwhile to mention that information circulated by social media is uncontrolled , which causes problems for private hospitals in Jordan.

The study assumes that many private hospitals in Jordan have account or on at least one social media. A field survey of private hospitals found that the most commonly used social media methods are websites, Facebook and Twitter.

Based on this information, the research questions were formulated as follow:

What is the impact of social media (e.g., websites, Facebook and Twitter) on patients' mental image of the healthcare services provided by private hospitals?



Study objectives

The current study aims to understand the impact of social media (websites, Facebook and Twitter) on the mental image of healthcare services provided by private hospitals.

Study model

The following diagram (Figure-1) represents the study model based on the study problem, objectives and hypotheses, with reference to [4,17-24].

Study tools

The study tool was (the questionnaire) and the data it provided to the researcher from the research sample. The opinions of many specialists in the field, such as researchers, scholars, the authors and university professors have been considered in finalizing the questionnaire and explaining it is related to the subject.

The questionnaire is divided into two part:, the first part is concerned with the demographic data of people respondents, and , the second part includes the paragraphs that measure the questionnaire domains (fields).

The uses five –point Likert scale as follows questionnaire answers, Likert Scale, of five scales, was relied on:

((5) strongly approve, (4) approve, (3) neutral, (2) do not approve, (1) strongly do not approve).

Study sample

The sample is derived from the population of patients who have received healthcare services at private hospitals in Amman, the capital of Jordan. The number of those hospitals 2015 was (41) covering different fields of medicine. A proper sample of (550) patient received, the questionnaire. They returned were (513) valid copies of the questionnaire, for a response rate of 93.27%.

stability of the study tool

The Cronbach's alpha test was used to measure the stability of the measurement tool. T the value of (α) reached (0.988) for the questionnaire as a whole. This is an excellent value since it is higher than the accepted value (0.60).

The following table (Table-1: Stability Test) presents the value of (α) for each variable.

Table 1. Stability test.

Variable	**(α) value**
Website	0.951
Facebook	0.919
Twitter	0.940
Cognitive Dimension	0.945
Affective Dimension	0.943
Behavioural Dimension	0.959
Social Media Methods	0.972
Mental Image	0.961

Overlapping (Correlated) relation test

The VIF test and the tolerance test were used to test the extent of the relationship between the independent variables. and of VIF was less than (0.10) and the value of tolerance is greater than (0.10) which is evidence that there is no multicollinearity

The statistical treatment used in the study

The researcher (scholar) relied on a number of

statistical tests to support the study objectives by using the Statistical Package for the Social Sciences (SPSS) program.

RESULTS

Many statistical methods were used within SPSS to reach the results of this study.

There were (66) questions in the questionnaire, which was designed especially for this study. They were distributed on six pivots (axes) of social media methods as explained in the following table (Table-3):

Table 2. Study questions distributed on pivots (Axes) of social media methods.

Serial	Pivot (Axis) of Social Media Methods	No. of Questions for Each Pivot
01	Website	18
02	Facebook	18
03	Twitter	18
	Mental Image Dimensions:	
04	# Cognitive Dimension	4
05	# Affective Dimension	4
06	# Behavioural Dimension	4
	Total	66

The Impact of Social Media Methods on Mental Image Dimensions Table-4 explains the impact of each method on mental image in a combined form, using (one-simple t-test) to test the branch hypotheses.

It is notable that the value for the t-test for the three methods is greater than the tabulated value (1.96); based on this, these hypotheses are accepted. In the following (Table-5), we present the regression coefficients (B, Beta, t, Sig.) for social media methods.

We notice that the value of F is (179.981) and is of statistical of significance at the level of (0.05; this indicates is a statistically significant impact of social media on patients 'mental image of healthcare services. The strength of the relationship R= 0.842 and the independent variables explain 61.2 % of the variation of the following variable.

In addition, the drawn value for each independent variable statistically significant at the level (0.05). This indicates that there is an impact for each variable on the following variable. Facebook has the highest impact because the value of Beta= 0.406 is the greatest value.

Discussion and conclusion

DISCUSSION

This study found the following results:

Social media has a statistically significant impact on the mental image of healthcare services, Facebook has the greatest effect. This result agrees with what is presented in the literature where social media methods play an important role in the marketing field. Furthermore, this result coincides with the results of previous studies, such as Hashem [19] Kaite and Piligrimiene [18], and Nikolova [17]. This confirms the importance of using social media in marketing campaigns, for hospitals, the scope of this study.

Statistical treatment finds the presence of a statistical significant impact of websites on mental image dimensions for healthcare services provided by private hospitals, at the level ($\alpha \leq 0.05$). Additionally, there is an impact of Facebook on mental image dimensions for healthcare services provided by private hospitals, at the level ($\alpha \leq 0.05$).In addition, there is an impact of Twitter

on mental image dimensions for healthcare services provided by private hospitals, at the level ($\alpha \leq 0.05$).

Social media has a statistically significant impact on the influence dimension for healthcare services provided by private hospitals. Twitter has the highest effect. This can be explained because Twitter is in interactive news site with users inside and outside Jordan, whose opinions may play an important role in creating the mental image of healthcare services. This result coincides with the results of previous studies, such as Hashem [19] Kaite and Piligrimiene [18], and Nikolova [17].

Moreover, social media has a statistically significant impact, on the cognitive dimension of healthcare services provided by private hospitals. Facebook has the highest effect. This can be explained because Facebook is an interactive social site connecting family and friends inside and outside of Jordan; this interaction increases users' cognitive about the healthcare services provided by private hospitals, the scope of the study. This result matches the results of previous studies, such as Hashem [19] Kaite and Piligrimiene [18], and Nikolova [17].

Social media also has statistically significant impact, on the behavioural dimension for healthcare services provided by private hospitals. Facebook has the highest effect. This can be explained because Facebook is an interactive social site connectin family and, friends inside and outside of Jordan; this interaction contributes to the development of behaviour plans for healthcare services provided by private hospitals, the scope of this study. This result matches the results of previous studies, such as Hashem [19] Kaite and Piligrimiene [18], and Nikolova [17].

The mental image dimensions, of g healthcare services provided by private hospitals, contribute to improving patients' mental image; at the level ($\alpha \leq 0.05$). This shows that the general average of (4.101) reflects a high level of approval towards cognitive dimension. Thus, there is a high level of positive cognition for the provided healthcare services. It also shows that the general average of (3.977) reflects a higher approval level towards the influence dimension. This means that there is a high level of positive influence for the provided healthcare services. It also shows, that the general average of (3.931) reflects a high level of approval towards behavioural dimension. This means that there is a high level of positive approval for the provided healthcare services.

CONCLUSION

Although this study is very limited, t it provides an important contribution to studying and investigating mental image and its three dimensions and the impact of social media on each dimension of mental image. It also explores how best to improve mental image in the healthcare sector, an important and vital field in Amman, Jordan. This issue concerns e society in a significant and vital way because everyone needs healthcare services regardless of ages.

Future studies must explore other aspects of the subject of healthcare services and social media , including how to create a positive mental image for these services.

Sequencing of the Exon 17 C/T, Intron 3 and Intron 8 in INSR (Insulin Receptor Gene) to Identification New SNPs in Iraqi Women with Polycystic Ovarian Syndrome (PCOS)

Noor H. Mohammad[1], Abdul Kareem A. AL-Kazaz [1]

[1]Department of Biotechnology, College of Science, University of Baghdad, Baghdad, Iraq

ABSTRACT

In this case-control design study , 46 clinically diagnosed Polycystic Ovarian Syndrome (PCOS) in Iraqi women and 20 healthy Iraqi female were enrolled for analysis of the Exon 17 C/T Single Nucleotide Polymorphisms in Insulin Receptor Gene *(INSR*) gene as predisposing molecular marker for PCOS and its relationship with diabetes. Genomic DNA was extracted from whole blood of each subject using wizard genomic DNA purification kit. Specific primers for Single Nucleotide Polymorphism (SNPs) analysis of *INSR* Exon 17, Intron 8 and 3 were used Single Nucleotide Polymorphism-Polymerase Chain Reaction (SNPs-PCR) amplification reaction. Post PCR Restriction Fragment Length Polymorphism (PCR-RFLP) was done for PCR-Products using the Restriction Enzyme *PMLI*. In conclusion, the Exon 17 C/T Single Nucleotide Polymorphism in *INSR* gene can consider as predisposing molecular marker for PCOS that can transmitted offspring, colorectal cancer (CRC) and Breast Cancer in Iraqi women and the Intron 8 Single Nucleotide Polymorphism can consider as predisposing molecular marker for PCOS and Diabetes that can be transmitted offspring in Iraqi women. The hormonal values were takes as detected markers for PCOS such as Luteinizing Hormone (LH) values that appears in high level in women with PCOS either they were married or unmarried and the Follicle Stimulating Hormone (FSH) that appear in low levels in women with PCOS.

Keywords: *Exon 17 C/T, Intron 3, Intron 8, Insulin Receptor Gene, SNPs, Polycystic Ovarian Syndrome.*

INTRODUCTION

Polycystic ovarian syndrome, which used to be called Stein and Leventhal Syndrome, is a common condition affecting 5-10% of women of childbearing age. This disorder is probably the most common hormonal abnormality in women of reproductive age. In 95% of women with PCOS, an ultrasound of the ovaries will reveal cysts that can be seen on the surface of the ovary. These ovarian cysts are often lined-up to form the appearance of a "pearl necklace" [1] .

The susceptibility genes for PCOS are unknown; several candidate genes have been evaluated. Most of researchers found the evidence that *INSR* gene show consistent; linkage and association with PCOS. The *INSR* receptor gene comprises 22 exons spanning 120kb on chromosome 19. Mutations in exon 17 and intron 13, 8 that encode the tyrosine kinase domain of the insulin receptor, have been shown severe insulin resistance and hyperinsulinemia. Two possible approaches are used to identify a genetic locus for PCOS genes: (i) association studies where a predisposing allele is expected to be found more frequently in the affected population than the normal individuals and (ii) linkage studies where the probands and their families are investigated to determined if particular genomics landmarks are distributed independently or in linkage with the phenotype. While the mode of inheritance is not required for the association studies, it requires a relatively large set of individual for a clear conclusion [2].

Many genes presented expression suggesting thus that the genetic abnormality in PCOS affects signal transduction ruling insulin action and their secretion.

Although the cause of PCOS is not well understood, insulin resistance may be a key factor. Insulin is vital for the transportation and storage of glucose at the cellular level; it's helps to regulate blood glucose level and has a role in carbohydrate and lipid metabolism. These conditions put those with PCOS at a higher risk of developing type 2 diabetes (T2D) and cardiovascular disease [3,4].

The aims of this study is to examine whether the insulin receptor *INSR* gene contributes to genetic susceptibility to the PCOS and to analyze the exon 17 C/T single nucleotide polymorphism in INSR a predisposing molecular marker for PCOS.

MATERIAL AND METHOD

Blood Samples.

The samples were collected from AL-Yarmok Hospital in Baghdad, from 17 December 2013 to 17 June 2014 using EDTA tubes and sterile syringe which consist of 70 unrelated females (20 controls, 50 patients). The samples were transferred to the laboratory for DNA extraction. Sixty-eight human blood samples consisting of 46 samples infected with PCOS that have different ages ranged between 11-67 years old and their weight ranged between 30-120 kg. According to these data there will be 4 groups that classified due to their ages and weight, these are the properties of each groups.

DNA extraction that used in this study.

DNA extraction that used in this study according to the Genomic® Wizard Purification Kit .

Estimation of the DNA concentration by the Nanodrop equipment.

The DNA concentration was determined by using the Nanodrop according to [5].

Estimation of DNA quality

Estimation of DNA quality also can assess by simple analyzing the DNA by Agarose gel electrophoresis [5].

Amplification of DNA by PCR technique.

PCR reaction performed using the following:

Specific primers and their preparation.

There are variant SNPs in the *INSR* gene were selected based on way of Xu *et al*. [6].

Go Taq@ Green Master Mix

The master mix reactions were used to achieve the homogeneity of reagents and reduced the risks of contamination. All amplifications were performed on ice in aseptic condition using a laminar air flow hood [6].

Table (1) the sequences and genes locations of specific primers [6].

Primers	Sequence	genes Locations

Protocol of specific PCR

This protocol consists of: PCR primers, PCR Mix , Amplification reaction, PCR programe according to [1,6].

Detection single nucleotide polymorphisms (SNPs) by RFLPs

Some samples were surveyed for characterizing single nucleotide polymorphisms (SNPs) on Insulin receptor gene **(INSR gene)** by RFLPs technique (PCR amplification, followed by restriction enzyme digestion [6].

Restriction Enzyme *PMlI*

PMLI* is** a restriction enzyme that isolates from product source ***Pseudomonas maltophilia . There are several key factors to consider when setting up a restriction endonucleases digest using the proper amount of DNA, (incubation time, temperature and buffer) provided by (Biolabs). enzyme and buffer components in the correct reaction volume that lead to having optimal digestion.

Detection of single nucleotide polymorphism (SNPs) by automated sequencing.

Several DNA sample from women that have PCOS were taken to have PCR reaction with different molecular markers, according to NICEM Company / USA to have an automated sequencing by ABI3730XL APPLIED BIOSYSTEM machine , which gave the identity of the genes comparison with the original genes in Gene Bank in NCBI.

Concerning molecular genetic studies, PCOS is one of the most extensively studied endocrinopathys in women and attention has been given to insulin resistance with special focus on the ***INSR*** gene. Therefore in this study we used family- based analysis in order to investigates the relationship between the INSR gene SNPs and the genetic component of PCOS [2,6,7].

Results of RFLP

After PCR technique for all the samples , several PCR product were selected such as (46 , 11 , 31 , 5 , 2 and 14) with different primers to incubate them with restriction enzyme PMLI at 37°C for 1 hour and then these samples were migrated in 0.5 X TBE buffer with 2.5% Agarose gel for (1 hour , 90 V). The result was three restriction fragments they are 317 bp , 264 bp and 43 bp.

In figure (1) that refer to have three restriction fragments on line 13 which belongs to sample N31 for the primer (rs17799817) which has 317bp, 264 bp but the last fragment which is 43 bp did not appear in the gel due to its small size.

While in figure (2) illustrate the line 1 which belongs to sample N5 for the primer (rs8108622 and rs10500204) has three restriction fragments they are 317 bp, 264bp, 43bp.

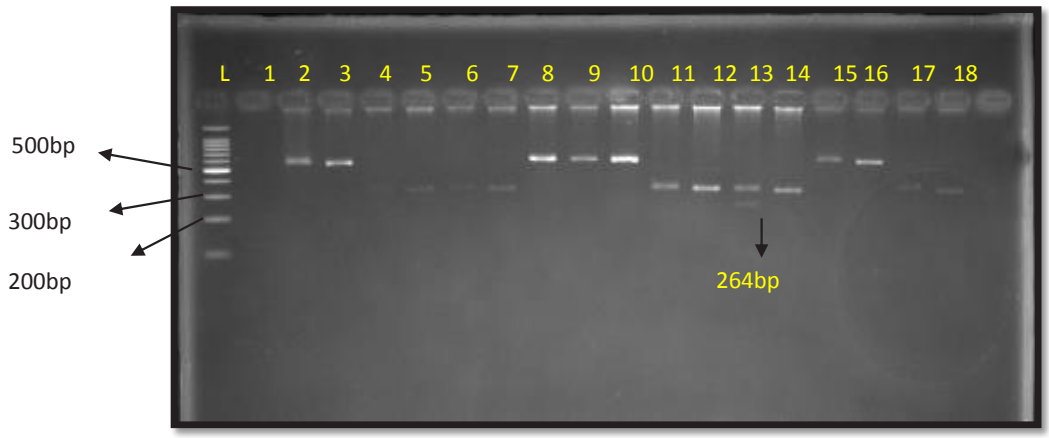

Figure (1): The PCR- RFLP analysis of intron 8 of the INSR gene. The line 13 that refer to sample N31 that has 317bp , 264bp only.

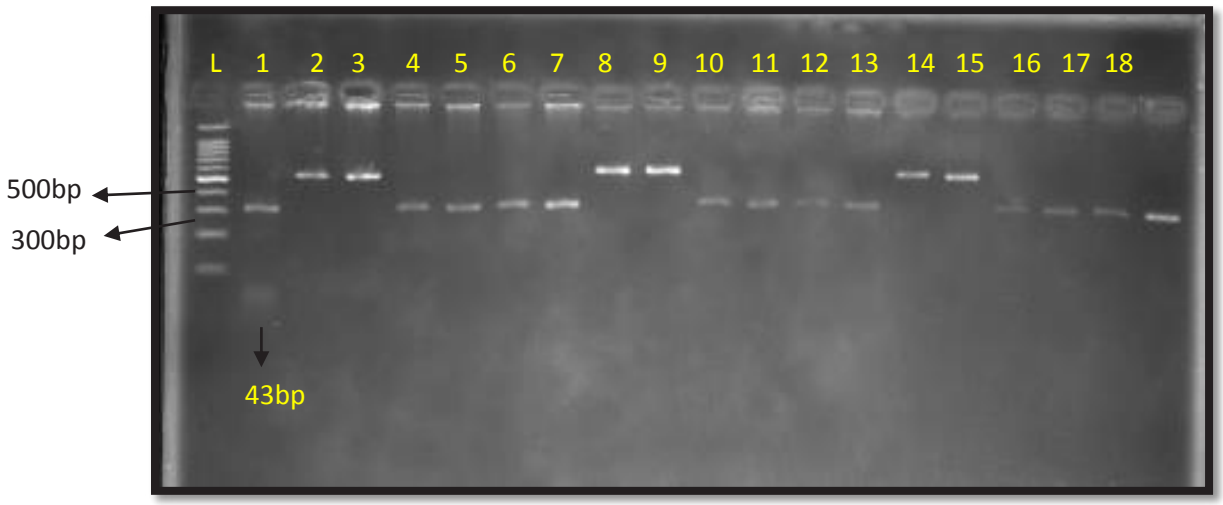

Figure (2): The PCR – RFLP analysis of exon 17 of the INSR gene. The line 1 that refer to the sample N5 that has 317bp, 264bp and 43bp.

That's mean that the sample N5 for primer (rs8108622 and rs10500204) and the sample N31 for the primer (rs17799817) have the same sequence as same as *PML1* sequence. The other samples that did not have any restriction fragments because of one of these reasons:

A. changing in their sequence.

B. has a mutation.

C. changing in their original replication

The SNPs in exon 17 of the INSR gene in the tyrosine kinase domain of the insulin receptor have paid more attention [2,8]. Found an association between rs1799819 and PCOS.

They argued for the first time that the INSR gene itself took part in the development of PCOS, that's was not similar to the data of this study whose found that the rs8108622 & rs10500204 and rs2059807 have an association with PCOS while the rs1799819 does not have an association with PCOS in Iraqi women.

In India, the researchers found an association of rs1799817 with indices of insulin resistance and hyperandrogenimia in the same subgroup [1,7]. According to the results of this study that found the rs1799817 have not significantly over transmitted to PCOS off spring from their parents by using a genetic approach of association analysis, while the rs2059807 and rs8108622 & rs10500204 were significantly over transmitted to PCOS off spring from their parents whose has an agreement with [9] and [1].

The insulin regulates cell growth and apoptosis by binding to its receptor (INSR) gene. Many studies show the variation in insulin pathway play a plausible role in the development of Colorectal Cancer (CRC) and breast cancer. The goal of their study was to evaluate the incidence of insulin receptor (*INSR* rs1799817) in people of Taleghani Hospital to investigate the role of this polymorphism in increased of CRC and breast cancer [10] ; also there are many research articles have been published in this site which give support to the hypothesis that patients with insulin resistance syndrome such as obesity and T2D , might be at higher risk for developing cancer than the general population [11] ,which is similar to the result of this study that found the rs1799819 have an association in increased of CRC and breast cancer in Iraqi women.

However, the precise mechanism that link insulin resistance and cancer have not yet been fully understood there were more details of molecular mechanistic understanding is required to interpret the existing data together with preclinical and clinical studies.

In addition, environmental factors are also involved in PCOS. The interaction with genes may be a key point of the pathogenesis in PCOS, not only the gene itself. When we use the family trios analyzing the subject's genotypes, the interaction would be exorcized. Therefore, there may be one reason for finding little association between two SNPs and PCOS instead of four

SNPs [1,6].

This study covered a large series of PCOS trios and represent the first family that association with providing data about INSR gene and PCOS in Iraqi women. Finally, we used to mention that PCOS in a multi factorial disease.

RESULTS OF SEQUENCING

These PCR product samples were sent outside the country to have an automated DNA sequencing at NICEM company/ USA and worked by ABI3730XL APPLIED BIOSYSTEM machine, the INSR gene sequence was investigated because this method is more discriminating [11]. From comparison of the sequence with that in the database in Gene Bank by BLAST program, the gene was identified (98%) with no gaps (0%), there were five circles that illustrates these comparisons and their means, the first and second circle means at the subject 173674 there is 2 SNPs linked to INSR gene they are: (Addition in sequence and Replace C instead of T [12] .

While the third circle mean at the subject 173914 there was 1 SNP linked to the same gene it`s.. (Replace G instead of T). The fourth and fifth circles means at the subject 173914 there were 2 SNPs linked to same gene and they are (Replace G instead of T and Replace C instead of A) as shown in figure(3).

This sample was belonging to sample no.5 of primer 3. This sequence was approved to have PCOS in patient that transmitted off spring from the parents and in future can have CRC or breast cancer, this result was decomentated for the first time in Iraq.

Figure (3): The automated sequencing of INSR (P1) from PCOS patient that have (98%) indentify with (0%) of gaps . This result was approved to have PCOS that transmitted off spring from the parent with CRC or breast cancer.

While the sample no. 14 of primer 2 that refer to was sent to the same company in USA to have an automated DNA sequencing, from comparison of the sequence with that in the database in Gene Bank by BLAST programs, the gene was identified as (97%) with (1%) of gaps. There were three circles that illustrates these comparisons and their means**.** The first circle mean at the subject 132782 there is 1 SNP that linked to INSR gene which is addition of nucleotide in the sequence, While the second circle mean at the subject 132842 there was 1 SNP which is replace G instead of T and the third circle mean there was a semi conservative sequence that refer to the of the gene. This result was approved to have PCOS in patient that transmitted off spring from the parents with diabetes disease.

CONCLUSION

The exon 17 C/T single nucleotide polymorphisms in INSR can`t consider as predisposing molecular marker for PCOS in Iraqi women , while the SNPs in intron 3 and intron 8 can be consider as predisposing molecular marker for PCOS in Iraqi women. **Found that INSR (P3)** can consider as a molecular marker that approved to have CRC or Breast cancer transmitted offspring

from the parent. **Found that the INSR (rs2059807)** can consider as a molecular marker that approved to have PCOS with diabetes disease which transmitted off spring from the parent.

[2]Department of Marketing, Faculty of Business, AL-Zaytoonah University of Jordan. Jordan

ABSTRACT

Women, nowadays, become more interested or more oriented to plastic surgery including smile improvement. Although smile improvement popularity is increasing among Iraqi women, but published researches are rare in this field. Consequently, the objective of this study is to determine the factors that affect woman behaviour and direct her to improve the smile.

The theory of planned behavior, developed by Ajzen in 1985 (1), and the variables were adopted and formed according to study objectives, i.e. attitude, social, perceive, cost and dentist. The study approach and methodology depended on collecting data from 367 women in Baghdad city, data was analyzed by using the proper statistical methods (SPSS) and AMOS analysis.

There are positive correlations between attitude, social, perceived, cost, dentist and intention; and the results show that the dentist has mostsignificant effect on intention with correlation215**and Sig 0.000.There is positive relationship between Intention and behavior with correlation 0.298** and Sig 0.000

This paper provides information about factors that impact behaviour of Iraqi woman to improve the smile, and as far as we know, it is considered to be the first study, in this field, in Iraq.

Keywords: *Dental Clinic, Smile, Attitude, Social, Perceived, Cost, Intention, Woman Behavior*

INTRODUCTION

Dentistry has developed, as other medical fields, especially in the last fifty years. This development does not focus only on dental treatment, but also ensures providing beauty services requested by the patient, smile improvement upon patient request (2,3). The patient need or request for plastic surgeries may be due to social pressures or perhaps due to change in beauty standards evaluations which represents the motive behind beauty revolution. It is known that media, concerned with beauty, feed this beauty revolution. As Morley, 1999 and Priest and Priest, 2004 mentioned(4,5).

In today's society, most people, including women, have the desire to be better than before concerning enhancement of the external look. The physical appearance has an important and efficient role in self-respect and achieving success in social, functional and work. The human nature makes individuals who own positive characteristics an attractive people; those are usually received proper behavior and treatment, in many different situations, and gain from it many benefits, due to Sarwer et al 2004 (6).

Chetan et al in 2013(7) , indicates that patients have to think before taking any decision towards any cosmetic dentistry. They must consider the nature of the process, benefits, costs, results. For this, this study will concentrate on smile improvement, costs and dentist capability. The woman approach towards improving her smile is a planned behavior that depends on intention which is affected by social factors and situations, awareness of benefits, costs and the dentist. For that, this study will be based on adaptation of planned behavior theory which was developed by Ajzen in 1985 (1).

The theory of planned behavior, developed by Ajzenin 1985 (1), is an explanatory model that has been widely applied in diverse studies on behavioral intention

[8,9]. The theory states that attitude toward behavior, subjective norms, and perceived behavioral control, together shape an individual's behavioral intentions and behaviors.

Previous studies and hypotheses development

Schmidt et al in 2003 [10], indicated in his study, concerning spontaneous face expressions that the smile considered to be one of the most important human face expressions which supports reward value for the attractive face. Goldstein in 1969[11]finds, in his study concentrated on the needs for beauties in dentistry, that smile comes in the second degree after eyes and considered to be the basic advantage that affects face attraction. Attractive smile helps to win elections and sell products for companies.

Cheng and Cheng in 2017 [12], indicate that smile is one of the most important expressions among faceexpressions in human that supports reward value for attractive face. Face attraction plays a major role in social interaction, character evaluation, performance and employment horizon [13]

The smile plays an important role in face expression and the look and smile represents face expressions that indicate to cordiality, agreement and appreciation. Distinctive and attractive smile leaves an impression in others. Those who have an attractive smile excite or inflame interest or the desire to smile. Teeth appearance proved that it affects other judgment for attraction of a person face beside the personal characters like quite, joy and relaxation [14,15]

Shavi et al in 2013[16], explains in his study, smile analysis in Haryanavi females, that people who own attractive smile got a bigger chance to success and social acceptance, because the un-harmonic smile reduces face beauty and may cause un comfortability in social and professional life while the happy smile represents a harmonic relation between teeth and the lips.

The women will do their best to hide any defects in the teeth. In fact this is the main motive for women to look for dentist, that is, to gain attractive smile. They will look for information from different resources like relatives, friends, social media, celebrities' photos, actresses and others whom they publish their photos on social media like Facebookand the comments of other users [17].

The study ofAhrari et al in 2015[18], concluded that face attractiveness, including teeth and smile beauty, influences on social reactions and on self-concept, psychological welfare and social behavior. Persons, who are more attractive, are more successful in school, employment interviews and even in selection of their partners [19].

No doubt, smile provides face with great beauty attraction which plays a major role in influencing the social interactions of a person, belonging to the group, acceptance from others, beside its effect on "being" or "self" concept and social behavior [20]. The objective from dental treatment, like dental implants or orthodontics appliances, is smile improvement [21].

Worldwide, smiles are known and evaluated as friendly. The real smile, that express person internal feeling, considered an indicator to acceptance and warm. Women, who have shining and friendly smile, will have less level of despair and sadness, say after 30 years, than their study colleagues [22] .

Al Taki et al in 2017 [23] mentions that smile is a remarkable express in the face distinguished and it used as efficient tool for the social interaction.

Piete et al in 2007[13], mentions that he underpins the psychosocial importance and thedental significance of an attractive smile.When a woman realizes that she is facing a problem by un-satisfaction of her smile, and the feeling of social and psychosocial pressures, then she starts to collect data about smile types by consulting the reference groups andthe media, then according to this information she shall take the proper decision to improve the smile [24].

Attitude

an attitude is a disposition to respond a positive or negative toward the object[25].

H1. Attitude has a negative effect on the attention

Subjective norm is defined as any social influence that may determine if theindividual performs or does not perform the behavior [26,27].

H2. Social norm has a negative effect on the attention

Perceived behavioral control is defined as the level of confidence an individual has about their ability to

perform the behavior based on how easy or difficult they perceive its performance as it relates to hindrances or facilitators [26, 27].

H3. Perceives has a negative effect on the attention

Cost

In spite of many women are seeking to improve the smile, aiming to gain an attractive look and achieve the benefits that will achieve satisfaction to them,psychological stability and social interaction, but costs are the decisive and final factor in making this decision.

Dental care request is the most health care types that are effected by prices, because patients, usually, sensitive towards prices [28, 29].

H4: Cost has a negative effect on the attention

Dentist

Dentist is the basic motive and the actual provider for the service of dental health care due to his distinguished knowledge, capabilities and skills that fit and match his job nature.

Dentist capability and services quality that he provides play a major role in attracting patients to request dental health careand provide services of very high quality [30,31,32].

H5. Dentist has a negative effect on the attention

The intention

The intention is the immediate antecedent of actual behavior and the relative degree of influence that attitude, subjective norm, and perceived behavior control have on intention may vary in significance by population and behavior studied [33,34,35,36].

H6. Intention has a negative effect on the behavior

STUDY METHODOLOGY

We tested our hypotheses by using the collected data returned fromapplying the questionnaire on sample of 420 women who have smile improvement, where (420) copies of the questionnaire were distributed for women, and (367) were returned and valid for analysis, which is 87%.

Data analyses

Test of Reliability

A reliability coefficient of (Cronbach's Alpha) 70% or higher is considered "acceptable" in most social science research situations. The result of this test in the current study is 72%

The structural model and the hypothesized relationships were tested by using Amos analysis

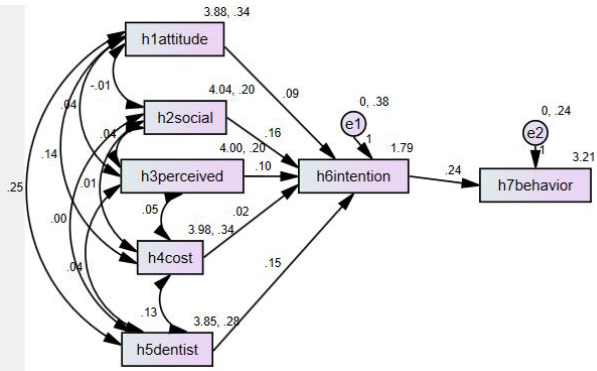

Fig1: Results of the structural model

Table (1) Person correlation coefficient

		h1attitud	h2socia	h3perceived	h4cost	h5dentist	h6intention
h6 intention	Pearson Correlation	.199**	.123*	.131*	.127*	.215**	1
	Sig. (2-tailed)	.000	.018	.012	.015	.000	
	N	367	367	367	367	367	367

RESULTS

The Person correlation coefficient

There are positive correlations between Attitude, Social, Perceived, Cost, Dentist and Intention and the results show that the dentist has most significant effect on intention withCorrelation.215** and Sig 0.000

Table (2)The Correlations between the intention and thebehavior

		h6intention	h7behavior
h6 intention	Pearson Correlation	1	.298**
	Sig. (2-tailed)		.000
	N	367	367
h7 behavior	Pearson Correlation	.298*	1
	Sig. (2-tailed)	.000	
	N	367	367

**. Correlation is significant at the 0.01 level (2-tailed).
There is positive correlations between intention and behavior

Table (3)Model Summary[b] -ANOVA[a]

Model	R	R Square	Adjusted R Square	Std. Error of the Estimate	df	F	Sig.
1	.263[a]	.069	.056	.62495	5 361 366	5.355	.000[b]

a. Predictors: (Constant), h5dentist, h2social, h3perceived, h4cost, h1attitude

The results of the table confirm the validity of the multiple linear regression model, where the calculated F value is 5.355, which is greater than the table value of 2.26, and the value of Sig is 0.000, indicating that there is an effect of the independent factors on the intention of the Woman to improve the smile The value of R Square indicates that the independent variables (position, cognition, social factor, cost, and dentist) explain what (.069) of the changes that affect the intention of the mirror to improve the smile

Table (4) Model Summary[b] -ANOVA[a]

Model	R	R Square	Adjusted R Square	Std. Error of the Estimate	df	F	B	t	sig	
1	.298[a]	.089	.086	.49478	1 365 366	35.495	.240	5.958	.000	
a. Predictors: (Constant), h6intention										
Dependent Variable: h7behavior										

The results of the table confirm the validity of the multiple linear regression model, where the calculated F value is greater than the table value 3.89, and the Sig value is 0.000, indicating that there is an effect of the intention on the behavior of the mirror to improve the smile, Square suggests that the intention is to explain what it is (.089) of the changes that affect the behavior of the woman to improve the smile

CONCLUSION AND DISCUSSION

The current study applied the theory of planned behavior to examine the factors influencing Woman behavior to improve the smile. In the absence of previous studies on the subject. Since existing studies examining this issue are limited, the present study can contribute in providing a better understanding of the factors influence the woman behavior to improve the smile in Iraq.

The main findings of this study indicate that all independent factors have a positive relationship with the intention to improve the smile and that the strongest relationship is between the dentist and the behavioral intention and the relationship between the behavior and intention positive relationship also.

The results indicate that the value of F is 5.355 and the sig is 0.000. This indicates that there is an effect of the independent factors on the behavioral intention of the woman to improve the smile. The F value is 35.495 and the sig is 0.000 which indicates the effect of the intention on the behavior of the woman to improve the smile

The results revealed significant relationship of five factors behavioral intentions, and significant relationship between the behavioral intentions and behavior of woman to improve the smile. This is consistent with the theory of planned behavior.

ABSTRACT

Background and Objective: The efficacy of red fruit (*Pandanus conoideus*) oil extract on CD4+ cells was evaluated in HIV infected patients with taking antiretroviral therapy. **Materials and Method:** Seventy patients with an age of 17-45 years, with confirmed HIV infection with a CD4 count of 200-349 cells/μL, were divided into the antiretroviral (ARV) control (n = 35) and the antiretroviral + red fruit capsule (ARV+RFC)-treated (n = 35) groups. In ARV+RFC group, they were given oral RFC (1 g daily for two months). Monitoring evaluations of the laboratory were performed at baseline (0 months) and two months during the study. **Results:** The result showed that the CD4+ cells count was increased in the patient who took ARV+RFC compared with ARV alone ($P<0.05$). **Conclusion:** By these result, it can be concluded that the red fruit oil extract may have an excellent immunomodulatory impact and has potential as an adjuvant in the management of HIV patients.

INTRODUCTION

The acquired immune deficiency syndrome (AIDS) is an infectious disease caused by a virus namely human immunodeficiency virus type 1 (HIV-1) [1, 2]. This disease remains a global public health problem with an estimated 690,000 people living with HIV in Indonesia area in 2015 [3]. The prevalence of HIV infection and AIDS of Papua Province was higher than another province of Indonesia [4]. In the Merauke District of Papua Province of Indonesia, the prevalence of HIV/AIDS has become a severe problem. In 1992-2017, the total number was 1,063 people living with HIV in Merauke Regency, 902 people had AIDS, and 537 died due to AIDS-related causes [4]. The populations of people HIV/AIDS include direct and indirect high-risk men, transgender people, female sex workers, people who inject the drug, and men who have sex with men [5].

Nowadays, antiretroviral therapy (ARV) was successful alternative treatment in people infected with human immunodeficiency virus (HIV) 6, 7. However, there were limited to ARV treatment in patients HIV/AIDS about by some factors, which include drug resistance 8-10, toxicity 11, drug-drug interaction 12 and drug-food interaction 13. Other than that ARV treatment required lifelong use, failed treatment response, the optimal time to start treatment and switching regimens 14. Therefore, management of patients HIV/AIDS are required to reduce the negative impact and improved impact the efficacy of highly active antiretroviral treatments

Numerous herbal medicines are being used in combination with ARV treatment to improve the efficacy of HIV/AIDS therapy. The metabolite compounds of

medicinal plants have been the most successful source of potential traditional medicine [15-21] and also can be used as an alternative for an interaction with antiretroviral therapy in patients HIV/AIDS [22]. Larson *et al.* [23] reported that the combination medicinal plant extracts from Papua New Guinea with ARV exhibited alter the concentration of antiretroviral drugs in the body and their efficacy. Another literature showed that medicinal plant extracts were considered as an excellent source for management of HIV/AID patients [24].

The red fruits (*Pandanus conoideus*), namely Buah Merah in Indonesia, is a plant in the family Pandanaceae [25]. It is an endemic plant that easily found in Papua regions of Indonesia and has been used as a traditional herb Papua community to treat cancer, rheumatoid arthritis, stroke, and HIV/AIDS [26]. Some other pharmacological activities that have been reported in recent years include its anti-inflammation and anticancer [27, 28].

In the current work was investigated the clinical efficacy of red fruits (*Pandanus conoideus*) oil extract in HIV infected patients with taking antiretroviral therapy. This working point to the potential of developing red fruits oil extracts for management HIV infected patients.

MATERIALS AND METHOD

Study Location and Design

Recruitment and drug administration took place in Merauke Hospital, Merauke Regency of Papua Province, Indonesia. Laboratory tests were performed at a Molecular Biology and Immunology Laboratory for Infectious Diseases, Faculty of Medicine, Hasanuddin University, Makassar, Indonesia.

In this work, ethical clearance was obtained from Hasanuddin University of Medicine Faculty Research Ethics Committee (532/H4.8.4.5.31/PP36-KOMETIK/2017) before data collection commenced. The study was conducted in randomized controlled groups. Patients qualified for inclusion in the study were ambulatory, with the base CD4 line was between 200-349 cells/μL, the body weight of 45-70 kg and treated with ARV. Excluded were pregnant women and kidney failure, body weight under than 45 kg and no treated ARV in three months.

Study Medication and Monitoring

Seventy HIV-infected patients of either gender aged between 17 and 45 years were selected in this study. The patients were divided into the ARV (antiretroviral) control (n = 35) and the antiretroviral + red fruit capsule (ARV+RFC)-treated (n = 35) groups. RFC gelatin (1000 mg red fruit extract per capsule) was administered to the patients. The dosage was 1000 mg (one capsule) daily for two months. Monitoring evaluations of the laboratory were performed at baseline (0 months) and two months during the study.

$CD4^+$ Cells Count

The efficacy determinations were the change from baseline (0 months) to month 2 in the $CD4^+$ cell count. $CD4^+$ cell counts were determined using Human CD4 ELISA Kit (Catalog No. LS-F11086, LSBio, LifeSpan BioSciences, Inc.).

Statistical Analysis

All data of results were analyzed by SPSS statistical software 16.0 (SPSS Inc., Chicago II, USA) and comparison ANOVA was used with considered significant at $p < 0.05$.

RESULTS AND DISCUSSION

A total of seventy HIV-infected patients participated in the research and were completed $CD4^+$ cell counts at baseline and final time points. There was a gradual increase in the mean $CD4^+$ cell counts from 71.78 (11.74-164.12) cells/μL at baseline to 123.62 (28.49-217.61) cells/μL after two months treatment of RFC (Figure 1). In ARV group showed that a lower increase in the mean $CD4^+$ cell counts from 83.90 (16.43-153.87) cells/μL at baseline to 96.15 (18.24-222.45) cells/μL after two months therapy. A significant increase ($P<0.05$) in the mean $CD4^+$ cell counts was observed in patients treated with ARV+RFC for two months (52.16%) when compared to control ARV (12.24%). These results indicated that the application of ARV+RFC could be an enhancement of the immune status of the patients compared with ARV only. Thus, red fruit has potential as an adjuvant in the management of HIV patients. This study can be completed information on previous research in the application of red fruit oils extract for improved immune systems [28]. This research evaluated the efficacy of red fruit oils extracts in HIV-infected patients. The efficacy effect of red fruit oils extract was probably derived from its bioactive compounds, one of which is carotenoid[25]. Carotenoid has been widely studied and

has been shown to possess anti-cancer [29], antioxidant [30], as well as immunomodulatory capacity [31]. As an immunomodulator, carotenoid has been shown enhance lymphocyte blastogenesis, increase the population of specific lymphocyte subsets, increase lymphocyte cytotoxic activity, and stimulate the production of various cytokines [32].

Results showed that $CD4^+$ cell counts in ARV+RCV treatment were significantly increased in HIV-infected patients as compared to ARV controls (123.62 cells/µL vs. 83.90 cells/µL, respectively). Results indicated that red fruits extract oils functional as immunostimulants; because the $CD4^+$ cell counts reflect the immunologic status of HIV-infected patients [33, 34]. Thus it is possible that the functional interaction of red fruit extract oils with antiretroviral therapy as an immunostimulant in HIV-infected patients occur at the level metabolism through enzyme induction or inhibition [23]. Another possible mechanism that metabolite constituents of red fruits extract oils remedies may affect ARV metabolism as a result of their efflux drug transporter systems [35, 36].

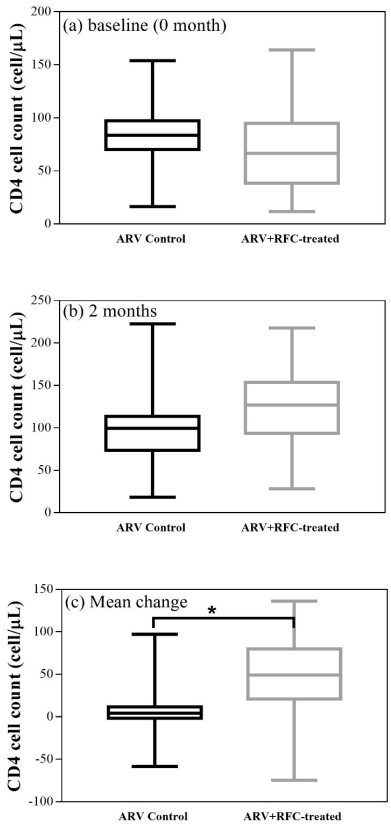

Figure 1 CD4 cell count response of ARV (antiretroviral) control and ARV+RFC (red fruit capsule)- treated in the baseline (a), two months (b), and mean change (c). *p<0.05 vs. ARV control.

CONCLUSION

In conclusion, our study shows that the increased level of $CD4^+$ cells count by ARV+RFC was provide positive benefits in HIV/AIDS therapy.

Effect of Iron Overload on Some Physiological and Biochemical Variables in Immature Female Rats

Wasan S. Sarhan[1], Raouf M. Fadhil[2], Alyaa S. Jawad[3]

[1]Lecturer, [2]Assistant Lecturer, College of Veterinary Medicine/ Department of Physiology and Chemistry and Pharmacology. Iraq, [3]Assistant Lecturer, AL-dour Technical Institute. Iraq

ABSTRACT

The current study was conducted to investigate the effect of (100 mg / kg b.w) on the weight of some organs (liver, heart, spleen, kidneys, ovaries, and uterus) and some physiological and biochemical parameters in immature female rats at the weaning age (22) days, the experimental animals were divided into two groups, the first group included (10) females were gave the solution of iron sulfate daily by mouth for 14 days, and the second group included (10) females were treated naturally and considered as a control group. The results of the iron treatment showed a significant increase ($P \leq 0.05$) in weight of the liver and spleen, and a significant decrease in body weight, while no significant difference was observed in the weight of the heart, kidney, ovaries and uterus. While in the physiological and biochemical parameters studied, the results showed a significant increase in the level of malondialdehyde, the concentration of hemoglobin (Hb), packed cell volume (PCV), and iron level, with a significant decrease in the level of glutathione compared to control group. It is concluded that iron has harmful effects on studied parameters and organs, indicating that iron is stressful and has a negative effect if it increases over the normal level.

Keywords: *iron overload, physiological criteria, immature female rats, oxidative stress, body weight.*

INTRODUCTION

Pollution is a common problem at present, and the world around us is saturated with polluting substances, such as those used in the environment by humans as well as many naturally occurring substances such as vapors rising from active volcanoes, similar to pollution from raw materials, factories, human and sewage products. [1] The evolution of the world and the geological changes in the earth crust have led to changes in the distribution of essential soil elements such as iron, zinc, copper, selenium, molybdenum, manganese, chromium, cobalt and iodine. [2] These elements are widely dispersed in the environment either through their natural presence or as industrial wastes. Human and animal species are exposed to these minerals from various sources, including air, soil, water and contaminated food. [3] Exposure to these minerals causes many functional disorders, including loss of fertility for many reasons; one of it is the increase of iron ratio in the body [iron overload) or iron deficiency. [4] Transitional metals (such as iron) are catalysts in the oxidation reactions in living organisms. Therefore; the damage caused by these minerals appears in the tissues as oxidative damage. The most affected organs are the liver, kidneys ,and testicles, these effects include dehydration, low body weight, loss of appetite, renal tubules necrosis and pulmonary hemorrhage. [5]

Excessive iron administration increases the amount of free iron that collected in the body and then participates in the Finton reaction, leading to the generation of active oxygen species, causing damage to the cells and tissues of the body as well as attacking the embryos in the of pregnancy and causing severe oxidative damage. The oxidative damage caused by free radicals due to excessive iron inside the body, is a clear indication of the body's access to the state of poisoning that has a negative impact on human health. [6]

The current study aims to

1- Investigation the effect of iron on some blood variables by measuring the: level of hemoglobin (Hb), the packed cell volume of blood (PCV), the level of iron blood serum.

2 - Detection of the negative effects caused by

the free radicals stimulated the iron formation in the immature female rats.

MATERIALS AND METHOD

In this study, 20 immature female albino rats were used at the age of 22 days. Their weights ranged from (30 - 45 g). They were raised in the animal house in the college of the Veterinary Medicine / University of Tikrit. The animals were subjected to laboratory conditions represented by temperature (5 ± 25 ° C), with light cycle (10) hours and (14) dark hours. The animals were kept in plastic hutch with a diameter (20 x 25 x 20 cm) and then divided into two groups, each group included (10) animals. The first group was treated with (100 mg / kg b.w) of ferrous sulphate solution in a daily dose for 15 days orally through tubular feeding, while the other group considered as a control group, and then the animals were killed at the age of 37 days.

The Weight of internal viscera and genitals

Animals were anesthetized using a special glass vessel containing ether-saturated cotton. The weight of the animals was recorded prior to the killing. The abdominal cavity was opened with forceps and scissors, the opening continued until the thoracic cavity reached the internal organs quickly. The internal organs, which included the liver, heart, spleen and kidneys, ovaries (right and left), and uterine, were extracted. After cleaning these organs from the surrounding tissue and by using a sensitive electrical balance, the weight of these organs was weighed.

The variable studied:

Determination the level of glutathione in the blood serum

The level of glutathione was estimated using the modified method used by **Rifai (2018)**. [7]

Determination the level of malondialdehyde in the blood serum

The serum lipid peroxidation level was assessed by measuring the level of malondialdehyde (MDA) as a final product of over-oxidation fat. [8]

Determination packed cell volume of the blood (PCV)

PCV was estimated according to **Guyton, (2006)** [9] , where the glass tube containing heparin was used by performing a minor vein wound in the internal eye organization and before filling the capillary tube with blood, blocked from the other end by the artificial clay, and then placed directly in the microhematocrit centrifuge for 5 minutes at 12000 xg. The results were then read on the microhematocrit reader.

Determination the concentration of hemoglobin (Hb)

Hemoglobin concentration was estimated by using the cyanomethemoglobin method, where the special kit was used to estimate Hb, from SYRBIO company, (French).

Determination of iron level in the blood serum

The iron level in blood serum was estimated by using the ready measurement kit from SYRBIO (French), and then the light absorption of the complex color produced was reading using the spectrophotometer at the wavelength 535 nm.

STATISTICAL ANALYSIS

The data were analyzed statistically by Sigma Stat program. One way analysis of variance was used, and the differences between variables were determined using: Duncan multiple range test.

THE RESULTS

Table (1) shows the effect of oral iron sulfate on body weight, heart, kidney, spleen, liver, ovaries, and uterus (mg)in female immature rats.

variables	Mean ± standard error	
	Control group	Iron treatment group
Body weight (gm)	97.64 ± 3.37 B	67.43 ± 2.71 a
Liver weight (mg)	347.67 ± 142.81 B	4632.17 ± 174.42 a
Spleen weight (mg)	698.83 ± 15.64 B	867.33 ± 12.78 a
Heart weight (mg)	496.83 ± 23.84 A	511.33 ± 22.91 a
Kidney weight (mg)	413.33 ± 9.82 A	423.50 ± 8.38 a
Ovary weight (mg)	12.16 ± 0.61 A	10.17 ± 0.61 a
Uterine weight (mg)	44.17 ± 1.92 A	45.83 ± 1.51 a

Horizontal different letters mean that there is a significant difference between groups at a significant level (P <0.05).

Number of animals in each group = 10

Table (2) shows the effect of oral iron therapy on the level of malondialdehyde, hemoglobin concentration, packed cell volume (PCV), level of iron and glutathione in immature adult rats.

variables	Mean ± standard error	
	Control group	Iron treatment group
Serum glutathione level (µmol/l)	5.12 ± 0.08 a	3.14 ± 0.13 b
MDA level (µmol/l)	0.32 ± 0.01 B	0.97 ± 0.02 a
Hb (gm/100ml)	11.12 ± 0.15 B	14.23 ± 0.17 a
PCV (%)	39.72 ± 0.54 B	44.22 ± 1.49 a
serum iron level (µgm/ml)	175.01 ± 2.24 B	242.84 ± 3.38 a

Horizontal different letters mean that there is a significant difference between groups at a significant level (P <0.05).

Number of animals in each group = 10

DISCUSSION

The current study showed that given the iron at dose (100 mg/ kg of body weight) caused a significant decrease in body weight, and this result came correspondent with the findings of **Han (2011)** [10] who pointed out that rats exposed to iron overload are susceptible to anorexia, which may be due to the irregular physiological functions of the body as well as the effect of iron overload on the absorption of food from the intestines. The result was identical to that indicated by **Garibay (2011)** [11] who observed a significant decrease in body weight in iron-treated animals excessively compared to control group, this was attributed to the fact that giving high doses of iron causes loss of appetite and then to the weight loss.

The results of this study showed a significant increase in the weight of the liver and spleen, this result was agreed to that of **Sharaf,.(2002)** [12] which indicated a direct relationship between the weight of the liver and spleen on the one hand and dietary iron content on the other hand; as the liver and spleen are the most organs affected by the quantity of Iron in the body and this may explain the moral increase in the weight of these two organs due to the iron overload in experimental animals. However, this result was contrary to the results of by **Eybl, (2011)**. [13] which did not record a relationship between the weight of the liver and spleen and the body iron level on the other hand, this result was consistent with that indicated by Stal, (1999) [14] that the rats treated with heavy metals suffered from a rise in the weight of the liver and spleen and he attributed that to the decrease of liver glutathione level; due to the lack of antioxidant enzymes in it and then the occurrence of oxidative damage, and functional disorder of the liver, and may be due to what pointed out by **Stohs, (1999)** [15] that the site of the main collection of iron in the body is the liver and the spleen, and the iron is responsible for cases of oxidative damage in each, this is confirmed by studies that patients exposed to iron overload suffering from hepatic cell damage. [16]

The significant increase in the weight of liver and spleen in the iron treatment group was corresponding with the findings of **Karaca. (2010)** [17], which indicated that this increase may be due to increased inflammatory processes in those organs as iron is an oxidative component and catalyst of this inflammatory processes at the same time, and that the liver and spleen are one of the main centers of the presence of iron in the body so the cause of iron overload doubling inflammatory processes, which ends with an increase in weight in these two organs. The small age of animals in this group may be helpful in increasing the inflammatory processes that occur within the body due to the high level of free radicals and the consequent increase in the rates of oxidative damage; due to the low efficiency of anti-

oxidant systems.

Treatment with iron showed no significant difference in heart, kidney, ovary, and uterine weight compared with the control group. This result was agreed with **Chandra, (2011)**. [18], which indicated that the exposure of immature rats to heavy metals did not cause a significant increase in heart, kidneys, testis weight, and subsequent sexual glands and growth in pre-puberty age are affected by the secretion of sex hormones, which begin to secrete at puberty. Sex hormones work on the retention of nitrogen, which is involved in the manufacture of amino acids and proteins, so no significant difference in weight at these ages. It may also be due to the shortening of the period of the dosage which is (14) days so that the iron cannot show the negative effects during this period to those values [17] [5]. The treatment with iron showed a significant decrease in the level of glutathione in the blood serum. The result was consistent with 14-**Stal, (1999)** [14], which observed" a decrease in the level of glutathione in rats treated with heavy metal"; as a result of the lack of antioxidant enzymes. The synthesis of active oxygen species by non-enzymatic reactions of iron with the thiol groups in plasma leads to a reduction in the ability of total antioxidants (catalase and superoxide dismutase) in plasma, as well as the treatment with iron significantly increased the level of malondialdehyde, and this result was consistent with **Girotti, (1994).** [19], which indicated "that the treatment of rats with heavy metals led to an increase in lipid peroxidation and a decrease in antioxidant enzymes". As the cellular membranes are rich in unsaturated fats, which is a major target for effective oxygen varieties, in addition, effective oxygen varieties are responsible for breaking down most of the main proteins involved in cell formation as well as reducing the levels of antioxidants.

Iron ion has the potential to facilitate the modification of hydrogen peroxide (H_2O_2) to the hydroxyl root through Fenton reaction, which is believed to be an important initiator for lipid peroxidation [20], the increase in the level of malondialdehyde is an important indicator of the increase in free radical which causes increase in the lipid peroxidation, which is the final product of it is the malondialdehyde. [21]

The results obtained showed a significant increase in the level of hemoglobin (Hb), the packed cell of blood (PCV), and the level of iron blood serum. This result was agreed with the findings of **Rincker, (2012)**. [22]," which confirmed a significant increase in hemoglobin in the case of continuous exposure to nutritional iron, which stimulates the synthesis of Hb, also he indicated" that the concentration of hemoglobin was directly proportional to the PCV", also he indicated "that the increase in iron leads to a decrease in the concentration of serum transferrin, which coincides with the high levels of hemoglobin synthesis" this decrease in the transferrin concentration; is due to the reduction of iron transport from its storage sites to the sites of the hem synthesis, and this is why the rise of iron liver and spleen in the iron overload.

CONCLUSIONS

It is concluded that iron overload has harmful effects on studied parameters and organs, indicating that iron is stressful and has a negative effect if it increases over the normal level which produce oxidative condition .

Factors Associated with the Occurrence of Anemia in Pregnant Women in the Work Area of Baraka Public Health Center, Enrekang District, South Sulawesi Indonesia

Kalma

Health Polytechnic of Ministry of Health in Makassar, Indonesia

ABSTRACT

Study of factors related to anemia in pregnant women in the work areas of Baraka Public Health Facility of Enrekang District aimed to know the parity, mother's age, and inter-pregnancy interval with anemia in pregnant women was conducted. The method used in this study is a laboratory observation method with a descriptive approach, where each respondent was examined for hemoglobin (Hb) levels as a dependent variable and data about independent variables. The study was conducted from June to October 2017. The results showed that the parity factor and age of pregnant women had a relationship with the incidence of anemia, where the p-value <ά (0.05), the distance of pregnancy did not have a significant relationship with the incidence of anemia, where the value of p> ά (0.05). From the results of the study concluded that the age of pregnant women is the most influential factor in the incidence of anemia in pregnant women in Baraka Public Health Center, Enrekang District.

INTRODUCTION

Public health development in Indonesia is mainly aiming to increase life expectancy, improve the quality of life of human resources, and improve the quality of life in order to improve family welfare so that it can deliver optimal levels of public health. Health is one of the basic human needs, so it needs to endeavor so that every citizen is increasingly aware of the importance of health for himself and his environment, and can increasingly behave good healthy life.

Undermutrition is one of the main problems of public health in Indonesia. Especially in poor pupulation[9]. Nutrition problem, especially in pregnant women, is a big problem because it is a supporting factor for anemia in pregnant women. Anemia during pregnancy is a significant health problem in order to improve public health. Regarding maternal and child health, anemia is a major nutritional problem in developing countries including Indonesia.

Anemia is one of the factors that become an indicator of the success of a nation's health development that describes socio-economic capabilities in meeting the needs of quality and quantity of people's nutrition [1].

Anemia during pregnancy is a significant health problem to improve the degree of public health related to public health. Regarding maternal and child health, anemia is a major nutritional problem in developing countries, including Indonesia.

Data from the World Health Organization (WHO) in 2010 showed that anemia in pregnant women ranged from 20-85% with hemoglobin levels (Hb ≤ 11 g/dL). In developing countries including Indonesia, the infant mortality rate and the percentage of anemia during pregnancy are the most sensitive indicators to describe health status, especially maternal health in infants. The Indonesian Health Demographic Survey (SKDI) in 2012 showed that maternal mortality (MMR) in Indonesia was 228/100,000 live births. The causes of maternal deaths due to bleeding were 29.67%, infections 5.51%,

abortion 1.77%, prolonged labor 1.65%, and others 34.35%. Maternal mortality is one indicator of the success of health services in a country. The direct cause of maternal death is bleeding, eclampsia and indirect causes are anemia [4].

Pregnancy is a natural process and not a pathological process. Pregnancy usually develops and results in the birth of a term healthy baby through the birth canal, but this is not always as expected, normal conditions can be pathological/abnormal. From the medical record data of Baraka Health Center in 2015 showed the number of pregnant women who had their pregnancies examined in 2015 as many as 196 people with some cases of anemia as many as 72 pregnant women. Nowadays, researchers interested to do research to determine factors related to the incidence of anemia in pregnant women in the working area of Baraka District Enrekang Health Center. The factors studied included: parity, age, and inter-pregnancy interval [2].

Anemia is a decrease in the number of red blood cells or the concentration of hemoglobin in the blood circulation. Causes of anemia include malnutrition, lack of iron, malabsorption, massive blood loss such as labor, abnormal menstruation, chronic infectious diseases such as pulmonary tuberculosis, intestinal worms, malaria, and others. According to World Health Organization, anemia in pregnant women is classified based on Hb levels of pregnant women into three categories as follows: normal (Hb ≥ 11 g/dL), mild anemia (Hb 8-10 g/dL), and severe anemia severe (Hb <8.0 g/dL) [10].

MATERIAL AND METHOD

The type of research used in this study was observational with a descriptive cross-sectional study approach. Pregnant women who examined themselves at the Baraka Public Health Center in Enrekang District included in this study were examined their hemoglobin (Hb) levels. Data on dependent and independent variables are collected simultaneously, to obtain information about the relationship of several factors to the incidence of anemia in pregnant women in the working area of the Baraka Public Health Center in Enrekang District.

This study was carried out from June to October 2017. The populations in this study were pregnant women who were in the working area of the Baraka Health Center in Enrekang Regency who came to have their pregnancies examined during the study period. The samples in this study were pregnant women who had their pregnancies examined at Baraka Health Center in Enrekang Regency. The sample size in this study was 65 people. The sampling technique in this study is the total sampling technique.

The independent variables in this study were factors related to the incidence of anemia in pregnant women: parity, the age of pregnant women, and inter-pregnancy interval. The dependent variable in this study was anemia in pregnant women.

The data obtained in this study include primary data, namely hemoglobin levels examined directly in pregnant women with the Sahli method. Also, other primary data obtained in this research is filling in questionnaires distributed to pregnant women to identify data relating to knowledge, education, age, parity, and inter-pregnancy interval. Other than that, secondary data also obtained including a profile of the Department of Health of Enrekang District and the medical record of the patients from Baraka Public Health Center in Enrekang District.

Materials and tools used in this study are 3 mL syringe, tourniquet, cotton, lancet, a reaction tube, 20 µl micropipette, Sahli hemometer, alcohol 70%, and HCl 0.1 N solution.

DATA ANALYSIS

The analysis used in this study is regression analysis which aims to determine the relationship of each independent variable to the dependent variable. Regression analysis also used to know which variable, from the three independent variables, is the most dominant relationship with the incidence of anemia in pregnant women.

FINDING

Hemoglobin level of pregnant women in the working area of Baraka Public Health Center displayed in Table 1. Twenty-six of respondents (40%) suffered from anemia based on their hemoglobin level while the other 39 pregnant women (60%) not. Table 2 displayed that as much as 84.6 % (55 pregnant women) are low-risk parity while 15.4 others are high-risk parity.

Table 1 Distribution of Respondents Based on Occurrence of Anemia in Pregnant Women in Baraka Health Center in Enrekang District in 2017

Hemoglobin level	(n)	(%)
Anemia	26	40
Normal	39	60
Total	65	100

Source: Primary Data 2017

Table 2 Distribution of pregnant women who examined their pregnancies according to parity at the Baraka Public Health Center in Enrekang District in 2017

Parity	(n)	(%)
High Risk	10	15.4
Low Risk	55	84.6
Total	65	100

Source: Primary Data 2017

Table 3 Distribution of pregnant women who check their pregnancies according to the age of pregnant women at the Baraka Health Center in Enrekang Regency in 2017

Age	(n)	(%)
High Risk	11	16,9
Low Risk	54	83,1
Total	65	100

Source: Primary Data 2017

Based on the age, it is shown in Table 3 that 11 of respondents (16.9%) are high risk, while the majority of them (83.1% or 54 people) are low risk. It is displayed in Table 4 that all (100%) of women included in this study were at low risk based on the inter-pregnancy interval.

Table 4 Distribution of pregnant women who check their pregnancies according to the inter-pregnancy interval at the Baraka Public Health Center, Enrekang District in 2017

Inter-pregnancy interval	(n)	(%)
High Risk	0	0
Low Risk	65	100
Total	65	100

Source: Primary Data 2017

DISCUSSION

Anemia in pregnancy is a condition where the hemoglobin (Hb) level is lower than the standard value which is less than 11.0 g/dL. Pregnant women whose hemoglobin levels 8.1-10 g/dL, 6.5-8 g/dL, and < 6.5 g/dL were classified as suffering mild, moderate, and severe anemia, respectively (Tabrizi and Barjasteh 2015). Anemia in Indonesia is still considered a public health problem since its high prevalence, especially for pregnant women. Anemia in adults can cause fatigue and weakness which resulting in lowering productivity and the declining of work capacity[3].

Anemia can be caused by malnutrition, lack of iron, malabsorption, massive blood loss (such as labor and abnormal menstruation), and chronic infectious diseases (including pulmonary tuberculosis, intestinal worms, malaria, and others)[6][7].

Parity is the number of deliveries performed or experienced by a woman with live births or stillbirths. The number of births can affect the body's metabolic process. The present data of prevalence of anemia in pregnant women (40%) was higher compared to national health survey conducted by Ministry of Health [5] .

The analysis using chi-squared with ά 0.05 showed that that there is strong association between parity and the incidence of anemia among pregnant women in Baraka Public Health Center of Enrekang District (p-*value* = 0.000). The result means that high risk parity (or pregnancy more than 3 times) has a higher chance of anemia compared to low risk parity. High risk parity in pregnant women usually relates to the

level of knowledge that the mother lacks in the impact of the number of pregnancies. There is still lack of dissemination of information through counseling about the normal number of pregnancies by every woman.

Age is one factor that cannot be changed. Epidemiological attention is made to certain age groups because it has its own important problems. Age grouping is usually based on the presence of a problem and is specifically associated with other health factors. The age referred to in this study is the age of pregnant women with high risk i.e. less than 20 years and more than 35 years. Mother's age is very influential on the development of reproductive organs. This relates to the physiological state of the mother's body in accepting presence and supporting the development of the fetus. A woman entering the age of marriage will experience a certain phase in her life where healthy reproductive age is between 20-35 years. There was a significant relationship (p *value*= 0.000) between the age of pregnant women with the incidence of anemia among pregnant women in Baraka Public Health Center of Enrekang District based on chi-squared test.

Inter-pregnancy interval is the interval between two consecutive births of a woman. Setting the interval between pregnancies has an impact on the health of the mother and her baby, the inter-pregnancy interval that is too tight (<2 years) is more risky than the longer inter-pregnancy interval (> 2 years). This is because the anatomy of a woman needs time to restore her health and adequate nutritional intake. Based on this research, there is no association between interpregnancy interval and the incidence of anemia in pregnant women in Baraka Public Health Center of Enrekang District based on chi-square test (p-*value* = 0.40).

CONCLUSION

there is a significant association between parity and the incidence of anemia in pregnant women in Baraka Public Health Center of Enrekang District

there is significant association between the age of pregnant women and the incidence of anemia in pregnant women in Baraka Public Health Center of Enrekang District

there is no association between the inter-pregnancy interval with the incidence of anemia in pregnant women in Baraka Public Health Center of Enrekang District

the age of pregnant women is the most factor that associated with anemia in pregnant women in Baraka Public Health Center of Enrekang District.

Conflict-Of-Interest Statement: In this study between researchers and research, subjects did not have a conflict of interest, because subjects did not have personal or informal relationships with researchers.

Source of Funding : The source of funds in this study came from the Research of Health Workforce Development of the Ministry of Health of the Republic of Indonesia.

Ethical Clearance : The ethics of this study were obtained from the Ethics Commission for Health Research, Poltekkes Kemenkes Makassar.

Assessment of Learning Disabilities among Deaf Adolescent

Wameedh Hamid Shaker

Lecturer, University of Kufa / faculty of Nursing / Head of pediatric Nursing Branch

ABSTRACT

Objective: To assess learning disabilities among deaf adolescent. To find association between sociodemographic and learning disorder of t deaf adolescent. **Methodology**: A cross sectional descriptive design was carried out through the present study in order to achieve the early stated objectives for period from February 2016 to March 2017.**Conclusion** the majority of the study sample was male. The study subjects have 12-14 for age was exceedingly and result study was residence mostly rural. Level of education for father and mother was generally primary school .The economic status was good during study, behavioral characteristics that most affect. Overall evidence of research on the prevalence of additional disabilities with deafness is very low. **Recommendation** needs to be made here is that a comprehensive research program focusing on deaf adolescent with multiple disabilities is very much needed. Data provide the basis for recommendation of a battery of tests for use by school, professional, and general psychologists in evaluating deaf adolescent

Key wards: *Assessment, Learning, Disabilities, Deaf, Adolescent.*

INTRODUCTION

Deaf and dump the term deaf is frequently applied to those who are deficient in hearing power in any degree, however slight, as well as to people who are unable to detect the loudest sounds by means of the auditory organs. It is impossible to draw a hard and fast line between the deaf and the hearing at any particular point[1].

Mentioned National Deaf Children's Society November (2012) known the incidence rates of lasting childhood hearing weakening for children in the Trent area. Study is identify 38.7% of the children were institute to have another clinical or developmental problem and half of these children had at least two additional problems. Since then there have been major developments in the technology used to assess deafness, with objective measures in place allowing for hearing testing from birth. In England, the newborn hearing screening program offers 99.9% of babies born a hearing screening test within the first few weeks of birth[2].

Deafness is either congenital or acquired. Congenital deafness arises from some natural cause which deprives the child of hearing from its birth. Acquired deafness arises from disease, accident, or other causes. The deaf are divided into two classes the totally deaf, and the partially deaf the latter being subdivided into five classes[3].

Those who perceive the human voice when it is used close to the ear, without being able, however, to distinguish the separate sounds, by those who can distinguish the vowels when they are loudly pronounced in the ear; those who understand (but with difficulty) some words known t0 them when these are clearly pronounced in their ear[4]. Without effort, understand all that is clearly pronounced in their ear; and finally those who can hear the raised voice, but not sufficiently well to follow general conversation, or to attend to what is going on in a class of hearing children. All those coming within this division are fit subjects for schools for the deaf and dumb[5].

Statement of problem:

Assessment of Learning Disabilities among Deaf Adolescent in AL-Amal Center of Al-Najaf Al- Ashraf Governorate

The study aims:

1- To assess Learning Disabilities among Deaf Adolescent.

2- To find association between sociodemographic and learning disorder of Deaf adolescent.

Methodology: A cross sectional descriptive design was carried out through the present study in order to achieve the early stated objectives for period from February 2016 to March 2017.

Design of the study: A cross sectional study descriptive design was conducted. Each individual in the sample was interviewed using a specific questionnaire form.

Setting of the study: The study was conducted at AL-Amal Center of Al- Najaf Al- Ashraf Governorate.

The sample of the study: The Simple purposeful sample of (60) Assessment of Learning Disabilities among Deaf Adolescent in AL -Amal Center.

RESULTS

Table (1): The Statistical distribution of study group by their Socio-Demographic Data

Items	Sub-groups	Study group Total = 60	
		Frequency	Percentage
Age / Years	12-14	41	**68.3**
	15-17	19	**31.7**
Gender	Male	34	**56.7**
	Female	26	43.3
Residency	Urban	22	**36.7**
	Rural	38	**63.3**
Level Education of father	Illiterate	17	**27.7**
	read and write	14	**23.3**
	Primary school	17	**28.9**
	Secondary school	7	**11.7**
	Institute or College	4	**6.7**
	Higher studies	1	**1.7**
Level Education of mother	Illiterate	11	**18.3**
	read and write	10	**16.7**
	Primary school	26	**43.3**
	Secondary school	8	**13.3**
	Institute or College	5	**8.3**
	Higher studies	0	**0.0**
Economic Status	Good	35	**58.3**
	Not good	25	**41.7**

Table (1) shows statistical distribution of patients group by their socio-demographic data, it explains that the majority of the patients subgroup are: patients with ages between (12-14) years old (68.3%), male patients (56.7%), those who live rural residents (63.3%), and finally those with good economic status (58.3%) the level of education father was Primary school (28.9) % and level of education mother was primary school was (43.3%).

Table (2) The mean of scores and assessment of behavioral characteristics for study group

Behavioral characteristics	mean of scores	Stander division	Assessment.
attention easily distracted	2.87	1.07	**Failure**
Impulsive	2.63	1.20	**Failure**
Famous to the point of folly	3.17	1.38	**Pass**
Behavior difficult to predict	3.35	1.33	Pass
cannot control himself (speaking without ear, jumping from a chair, etc.)	2.80	1.45	Failure
Intensive	2.57	1.26	**Failure**
Always rude with others	3.62	0.98	**Pass**
movement cannot stabilize	2.78	1.11	**Failure**
Very easily consulted other children	3.17	1.11	Pass
behavior often does not suit the attitude	3.38	1.02	**Pass**
Furious and irritable	2.72	1.13	**Failure**
Moody	2.88	1.20	**Failure**
Global Mean of Score	2.99	1.19	**Failure**

This table shows the mean of scores and assessment of behavioral characteristics for study group, the statistical assessment considers any item (pass) when the mean of score is higher than the cut-off point for the mean of score (cut-off point = 3) .

Table (3)The mean of scores and assessment of cognitive difficulties for study group

Cognitive difficulties	M.S.	S.D.	Assessment
Unable to remember the printed word	2.95	1.27	**Failure**
It is difficult for him to recognize letters and numbers	3.10	1.31	**Pass**
It lacks the ability to distinguish sizes	3.57	1.26	**Pass**
The ability to distinguish (right, left, up, below)	4.12	1.21	**Pass**
His ability to balance is very weak	3.82	1.01	**Pass**
Has a weak audio memory	1.85	1.30	**Failure**

Cont... **Table (3)The mean of scores and assessment of cognitive difficulties for study group**

He finds it difficult to distinguish sound stimuli	1.48	1.09	**Failure**
Its kinetic coherence is generally very weak	3.58	1.16	**Pass**
Has a weak visual memory	3.48	1.55	**Pass**
His ability to use his hands is very weak	3.87	1.13	**Pass**
Lack of skill in the performance of motor skills in general	4.03	0.87	**Pass**
He is able to listen but he does not understand what he hears	3.67	1.55	**Pass**
It lacks the ability to retrieve simple geometric shapes	3.65	1.18	**Pass**
Global Mean of Score	3.32	1.22	**Pass**

Table shows the mean of scores and assessment of cognitive difficulties for study group, the statistical assessment considers any item (pass) when the mean of score is higher than the cut-off point for the mean of score (cut-off point = 3) .

Table (4): the correlation between demographic data and behavioral characteristics for study group

Demographic items	Chi Square	Coefficient of Contingency	P value
Age	0.00	0.01	0.94
Gender	0.46	0.09	0.50
Residence	0.03	0.02	0.86
Economic Status	3.77	0.24	0.58
Level of education of father	2.19	0.19	0.70
Level of education of mother	0.00	0.01	0.94

This table shows the correlation between demographic data and behavioral characteristics for study group, it is clear from the table that there is no significant correlation; because the p-value is higher than 0.05, except for the residence which shows a significant correlation cognitive difficulties.

DISCUSSION

Discussion of study results will be presented in with assessment of learning disabilities among deaf adolescent.

In the current study show higher incidence in the age (12-14). Concerning the gender, the study results reveal that the majority of the subject are male, this study subject reveal the most of participant is male[6].

Their results indicate that the majority of subjects are rural residents rather than the

big cities. Regarding fathers and mothers education level most of participant are

Primary school. Their results indicate that the majority of study subjects are low monthly income[7].

The study result shows that the final assessment of academic difficulties and determination of cognitive patients domains are pass except the assessment of knowledge patient regarding behavioral domain is poor. While the overall assessment for the patients knowledge regarding learning difficulties is good[8].

The study results show that there is a no significant relationship between academic behavioral and cognitive difficulties and their demographical data that mean the age, gender, residency, economic status and fathers and mothers level of education do not effect on their learning difficulties[9].

Assessments should also be go together with by observations of the integrity of the implementation of the intervention, including the amount of time paid on supplemental instruction, especially if the child does not appear to be making progress. School psychologists are often well organized in this area of assessment. Although

a psychologist operating outside of a school may not be in a position to do curriculum-based assessments or to in my opinion evaluate the intervention, such assessments should be expected, especially if the referral is to a private academic therapist[10].

Impost of written expression is especially important because it is the most common type of LD in clinical children and because writing problems are more common in general population studies in school students than are reading problems[11].

CONCLUSIONS

According to the present study findings, the researcher can make the following conclusions: Most of the sample male was majority; the study subjects have 12-14 for age was exceedingly. The result study was residence mostly rural, the level of education for father and mother was generally primary school. Economic status was good during study. The behavioral characteristics that most affect. Cognitive difficulties assessment was no affect. The correlation between demographic data and behavioral no significant correlation. The overall evidence of research on the prevalence of additional disabilities with deafness is very low.

Recommendations:

1-The recommendation that needs to be made here is that a comprehensive research program focusing on deaf adolescent with multiple disabilities is very much needed.

2-These data provide the basis for recommendation of a battery of tests for use by school, professional, and general psychologists in evaluating deaf adolescent.

Declaration of Interest: Nil.

Source of Funding: Self.

Ethical Clearance: After the approval of protocol by the Ethical Review Board, university of kufa/Iraq and before enrollment, all subjects gave their written informed consent.

Evaluation of Drug Management Information System to Improve Quality and Users Satisfaction: Case Study at a Primary Health Center

Rico Kurniawan[1], Popy Yuniar[1], Tris Eryando[1], Kenji Fadlin Azimi[2], Retnowati[2], Devi Maryori[3]

[1]Department of Biostatistics and Population Studies, Faculty of Public Health, Universitas Indonesia, 16424 Depok, Indonesia, [2]Research Center for Biostatistics and Health Informatics Faculty of Public Health, Universitas Indonesia, 16424 Depok, Indonesia, [3]City of Depok Health Office, 16424 Depok, Indonesia

ABSTRACT

Drug and supplies management plays an important role in health systems. A web-based drug management information system, *Sistem Informasi Pengelolaan Obat* (SIPO) was developed to support interaction and communication among the internal entities of a district health office (DHO), including primary health centers (PHC). Using a qualitative approach, the objective of this descriptive study is to assess SIPO's performance in terms of success in addressing problems related to drug and medical supplies management. The results indicate that SIPO has a positive impact for both PHCs and the DHO. The result found that the users are satisfied with the system. One element that needs to be improved is integration ability; currently, SIPO cannot connect to other health-related information systems. Generally, SIPO is considered to have a positive impact, both individually and on the organization.

Key words: *health information systems, supply chain management, medicine*

INTRODUCTION

Information technology has a positive impact on healthcare[1]. Health information technology (HIT) can potentially improve healthcare quality and outcomes by innovating healthcare delivery processes, including (a) providing clinicians with timely and appropriate patient information; (b) enhancing care coordination; (c) increasing physician compliance with care guidelines; (d) facilitating clinical monitoring by means of large-scale screening and aggregation of data; (e) improving clinical workflows; (f) improving communication among clinicians, and between clinicians and patients; and (g) decreasing medication.

Correspondence Author:
Rico Kurniawan
Department of Biostatistics and Population Studies, Faculty of Public Health, University of Indonesia, 16424 Depok, Indonesia,
e-mail: ricokurniawan@ui.ac.id

One of the uses of HIT in the health sector is on supply chain management (SCM) for drug and medical supplies[2]. SCM can be defined as a system of suppliers, manufacturers, distributors, retailers, and customers, in which material typically flows downstream from suppliers to customers (except for reverse logistics), while information flows in both directions. SCM can improve efficiency and effectiveness in terms of planning, coordinating, and controlling the movement of materials[3]. In Indonesia, medicines and medical supplies are assigned particular importance in health sector management because, as valued assets with a monetary dimension, drugs and medical devices are audited periodically.

Effective and transparent tracking systems allow pharmacies to accurately record inventory components, such as medication expiration dates and physical quantities[4]. Accordingly, there has been significant research emphasis on the role of information sharing and information integration as a way of achieving better supply chain performance[5].

Drugs and medical supplies are an important component of modern healthcare systems, reducing the burden of diseases across the globe[6]. The application of SCM practices in the healthcare sector relates not only to physical goods, like drugs, pharmaceuticals, medical devices, and health aids, but also to the flow of patients [7]. In managing medicines and medical supplies, one of the key objectives is to ensure the availability and quality of drugs at every level, both in healthcare institutions and in pharmaceutical installations in regions, provinces, and centrally. In accordance with the Indonesia Presidential Regulation concerning National Health Systems, SCM must be properly designed to maintain an adequate supply of drugs; maintain the availability of drugs according to buffer stock; maintain drugs in good condition during the distribution process to ensure their quality, safety, and efficacy; minimize drug wastage due to damage or expiration; ensure the accuracy of documents and logistics information systems; provide information for estimating drug needs; and ensure that each district's drug needs are met through appropriate planning.

One entity that plays an important role in Indonesia's national health system is the Puskesmas, or primary health center (PHC), which is responsible for local delivery of public health services. In carrying out its functions, which include prevention, promotion, and basic treatment, the PHCs depend on the supply of medicines and medical supplies to ensure delivery of health services to the community. PHCs receive drugs and medical supplies from the pharmaceutical installation at the district or city level; to maintain accountability, each PHC must send monthly reports on stock and usage of these items to the pharmaceutical installation at the district health office (DHO). These reports are then used as the basis for supplies allocation for the following month.

One common difficulty in SCM is controlling the movement of drugs and medical supplies at the healthcare facility level; the inefficient and irrational use of medicines has also become a problem at all levels of the health service[4]. In the city of Depok, the health office has complained about the difficulty of promptly obtaining accurate information about stock, expenditure, and usage of drugs and other medical supplies, which has adversely impacted planning, budgeting, procurement, and distribution.

In 2014, in collaboration with the Faculty of Public Health at Universitas Indonesia, the Depok Health Office developed an information system called *Sistem Informasi Pengelolaan Obat* (Drugs and Medical Supplies Management Information System; SIPO) for managing medicines and medical supplies. Depok City's PHCs and DHO had previously used a paper-based system to record and report drug and medical supplies, which was tabulated on spreadsheets and saved as separate files. SIPO is an internet-based system that connects PHCs with the DHO. The system was developed to assist distribution of drugs and medical supplies and to automate report preparation, meaning that PHCs and health offices are no longer charged with manual reporting to the DHO. In this study, we evaluate and assess the utilization of SIPO in terms of its success as an information system.

METHOD

This is a descriptive study, which employs qualitative methods to assess the success of SIPO. We apply DeLone and McLean's model for measuring the success of an information system[8], using six aspects, each of which has its own variables. These are **system quality** (flexibility, integration, response time, error recovery, system convenience, and language), **information quality** (completeness, precision, reliability, currency, and output format), **service quality** (assurance, empathy, and responsiveness), **user satisfaction** (repeat purchases and repeat visits), **individual benefit** (usefulness, ease of use, speed of use, productivity, and effectiveness), and **organizational benefit** (organizational effectiveness, service effectiveness, contributing to achieving goals, and productivity).

There are seven informants involved in this assessment, six users from the PHCs and one from the DHO. The informants were selected purposefully for their familiarity with the system. Informants were asked to give a mark or score using ten point scale to measure users satisfaction for each variable[9]. Zero (0) is represent for very dissatisfied, five is represent for neutral, and ten (10) is represent for very satisfied. In this study, we only conducted a descriptive analysis to know how much user satisfaction regarding to the SIPO.

RESULTS AND DISCUSSION

The SIPO system was developed to aid monitoring and management of drugs across health centers

and pharmaceutical installations, and to facilitate communication relating to drug management. At the DHO level, SIPO is used for recording receipts, distribution, and monitoring of stock at health centers and in warehouses (pharmaceutical installations), and for making required reports. At PHC level, SIPO is also used to record recipe-based drug expenditures. All required reports are created automatically.

Table 1. Score Results

Aspect	Scores (n=7)
System quality	
Flexibility	7.9
Response time	6.8
Integration	0.0
Error recovery	7.8
System convenience	8.0
Language	8.3
Average	6.5
Information quality	
Completeness	7.3
Precision	7.9
Reliability	8.0
Currency	7.9
Output format	8.8
Average	8.0
Service quality	
Assurance	8.3
Empathy	7.4
Responsiveness	8.1
Average	7.9
User satisfaction	
Repeat purchases	8.0
Repeat visits	8.0
Average	8.0
Individual benefit	
Usefulness	8.3
Ease of use	8.5
Speed of use	8.4
Productivity	7.9
Effectiveness	8.5
Average	8.3
Organizational benefit	
Organizational effectiveness	8.5
Service effectiveness	8.8
Contributing to goals	8.5
Productivity	8.5
Average	8.5
Overall average	7.9

Based on these results, users feel that the quality of the SIPO system is slightly satisfy (average 6.5), except for integration. The integration indicator has the lowest score because SIPO cannot yet connect to other systems to facilitate the users' work.

On information quality, the lowest score from users is for completeness (average 8.0) SIPO does not yet facilitate the input of all information regarding drugs that expire, which is very important because drugs that expire earlier must be issued before drugs that expire later (first expired, first out) and drugs that arrive first must be removed before drugs that arrive later (first in, first out). In other words, there are several indicators that need to be added to SIPO, both for input and output.

In terms of user satisfaction, informant stated that they are satisfied with SIPO (average 8.0). Users say that they will continue to use SIPO even if it is not required, because the data and information produced helps simplify work, especially in terms of reporting.

For individual benefits, the informants consider that SIPO has a significant individual impact and supports their daily work, including improving productivity, and particularly report generation. Overall, informants at both the PHC and DHO feel that SIPO has a positive effect on their organizations, particularly on drug and medical supplies management. The DHO can control every transaction at every PHC, with manual reporting no longer required.

SIPO was developed as an electronic recording and reporting system to replace the previous paper-based approach. As changing methods to improve a system always present major challenges, it is important to assess the level of user acceptance. An information system must be useful if it is to improve performance[10].

To ensure that drugs and medical supplies are made available in a timely way at health facilities, a functioning country-wide drug supply system should be in place. Each player in the system should also be responsible and accountable for the system's operation[11]. SCM integrates all aspects of the supply chain from first supplier to end user. The main objectives of SCM are (a) overall cost reduction, (b) lead-time reduction, (c) inventory and shortfall reduction, (d) transportation cost reduction, and (e) purchase cost reduction[12].

Effective management and distribution of drugs

helps to ensure availability and assessment of future need[4]. There is extensive evidence that the use of information technology to manage work provides many advantages, including cost effectiveness, efficiency, and quality of care[13]. To achieve improved performance, the healthcare supply chain must be efficient and integrated[3]. To meet these needs, SIPO integrates the recording and reporting of drug and medical supplies at PHC and DHO levels by incorporating information technology into the business process. Both directly and indirectly, SIPO has changed the flow of the business process and bureaucratic management of drugs and medical supplies in the city of Depok.

To ensure a system's sustainability, several factors must be considered, including user motivation, leadership, and user satisfaction. Having the right user attitude and skills base—together with good leadership, an IT-friendly environment, and good communication—can have a positive influence on system adoption[14]. The Depok City Health Office stipulates that each health center must use SIPO to record and report its drugs or be denied access to drug distribution. This is an important motivator for the use of SIPO in health centers.

Leaders play an important role in information technology implementation[15]. The implementation of SIPO was strongly encouraged by leaders at both PHC and DHO levels. One important role of leadership in this context was the approval function built into the system; at the DHO, the head of the pharmaceutical installation must give online approval for any item to be distributed to health centers, and the item can only be processed if it has been approved. To address the problem of bureaucracy, the process can continue even when the leader is not present in the office, the leader still can approve through their smartphone. Approval function also can be giving to another person who responsible to this. Similarly, the head of each PHC plays a leadership role in system sustainability by means of a monthly approval action, and monthly reports are then sent automatically to the DHO.

The role of leadership in driving HIT use and innovation is informed by the technology-enabled environment principle[16]. User satisfaction is influenced by several factors, including perceived usefulness, ease of use, user expectations, user experience, user skills, user involvement in system development, organizational support, perceived attitude of top management, and user attitude to information systems[17].

Our observations indicate that SIPO can improve users' performance in drug recording and reporting. Using SIPO, reports are automatically produced each month, meaning that users no longer need to print and send hard copies to the DHO. Users at the DHO receive information directly about the number and types of drugs needed by each PHC in Depok City, making the process of distributing drugs faster and timelier. Other studies have identified a close relationship between SCM practices and organizational improvement[18,19]. Successful use of HIT can assist such organizations in leveraging resources[20].

CONCLUSIONS

Success of a system can be assessed in six main aspects: system quality, information quality, service quality, user satisfaction, impact on individuals, and impact on the organization. Generally, SIPO is considered to have had a positive impact, both individually and on the organization.

Although the SIPO system can be said to be a success, the issue of system integration remains a problem, because SIPO is still a stand-alone system. From the viewpoint of the quality of information produced by SIPO, the completeness of the indicators is also a goal for future system improvements, because there are several reports that have not yet been implemented in SIPO. Another required improvement is in the input systems.

Users report satisfaction with SIPO at both the PHC and DHO levels; they feel helped by SIPO and do not feel forced to use it, even though it is actually mandatory. Users at the PHC and DHO also assess SIPO as having a positive individual impact; however, productivity is scored lower because, even if users feel more productive using SIPO, further improvements are needed to be able to monitor drug and medical supplies.

Users at the PHC and DHO also assess SIPO as having a positive organizational impact. Drug management at the PHC and DHO has become more effective and efficient and contributes to achieving organizational goals in terms of drug supervision and monitoring.

Conflict of Interest Statement: The authors of this research declare that there are no conflicts of interest

related to this study.

Ethical Clearance: Ethical clearance for this research was received from the Ethics Committee of the Faculty of Public Health, Universitas Indonesia.

Analysis of Risk Factors for Changing Conversion of Pulmonary Tuberculosis AFB Positive Patients in the Intensive Phase, Makassar City, Indonesia

Ummi Kalsum Supardi[1], Mondastri Korib Sudaryo[2], Ida Leida. M. Thaha[2]

[1]Master of Epidemiology, [2]Departement of Epidemiology, School of Public Health, University of Indonesia

ABSTRACT

Objective. The association of risk factors of tuberculosis has been known but still rarely performed risk factors to result of convertion among patient tuberculosis in 2 month treatment of DOTS. The study aims to know the risk factors of convertion against pulmonary tuberculosis BTA positive in Makassar.

Method. This was a case control study. Subjects of this study were pulmonary tuberculosis AFB positive patients in 2 month treatment of DOTS (intensive phase) in Labuang Baji hospital and Lung Health Center, 111 patients from December 2013 until February 2014. Cases were positive smear pulmonary tuberculosis patient who experiences no conversion at the end of the intensive phase of treatment and control were patients with positive smear pulmonary tuberculosis who did not experience conversion at the end of the intensive phase.

Result. The proportion of pulmonary tuberculosis AFB positive patients were convertion 33,3% and no convertion 66,7%. Chi square test showed statistically significant association against convertion ($p<0,05$) were education.

Conclusion. Education was important factor for changing convertion of pulmonary tuberculosis AFB patients. Health promotion program about tuberculosis should be the best solution to improve the proportion convertion among patients.

***Keywords**: Risk Factors, Convertion, pulmonary tuberculosis AFB Positive patients.*

INTRODUCTION

Tuberculosis is still a public health problem that is a global challenge. Tuberculosis is a direct infectious disease caused by *Mycobacterium tuberculosis* and can be transmitted by air. *Mycobacterium tuberculosis* when, sneezing, talking or laughing. it attacks the lungs, but can also attack other organs. This causes health problems in millions of people every year and the second rank as a cause of death in infectious diseases worldwide after HIV[1].

WHO has global target in the context of eradicating pulmonary tuberculosis in 2030. It is monitoring the progress of the pulmonary tuberculosis eradication program to ensure failure of treatment for pulmonary tuberculosis up to 85%. Based on 2009 data. Globally, the incidence of pulmonary tuberculosis reached 137 cases per 100,000 population. While the highest percentage of achievement of treatment success occurred in 2008 at 86%[5]. And in 2013 the success rate of TB treatment increased to 90.5%. In this case, eventhough the National tuberculosis control program has succeeded in achieving global targets but in 2013, Indonesia will still got the fifth rank in the country with the highest tuberculosis burden in the world, an estimated number of new cases of 410,000-520,000 tuberculosis prevalence rates of 272 per 100,000 residents while the estimated incidence is 183 per 100,000 population[2].

A study conducted by Tierney DB, On MDR TB patients who started treatment between 1999-2002 were 87.7% experienced sputum conversion with a median conversion time of 59 days (IQR:31-92). Normally, tuberculosis patient would experience convertion after 2 month treatment (intensive phase) except for patients were not regularly to do treatment DOTS[10].

Based on the target proportion of conversions in the South Sulawesi was 85% while in the main health care services proportion of conversion were low. Labuang Baji hospital and Lung Health Center in Makassar had proportion of convertion were 12% and 15% in 2013. Due to the above data, it can be seen that the level of achievement of targets at both health services very low. So, it was needed a study to determine the risk factors for changing conversion of pulmonary tuberculosis patients.

METHOD

Study Sample

Ethical Consideration

Written informed consent was obtained from all respondents before data collection was carried out.

Study Design

This study uses a case control design. Data collection was conducted in December 2013 to February 2014.

Population and Sampel

The study population was new positive smear pulmonary tuberculosis patients who underwent an intensive treatment period in the DOTS strategy, Makassar city, Indonesia. Samples were a part of the population who had completed intensive phase treatment at Labuang Baji General Hospital and Community Lung Health Center, there were 111 patients. Cases were positive smear pulmonary tuberculosis patient who experiences no conversion at the end of the intensive phase of treatment and control were patients with positive smear pulmonary tuberculosis who did not experience conversion at the end of the intensive phase. The sampling technique used exhaustive sampling techniques to select cases while controls were selected by accidental sampling technique[3].

Socio-Demographic Characteristics and Risk Factors

We include demographic information and individual characteristics (age, gender, education, occupation, socio-economic, tuberculosis, knowledge measured using the *guttman* scale), DM, regular treatment DOTS, role of PMO, and side effects of tuberculosis drugs as risk factors analyzed in this study.

Measures

Measurement of Sputum Convertion

Measurement of sputum conversion was seen based on AFB microscopic examination in positive smear pulmonary TB patients at the end of the 2-month intensive phase of treatment.

Tuberculosis Measurement

The diagnosis of tuberculosis was based on the results of microscopic smear positive smear in patients before receiving intensive phase treatment for 2 months.

Statistical Analysis

Analysis was carried out after getting information about risk factors using a questionnaire that had been tested for validity and reliability. Data processing was done electrically using computerized SPSS 20 for Windows programs. Data analysis was done by univariate by looking at the description of the frequency distribution of each independent variable, bivariate by *Chi-square* test to determine the relationship of the frequency of the dependent variable with the independent variable to see the risk factors against the results of conversion in patients pulmonary tuberculosis AFB positive.

RESULTS

Analysis and description of each study variable as a risk factor against result convertion of 111 patients, the proportion of convertion (33,3%) and no convertion (66,7%).

Tabel 1. Analysis of Risk Factors for Changing Conversion of Pulmonary Tuberculosis AFB Positive Patients in The Intensive Phase.

Effect of Drugs								
Yes	24	64,9	55	74,3	79	**1,568**	0,668-3,679	0,300
No	13	35,1	19	25,7	32			

Based on risk factor variables, the largest proportion were in no control group (table 1 and table 2). It can also be seen that the highest risk factor internal was of gender (OR=1.252), knowledge (OR=1.723) and the highest risk factor eksternal was of social economy (OR=1.350), regular treatment DOTS (OR=1.243), effect of drugs (OR=1,568).

DISCUSSION

Based on the results of the analysis, it is known that gender, Kowledge, sosial economy, regular treatment DOTS and effect of drugs, are risk factors for conversion among smear pulmonary tuberculosis patients in Makassar. Cases of smear-positive TB, especially men and those with risk factors identified for non-conversion, must be monitored closely during their treatment period. In patient compliance counseling and education to reduce TB non-conversion risk factors, and to increase TB conversion and cure rates[4].

In a study, which stated that TB knowledge was poor among respondents and many misconceptions about TB[6]. stated that the lack of education and distance from home to health center were significantly related to the delay in seeking care from the service provider. This was further demonstrated by a prospective cohort study conducted in South Africa, which found that illiterate patients were more likely to interfere with treatment[7]. Patients in this study demonstrated a good understanding of transmission and risk factors for TB. However, some patients are not aware the causes of TB and the transmission. Health education efforts must take advantage of these positive findings of learning[8]. Explained the knowledge of patients who are very low can determine the patient's disobedience to take medication because of the lack of information provided by health workers about pulmonary tuberculosis disease, treatment and its prevention[12]. Knowledge of patients about TB does not directly affect the increase motivation. Social support directly affects the increase in knowledge TB sufferers. The most powerful aspects of knowledge are treatment methods and side effects[15].

The results of this study are in not accordance with the research conducted by Maulidya states there is no relationship between knowledge and compliance with treatment for TB patients.This means, the higher or the lower of patient's knowledge does not affect his recovery[14]. TB knowledge is low and many misconceptions about TB these should be targeted through health education programs. Both TB knowledge gaps could be better addressed through anintegrated health education program[16]. These findings highlight the need for health education efforts to strengthen accurate information dissemination to promote sound TB knowledge and attitudes among patients[17]**.** Lower education was an important factor in TB[20].

while social support for TB patients reduced default. Further prospective randomised studies are necessary to evaluate the impact and to determine the most cost-effective social support for improving treatment outcomes of TB in patients, especially among populations at risk of default[25]. Interventions to reduce default should therefore concentrate on socially disadvantaged patients[23]. Our findings measure the risks associated with a variety of social factors and tuberculosis. Poverty, diabetes were independently associated with an increased risk of tuberculosis[21].

The consistent study in evaluating and comparing time and predictors of culture conversion, in Latvia got results a median sputum conversion rate of 60 days (range 4-462 days) of 77% of patients who experienced sputum conversion19. Shortening treatment from 6 to 4 months in adults with noncavitary disease and culture conversion after 2 months using current drugs resulted in a greater relapse rate. The combination of noncavitary diseaseand 2-month culture conversion was insufficient to identify patients with decreased risk for relapse18. TB patients remained smear-positive after 2 months of treatment. Patients with cavitation, higher smear grading and those who had not used DOTS continu ouslyin the initial treatment

phasehadalonger time to sputum smear conversion22

The recommended tuberculosis treatment is at least 6 months. It must be completed but if the patient feels healed, patients stopped the treatment. This is due to the lack of knowledge of the informantion about the importance of treatment. Therefore, there should be counseling about the importance of TB treatment and the consequences of uncomplete treatment[11]. Relationship between age and type of treatment is found 36 people (100%) productive age respondents get OAT category 1. Based on the results of statistical tests, p value is 0.023 where ρ <0.05 so it can be concluded that there is a significant relationship between age with type of treatment. It is possible that immunological systems at unproductive age (>50 years) are very susceptible to various diseases, including pulmonary tubeculosis. The older the age will be a functional change in physiological, pathological and decreased body defense systems. It will affect the body's ability of tuberculosis treatment[13].

Duration of Tuberculosis treatment more than 2 months can result dropping out. After the intensive treatment, Patients must take antibiotics for at least six months to nine months. Uncomplete treatment will cause drug resistance. Therefore, it is needed to educate TB patients about the importance of completing each stage of TB treatment, so that patients can complete the treatment[10].

In 1107 eligible patients, the treatment success rate was 81.5% and the default rate 9.4% (respectively 60.4% and 17.0%).The main risk factors for treatment default can be infl uenced. Interventions to reduce default should therefore concentrate on socially disadvantaged patients[23]. 2–3 drugs, HR 7.2, 95%CI 3.3–16.0, P<0.001) was significantly associated with an increased risk of default for MDR- TB treatment[24].

LIMITATION

The results obtained in this study may still be influenced by selection bias when choosing controls from accident sampling. The use of the control case design has a weakness because it has valid controls to compare with the case and the sample in this study is unadequat while this study has several variables, it makes the actual risk factors in the theory do not match with the results of this study.

Role Therapy of Camel Milk to Treatment Hepatitis Mice Which Induce *Via Listeria Monocytogenes*

Assistant Lecturer Shereen Hussein Ameen[1] and Professor Azeez Khalid Hameed[2]

[1]Chamchamal Technical institute, Sulaimania Polytechnic University, Sulaimania, Iraq,
[2]College of Science, University of Tikrit, Tikrit, Iraq

ABSTRACT

The goal of the current study was to administered the role of camel milk on hepatic histopathological induced via experimental infection with *L.monocytogenes* in Swiss albino mice. The mice were divided into four groups (A, B, C and D). The control group received water and fed *ad libitum*. The other groups received orally *L. monocytogenes*, Group B sacrificed after fourteen days. Group C received 1ml of camel milk, Group D received *ad libitum* of camel milk. Mice of both groups sacrificed after two weeks. Livers of all mice groups were taken to histological study. Histological sections of the liver of group B detected more sever changes including the acquisition of granular appearance for most tissue of liver lobes, hepatic cells necrosis with multiply micro abscesses compared with control groups. While liver of groups C and D showed normal structure of liver in most sections were represented via reduce the acquisition of granular appearance and increases number of Kupffer cells and in liver of group C while in group D showed several Hepatic cells to be ready for division, hyperplasia and hypertrophy of kupffer cells.

Keywords*: Role therapy, Camel milk, hepatitis, L. monocytogenes, Adult mice*

INTRODUCTION

Each year in developed countries, food-borne pathogens are responsible for causing millions of gastrointestinal disorders [1] . *L . monocytogenes* is an important food–borne opportunistic human and animal pathogen [2]. It was responsible for numerous food-borne outbreaks with high hospitalization and mortality average worldwide, specially affecting patient immune compromised adult, elderly and pregnant women [3]. These due to the *L. monocytogenes* is widely spread in natural and has been isolated form diverse of environmental source [4] like soil, plants, water, food chain, food processing [3] dairy product, raw milk, fruit and vegetables [5].As found on nonfood contact surface [6]. This wide spread of bacteria is due to resistant to hard environmental conditions, including psychotropic, high NaCl concentration and low pH. In numerous ways, *L. monocytogenes* can enter into food, processing plants, its ability to survive for long period in the environment, on food processing plants and its ability to grow at very low temperature (2C° -4C°), also to survive in or on food for prolonged period under bad conditions [7, 8].

In many parts of the world, Camel milk considered as one of the key ingredients of several traditional medicines as well as for human diet. It has a high bioactive value as result of higher composed of antimicrobial factors like Immunoglobulins, Lactoferrin and Lysozyme [9]. Recent studies confirmed that the composition of camel milk is unique in terms of anti-oxidative factors, antibacterial, antiviral, antifungal, antitumor activity, hypoglycemic and anti-cancer, to prevent aging for autoimmune diseases effect [10, 11].

The present research was proposed with an objective to study pathogenicity of *L. monocytogenes in* adult mice and role of camel milk to reduce pathological changes which induced by this bacteria.

MATERIAL AND METHOD

Bacteria strains and preparation of inoculums

The standard culture of *L. monocytogenes* (ATCC) was obtained from Medya Diagnostic center/ Erbil city/ Iraq. It was assessed for it purity carried out some recommended biochemical tests to ensure that the diagnosis was correct.

Camel's milk source

The milk sample was collected from Hawija which is 45 Km far from Kirkuk city/ Iraq. Camel was in the first month of lactation period fed mainly on pasture, which grows in the natural grassland in addition to the dates, bran and water. It was obtained milk samples by a manual way milking (Hand milking). Milk was transported to the laboratory in cooled conditions, then keeping it in the refrigerator under temperature (4-2) º C until use.

Pathogenicity of bacteria

L. monocytogenes were grown overnight in Brain Heart infusion liquid medium plus 6% glucose and yeast extra in an incubator at 37Cº. Bacterial cells were harvested by centrifugation 3000 rpm for 10 minutes, washed three times in phosphate-buffered saline. The bacterial suspensions were diluted to achieve the final suspension 4.5×10^6 CFU/ml and numbers of viable *L. monocytogenes* was done according to [12].

Animals used in the experiment

A total of 40 Swiss albino mice 27±2 in weigh, aged 4-6 weeks were used in this study. They were purchased from college of Veterinary Medicine/ University of Tikrit/ Iraq. Mice were kept in the animal house in wire-meshed stainless steel cages (five/ cags). The environment in the animal house was controlled in which the temperature was maintained at (20 - 24C°) with 12 h light/ dark cycle with good ventilation. They were fed by commercial pellet diet. The animals were kept in this environment for 7 days before starting the experiment for acclimatization.

Experimental Groups and Histology:

Mice divided randomly into four groups comprising 10 mice in each group and fed the same diet throughout the experimental period. Group A: given water and fed *ad libitum*. Group B: given dose of bacteria suspension 4.5×10^6 CFU orally one time for one a day. Group C: given 1ml of Camel milk orally two times a day. Group D: given *ad libitum* of Camel milk .

All animals in group A and B were scarified and dissected after 14 days. As for the rest of group C and D the same procedure was used for bringing about a bacterial infection. Then animals were left for 14 days and treatment will be started in the morning of fourteen days by camel milk for the groups B and C. finally scarified the animals of two groups after two weeks of the treatment. Liver of all groups were fixed in 10% neutral buffer formalin. After 48 hours, livers were trimmed and processed routinely in paraffin, sectioned at 5µm ,and stained with hematoxylin and Eosin stain [13]

RESULT & DISCUSSION

Histological examination of liver controlling mice group (group A) showed that hepatic cell, portal area and vasculature appear normal .The liver of group mice B showed hepatitis which acquisition of granular appearance for most tissue of liver lobes (Fig 1) as compared to the normal architecture of hepatic cells. In other sections observed focal necrosis, vacuolated and karyolysis most of hepatic cell's nucleus also infiltration of inflammatory cells in central vein and hyperplasia of their endothelium (Fig 2). Additionally, results showed multiple micro abscesses sprinkled in parenchyma in liver sections for all mice of group B characterized by necrosis of hepatic cells, dense infiltration of lymphocytes and few neutrophils (Fig 3). Also, there was macrophages in some sections (Fig 4). The granular appearance of liver tissue attributed to infiltration of inflammatory cells between hepatic cells where [14] mentioned that *L. monocytogenes* have a cell wall component that is mitogenic for lymphocytes and lipid components, which stimulate the monocytosis for which it is named. On the other hand, these bacteria have listeriolysin O which have highly lytic role for nucleated cells and it can prompting abroad range of various cells death kinds. Perhaps this explains the presence of nuclei at different stages of lysis [15]. Additionally, *L. monocytogenes* carried via blood to liver after crossing the intestinal barrier, this is the majority of the invading bacteria be trapped in the liver [16]. Infected hepatic cells react to *listeria* infection via liberation neutrophil chemoattractions and display boost in adhesion to neutrophils, leading to micro abscess [17]. Monocytes are other early responding cell type that infiltrates infectious foci within 24 -48 hours and this occurs following both oral and iv infection [18].

While the microscope examination of mice group C showed normal structure of liver in most sections with reducing granular appearance and demonstrated normal central vein. Also, normal arrangement of hepatocytes and sinusoids Liver with few numbers of inflammatory cells around central vein in some sections (10).

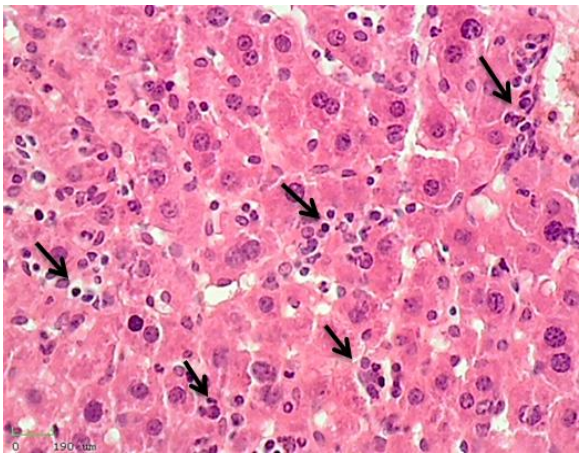

Figure 1. Liver section showing acquisition of granular appearance (H & E)X400

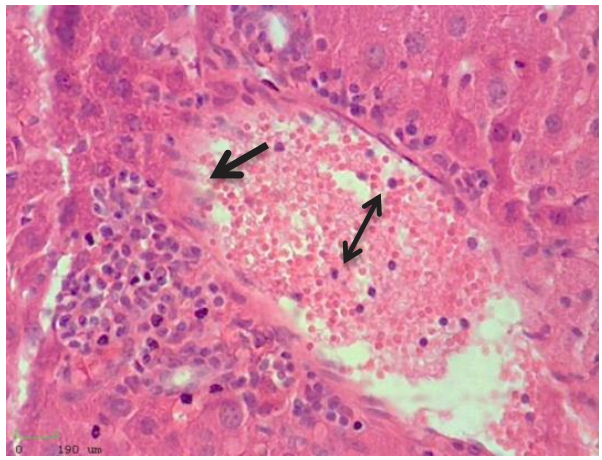

Figure2. Liver section showing infiltration of inflammatory cells in central vein, hyperplasia their endothelium (H & E) X400

In parenchyma , hyperplasia of kupffer cells was noticed in some sections of this group with (11) in other hand there was showed absent of the inflammatory cells inside central and portal vein, and normal endothelial lining them. While the histological architecture of the liver of mice group D was similar to mice group A. Absent granular appearance, micro abscesses (12). Several hepatic cells also were showed to be ready for division (13), hyperplasia and hypertrophy of kupffer cells (14).

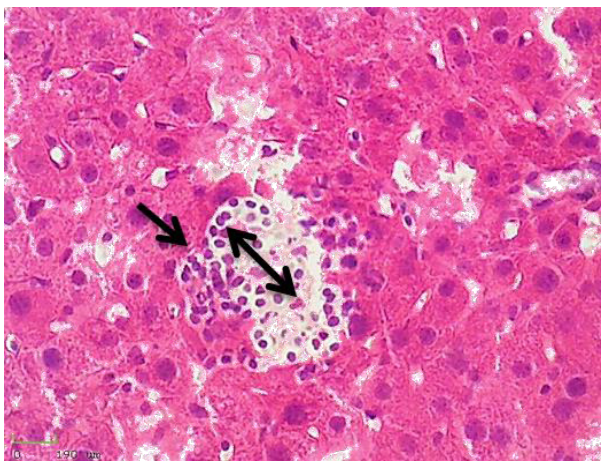

Figure3. Liver section showing i micro abscesses in parenchyma of liver , necrosis of hepatic cells (H & E)X400

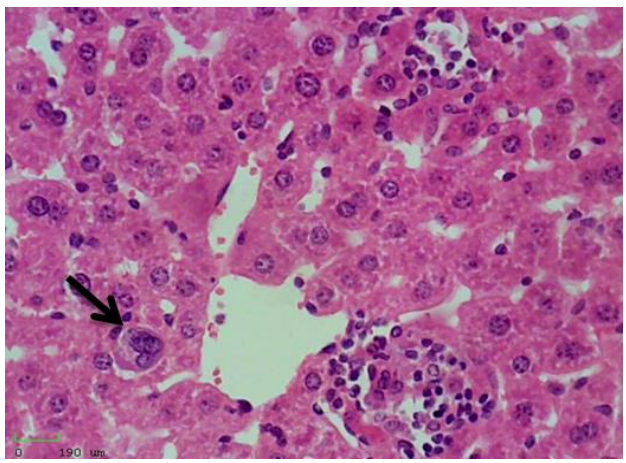

Figure 4. Liver section showing macrophages (H&E)X400

Many studies in vivo and vitro have proofed a significant backing for proving camel milk protective effects on liver destruction. It acts as antibacterial, antiviral, anti-fungal and anti-parasitic activity [19, 20] because it has antibacterial enzyme like Lactoferrin, lysozyme, immunoglobulins, N-acetyl –S– glucosaminidase, protective protein like casein, stronger immune system and smaller immunoglobulins than other ruminates [21]. The reduction of granular appearance of liver tissue of mice group C and its absent in mice group D may be due to the role of anti-inflammatory ingredients of camel milk it is Lactoferrin which has been distinguished avoid TNF-α, IL-1 and IL-6 in mononuclear cell in vitro and vivo response to LPS stimulation [22]. The anti-inflammatory role of Lactoferrin can be attributed as it has positive charge in its surface, which interacts with negatively charged moieties like proteoglycan on the surface of immune cells.

This combination can trigger signaling pathways that produce physiological anti- inflammatory [23]. Not only have these actions also Lactoferrin acts as antibacterial which prevents the reach of iron at the site of infection which is nutrient for the bacteria. In this case it plays bacteriostatic effect [24]. Lack of iron in the environment obliges bacteria to move because it cannot adhere to the host surfaces [25]. Additionally [25, 26] reported that Lactoferrin blocks pathogens adhesion to target cells. This characteristic was suggested for the first time gainst enteroinvasive *Escherichia coli* (HB. 101) and later against *Staphylococcus aureus, Yersinia enterocolitica, Shigella dysenteriae, L. monocytogenes, Helicobacter pylori, Neisseria gonorrhoeae, Pemphigus neonatorum, Bordetella pertussis, Streptococcus pyogenes and Y. pseudotuberculosis*. The repair of liver to normal architecture can be attributed to the role of synerging of Lactoferrin and lysozyme. Where they mentioned [27, 28, 29] that the gram positive bacteria have anionic molecules like lipoteichoic acid of the surface, Lactoferrin which binds with this molecules and this electrostatic binding decreases the overall negative charge of cell wall making easy effectiveness of antibacterial ingredients like lysozyme and antibiotics. This improvement due to the effective effect of the ingredient of this milk and its unique medicinal properties in terms of its high concentration of vitamins and protective proteins and immunological. This feature made it distinctive different from other animals in terms of containing high concentration of antioxidants of vitamins A, B2, C and E [30, 31]. These anti-oxidant vitamins play an important role in preventing tissue damages by removing free radicals [32]. It also works to protect the cells from the effect on internal toxins, which act on the oxidation process that is accompanied different tissue changes [33]. Also, it contains high concentration of Magnesium, Potassium, Sodium, Copper and Zinc [34]. While, [35] suggested that the Zinc in camel milk plays an important role in stimulating hepatic cell to mitotic division and differentiation the cells of the immune system. It may elaborate the increase of numbers of Kupffer and increase the volume of hepatic cells prepared for division.

Physical Activity: Mine Workers' Behavior Related With Metabolic Syndrome

Dwi Okta Rizkiani[1], Robiana Modjo[1]

[1]Occupational Health and Safety Department, Faculty of Public Health, Universitas Indonesia, Kampus UI, Depok, 16424, Indonesia

ABSTRACT

Metabolic syndrome is a term for risk factors for heart disease and diabetes mellitus. Workers have different lifestyle behaviors and work patterns that can cause metabolic syndrome. Based on medical check-up data in 2016, there were found several cases of dyslipidemia (97.5%), visual impairment (47.8%), BMI> 25 (45.2%), abnormal audiometry (17%), liver enzyme disorder (1.7%), and hypertension (10 %). Among those cases, there are 3 problems which are identified as the components of the metabolic syndrome. This study was conducted to explain the factors related to metabolic syndrome in mine workers to make control and prevention programs. A cross-sectional design was used to obtain workers lifestyle data by analyzing lifestyle questionnaire results and medical check-up data which includes central obesity, triglycerides, HDL, blood pressure and fasting blood sugar. There were significant relationships between physical activities with metabolic syndrome. No significant relationship was found between diet pattern, sleep duration, and knowledge of metabolic syndrome. Promotion and preventive controls are needed to prevent the metabolic syndrome in population, and screening of metabolic syndrome in all workers need to perform by the company to find out the magnitude of the problems.

INTRODUCTION

The metabolic syndrome (METS) consists of five factors for Atherosclerotic Cardiovascular Disease (ASCVD), that is atherogenic dyslipidemia, high blood pressure, dysglycemia, pro-thrombotic state, and inflammatory state, which occurs most often in obese people. The contribution of each component to cardiovascular risk necessarily varies between individuals but, in combination, both multiply the risk of ASCVD (1).

According to the American Heart Association / National Heart, Lung, Blood Institute update ATP III MS and IDF report, the main purpose for diagnosing METS is to identify patients at high risk of heart disease and type 2 diabetes mellitus who require lifestyle therapy to reduce this risk [(2)]. Most people with METS are obese and do not settle. Urbanization and access to cheap food create a pandemic of METS. Thus, primary interventions should be lifestyle changes, ie calorie restriction, improved food quality, and increased physical activity [(1)].

Some research on METS of International Diabetes Federation (IDF) decided to use the definition of ATP III 2001 as a starting point and modify and update it to reflect the current goals [(3)]. According to a new definition, a person suffering from METS, they should have central obesity plus two of the other four additional factors. These four factors were elevated triglyceride levels ≥ 1.7 mmol / l (150 mg/dl), decreased HDL cholesterol: <1.03 mmol / l (40 mg/dl) in men and <1.29 mmol / l (50 mg/dl), in women (or specific treatment for these lipid abnormalities), elevated blood pressure (systolic ≥ 130 or diastolic 85 mmHg) or treatment of previously diagnosed hypertension, fasting blood glucose ≥ 5.6 mmol / l (100 mg/dl) or previously diagnosed type 2 diabetes.

METS was found in 22.8% and 22.6% of US men and women. METS was found in 4.6%, 22.4%, and 59.6% of men of normal weight, overweight, and obese,

respectively, and a similar distribution was observed in women. Older age, postmenopausal status, Mexican American ethnicity, higher body mass index, smoking, low household income, high carbohydrate intake, and physical inactivity were associated with increased likelihood of METS [4]

A METS-related study conducted on executive workers in Jakarta in 2011 showed that in general, the prevalence of METS was high (21.6%). The prevalence of METS in male executives (24.7%) was higher than for female executives (11.8%). Demographic, lifestyle, sex, and physical activity characteristics are associated with METS [5].

XYZ is a coal mining company, where the mining processing environment takes place has a health impact. Based on preliminary research by reviewing HIRADC (Hazard Identification Risk Assessment and Determining Control), medical check-up result and clinic visit found that disease that occurs among workers not only related to work environment but related to work behavior and healthy lifestyle.

MATERIAL AND METHOD

This cross-sectional study used questionnaire and medical check-up in 2017. This study aimed to describe the prevalence and factors related to METS in coal mining company XYZ. Hypothesis test using Chi-Square test and T-test to see the relation between dietary pattern, physical activity, sleep duration and knowledge with METS. Research conducted at XYZ, a coal mining company operating in South Kalimantan. The study was conducted in January - May 2018.the population study is the workers of XYZ coal mining site of South Kalimantan. From the total of 196 workers, 105 workers selected after adjusting with inclusion criteria. This research was using FFQ to get dietary pattern information, GPAQ for physical activity and questionnaire that develop by the researcher for sleep duration and knowledge.

FINDINGS

Table 1 Prevalence of METS From 2012-2017

Year	METS		Total
	Yes	No	
2012	6	74	80
	7,5%	92,5%	100.0%
2013	6	92	98
	6,1%	93,9%	100.0%
2014	17	81	98
	17,3%	82,7%	100.0%
2015	16	83	99
	16,2%	83,8%	100.0%
2016	20	77	97
	20.6%	79,4%	100.0%
2017	44 47,8%	48 52,2%	92 100%

The prevalence of METS obtained by analyzing medical check-up result. It was found that METS in miners increase from 2012-2017. In 2017, employees with METS were 47.8%, while those without METS were 52.2%.

Table 2 Distribution of Component METS in 2017

Component	Normal		Abnormal	
	N	%	N	%
Central Obesity	58	63	34	37
Triglycerides	33	35,9	59	64,1
HDL	50	54,3	42	45,7
Blood Pressure	11	12	81	88
Fasting Blood Sugar	84	91,3	8	8,7

The METS component which many respondents had is a high blood pressure of (88%), followed by triglycerides, HDL, central obesity, and fasting blood sugar respectively.

Table 3 Distribution of METS Based on Numeric Independent Variable

METS	Min	Max	Mean	SD	SE	P value
Knowledge Score						
No METS	33,30	100,00	68,76	15,616	2,254	
METS			69,89	16,49	2,485	0,736

It was found that there was no difference in the mean score of knowledge in the group who had METS and did not have METS (p-value = 0,736). In the group with METS, the mean score was 68,76, whereas in the group with no METS the mean score was 69,89.

Table 4 Distribution of METS Based on Categoric Independent Variable

		METS		P-value	OR (95% CI)
Variable		**Yes**	**No**		
		%	%		
Sleep duration	Short sleep duration (<6 hours)	57,1	42,9	0,364	1,600 (0,580-4,412)
	Long sleep duration (>8 hours)	43,8	56,3	0,904	0,933 (0,304-2,864)
	Normal sleep duration (6-8 hours)	45,5	54,5		
Diet Pattern	Often	2 (33,3)	4 (66,7)	0,469	0,524 (0,091-3,012)
	Rare	42 (48,8)	44 (51,2%)		
Physical Activity	Inactive (<600 METs-min per week)	15 (68,2)	7 (31,8)	0,032	3,030 (1,097-8,363)
	Active (≥600 METs-min per week	29 (41,4)	41 (58,6)		

Bivariate analysis showed that there was no difference in the proportion of metabolic syndrome in the type of food consumed rarely and often consumed. In the diet often groups as much as 48,8% had METS and on rare diet groups as much as 33,3% had METS. The odds -ratio (OR) value obtained at 0,524 (95% CI 0,091-3,012); it means that diet often has a risk for METS of 0,524 times compared with rare diet. The results showed that there was no significant relationship between frequent food intake with METS (p-value = 0,469).

In variable sleep duration, the group that had the highest percentage of METS was the short sleep duration group, which was 57,1% with an OR value of 1,600 (95% CI 0,580-4,412). The OR value for the long sleep duration group was obtained at 0.933 (95% CI 0,304-2,864). However, it can be seen from the p-value, both short sleep duration and long sleep duration are not related to the METS (p-value = 0,364; p-value = 0,904).

The results of data analysis demonstrated that there is a difference in the proportion of METS in both groups of physical activity. The OR value was obtained at 3,030 (95% CI 1.097-8,363); it mean that less physical activity had a risk of METS of 3,030 times compared to active physical activity. P-value showed that there was a significant relationship between physical activity with METS (p-value = 0,032).

DISCUSSION

Based on the results of research on 92 mining workers XYZ coal mining company located in South Kalimantan found the prevalence of METS in 2017 amounted to 47,8%. When compared with previous research on METS in Indonesia, this result higher than result from Soewondo's study 28,4%. [6]

According to the consensus of the definition of METS, there was the fact that METS was a progressive disease and increases the risks of ASCVD, for example, some components tend to worsen over time. Some things that usually increase annually are weight gain, gradual loss of muscle mass, stiffness in the arteries, decreased capacity of pancreatic beta cell secretion, mitochondrial dysfunction, and increased inflammatory changes in adipose tissue, and age-related [1].

The largest component of the METS contributing to this study was high blood pressure obtained in 88% of

respondents.

Dietary Pattern

Food intake is a determinant factor in the diet, which is described in the frequency of eating, skips breakfast and eating habits outside the home associated with obesity. It has been agreed that a high-fat diet will increase total energy intake and increase the likelihood of obesity. [7]

Assessment of the frequency of food consumption was done using the Food Frequency Questionnaire (FFQ). Food consumption was divided into carbohydrates, animal protein, vegetable protein, vegetables, fruit, milk and its products, fast food, snacks and soft drinks. After obtaining the overall food frequency data, then the food ingredients are determined which are at risk of causing METS. In this study, diet pattern was not related with METS. This result was not in line with several studies that suggest that diet was related with METS. Dietary patterns characterized by high consumption of fish and foods with whole grains and low consumption of processed products, sugar and sweets and preserved meat are associated with a lower risk of METS with a reduced risk of lower HDL cholesterol concentrations and increased glucose concentration [8]. This might be happening because there was no difference in the variety of food consumed by each worker because the company has provided canteen facilities and meal menu settings.

Physical Activity

Physical inactivity increases the risk of CVD and types 2 diabetes mellitus and other can worsen other risk factors. Increased physical activity promotes weight loss and maintenance in obese people and modifies obesity-related risk factors, including increasing visceral adipose tissue loss, improving insulin sensitivity, increasing HDL cholesterol, and decreasing triglyceride levels [4]: "

The results of this study showed that workers who were an inactive category (<600 METs-minutes per week) 3 times (OR = 3,030) were at risk of having METS compared with workers who were an inactive category and statistical tests showed that physical activity significantly related with the incidence of METS. These findings are in line with studies showing that the percentage of adults who do most of the sedentary activity was more at risk of developing METS [9] 21.4% of the participants studied had 3 or more risk factors for METS with low HDL levels as the most risk factor, Moderate-Vigorous Physical Activity (MVPA) with at least 10 minutes per session, Low Physical Activity (LPA) and body mass index explained 16% HDL variation. [10]

Sleep Duration

Sleep duration was not significantly related with METS. Sleep was recognized as an important mediator in an individual's health status. Given that the number of short and long sleep gradually increases [11]. The results of this study are not in line with some studies that have reported that short sleep hours (generally less than 6 hours per day) or long (generally more than 8-9 hours per day) sleep duration was associated with an increased risk of chronic diseases such as obesity, hypertension, diabetes, and METS [12]

Several studies have reported that short sleep duration was associated with an increased risk of METS, but conversely, long sleep duration was not associated with METS [13–15].

In this study, there was no association between short sleep hours and long sleep hours with METS. This was due to the working hours arranged by the company so that very few workers work overtime or leave early. Workers who live in the company accommodation can go straight back home to rest, and workers living outside the company accomodation are provided with shuttle buses so that they return home on time. With a working system like this, it was very possible for a person to return to his place of residence and immediately rest.

Knowledge

Worker's knowledge was measured using a questionnaire that contained several questions about METS. None of this research results are suitable for groups that are not with METS. The results show that no difference in the scores of knowledge in the group who had METS and did not have METS. This was in line with Kamso et al (2011) research on the groups in Jakarta who see the level of education as the uniqueness of the METS. In the study, there was no significant relationship between education and METS [5]. This was in contrast to several studies that have shown that the level of education has a significant relationship with METS [6].

Previous studies show that women have a lack of understanding of diet and exercise in reducing CVD. One way to reduce CVD incidence was to improve adherence to healthy lifestyles by educating, filtering, detecting and treating the modifiable risk factors because women do not practice heart-healthy behavior on a regular basis. This attributed to their limited knowledge and lack of attention and knowledge to CVD which can lead to poor motivation to change behaviour [16,17].

CONCLUSION

Dietary pattern, sleep duration, and knowledge were not related to METS. Factor contributed to METS in miners based on the results of was physical activity. Promotion and preventive controls are needed to prevent the METS in population. The researcher suggests performing screening of METS in all workers to find out the magnitude of the problems that occur in the company. It is necessary to improve physical activity and exercise programs for workers who had METS and all workers.

Conflict of Interest: Hereby the authors declared that there is no conflict of interest in this research with any other parties.

Correlation Analysis of Sleep Duration, Dietary Habits, Physical Activity and Knowledge with Blood Pressure on Engineering Workers, Procurement, and Construction (EPC)

Wardatul Hamro[1], Robiana Modjo[1]

Occupational Health and Safety Department, Faculty of Public Health, Universitas Indonesia, Kampus UI, Depok, 16424, Indonesia

ABSTRACT

Background: There have been five cases of hypertension to EPC workers in the last five years (2012-2017). To minimize the risk of hypertension in workers and to prevent greater losses in terms of productivity and medical costs arised from the disease, it is necessary to acknowledge the distribution of blood pressure in EPC workers and analyze any factors related to blood pressure, as a screening of hypertension occurred related to worker health promotion program.

Objective: The aim of this study is to analyze the risk factors associated with blood pressure (systolic, diastolic) on workers of EPC.

Method: A quantitative approach in a cross-sectional design which comprised the subjects of the study as samples are 97 workers of EPC

Result: The systolic blood pressure (SBP) and diastolic blood pressure (DBP) is higher among workers with abnormal sleep duration (SBP: 125,15±8,57, DBP: 84,71±6,02), frequently dietary habits in fast food consumption (SBP: 140,00±0,00, DBP: 90,00±0,00), lack of physical activity (SBP: 122,75±9,20) and lack of knowledge about hypertension. There were significant differences in the mean systolic (R^2 = 0,049) and diastolic blood pressure (R^2 = 0,061) in workers in the form of sleep duration.

Conclusion: The majority of worker's blood pressure is categorized prehypertension based on blood pressure category by JNC-7. Results indicate that abnormal sleep duration, the frequency of protein consumption, physical activity that does not fit with the recommendation and lack of knowledge about hypertension contribute to higher of worker's blood pressure.

***Keywords**: blood pressure (systolic, diastolic), risk factors, EPC workers*

INTRODUCTION

Hypertension is regarded the main factors of heart disease and stroke which lead to premature death worldwide. At least, 970 million people experiencing hypertension. In high-income countries, about 330 million people experienced hypertension compared to about 640 million people in developing countries. By 2025 it is estimated that there will be 1.56 billion adults living with hypertension [(1)].

Several factors related to hypertension comprised of modifiable risk factors (lack of physical activity, unhealthy diet, obesity, alcoholism, sleep apnea, high cholesterol, diabetes, smoking, and stress) and unmodified risk factors (family history, age, gender, and chronic kidney disease[(4)]. Many studies linked genetic factors, such as age, sex, ethnicity and family history and lifestyle factors, such as alcohol consumption, smoking, poor diet, lack of physical activity, stress with hypertension [(2)]. Furthermore, some research mentions that hypertension is related to the level of knowledge [(3)].

EPC company, whose biggest asset is workers, is engaged in providing engineering, procurement and construction services for development and maintenance

of oil and gas companies. It is expected that workers is able to maintain their health, resulting more productiveness to perform. Yet, there occurred five cases of hypertension in EPC company over the past five years (2012-2017). Nevertheless, a health promotion program is not available in the company which causing them hardly to prevent and control risks of hypertension. In order to minimize the risk of hypertension in workers and to prevent greater harm in terms of productivity and medical costs due to hypertension in EPC company, it is crucial to measure the frequency distribution of blood pressure among the workers and analyze the factors which contributed to the elevation of the blood pressure.

MATERIAL AND METHOD

This cross-sectional study aimed to determine the correlation between the independents and dependent variable. This research was conducted in an EPC company from January to June 2018 where gathering 97 workers. The study conducted BP measurement using sphygmomanometer by a competent paramedic. An interview-administered questionnaire was used to collect data, which included the respondent's identity, knowledge, sleep duration, physical activities, and food frequency. Workers knowledge was recorded by the questionnaire adopted from American Heart Association (AHA). Data on self-reported physical activity were collected using the Global Physical Activity Questionnaire (GPAQ) by WHO, whereas the food frequency was adopted from the FFQ (Food Frequency Questionnaire). The data were analyzed with the SPSS program, univariate and bivariate data analysis using comparative hypothesis testing which is the Mann-Whitney test.

FINDINGS

The bivariate analysis of two variables, BP and modified risk factors, showed that the mean of SBP and DBP are higher among workers with abnormal sleep duration (SBP: 125,15±8,57, DBP: 84,71±6,02), frequently dietary habits in fast food consumption (SBP: 140,00±0,00, DBP: 90,00±0,00), lack of physical activity (SBP: 122,75±9,20) and lack of knowledge about hypertension (SBP: 122,59±9,88, DBP: 82,21±9,52), this finding may contribute to high BP among workers. Whereas, in the dietary habit, frequently protein consumption has the highest average SBP (124,09±10,21) while the frequency of rarely protein consumption has the highest DBP average. (83,64±8,09) as well as with snack consumption (SBP: 123,06±8,59, DBP: 82,39±8,81). A rare frequency beverage consumption (SBP: 123,32±9,33, DBP: 82,87±8,52) have higher blood pressure compared to other categories (see Table 1).

Table 2 Comparison of Blood Pressure (Systolic, Diastolic) Based on Modifiable Factors in EPC Workers

Variable	SBP			DBP		
	Mean (Min-Max)	SD	R^2	Mean (Min-Max)	SD	R^2
Sleep duration						
Abnormal (<6 hours or >8 hours)	125,15(110,00-140,00)	8,57	0,049*	84,71 (75,00-95,00)	6,02	0,061
Normal (6-8 hours)	120,71(100,00-140,00)	9,79		80,32 (60,00-100,00)	9,28	
Dietary habit - Protein (red meat)						
Frequently	124,09 (100,00-140,00)	10,21		81,63(60,00-100,00)	8,59	
Rarely	122,03 (110,00-140,00)	9,53	0,065	83,64 (70,00-100,00)	8,09	0,066
Never	0	0		0	0	
Dietary habit - Fast Food

Never	124,55(140,00-140,00)	10,11		84,54(90,00-90,00)	11,51	
Dietary habit - Snacks						
Frequently	121,49 (105,00-140,00)	10,52		82,39 (60,00-95,00)	8,81	
Rarely	123,06 (100,00-140,00)	8,59	0,058	81,33 (60,00-100,00)	8,27	0,075
Never	0	0		0	0	
Dietary habit - Beverages (coffee, Soda, Alcohol)						
Frequently	117,28 (100,00-140,00)	10,09		78,18(60,00-90,00)	8,15	
Rarely	123,32 (100,00-140,00)	9,33	0,069	82,87(60,00-100,00)	8,52	0,076
Never	121,39 (110,00-140,00)	9,67		80,28 (70,00-90,00)	8,31	
Physical activity						
Not fit the recommendation (<600)	122,75(110,00-140,00)	9,20	0,070	81,88 (70,00-100,00)	8,14	0,076
Fit the recommendation (≥600)	121,93 (100,00-140,00)	9,90		81,84 (60,00-100,00)	8,85	
Knowledge						
Lack (<70)	122,59 (100,00-140,00)	9,88	0,070	82,21(60,00-100,00)	9,52	0,076
Good (≥70)	121,89 (100,00-140,00)	9,31		81,44 (60,00-95,00)	7,27	

Table 2 presents results from statistic test against differences in mean BP on modifiable risk factor variables. The only statistically significant variables were sleep duration against SBP (R^2 = 0,049) and DBP (R^2 = 0,061). Whereas, other modified risk factors such as dietary habits-protein (SBP R^2 = 0,065; DBP R^2 = 0,066), fast-food (SBP R^2 = 0,070; DBP R^2 = 0,072), snacks (SBP R^2 = 0,058; DBP R^2 = 0,075), beverages (SBP R^2 = 0,069; DBP R^2 = 0,076), physical activity (SBP R^2 = 0,070; DBP R^2 = 0,076) and knowledge (SBP R^2 = 0,070; DBP R^2 = 0,076) did not show significant results, meaning there was no difference in mean BP between categories in these variables against SBP and DBP.

Table 2 Comparison of Blood Pressure (Systolic, Diastolic) Based on Modifiable Factors in EPC Workers

DISCUSSION

Our findings showed that dietary habit, mean of BP among workers is higher in frequently consumption of fast food and beverages such as coffee, alcohol, and soda. Supporting to our findings, Ugorji [4] stated that the implementation of the Dietary Approach to Stop Hypertension (DASH) intervention program for African-American women with hypertension doing a healthy diet by consuming fruits, vegetables, low-fat dairy products and increasing potassium intake can reduce SBP by 8-14 mmHg and reduce sodium intake by consuming no more than 100 mmol (2.6 grams of sodium or 6 grams of sodium chloride) per day can reduce SBP by 2-8 mmHg [4,5].

In our study, similar with a study conducted by Bosu [6], workers with physical activity which unmeet with WHO recommendations (MET < 600) have a greater average blood pressure compared to the group with WHO recommendations of physical activity (MET ≥600). Bosu [6] suggested that the prevalence of hypertension was significantly higher in people with low physical activity compared with people who performed moderate or intense physical activity. This applies to workers with high activity demands such as car workers, plant operators and planter who have a lower prevalence of hypertension compared to workers in individually task such as traders, executives, and civil service [6,7]. In sleep duration, the mean difference of SBP and DBP in respondents who had abnormal sleep duration was higher

than respondents who had normal sleep duration, similar to Gangswisch study [8]with widespread consequences for health and safety.(1. Sleep duration of ≤5 hours per night was significantly associated with increased risk of hypertension (hazard ratio, 2.10; 95%, CI, 1.58-2.79) with the age range of the study subjects as 32-59 years.

This study underlines that workers with lack of knowledge about hypertension have higher SBP and DBP compared to workers with good knowledge. The earlier study showed that knowledge about hypertension is better for participants who have control than participants who did not, then the results of the logistic regression model analysis showed that men participants (OR = 1.31) with better knowledge of hypertension (OR = 1.19), awareness of suffering from hypertension (OR = 2) and adhering to regular treatment (OR = 1.48,) are more likely to control hypertension.

Our findings highlight several modifiable factors which are sleep duration, dietary habit, physical activity, and knowledge, only the sleep duration variable, have a correlation with systolic blood pressure with $R^2 = 0{,}049$. The correlation between sleep duration and high BP had been examined in Song [9]. This study revealed that respondents who had sleep duration <6 hours had higher mean SBP (111.9 ± 0.9) compared with respondents who had a duration of sleep 6 - 8 hours (108.9 ± 0.3) and >8 hours (106.7 ± 0.7) with $R^2 = 0{,}049$, while the mean DBP was also related to sleep duration, respondents with sleep duration <6 hours had the highest mean diastolic blood pressure (73.8 ± 0.6) with $R^2 = 0{,}061$. It occurs due to excess sympathetic nerve activity after a short period of sleep, if short duration of sleep continues, structural adaptations such as left arterial and ventricular hypertrophy can occur due to an increase in hemodynamic load, so that the cardiovascular system is adjusted to maintain a higher blood pressure balance. Several other studies have shown that this finding usually occur in women, the mechanism has not been clearly identified, but this may be due to hormonal and psychosocial changes associated with menopausal [9] . Moreover, it is suggested that an increase in systolic blood pressure due to insufficient sleep can be related to the risk of isolated systolic hypertension in the future, besides the possibility of decreasing sleep duration can be related to hardening of the material which will cause arteriosclerosis and isolated systolic hypertension [10].

CONCLUSION

The findings show that the majority of workers' BP is determined prehypertension based on BP category by JNC-7. Evidence of this study indicates that modified risk factors (abnormal sleep duration, the frequency of protein consumption, proper physical activity and lack of knowledge about hypertension) contribute to higher of worker's blood pressure. Data analysis signify that there were significant differences in the mean SBP in workers in the form of sleep duration.

Conflict of Interest: Hereby the authors declared that there is no conflict of interest in this research with any other parties.

Phenotypic and Molecular Study of *mecA* Gene in MRSA Isolated from Clinical Cases in Misan Province /Iraq

Zahid S. Aziz[1], Marwa A. Hassan[2]

[1]Assistant Professor Dr and Head of the Department of Biology, [2]Postgraduate Student, University of Misan, College of Science, Department of Biology, Misan, Iraq

ABSTRACT

Methicillin-Resistant *Staphylococcus aureus* (MRSA) is a common strain of *S. aureus* caused infections lead to increased of risk in clinical outcomes and death, and compared with infections caused by non-resistant strains of the same bacteria patients consume more resources of health-care, where their hospitalization was prolonged because most preferred drugs such as β-lactam antibiotics not have the ability to produce bactericidal effect on this bacteria. Therefore this study aimed to: Isolation and identification of MRSA by using conventional and confirmatory techniques, detection of phenotypic traits related to their antibiotic resistance and estimation the occurrence of *mecA* gene in identified bacteria. A total of 274 samples, were collected from local hospitals in Misan Province during the period from December 2017 to April 2018. Diagnostic results using microscopic, cultural, biochemical tests and vitek 2 system proved that 106 bacterial isolates belong to *Staphylococcus aureus.* The susceptibility test of *S. aureus* isolates was performed toward many types of antibiotics, from all isolates 99(93.4%) were determined as MRSA by oxacillin antibiotic and 93(87.7%) were determined as MRSA by cefoxitin antibiotic. The results of molecular estimation of *mecA* gene showed that 89(89.9%) and 91(97.8%) from phenotypically positive MRSA isolates had this gene for oxacillin and cefoxitin antibiotics respectively.

Keywords: *Staphylococcus aureus, MRSA, Antibiotic resistance, mecA gene.*

INTRODUCTION

Methicillin-Resistance *Staphylococcus aureus* (MRSA) is a pathogenic bacteria causing diseases extended from surface skin and tissue infections to severe and lethal infections.[1,2]It has been generally considered as a public health problem, thus it was classified into two different groups, community-acquired (CA-MRSA) and healthcare-acquired (HA-MRSA).[3,4]

MRSA has the capacity to rapidly develop drug resistance.[5] Because it can develop several mutations conferring it high resistance for wide range of antibiotics. [6] Penicillin binding proteins (PBPs) involved in the collecting of the peptidoglycan in bacterial cell wall. These proteins have a high affinity to β-lactams, by bind these antibiotics the active site of PBPs thus cell wall synthesis inhibited.

PBP2a alternative proteins with low tropism to these antibiotics.[7] So PBP2 continues in cell wall synthesis even in the presence of high concentrations of β-lactam antibiotics.[8] These proteins encoded by *mecA* gene, which carrying on a mobile genetic element called Staphylococcal chromosomal cassette *mec* (SCC*mec*).[9] The transcription of this gene regulated by two regulatory systems that mecI-mecR1 and the penicillinase blaR1-blaI-encoded regulatory elements.[10] The majority of researches in this field suggested that *mecA* gene presented in all MRSA strains.[11] Thus it considered the corner stone responsible for MRSA phenomenon.[11] Also MRSA produce a β-lactamase enzyme, which damages the functional perfection of the β-lactam antibiotics by split the β-lactam ring of penicillin molecules.[12]

MATERIALS AND METHOD

Collection of samples

A total of 274 samples, were collected from different clinical cases (Burns, Wound, Nasal, Oral, Ear, Throat, Vaginal, Bedsore and Urinary tract infections) from local hospitals in Misan Province during the period from December 2017 to April 2018. Collected swabs were

streaked on mannitol salt agar then incubated at 37C° for 24 hours, the suspected colonies depending on the morphological bases were selected for the identification by conventional methods and Vitek2 system.

Antimicrobial susceptibility test

Susceptibility testing was determined by the agar disk diffusion method,[13] and national committee for Clinical and Laboratory Standards Institute guidelines,[14] using antibiotics utilizes as conventional therapy for MRSA infections.

Extraction of bacterial chromosomal DNA

DNA extraction was done toward *S. aureus* isolates according to Presto™MinigDNA Bacteria Kit protocol. The Chromosomal DNA then subjected to monoplex PCR. The integrity of extracted DNA was tested using Agarose Gel Electrophoresis.

Molecular estimation of *mecA*gene using PCR technique

The protocol used depending on Bioneer manufacturer's instructions. All PCR components were assembled in PCR tube. The specific primer for *mecA* gene have been choose according to [15] as in table (1), was prepared by the company of Bioneer, South Korea.

Table (1): Primers used in this study

Gene	Primer sequences (5' → 3')	Product length (bp)
mecA	F: CGGTAACATTGATCGCAACG R: TTTGCCAACCTTTACCATCG	985

Then template DNA and primers were added into the AccuPower®. Taq premix tubes for get 20ml reaction volume.Eppendorf PCR tubes were placed in the thermocycler (Eppendorf, Germany) and the right PCR cycling program parameter conditions were conducted as in table (2), then seven microliters of amplified PCR product were loaded to the agarose gel wells with standard molecular weight of DNA ladder was loaded in one well and running using TBE 1X buffer was added to the electrophoresis tank, tray with agarose was immersed in electrophoresis tank. Electrophoreses run at 65 volt for 120 min, the gel stained with 0.5 µg/ml of ethidium bromide was visualized by Gel Documentation.[16]

Table (2): PCR cycling program parameter conditions

Genes	Temperature °C/ time					Cycles number
	Initial denaturation	Cycling conditions			Final extension	
		Denaturation	Annealing	Extension		
mecA	95/5 min	95/45 sec	55/1 min	72/2 min	72/7 min	35

RESULTS AND DISCUSSION

Susceptibility test

The results of susceptibility testing showed that all *S. aureus* isolates were multi-drug resistant (MDR) when done toward 18 antibiotics from different groups, therefore the percentage of resistance of these isolates is that; ß-lactam group: Methicillin, Ampicillin, Oxacillin, Cefoxitin, Cefotaxime which showed percentage of resistance were 100, 98.1, 93.4, 87.7, 84% respectively, to Erythromycin was 80.2%, to Tetracycline and Doxycycline were 79.2, 56.6% respectively, and to Trimethoprim-sulfamethoxazole the resistance was 71.7%.

The resistance to Gentamicin and Amikacin appeared in 63.2, 49.1% of *S. aureus* respectively and the rate of resistance was 61.3% to Rifampin. *S. aureus* isolates also were resistant to Levofloxacin and Ciprofloxacin in rate 59.4, 49.1% respectively, to Clindamycin was 51% and to Vancomycin was 50%. The rate of resistance to Imipenem was 47.2%, while to Nitrofurantoin was 38.7%.

The bacterial isolates show a contrast in antibiotics resistance, due to the diversity in the mechanisms of resistance of *S. aureus* isolates such as the production of PBP2a and ß-lactamase enzymes that inhibit these antibiotics.[17] The reason for the other depends on the virulence factors of bacteria, where some isolates show amount of virulence more than others,[18] as well as the difference in the sources of sampling, tests circumstances and the type of techniques that used in the study, all these combined may lead to a difference in resistance and sensitivity levels.[19] the point of high resistance is noticeable, because it may lead to failure in therapy, extended disease, increased health care expenses and death.[20]

Out of 106 *S. aureus* isolates 99(93.4%) and 93(87.7%) were identified as MRSA determined by oxacillin and cefoxitin antibiotics respectively, because for susceptibility testing now typically uses oxacillin and/or cefoxitin.[21] Oxacillin can be considered a representative antibiotic for susceptibility test to all β-lactams.[4] Cefoxitin also used for MRSA detection, because it is a powerful influence of *mecA* gene that shows to be less affected than oxacillin by isolates have the ability to produce penicillinase excessively.[21]

Molecular estimation of *mecA*

Polymerase chain reaction technique (PCR) utilize in the amplification of *mecA* gene. This gene is one of the most common and important virulence genes in *S. aureus* where it considered the primarily gene responsible for the widely antibiotic resistance, therefore was selected in this study. Also the molecular amplification of this gene is recognized as a hallmark to diagnose MRSA because these genes are highly conserved among these bacteria.[11]

The results for *mecA* gene detection illustrate that 89(89.9%) and 91(97.8%) from phenotypically positive MRSA isolates had this gene for oxacillin and cefoxitin respectively, figure (1-A,B).In present study the occurrence of *mecA* gene was higher than that obtained by other researchers such as[22-26] which were (18.8, 29, 39.2, 45.1, 54.5%) respectively. While other studies revealed that the percentage of incidence of *mecA* gene has been more than this study such as[11, 27-30] which were (90.2, 95, 96, 98.1, 98.3%) respectively.

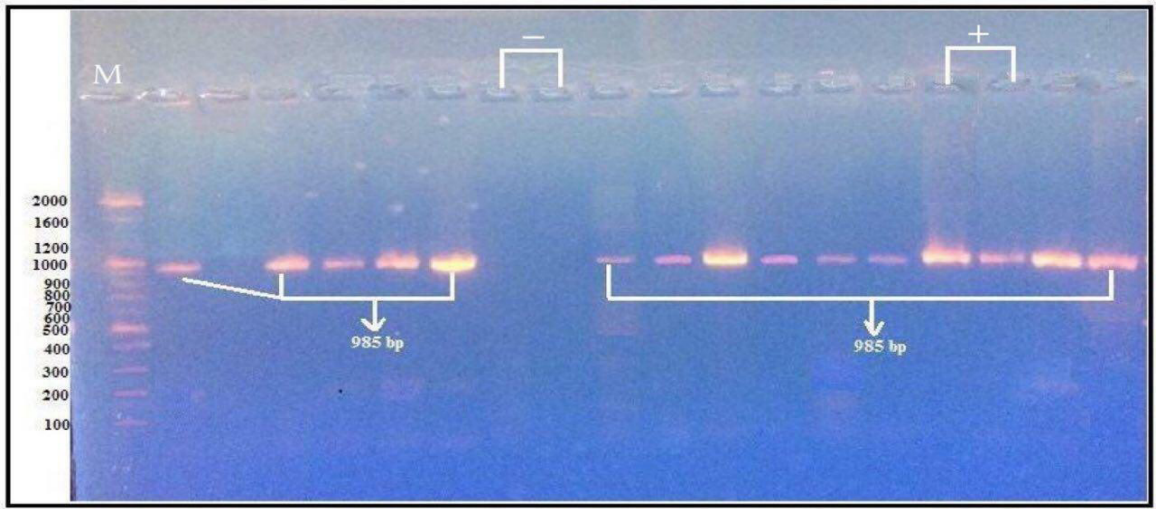

Figure 1-A: Ethidium bromide-stained Agarose Gel Electrophoresis of *mecA* gene of MRSA isolates, Lane M DNA molecular size Ladder (100-2000)bp, Lane with positive marker refer to the isolates that have *mecA* gene, Lane with negative marker refer to the isolates that not have this gene.

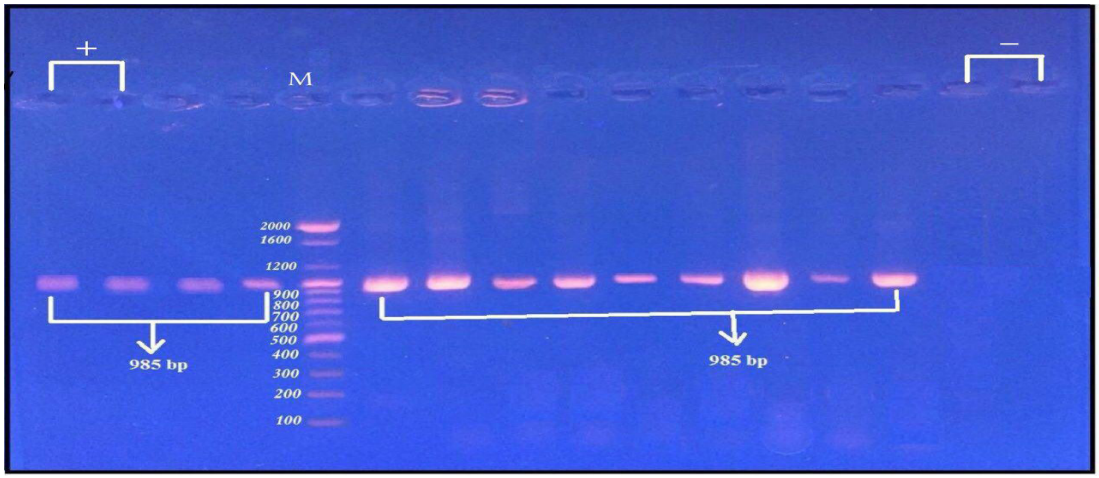

Figure 1-B: Ethidium bromide-stained Agarose Gel Electrophoresis of *mecA* gene of MRSA isolates, Lane M DNA molecular size Ladder (100-2000)bp, Lane with positive marker refer to the isolates that have*mecA*gene, Lane with negative marker refer to the isolates that not have this gene.

According to the results in present study we can concluded that cefoxitin is more reliable than oxacillin in MRSA identification, and this confirmed by study conducted by.[31] Therefore it currently recommended by CLSI (2017) for MRSA detection.

S. aureus which phenotypically positive MRSA while gave a negative results to *mecA* gene, this could be referred they have an alternative mechanism instead of this gene for antibiotic resistance including the alteration of the penicillin binding proteins (PBPs) leading to the hyper-production of methicillinase or β-lactamase,[14] subsequently this can explain why not all isolates that resistant to β-lactams not have this gene.

The studies has been showed that 90% of *S. aureus* resist penicillins due to β-lactamase (penicillinase) production,[33] also[34] confirmed that resistance to penicillins occur also by the production of trans-membrane proteins associated with the cell wall. These proteins represent enzymatic activity such as Transpeptidases and carboxypeptidases a target of penicillins and cephalosporins, where it works to change the target of ß-lactams.[35] The study of [36] affirmed the role of plasmids in the production of β-lactamase enzymes and their responsibility on the encoding of some PBP2a, and study by[33] has been linked between the resistance to antibiotics and sources responsible for this resistance, where they were found that most of the resistance shown by the strains of *S. aureus* has plasmid origin.

CONCLUSIONS

MRSA strains have a high resistance to ß-lactam group and most other antibiotics,the greatest antibiotic resistance in this study is returned to the isolates that taken from burns and wounds,cefoxitin antibiotic is more reliable than oxacillin antibiotic in MRSA detection and the *mecA* gene was high prevalence within MRSA strains.

A Solution for Nosocomial Infection in Healthcare Facilities

Yasaman Parsia[1], Puteri Fadzline Mohamad Tamyez[2]

[1] Researcher, [2] Senior Lecturer, University Malaysia Pahang, Pahang, Malaysia

ABSTRACT

Cross-infections in healthcare facilities, collectively known as Nosocomial Infection (NI), remain a global issue. Numerous people in Healthcare facilities (HFs) die all the time due to the spread of such diseases, specially NIs. Governmental HFs are burdened with increased expenses as a result of the unchecked transmission of cross-infections across their departments. This conceptual paper, firstly, attempts to present the severity of NI prevalence and propose a hypothesis in discussions of the role of HF layouts in controlling such cross-infections. Lastly, it focuses on the comprehension for controlling of the risks of cross-infections transiting between HF departments and facilities.

Keywords: *Nosocomial infections, cross infection, healthcare facility, Risky departments.*

INTRODUCTION

A healthy societal culture is one that is educated, work-oriented, and makes contributions to the arts while providing services that are usually inaccessible to less healthy societies [1, 2]. Therefore, societies have developed obligations for provisioning better health services to every patient [1, 3]. Among such measures would be the establishment of more Healthcare Facilities (HF) units within various regions throughout the country, which could lead to increased prosperity that brings improvements to people's quality of life [4].

For every healthcare facility, there are certain problems that can affect institutional service quality. Increasing healthcare-related errors, injuries among workers, and decreasing patient recovery can all lead to increased nursing and other staff turnover, loss of work time, and further disabilities. Increasing costs as well as infection rates are among the problems which every HF experiences as a result [5]. Of these, Nosocomial Infections (NIs) are among the main hurdles facing HFs and the medical establishment. This article intends to scrutinise the risk of NIs.

MATERIAL AND METHOD

The current study can be classified as a qualitative research. The valuation of research literature made through reading of published manuscripts from scholarly database. Near 50 manuscripts was studied which comprises articles from the national and global studies with considerable effect on the topic.

First, the literature review tries to present fundamentals of cross-infection especially in HFs. Then, the review of the literature focused on the role of HF layout in controlling of NI risk. Lastly, based on the existing literature, the knowledge gap in this area is highlighted.

FINDING AND DISCUSSION

'Nosocomial' as a term derives from the Greek wording of '*Nosos*' in reference to 'disease', along with '*Komeion*', which refers to care [6]. NI, also termed as HF cross-infection, comprises a type infectious process whereby patients acquire infections during hospitalisations [6-10]. 'Nosocomial' describes a disease that is inflicted on patients subject to treatments for other ailments or else undergoing general healthcare [7, 11]. Berket [7] noted that NIs are clinically observed in hospitalised patients or else in subjects who have been discharged for a few days.

A fuller understanding regarding cross-infections followed the early breakthroughs of Pasteur, Koch, and Lister, during the advent of the 'Bacteriological Era' of modern science. Microorganisms were found to transfer between objects and persons across sites [12]. With late 19th-century medical progress came great Western advances in disinfection and treatment via asepsis. These appeared to signal a final triumph over cross-infections, an achievement that was short-lived however [13]. Moreover, as the initial model for this study, the existence of cross-infections in healthcare facilities was first reported by Cruickshank [14] (as mentioned by Ayliffe and Lilly [15]) in his description of *Streptococcus pyogenes* infections among patients admitted to hospitals. The report by Cruickshank [14] remains the foundational basis for studies of NIs, which this paper also covers. Modern primary care units continue to host dense populations of very ill subjects that are exposed to far greater risks regarding cross-infection [16]. NI prevalence is considered to be a primary socio-economic and medical issue that affects all developing as well as developed countries [17, 18].

By 1941, memoranda regarding the prevention of NIs in wounds were advising that each hospital appoint '. . . full-time specialised officers to supervise infectious disease control . . .' [19]. By 1944, it was being suggested that all hospitals establish representative committees for doctor, nursing, and laboratory staff as well as administrators, for investigating and designing measures to manage cross-infections [19]. The NI pandemic of *Staphylococcus aureus* from the 1940s through to the 1950s resulted in the mandating of further guidelines [19]. Jacoby [20] noted that cross-infections remain a critical problem in HF management. Fisher [21] noted that medical decision-making should regard a germicide's value (capacity for killing pathogens) on its ability to fight cross-infections and not in terms of price alone.

With several hospitals for communicable diseases being operational in the last century, soon it was realised that contagions occurred not only in surgical and obstetric patients (which was emphasised in the later part of the 19th century) but also in the medical patients. Soon it was realised that several bacterial, as well as viral, contagions spread in HFs and brought about these contagions [13]. Also in the recent years, Hertzberg [22] highlights that the threat of spreading of the infections in certain HF units, for instance, SARS (Severe Acute Respiratory Syndrome) epidemic that occurred in 2003, wherein there were 128 instances of patients getting infected from direct or indirect exposure to a patient of SARS [23]. Recently, the admission of a patient infected with Ebola virus to HFs in Dallas, Texas, gave rise to a need to test and supervise more than 180 other individuals, among whom several were hospital staff, who had been in close contact with the Ebola virus patient or with 2 other nurses who got infected after being exposed to that patient [22].

Studies have mentioned that several people are infected with NIs across the globe [24, 25]. The infection from dispersal of microorganisms in NIs, HFs, cause an unwanted and a grave threat to the healthcare system quality in the nation [17, 18]. NIs extend the stay of the HF, causing long-term ailment for the patient, increasing the resistance of the patients to the antimicrobials, can result in death, raises the cost of the HF to be borne by the patients and their families and bring about a tremendous monetary burden on the nation's present healthcare system [18, 26]. On a yearly basis about 400,000 - 600,000 NIs impact the German patients, causing 10,000 – 15,000 deaths [27, 28]. NIs are to blame for 37,000 demises in Europe annually [26]. Also, 722,000 severe NI cases were reported in the US HFs in the year 2011 [29, 30]. Based on a 2016 report, it was stated that, in Pennsylvania, around 247 HFs had provided data (about NIs) to the National Healthcare Safety Network for the duration of a year [31]. Also, on any specified day, 1 patient out of every 25 in the HFs would be having at least 1 NI [29, 30]. NIs also causes huge economic losses each year. In Europe, these total about €7 billion, which involves direct expenses and causes an additional 16 million-day stay at the HF; also the United States of America registered a loss of $6.5 billion due to NIs [26]. Riu, Chiarello[32] calculated the expenditure of 12 hospitals in Spain and noticed that just NIs had been responsible for 64.2 percent of the total expenses of opposing occurrences.

Nowadays, the growth of antimicrobials use and improvements in the medical procedures have caused several invasive processes being utilised on the patients, which in turn increases the risk of new NIs [28]. These diseases are still regarded as a hazard to this day in the age of modern antibiotics [7, 33]. Congestion in the hospitals, lags in implementing extra precautions, crowding and combining patients having contagious diseases, shifting of patients from one part of the hospital to another, defects in the building structure, insufficient staff preparation and scarcity of personal safety devices

also play an important role towards the threat of cross-infections [34].

The HF environment is contaminated by several types of infectious organisms and moreover it is a store of the nosocomial microbes that could contaminate the patients at the time of their HF stay [35]. Khan [36] mentioned that, while the rates of infection in the various HFs cannot be determined exactly, one can get a rough approximation of these rates based on several dependent parameters like the sort of HFs (i.e., private or public), service offered by these HFs, etc. [36].

Hospital is an instance of a multi-product establishment which provides several facilities like patient care, fitness promotion, training of health personnel, and even assist research regarding health-related issues [3, 37]. Every HF structure (such as the hospital) accommodates many divisions which offer their specific services [38]. For having a valid HF, several other factors like the quality of design of the HF blueprint must also be taken into account. A good and accommodating HF environment avoids further injuries and also offers help and emotional support to the sick persons during the recuperation process [5].

The physical structure of the HF contributes significantly in regulating NIs and reducing the risk of infection transmission [39]. Nonetheless, there are several variations in the layout of the HF around the globe, and regulation of infections by using specific engineering structures is still a matter of debate [40]. The technical research is concentrated on resolving the way in which an enhanced design can minimise the threats in the HFs [41]. The essential safety risk considerations must be made at the time of the planning phase and must be a recurrent process at the time of reviewing the design [38]. Now, it has been understood that the measures for regulating infections must be combined with the design and development of HF structures together with its operations [42]. These days, a lot of focus is given to the HF environment and its correlation with health of the patient, which has brought about the development of efficient blueprints [43]. Risk of NIs due to shifting of the patients to another hospital or area or to another division in the same facility has been recorded [44]. As per Ong [45], cross-infections can take place via transmission of microbes from personnel-to-personnel, patient-to-patient and department-to-department. With regards to the NIs, certain departments are impacted more than the others, and few can be the causes because of the existence of cross-infection. The cause and effect department are termed as risky. Therefore, risky departments are separated from one HF to another; it can be determined from Ducel [46] who substantiate the impact of extent of prevention, policies, type, size, technology and other parameters related to HFs. Although there is considerable amount of evidence which connects the HF environment to the transmission of infections, it is dispersed among several domains and is yet not systematically evaluated [47].

CONCLUSION

Therefore, it can be summarised that for every government of countries and HF, the control of NIs is a significant issue. The theory described in this article implies that NIs has a long history, but till now, no decisive way has been found to minimise the severity of risks for them. In relation to this field, some advancements have been made in medicine and other science, which the scientists believe require more research. The major challenge is that these infections can get transmitted across HFs and various departments. There is a considerable gap in the endeavour to find a solution for the prevention of this problem. In addition, as mentioned in this article, the HFs layout has a critical role in controlling of NIs. The discovery of a solution in this field, specifically for the departments at high risk, will prove to be more beneficial and appropriate.

Conflict of Interest and Source of Funding: None.

Ethical Clearance: Not applicable.

Quality of Life Determination among Hemophiliac Children

Wameedh Hamid Shaker[1], Mohmmed Baqer Hassan[2], Ibrahim ALwan Kadhim Al-Ashour[3]

University of Kufa / faculty of Nursing, Iraq

ABSTRACT

Objective: To identify the quality of life determination among hemophilic children at al -hakeem general hospital. To find out the relationship between hemophiliac children quality of life and their socio-demographic characteristic of age, gender, parents educational levels, family type and socio-economic status

Methodology: A descriptive study designed to find the quality of life among hemophilic children. The study was carried out the period from March 6th to April 4th 2016.

Conclusion: The result of this study indicated that the quality of live sample of male children with hemophilia was impaired, and that impairment according to the total Hemophilia –Quality of live score was greater among adolescents than children aged 8-12 years. Moreover, number of bleeding event, number of school absences, mother s' education level, severity of hemophilia, insight to health status and insight to suffering from hemophilia were associated with hemophilia –Quality of live. In addition, family income and parent- administration of the product were the factors which predict the quality of live in children with hemophilia. Therefore, in order to improve Hemophilia –Quality of live adolescents, patients who were given drug infusion by third party care givers excluding parents and also patients with lower familial income are suggested to receive more effective interventions by authorities, managers and health care providers. For evidence based practice, further studies on Hemophilia –Quality of live in children are recommended.

Keywards: *Quality of life, Determination, among, Hemophiliac, Children.*

INTRODUCTION

Hemophilia is a group of genetic diseases characterized by reduced to obviously altered blood clotting resulting from a deficiency of one of the factors essential for blood coagulation, Hemophilia is an X-linked congenital bleeding disorder which occurs at a frequency of approximately 1 in every 10,000 births; it is caused by a deficiency in coagulation factor VIII hemophilia A, representing 80–85 % of the total number of diagnosed cases or factor IX hemophilia B, both of which are related to a mutation of the clotting factor gene. The number of affected persons worldwide is estimated to be about 400,000 [1].

The life expectancy among people born with hemophilia who have access to currently available, adequate forms of treatment should approach normal. The rising life expectancy of men living with hemophilia. is related to advances in bleeding prevention and hemostatic control, and the general consensus of experts in the field is that it is becoming increasingly practicable for hemophilia patients to lead more ,for example, to participate in sports activities, have a professional career, and build a family [2].

Hemophilia is a rare, chronic, inherited disease primarily affecting males [1]. It is an X-linked bleeding disorder caused by a defective Factor VIII or Factor IX allele and leading to impaired clotting characterized by spontaneous bleeding and excessive bleeding after surgery or trauma. Many genetic illnesses exhibit a range of expressivity. Expressivity refers to the severity of the disease. Some children with hemophilia will exhibit mild expressivity. Among them, there are 3957 (61%) Factor VIII deficiency hemophilia A frequency of severe, moderate and mild hemophilia A was 47, 33 and 20%, respectively [3].

Children with hemophilia may lose opportunities to achieve their potentialities during school and later in life.4 Individuals with severe hemophilia A Factor VIII level (≤1%) experience frequent bleedings, often into soft tissue and joints, leading to joint damage[4].

According to individuals with hemophilia experience the impairment in quality of live and among children aged 8-16 years old the highest impairment was in the "physical health" subscale It was also shown that the dimension of "physical health" was lowest in the subscale of quality of live in children and adolescents with hemophilia A[5].

Statement of problem:

Quality of Life among Hemophiliac Children:

1. To identify the Quality of Life among Hemophilic Children At Al Hakeem General Hospital.

2. To find out the relationship between hemophiliac children quality of life and their socio-demographic characteristic of age, gender, parents educational levels, family type and socio-economic status.

Design of the study: A descriptive study designed to find the Quality of Life among Hemophilic Children. The study was carried out the period from March 6th to April 4th 2016.

Setting of the study: The study was carried out in At Al Hakeem General Hospital in Al-najaf Al-Ashraf governorate.

The sample of the study: Collected sample of (40) patient of the Quality of Life among Hemophilic Children.

RESULTS

Table (1) The observed frequencies and percentages of patients' groups according to socio-demographic data and clinical characterizations

Groups		Frequency (total 40)	Percentage (%)
Age (years)	12 ≤	22	55
	≥ 12	18	45
Gender	Male	36	90
	Female	4	10
Residence	Urban	31	77.5
	Rural	9	22.5
Educational Level	Illiterate	0	0
	Read & Write	3	7.5
	Primary School	24	60
	Secondary School	13	32.5
	Graduate	0	0
	Postgraduate	0	0
Father Educational Level	Illiterate	4	10
	Read & Write	11	27.5
	Primary School	6	15
	Secondary School	6	15
	Graduate	13	32.5
	Postgraduate	0	0
Mother Educational Level	Illiterate	4	10
	Read & Write	11	27.5
	Primary School	10	25
	Secondary School	9	22.5
	Graduate	6	15
	Postgraduate	0	0

Cont... **Table (1) The observed frequencies and percentages of patients' groups according to socio-demographic data and clinical characterizations**

Socio-economic Status	High	13	32.5
	Middle	19	47.5
	Low	8	20
Type of Hemophilia	A	27	67.5
	B	13	32.5
	C	0	0
Intensity of the disease	Mild	14	35
	Moderate	17	42.5
	Severe	9	22.5
Suffering from bleeding	Mild	9	22.5
	Moderate	23	57.5
	Very severe	8	20

This table shows that most of the study sample (55%) are leass than 12 years old, (90%) are males, (77.5%) are urban residents, (60%) are primary school graduated, (32.5%) of the study sample fathers levels of education is graduate, (27.5%) of the study sample mothers levels of education is able to read and write, and (47.5%) of the study sample present with a middle socio-economic status.

Above table shows that (67.5%) are patients suffering from type A of hemophilia, (42.5%) are present with moderate intensity of the disease, and, (57.5%) are suffering from moderate bleeding.

Table (2): Descriptive statistics of initial assessment for determination of quality of life for hemophilic children patients towards physical domain

Physical domain	Groups	Freq.	Percentage (%)	M	SD	Assessment
Difficulty in Walking	Always	5	12.5	2.13	0.53	Failure
	Sometimes	**25**	**62.5**			
	Never	10	25			
Difficulty in Running	Always	11	27.5	1.93	0.48	Failure
	Sometimes	**21**	**52.5**			
	Never	8	20			
Difficulty in daily activity	Always	9	22.5	2.18	0.54	Failure
	Sometimes	15	37.5			
	Never	**16**	**40**			
Difficulty in Lifting something	Always	**16**	**40**	1.88	0.47	Failure
	Sometimes	13	32.5			
	Never	11	27.5			
Difficulty in Taking a bath	Always	7	17.5	2.48	0.62	pass
	Sometimes	7	17.5			
	Never	**26**	**65**			
Difficulty in Doing chores	Always	10	25	2.05	0.51	Failure
	Sometimes	**18**	**45**			
	Never	12	30			
Body pain	Always	10	25	1.98	0.49	Failure
	Sometimes	**21**	**52.5**			
	Never	9	22.5			

Cont... **Table (2): Descriptive statistics of initial assessment for determination of quality of life for hemophilic children patients towards physical domain**

Muscle spasm	Always	7	17.5	2.25	0.56	Failure
	Sometimes	16	40			
	Never	**17**	**42.5**			
Joints pain	Always	**19**	**47.5**	1.68	0.42	Failure
	Sometimes	15	37.5			
	Never	6	15			
Bleeding after injury	Always	**23**	**57.5**	1.55	0.39	Failure
	Sometimes	12	30			
	Never	5	12.5			

This table shows assessment for determination of quality of life for hemophilic children patients towards physical domain. In relation to all of variable have failure assessment accept Difficulty in Taking a bath was pass assessment for determination of quality of life.

Table (3): Descriptive Statistics of Initial Assessment For Determination of Quality of Life For Hemophilic Children Patients Towards Emotional Domain

Emotional domain	Groups	Freq.	Percentage (%)	M	SD	Assessment
Being afraid	Always	14	35	1.88	0.47	Failure
	Sometimes	17	42.5			
	Never	9	22.5			
Being sad	Always	7	17.5	2.15	0.54	Failure
	Sometimes	20	50			
	Never	13	32.5			
Being angry	Always	12	30	2.05	0.51	Failure
	Sometimes	14	35			
	Never	14	35			
sleeping trouble	Always	6	15	2.35	0.59	pass
	Sometimes	14	35			
	Never	20	50			
Being worried	Always	4	10	2.48	0.62	pass
	Sometimes	13	32.5			
	Never	23	57.5			
Feeling depressed	Always	7	17.5	2.48	0.62	pass
	Sometimes	7	17.5			
	Never	26	65			
Feeling despair	Always	7	17.5	2.50	0.63	pass
	Sometimes	6	15			
	Never	27	67.5			
Loss of Confidence	Always	4	10	2.10	0.53	Failure
	Sometimes	25	62.5			
	Never	10	25			

This table shows assessment for determination of Quality of Life For Hemophilic Children Patients Towards Emotional Domain. In relation to all of variable have failure assessment accept sleeping trouble, Being worried, Feeling depressed and Feeling despair was pass assessment.

Table (4): Descriptive Statistics of Initial Assessment for Determination of Quality of Life for Hemophilic Children Patients towards Social Domain

Social domain	Groups	Freq. (40)	Percentage (%)	M	SD	Assessment
Other kids don't support him	Always	13	85.7	2.13	0.53	Failure
	Sometimes	9	8.6			
	Never	18	5.7			
Other kids refuse him	Always	2	84.3	2.50	0.63	Failure
	Sometimes	16	11.4			
	Never	22	4.3			
Teasing from other kids	Always	2	62.9	2.53	0.63	Failure
	Sometimes	15	24.3			
	Never	23	12.9			
Can't do things as others	Always	8	42.9	2.03	0.51	Failure
	Sometimes	23	35.7			
	Never	9	21.4			
Keeping up when play	Always	12	65.7	1.90	0.48	Failure
	Sometimes	20	22.9			
	Never	8	11.4			
Don't going to the touristic journeys	Always	9	91.4	2.28	0.57	Failure
	Sometimes	11	4.3			
	Never	20	4.3			
Do not going to the gardens	Always	15	85.7	2.00	0.50	Failure
	Sometimes	10	8.6			
	Never	15	5.7			
Do not like the visitors	Always	7	80	2.45	0.61	pass
	Sometimes	8	11.4			
	Never	25	8.6			
Don't like to visit the relatives	Always	23	87.1	1.68	0.42	Failure
	Sometimes	7	8.6			
	Never	10	4.3			
Do not Sharing conversations with my family members	Always	14	78.6	2.13	0.53	Failure
	Sometimes	5	17.1			
	Never	21	4.3			

This table shows Assessment For Determination of Quality of Life For Hemophilic Children Patients Towards Social Domain. In relation to all of variable have failure assessment accept Do not like the visitors was pass assessment.

Table (5): Descriptive Statistics of Initial Assessment For Determination of Quality of Life For Hemophilic Children Patients Towards School Domain

School domain	Groups	Freq.	Percentage (%)	M±SD		Assessment
Pay attention in class	Always	5	12.5	2.30	0.58	Failure
	Sometimes	18	45			
	Never	17	42.5			
Forgetting things	Always	1	2.5	2.48	0.62	pass
	Sometimes	19	47.5			
	Never	20	50			
School work	Always	5	12.5	2.18	0.54	Failure
	Sometimes	23	57.5			
	Never	12	30			
Missing school due to illness	Always	17	42.5	1.83	0.46	Failure
	Sometimes	13	32.5			
	Never	10	25			
Missing school to go to hospital	Always	19	47.5	1.70	0.43	Failure
	Sometimes	14	35			
	Never	7	17.5			
Decrease in activity due to sudden bleeding	Always	11	27.5	1.85	0.46	Failure
	Sometimes	24	60			
	Never	5	12.5			
Missing school due to joint pain	Always	18	45	1.58	0.39	Failure
	Sometimes	21	52.5			
	Never	1	2.5			
Difficulty in sitting on sharp-edged seats	Always	22	55	1.48	0.37	Failure
	Sometimes	17	42.5			
	Never	1	2.5			
Prevented from sport to avoid bleeding	Always	30	75	1.38	0.34	Failure
	Sometimes	5	12.5			
	Never	5	12.5			

This table show Assessment For Determination of Quality of Life For Hemophilic Children Patients Towards School Domain. In relation to all of variable have failure assessment accept Forgetting things was pass assessment.

Table(6): Association Between Demographical Characteristics and Overall Assessments Due To Quality of Life Towards Hemophilic Children Patients (Under/Upper) Cutoff Point

Demographical Characteristics & Overall assessments due to quality of life	Contingency Coefficient	P-value	C.S.
Age Groups	0.233	0.413	NS
Gender	0.087	0.683	NS
Residence	0.045	0.740	NS
Father education Level	0.019	0.872	NS
Mother education Level	**0.034**	**0.044**	S
Socio-Economic Status	0.209	0.074	NS

Non-Significant at P<0.05

This table show significant correlation between Quality of Life Towards Hemophilic Children and Mother education Level at p-value (0.044). Other variables have no significant correlation between Demographical Characteristics and Assessments Due To Quality of Life Towards Hemophilic Children Patients. In relation to Age Groups, Gender, Residence, Father education Level and Socio-Economic Status at p-value (0.413, 0.683, 0.740, 0.872,and 0.074) respectively.

This chapter present a systemically organized interpretation and reasonably derived Discussion of results the support of available literatures and related studies.

DISCUSSION

Determination of the quality of life of children and adolescents with hemophilia is an important part in the holistic management of this chronic disease, and this is attainable through the use of disease - related Quality of live questionnaires. Hemophilia is an X-linked congenital bleeding disorder caused by a deficiency of coagulation factor VIII (FVIII) (in hemophilia A) or factor IX (FIX) (in hemophilia B). The deficiency is the result of mutations of the respective clotting factor genes. Hemophilia has an estimated frequency of approximately one in 10,000 births [6].

Throughout the course of the present study, as shown in table (1) which refers to the statistically distribution of the observed frequencies, percentages of some related demographical characteristics variables for all the studied sample. Regarding to the gender, the findings indicate that gender (90%) are males. Regarding to the Residence (77.5%) are urban residents. Regarding to the father and mother education level the study findings show that almost one third of the study sample their father Graduated and mother are Read & Write (32.5%), (27.5%) respectively. Regarding to the socioeconomic status, it was found that most of the study sample are from middle level of SES[7].

Table (2) Shows that the study findings represent that (67.5%) are patients suffering from type A of hemophilia, (42.5%) are present with moderate intensity of the disease, and, (57.5%) are suffering from moderate bleeding. The association between the severity of hemophilia and quality of live in our study was consistent with other studies. Poon et al. was demonstrated that individuals with more severe hemophilia and higher self-reported joint pain and motion limitation had poorer HR quality of live scores, particularly in the physical aspects of HR quality of live[8].

It was also revealed that the patients with various severities of hemophilia showed different impairments in their HR Quality of live. Severely affected patients were more impaired in their 'physical functioning' than moderate or mild patients. The severity of the disease may influence joint movement, physical activity, treatment and relationships with others, and these factors might negatively impact the quality of live[9].

CONCLUSION

The result of this study indicated that the quality of live sample of male children with hemophilia was impaired, and that impairment according to the total Hemophilia –Quality of live score was greater among adolescents than children aged 8-12 years. Moreover, number of bleeding event, number of school absences, mother s' education level, severity of hemophilia, insight to health status and insight to suffering from hemophilia were associated with hemophilia –Quality of live. In addition, family income and parent- administration of the product were the factors which predict the quality of live in children with hemophilia.

ABSTRACT

Introduction: Strikingly, more than 95% pediatric HIV infections worldwide are in developing countries. Although ART can reduce significantly the risk of HIV transmission to children born from HIV-infected mothers, this can be effective only if the women know their HIV status. In many developing countries, such as Indonesia, the lack of access by pregnant mothers to laboratory facilities may deprive them of knowing their HIV status, thus the opportunity to transmit the disease to their children is high, knowing no preventive intervention is attempted. To date, it is estimated that the number of HIV infected children in Indonesia who are left undiagnosed is still high, therefore a study on clinical markers of HIV that can aid in the diagnosis and predict the severity of the disease among children is critical. In this study, Linear Gingival Erythema is assessed on its correlation to degree of immune suppression to be used as HIV clinical marker in laboratory-poor settings in Indonesia. **Method**: HIV-infected children admitted to Soetomo General Hospital between June – October 2017 were screened and examined intraorally for the presence of LGE. Other relevant data were obtained from questionnaire-guided interview to parents/guardians and from patient's medical record. **Results**: LGE was found in 21.43% children and statistical analysis shows significant correlation of LGE to degree of immune suppression. **Conclusion**: Further study with larger study population size is required to analyze the sensitivity and specificity of LGE to be used as HIV marker in predicting a particular degree of immune suppression, specific to Indonesian pediatric population.

INTRODUCTION

Human Immunodeficiency Virus (HIV) continues to be a major global health issue. United Nations Program on HIV/AIDS (UNAIDS) estimated 36.7 million people worldwide were living with the infection in 2016, with an extremely high proportion (95%) resides in developing countries. Despite the discovery of ART decades ago, the growth rate of HIV-infected population is still unacceptably high; 5.000 new infections per day, which 400 among them are children below 15 years.[1,2]

Most (90%) children were infected with HIV through mother to-child transmission (MTCT).[3] Although the administration of ART during pregnancy and other preventive interventions can significantly lower the risk of MTCT from 45% to less than 2%, this is not the case for many developing countries, such as Indonesia.[4]

Indonesia does not screen for HIV infection as part of its routine antenatal care due to laboratory limitations in many areas.[5] This concerning condition causes many children born from unaware women of their HIV status do not get the necessary preventive interventions from the outset, thus they are very vulnerable to get vertically infected. This is proven by the drastic increase of reported new HIV infections among Indonesian children below 4 years between 2010-2015 by >230%.[6]

To date, it is estimated that the number of HIV infected children who are left undiagnosed in Indonesia is still high.[1] When no laboratory facilities are available, clinical indicators becomes the solely most important marker in making presumptive diagnosis of HIV infection and predict the severity of the disease.[7,8] Oral manifestations have longed been studied to be used as HIV clinical indicators, however no studies to date have analyzed the correlation of these oral lesions to predict certain degree of immune suppression among Indonesian pediatric population. One of the most commonly found oral lesions in HIV pediatric infection is Linear Gingival Erythema (LGE).[9] The aim of this study is therefore to analyze the correlation of LGE to degree of immune suppression among pediatric patients admitted to Intermediate Care and Infectious Disease Centre (UPIPI), Soetomo General Hospital, Surabaya, Indonesia.

MATERIAL AND METHOD

A cross-sectional study was carried between June – October 2017 at the outpatient clinic UPIPI, Soetomo General Hospital. The study protocol was approved by Ethics Committee of Dr. Soetomo Hospital (No:326/Panke.KKE/V/2017) and Health Research Ethical Clearance Commission Universitas Airlangga (No:137/HRECC.FODM/VIII/2017). Pediatric patients under 18 years with confirmed HIV diagnosis according to the Indonesian Ministry of Health guidelines and attended the center between the study period were screened. The age limit set for pediatric patients in this study follows the regulations applied by the Indonesian legal system.[10]

Prior to the study, attending parents/guardians of the eligible patients were explained about the study objectives. Approval from parents/guardians regarding the participation of their children in the study was obtained by written consents. Oral mucosal status of each patient was then assessed by a trained oral medicine specialist using disposable plastic mouth mirrors and sterile gauze pads under artificial lighting. Identification of LGE was based on its clinical features according to EC-Clearinghouse diagnostic criteria as a distinct fiery red band along the margin of the free gingiva, with the amount of erythema is disproportionately intense for the amount of plaque seen.[9]

Other relevant data of the patients were obtained from their respective parents/guardians through questionnaire-guided interview and from their medical records. Data collected include age, gender, use of ART, and latest laboratory result on CD4 values (CD4% or CD4 counts). Viral load counts were not accessible to most patients; thus, this parameter was excluded from the present study. To determine patients' immune status closest to the condition at oral examination, CD4 values were restricted only up to 6 months interval from the date of examination. This time range follows the Indonesian Ministry of Health guidelines on pediatric CD4 monitoring[11]. CD4 value of each patient served as a baseline to determine patient's degree of immune suppression according to classification system of Centers for Disease Control (CDC) (Table 1).[12,13]

Correlation between LGE and degree of immune suppression was analyzed using chi-square test. Statistical Package of Social Sciences (SPSS) 17.0 for windows was used and p values <0.05 were considered significant.

RESULTS

The study was conducted among HIV-positive children admitted to the outpatient clinic at UPIPI, Soetomo General Hospital, Indonesia. Between June – October 2017, a total of 47 HIV-positive children who attended the center were screened. This number is much lower than the total number of children registered at the center. Although all HIV-positive children are required to pay periodic visit to the center for monitoring, the reality did not seem so. Many parents/guardians did not attend the center with their children, unless their children show any symptoms. Far distance between the center and their homes and the fact that their children need to attend classes at schools were the most-heard reasons from parents/guardians who came to the center to get the prescribed ART for free on behalf of their children.

Out of the 47 children screened, a relatively high proportion (19 children) had to be further excluded. Reasons for exclusion were parental refusal in providing consents, children being not cooperative during examination, and no CD4 values found within 6 months interval from the date of oral examination on patients' medical record. Not all children were routinely get their CD4 tested due to the high laboratory cost. Consequently, the total number of children included in the study is 28 children.

Summary of age range, ART status, and degree of immune suppression of these children are presented in Table 2. Oral examinations on 28 Indonesian children found LGE in 6 (21.43%) children (Fig 1 & 2). Three (10.71%) children with LGE were on ART while the other 3 (10.71%) were ART naïve (Table 2).

Indonesian children were categorized into several degrees of immune suppression. Two (7.14%) children with LGE were in degree of no immune suppression, while the other 4 (14.29%) children with LGE were in degree of severe immune suppression (Table 2). Statistical analysis to correlate the occurrence of OHL according to child's immune suppression was found to be statistically significant (p value = 0.027) (Table 3).

Table 1. **Immunologic categories based on age-specific CD4 % and CD4 counts.**

Immunologic category	**Age of child**				
	< 12 months		**1-5 years**		**> 5 years**

DISCUSSION

Oral lesions can not only indicate HIV infection, they are also among the earliest clinical features of the infection that can aid in predicting the course of the disease. EC-Clearinghouse clinical diagnostic criteria, the term of reference for most studies in HIV-associated oral diseases, classified LGE into lesions commonly associated with pediatric HIV infection. LGE was formerly known as HIV-gingivitis and it is the most common form of HIV-associated periodontal disease in infected children.[14]

LGE has been correlated to fungal infection of the Candida species, yet the nature etiology of this lesion is still a controversy, as other studies reported different findings.[15] Umadevi et al reported the possibility of certain viruses, such as CMV, EBV, and papillomavirus in initiating and causing LGE progression.[16] On the contrary, Aas et al. found *Saccharomyces cerevisiae*, *Gamella spp*., *Dialister spp*., *Streptococcus spp*., and *Veillonella spp*. as the causative agents of LGE [17]. Despite the discrepancies between studies, it is now widely accepted that Candida contributes to the occurrence of LGE as many clinical cases were effectively treated with antifungal treatment.[15,18]

In this study, the prevalence of LGE was found to be 21.43%. This prevalence is higher than other studies in developing countries in Uganda (0.84%) [19] and India (2.27% [20] and 9.05% [21]) yet lower than a study conducted in Venezuela (27.03%) [22]. The varying prevalence of LGE between countries may be due to the distinct characteristics among the populations (proportion of the population on ART, their adherence to ART, immune status of the population, nutritional status, etc.), as well as the influence of cultural and geographical factors of each country.

Furthermore, EC-Clearinghouse classification has also associated LGE to be more prevalent in children HIV infection than in adults.[18] Comparing this study to another study conducted in 2014 among adult patients at the same centre (UPIPI, Soetomo General Hospital) supports this classification as LGE was found to be much lower in adult patients (5.83%) than among pediatric children in this study.[23]

ART has been widely accepted to be highly effective at inhibiting HIV replication, although it is not curative. Combination of ART can dramatically suppress the number of virus circulating in the plasma, even to a level of undetectable. With the successful viral suppression, immunologic recovery is expected and the number of opportunistic infections to manifest should be lower.[24] In this study, although LGE were also found in children undergoing ART, LGE were found more predominantly in children who had not received treatment as seen in Table 2.

Although LGE in this study were found in children with severe immune suppression yet also in children with no immune suppression, the occurrence of LGE is more notable in children with severe immune suppression (4 children with LGE among 7 children with severe immune suppression) than in children with no immune suppression (2 children with LGE among 18 children with no immune suppression). This trend indicates that LGE will be more likely to manifest when immune status of the host is continuously declining. Statistical analysis between the presence of LGE with degree of immune suppression is also proven to have a solid relationship (p value = 0.027) (Table 3).

CONCLUSION

Immune status was significantly correlated with the presence of LGE in this study. However, its sensitivities and specificities to predict a specific degree of immune suppression is yet still need to be assessed. Further study with larger Indonesian pediatric HIV/AIDS population size is thus recommended.

Maternal Mortality with Panel Regression Approach Model based on Maternal and Child Health Revolution Program or etc Performance Indicators at Nusa Tenggara Timur Province Indonesia

Yuanita Clara Rogaleli [1,2], Irfan[2], Kuntoro[3]

[1]Doctoral Student, Program of Public Health, Faculty of Public Health, Universitas Airlangga, Surabaya, Indonesia, [2]Lecturer, Health Polytechnic of Kupang, Nusa Tenggara Timur, Indonesia, [3] Professor of Biostatistics, Department of Biostatistic and Demographic, Faculty of Public Health, Airlangga University, Surabaya, Indonesia

ABSTRACT

Nusa Tenggara Timur (NTT) government had launched a local specific program, namely Maternal and Child Health Revolution Program (MCHRP) or *Revolusi KIA* at 2009. However, maternal mortality still becomes one of the biggest public health problems in NTT Province in Indonesia.

The slow decreasing of Maternal Mortality Ratio (MMR) need a study in order to determine MCHRP performance indicators that have the biggest influence in decreasing maternal mortality ratio at each district of NTT Province at a specific range of time in order to develop a more effective, efficient and directed plan or policy for maternal and child health intervention program.

The aim of this research is to identify and analysis factors that influence the maternal mortality ratio of 2011 – 2015 based on MCHRP performance indicators at every district and municipality of NTT Province.

This applied research used data from MCHRP indicators program reports from 2011 to 2015 at Public Health Division of NTT Health Office with 22 districts and municipalities as unit analysis. The data analyzed using panel data regression.

Result from this analysis shows that the trend of performance indicator achievements tends to fluctuate and imbalanced for every district and municipality. The best Panel Data Regression Model that can be used for evaluating the achievement of MCHRP performance indicators toward MMR at NTT is the Random Effect Model that takes into account the place and time effect error. Indicators that have significantly influenced in decreasing MMR at NTT are the complete Ante Natal Care (ANC) visit, childbirth assisted by a skilled health professional with midwifery competence, complete postpartum care (PNC) visit and complication care with determination coefficient (R^2) 90%.

INTRODUCTION

Indonesia is one of developing countries that did not reach MDG's target in decreasing MMR to 102/100,000 live birth in 2015[(1)] Based on data from Demographic and Health Survey (DHS) there was a significant increasing of MMR in Indonesia from 228/100,000 live births in

2007 to 359/100,000 live births in 2012. Furthermore, based on Beetwen Sensus Population Survey in 2015 the MMR in Indonesia is 305/100,000 live births, which is still far from the MDG's target.

Since 2009, NTT as one of the provinces in Indonesia that has a highest MMR has been trying to accelerate the decreasing of maternal and child morbidities and mortalities with a tremendous program called Maternal and Child Health Revolution Program (MCHRP) or *Revolusi KIA*.

This program runs through a regulation that all childbirth must be assisted by skilled health professional with midwifery competence at adequate health care facility for 24 hours[3]. This regulation has an impact on the increased numbers of health care facilities and health care facilities with basic obstetric and neonatal emergency care at NTT from 292 sub district health center or *puskesmas* with 61 *puskesmas* equipped by basic obstetric and neonatal emergency care (20.89%) in 2009 to 374 *puskesmas* with 374 *puskesmas* equipped by basic obstetric and neonatal emergency care (62.57%).

However, this MCHRP seems to be not yet effective in reducing the MMR at NTT. The annual reduction of MMR tends to slowly decrease which is 220/100,000 live birth in 2011, 200/100,000 live birth in 2012, 185,6/100,000 live birth in 2013, 169/100,000 live birth in 2014 and 133/100,000 live birth in 2015.The low achievements of MCHRP performance indicators which are complete ANC visit coverage is 61.63%, childbirth assisted by skilled health professional with midwifery competence coverage is 69.97% and childbirth at health care facilities coverage is 69.95%[4]. These facts showed that there are still 34% childbirth delivered at home and around 30% childbirth still assisted by traditional birth attendance that put the maternal at risk. When obstetric complication on childbirth happened it can be lead to maternal and child dead if handling late that can be caused by late referee caused by geographic, social cultural or economic factors[5][6].

There are some challenges and obstacles in the process of reducing MMR at NTT such as the insufficient knowledge and awareness from the community toward the importance of maintaining health and safety of pregnant women; insufficient nutrition status and health of pregnant women; limited access of pregnant women to qualified health care facilities and comprehensive obstetric care caused by geographic and topographic factors (archipelago, highland and hill) and the patriarchy culture; insufficient numbers of health care facilities and insufficient of health professionals (quantity, quality and distribution)[7][8].

Thus to make the initiatives in reducing MMR program at NTT succeed, it is important to define the achievement indicators of MCHRP that have the biggest effect in reducing MMR at every district and municipality at NTT at a specific period of time in order to develop a more effective, efficient and directed plan or policy for maternal and child health intervention program.

The aim of this research is to identify and analysis factors that influence the maternal mortality ratio of 2011 – 2015 based on performance indicators of MCHRP at each district and municipality of NTT Province.

MATERIAL AND METHOD

This applied research used data from MCHRP indicators program reports from 2011 to 2015 at Public Health Division of NTT Health Office with 22 districts and municipalities as unit analysis. The data analyzed using panel data regression because it takes into account the weighting of individual effect (district/municipality) and time period (2011 – 2015).

Analyzed variables in this research are the response variables, i.e. MMR, predictor variables, i.e. ANC 1st coverage, 4 times ANC coverage, childbirth assisted by skilled health professionals with midwifery competent coverage, 3 times PNC visits, complication care coverage and the number of puskesmas equipped by basic obstetric neonatal emergency care at every district and municipality.

Panel Regression Model analyzed by eviews7 software consists of three models which are the common effect model, the fixed effect model and the random effect model.

The best regression model was selected by using Chow test and Hausman test. Chow test is used to choose between the common effect model and the fixed effect model. If the null hypothesis accepted, then the common effect model chose, whereas Hausman test used to choose between the fixed effect model and the random effect model. If the null hypothesis accepted, then random effect model chose. The best regression

model will use to estimate the panel data.

FINDINGS

Table 1 shows that MMR average and the achievements of MCHRP performance indicators tends to fluctuate and imbalance at every district and municipality in NTT Province, which are shown from standard deviation and the big difference of minimum and maximum at every research variable. MMR average from 2011 to 2015 is 181.5/100.000 live birth.

There is a significant difference between every district and municipality with range between 107.40/100.000 live births to 219.8/100.000 live birth. PNC visit indicator and complication care indicator coverage also showed a big significant difference between every district and municipality in the 5 years time period.

Table 1: Description of research variables of NTT Province 2011 – 2015

Indicator/Research Variables	Mean	SD	Min	Max
MMR	181.50	32.96	107.40	219.8
ANC (1th visit) coverage	86,00	11.82	38.9	127.5
Complete ANC (minimum 4 times visit) coverage	61.80	14.41	30.7	92.1
Skilled health professional with midwifery competence birth delivery assisted coverage	74.00	5.30	69.10	76.60
PNC (minimum 3 times visit)	77.10	18.4	11.3	102.6
Complication care coverage	52.00	26.00	6.9	117.4
Puskesmas equipped by obstetric and neonatal emergency care coverage at every district/municipality	5.00	3.00	2.00	16.00

The data panel regression analysis benefit to look for MMR difference at every district and municipality in the time period. Every indicator very depended by the difference of time (year) and place (district/ municipality).

The test result of the best panel data regression can be seen in table 2. The result from Chow test shown p value = 0.000 meaning that the common effect model rejected. Whereas the result from Hausman test show p value = 0.138 meaning that the random effect model accepted that can be used further to estimate performance indicator of MCHRP toward MMR at every district and municipality NTT in 2011 – 2015 time period. Random effect model resulting from the analysis for MMR estimation at NTT province has taken into account the heterogeneity of unobservable place and time variables and reduce the colinearity between predictor that resulted a more efficient estimation[9]

Table 2: The best panel regression model test result

Test	Statistic value	*p*-value
Chow Test	F = 5.1631	0.000
Hausman Test	X^2 = 2199	0.138

Based on the result on table 3 performance indicators of MCHRP that significantly influence the MMR in NTT are ANC visit, childbirth assisted by skilled health professionals with midwifery competence, PNC visit and complication care. The indicator that has the biggest influence in reducing MMR in NTT Province is the complete ANC visit.

Every regression coefficient in the Random Effect Model that has negative value means that if we increase the four indicators mention above then the MMR will decrease, vice versa.

The R^2 *adjusted* values of this model is 0.9008 which is included in the very good category that mean about 90.08% change in MMR can be explained by these four predictor variables in the model.

Regression coefficient of the complete ANC visit i.e. -0.4814 mean that if the complete ANC visit increase 10%, then the MMR will have a chance to decrease at about of 4/100,000 live births annually both for the district and municipal level estimation and province level estimation. The interpretation of coefficient regression of other variables in the model can be done similarly.

Table 3 Results from Random Effect Model Analyze

Specifications of the indicators				
Variable	**Coefficient**	**Standard Error**	**t-statistic**	**P value**
Constanta (C)	6.6354	2.2724	2.9199	0.0043
Complete ANC (minimum 4 times visits) coverage	-0.4814	0.1808	-2.6626	0.0205
Childbirth delivery assisted by a skilled health professional coverage	-0.0952	0.0436	-2.2319	0.0267
PNC (minimum 3 times visits) coverage	-0.0950	0.0418	-2.3167	0.0258
Complication care coverage	-0.0942	0.0367	-2.4810	0.0238
The best model specification				
R^2	0.9276	F statistic	123.6292	
R^2*Adjusted*	0.9008	p value	0.0000	

DISCUSSION

The result of this research shows that the MCHRP performance indicator that has the biggest contribution in decreasing MMR at every district and municipality in NTT on 2011 – 2015 time period is the complete ANC visit or a minimum 4 times ANC visits indicator. Increasing 10% complete ANC visit coverage will have a chance to decrease MMR in the amount of 4/100.000 live birth.

Hence this indicator needs to get more attention in order to prevent complication and maternal and child mortality. ANC visit related with maternal behavior in health caring and access to health care facilities [(10)].

In the reality, many community members at NTT still consider that the pregnancy is a usual and natural stage of life that lead pregnant women not regularly visit health professional.

These beliefs have an implication of the high numbers of un-detection of maternal with high risk factors. These un-threaten maternal high risk factors lead to the delay on getting care that can cause a serious health consequences such as hospitalization or even death both for the mother or the baby[(11)]. Even though around 80% of maternal mortality are preventable if they regularly visit health professional for ANC. ANC visits is important in order to early detection and on time care for threaten the complication at pregnancy, labor and post partum which can help in reducing MMR [(12).]

This research also found that the average of ANC visit at NTT Province at 2001 – 2015 period was 61.80%.

The utility of the ANC at health facilities influenced by the low of women's autonomy in economic (freedom to regulate their family budget allocation), low freedom on mobility and low authority in decision making which can be caused by maternal status in their family and community. The other factors that can influence ANC visits are the attitude of pregnant women themselves of the importance of their health care especially antenatal care. Supports from family members and community leaders and also information and assistance from heath professionals toward ANC visits can increase maternal intention[(13)(14)] but also in reproductive health since ICPD 1994. However, very little empirical evidence is available about women's role on maternal health service utilization in Nepal. This paper explores dimensions of women's autonomy and their relationship to utilization of maternal health services. METHODS The analysis uses data from the Nepal Demographic and Health Survey, 2011. The analysis is confined to women who had given birth in the 5 years preceding the survey (n = 4,148. Therefore, in order to increase the ANC visits coverage at NTT as the most influenced factor in reducing MMR, factors that need more attention are women's autonomy.

The Prenatal class or *Kelas Ibu Hamil* can become a medium for increasing women's autonomy with target and material modification. The Prenatal class that used to target the pregnant women can also make the husband and childbearing age couples as target to prepare them for their pregnancies later. The materials that can be added in the Prenatal class, such as the rule of women in fulfill the reproduction's health right and the need for reproductive health at every cycle. Hopefully with the increasing knowledge of the pregnant mother and the husband about the reproduction's health will benefit from increasing the complete ANC visit coverage, childbirth assisted by skilled health professionals with midwifery competence coverage and PNC visit coverage.

Besides that, the network that already exists between health professionals with the traditional birth attendance must be more developed in order to make a safe pregnancy, clean and safe childbirth and postpartum by reducing negative myths regarding pregnancy, childbirth and postpartum but still keep culture values that exist in the community in order to reduce MMR and Child Mortality Ratio. This is also important because many pregnant women still choose the traditional birth attendant assist in childbirth, reasoned by their personal reasons such as more familiar, understand and can help with traditional childbirth ritual and also because the traditional birth attendant can assist the maternal and the child up to 40 days after delivery.

CONCLUSIONS

In order to decrease MMR at NTT through the MCHRP, the performance indicators that have the biggest influence are increase the complete ANC visit coverage, the complete PNC visit coverage and childbirth assisted by skilled health professionals with midwifery competence coverage and PNC care visit coverage, respectively, which can increase by target and material modification in Prenatal Class and also by strengthening the network between health professional and traditional birth attendance.

Role of microRNA-423 Gene Variation in Women at Higher Risk of Breast Cancer in Tabuk of Saudi Arabia

Rashid Mir[1], Ibrahim Abdullah Al Balawi[2], FM Abu-Duhier[1]

[1]Department of Medical Laboratory Technology, Faculty of Applied Medical Sciences, Prince Fahd Bin Sultan Research Chair, University of Tabuk, Kingdom of Saudi Arabia, [2]Department of Surgical Oncology, Faculty of Medicine, University of Tabuk

ABSTRACT

Aim: Background- MicroRNA has attracted increasing attention due to their possible involvement in the development of various types of cancer. Many studies have been conducted to investigate the association between miR-423 rs6505162C/T and Breast cancer risk; however, the results are not consistent. Therefore, we investigated the association of microRNA-423 rs6505162C>A gene variations with Breast cancer cases, sex match healthy controls and *Women* at higher *risk* of *breast cancer* susceptibility in Saudi women.

Methodology: This study was conducted on 90 subjects among whom 30 were *Women* at higher *risk* of *breast cancer* (WHR), 30 were Breast cancer cases and 30 were gender matched healthy controls. The microRNA-423 rs6505162C>A gene variations was performed using Amplification refractory mutation system PCR method.

Results: A significant difference was observed in genotype distribution between w*omen* at higher *risk* of *breast cancer* and Breast cancer cases (P=0.04) and between sex match healthy controls and *Women* at higher *risk* of *breast cancer* (P=0.009). The frequencies of all three genotypes CC,CT,TT reported in the w*omen* at higher *risk* of *breast cancer* were 20%, 43% and 37% , Breast cancer patients 53%,37% and 10% and in sex matched healthy controls 57%, 30% and 13% respectively. Our results indicated that the miR-423-rs6505162C>T gene variant is associated with an increased risk of *Women* at higher *risk* of *breast cancer* in Codominant inheritance model (OR=0.20, 95% CI=(0.05-0.80) p=0.020, TT vs CC; Dominant model (OR=0.26, 95% CI= (0.86-0.81), p=0.020, CT+TT vs CC) and no significance was reported in Recessive model (OR=0.38, 95%CI= (0.12-1.21), P=0.07, TT vs CC+CT) inheritance models tested. While, the T allele significantly increased the risk in *Women* at higher *risk* of *breast cancer* (OR= 0.38; 95% CI= (0.18-0.78); p=0.009 compared to C allele.

Conclusion: Our findings indicated that microRNA-423 TT genotype and T allele are associated with an increased susceptibility to Breast cancer in high risk w*omen* . Furthers studies with larger sample sizes are necessary to confirm our findings.

INTRODUCTION

Breast cancer is the second most commonly diagnosed cancer worldwide [(1)]. Breast cancer (BC) has a major impact on health of women worldwide and the Kingdom of Saudi Arabia (KSA) is no exception. It is considered the most common malignancy and embodies the second leading cause of cancer deaths after lung

cancer. The malignancy carries tremendous socio-economic, emotional, and public health implications. It is estimated that more than one million new cases of BC are diagnosed annually. Breast cancer incidence rates in Arab women have increased during the last 24 years, but women are still being diagnosed with BC at more advanced stages of the disease [2,3] .An estimated 5-10% of all breast cancer cases are thought to be hereditary or caused by known genetic factors. A mutation in the BRCA1 or BRCA2 gene is one of the main known causes of hereditary breast cancer.MicroRNAs are a class of small, endogenous, non-coding, single-stranded, highly conserved and tissue-specific RNA molecules which take part in the regulation of target mRNAs expression at the post-transcriptional level [4] . The discovery of miRNAs has been followed by findings highlighting their important and diverse roles in many molecular pathways and biological processes, including development, apoptosis, differentiation, and cell proliferation [5] , as well as their implication in various human diseases including cancer. Growing evidence indicates that miRNAs can work as oncogenes or tumor suppressors, depending on which gene(s) they modulate [6] .Recent evidence suggests a role for miR-SNPs in breast cancer susceptibility including work by Hu et al. where the presence of mutant alleles of MIR196A2 rs11614913 and MIR499A rs3746444 significantly increased breast cancer risk in Chinese women [7]. However in genetic association analysis of Caucasian populations and functional studies in breast cancer cell lines performed by Hoffman et al. the presence of SNP in MIR196A2 rs11614913 was significantly associated with reduced risk of breast cancer, as well as less efficient processing of MIR196A2 and reduced capacity to regulate target genes, indicating additional factors may be at work in this SNP's effect on breast cancer [8]. Additionally, Kontorovich et al. found 2 SNPs, rs6505162 and rs895819 located in MIR423 and MIR27A precursors respectively, to be significantly associated with decreased risk of breast cancer in BRCA2 mutation carriers from a Jewish population [9].However the SNP rs895819 was also significantly associated with reduced risk of developing breast cancer in families with a history of non-BRCA related breast cancer in a later study performed by Yang et al [10]. Finally rs2910164, a miR-SNP located in the 3p strand of MIR146A, was found to be associated with a younger age of diagnosis in familial breast cancer for BRCA1 mutation carriers [11].Many epidemiological studies have examined the association of miRNA SNPs with cancer susceptibility [12]. In BC, several case–control studies and meta-analyses have evaluated associations between miRNA gene polymorphisms and BC risk in European,[13] Asian [14], Arab[15], and Jewish[9],] populations. Many studies have been conducted to investigate the association between miR-423 rs6505162C/T and Breast cancer risk; however, the results were not consistent.

MATERIAL AND METHOD

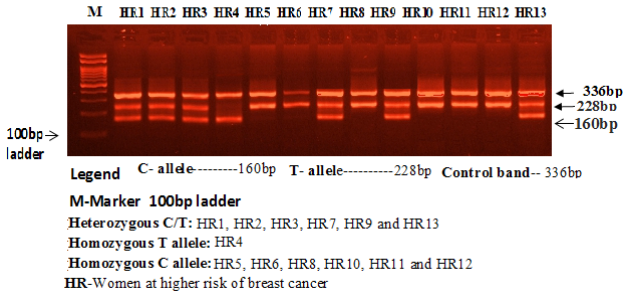
This study was conducted on 90 subjects among whom 30 were Breast cancer cases, 30 were *Women* at higher *risk* of *breast cancer* (WHR) and 30 were sex matched healthy controls. The Breast cancer cases were histologically confirmed .The sex-matched healthy women with no history of any types of cancer and not related to the patients. The first degree relatives of Breast cancer patients were selected as Women at higher *risk* of *breast cancer*. Patients with any previous history of cancer were excluded from this study.

Sample collection

After assessing the clinicopathological findings of Breast cancer patients, a 4ml sample of peripheral blood was collected by venipuncture in EDTA tubes from each patient and healthy control.

DNA extraction

DNA extraction was done by using DNeasy Blood Kit (cat 69506) from Qiagen (Germany) as per the manufactures instructions. The extracted DNA was dissolved in nuclease-free water and stored at 4°C until use. Quality and integrity of DNA were checked by NanoDrop™ (Thermo Scientific, USA).



Genotyping for miR-423 rs6505162C>T) by using amplification-refractory mutation system PCR

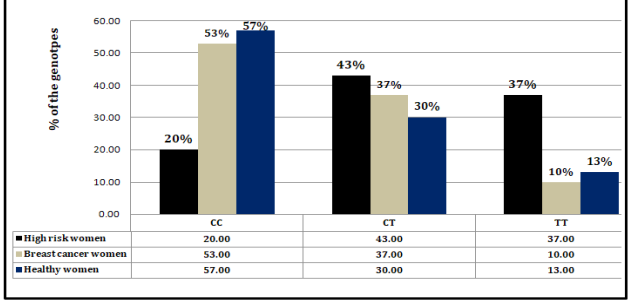
The miR-423-rs6505162 C>T genotyping was done by using amplification-refractory mutation system PCR .The ARMS primers were designed by using Primer3 software as depicted in Table 1.

Table 1. Primer sequence of miR-423 genotyping (rs6505162 C>T)		
Direction	Sequence	Product size
miR-423 FO:	5′-TTTTCCCGGATGGAAGCCCGAAGTTTGA-3′	336 bp
miR-423 RO:	5′-TTTTGCGGCAACGTATACCCCAATTTCC-3′	
miR-423FI (T allele):	5′-TGAGGCCCCTCAGTCTTGCTTCCCAA-3′	228bp
miR-423 RI (C allele):	5′-CAAGCGGGGAGAAACTCAAGCGCGAGG-3′	160bp

The ARMS-PCR was performed in a reaction volume of 25uL containing template DNA (50ng), FO -0.30uL , RO -0.30uL , FI-0.20uL , RI -0.20uL of 25pmol of each primers and 10uL from GoTaq® Green Master Mix (cat no M7122) (Promega, USA). The final volume of 25 uL was adjusted by adding nuclease free ddH2O .Finally 2ul of DNA was added from each patient. The amplification conditions used were at 94 ^{0}C for 12 minutes followed by 35 cycles of 94^{0}C for 35sec, 62^{0}C for 40 sec, 72^{0}C for 40 sec followed by the final extension at 72^{0}C for 10 minutes. The amplification products were separated by electrophoresis through 2% agarose gel stained with 0.5µg/mL ethidium bromide and visualized on a UV transilluminator. Primers FO and RO flank the exon of the miR-423-rs6505162 C/T gene, resulting a band of 336bp to act as a control for DNA quality and quantity. Primers Fwt and RO amplify a wild-type allele (C allele), generating a band of 160bp, and primers FO and Rmt generate a band of 228bp from the mutant allele (T allele) as depicted in **Figure 1**).

Figure 1 Genotyping for miR-423 rs6505162C>T) by using amplification-refractory mutation system PCR

STATISTICAL ANALYSIS



The differences in the miR-423 gene allele and genotype frequencies between the three groups were evaluated using Chi-square test. The associations between miR-423 (rs6505162 C>T) genotypes and w*omen* at higher *risk* of *breast cancer,* breast cancer cases and healthy controls were estimated by computing the odds ratios (ORs), risk ratios (RRs) and risk differences (RDs) with 95 % confidence intervals (CIs A p-value < 0.05 was considered significant. All statistical analyses were performed using SPSS 16.0.

RESULTS

This case controls study was performed on ninety subjects .Thirty of ninety (30/90) were Breast cancer cases, Thirty of ninety (30/90) were w*omen* at higher *risk* of *breast cancer* (WHR) and Thirty of ninety (30/90) were sex matched healthy controls .All the samples were screened for miR-423 rs6505162 C>T genotyping by using amplification-refractory mutation system PCR assay. The frequencies of all three genotypes of miR-423 rs6505162 gene polymorphism CC,CT and TT in three groups was analyzed as depicted in the **Figure 2.**

The frequencies of all three genotypes CC,CT,TT reported in the w*omen* at higher *risk* of *breast cancer* was CC 20%, CT 43% and TT 37% , Breast cancer patients was CC 53%, CT 37% and TT 10% and in sex matched healthy controls was CC 57%, CT 30% and TT 13%.The significant difference was observed in genotype distribution between w*omen* at higher *risk* of *breast cancer* and Breast cancer cases (P=0.04) and between sex match healthy controls and *Women* at higher *risk* of *breast cancer* (P=0.009).

Figure 2 Genotype distribution of miR-423 rs6505162 C>T gene polymorphism in three groups - , women at higher risk of breast cancer ,Breast cancer cases and healthy controls

miR-423 rs6505162 C>T gene variation between women at higher risk of breast cancer (WHR) and Breast cancer Case

The genotype distribution of miR-423 rs6505162C>T gene variation between w*omen* at higher *risk* of *breast cancer* (WHR) and Breast cancer Case is summarized in Table 3. A statistically significant difference was observed in the frequencies of miR-423CC, CT and TT genotypes among w*omen* at higher *risk* of *breast cancer* (WHR) and Breast cancer Case (p=0.040). The frequency of T allele (fT) was found to be higher among w*omen* at higher *risk* of *breast cancer* (0.58) than the breast cancer cases (0.29) whereas, the higher frequency of C allele (fC) was observed among Breast cancer cases (0.71) than the w*omen* at higher *risk* of *breast cancer* (WHR) (0.42). The T allele was found to be a risk factor Breast cancer as depicted in table 2.

Risk of Women at higher risk of breast cancer, Breast Cancer with miR-423 (rs6505162C/T) gene polymorphism in BC patients:

A multivariate analysis based on logistic regression like odds ratio, risk ratio and risk difference with 95% confidence intervals were calculated for each group to estimate the association between the miR423-rs6505162C>T genotypes and risk of *Women* at higher *risk* of *breast cancer* in Saudi patients as depicted in **table 4.**

Our findings showed that the miR-423-rs6505162C>T gene variant was associated with an increased risk of *Women* at higher *risk* of *breast cancer* in Codominant inheritance model (OR=0.20, 95% CI=(0.05-0.80) p=0.020, TT vs CC; Dominant model (OR=0.26, 95% CI= (0.86-0.81), p=0.020, CT+TT vs CC) and no significance was reported in Recessive model (OR=0.38, 95%CI= (0.12-1.21), P=0.07, TT vs CC+CT) inheritance models tested. While, the T allele significantly increased the risk in *Women* at higher *risk* of *breast cancer* (OR= 0.38; 95% CI= (0.18-0.78); p=0.009 compared to C allele.

DISCUSSION

In the present study, we analyzed the correlation between genetic polymorphisms in *miR-423*- rs6505162 and susceptibility to w*omen* at higher *risk* of *breast cancer* (WHR) in Saudi Arabian population. The mi*R-423* - rs6505162 polymorphism was revealed to be associated with an overall increased risk in w*omen* at higher *risk* of *breast cancer* (WHR). The higher prevalence of miR-423-TT genotypes were reported in w*omen* at higher *risk* of *breast cancer* 37% vs *breast cancer* 10% & gender matched controls 13% similarly the higher prevalence of miR-423-CT genotypes were reported in w*omen* at higher *risk* of *breast cancer 43*% vs *breast cancer* 37% & gender matched controls 30% . The significant difference was observed in genotype distribution between w*omen* at higher *risk* of *breast cancer* and Breast cancer cases (P=0.04) and between sex match healthy controls and *Women* at higher *risk* of *breast cancer* (P=0.009).A confirmed carrier of a genetic mutation that increases the risk for breast cancer, (BRCA1or BRCA2). Confirmed" means the person has had genetic testing and a genetic mutation was found. They may not have breast cancer but they "carry" the genetic mutation and are at a higher risk for developing the disease .Most inherited cases of breast cancer are associated with one of two abnormal genes: BRCA1 or BRCA2 gene. Women with an abnormal BRCA1 or BRCA2 gene have up to an 85% lifetime risk of developing breast cancer besides have a much higher-than-average lifetime risk of ovarian cancer; estimates range from 15% to 60% .

CONCLUSION

Our findings indicated that microRNA-423 TT genotype and T allele are associated with an increased susceptibility to Breast cancer in high risk w*omen* . Furthers studies with larger sample sizes are necessary to confirm our findings.

ABSTRACT

Background: Cypermethrin is an insecticide commonly used in dengue vector control program. Reasonably different levels of susceptibility in mosquitoes of Aedes aegypti in the two districts of Central Java Indonesia are suspected to occur as a result of using cypermethrin continuously.

Method: The study was conducted using a survey method to the community to take samples of Aedes aegypti eggs after becoming an adult female mosquito toward the susceptibility of 0.05% cypermethrin.

Results: The results showed that the mosquito Aedes aegypti in Kebumen are resistant to the insecticide 0.05% cypermethrin. Similarly, the mosquito Aedes aegypti in Banyumas also is immune to the same insecticide.

Conclusion: Mosquitoes in the district of Kebumen and Banyumas regency are resistant to the insecticide of 0.05% cypermethrin. It is suggested for health agencies to conduct periodic evaluations (3-5 years) on the effectiveness of pesticides used, especially in areas with high endemicity status so that control can be applied efficiently.

Keywords: *vulnerability, Aedes aegypti, cypermethrin*

INTRODUCTION

The number of cases of DHF (Dengue) always fluctuate annually [(1)]. Various efforts to control dengue vector has been implemented either physically, chemically or biologically. Physical controls in Indonesia are commonly known as the practice of 3M, (*Menguras, Menutup, Mengubur*- to drain, to shut, to burry namely mosquito nest elimination using 3 M (drain, close and bury or destroy) that remove the tub or toilet, shut the water reservoirs (buckets, drums, jars) and bury or destroy the used goods such as cans, tires, plastic, and others. This method, however, has not worked satisfactorily proved by the number of dengue cases are still common [(2)].

Some vector control method has been widely known and used by the dengue control program at the central level in the areas of environmental management, biological control, chemical control, community participation, protection of individuals and the rule of law. Control of Dengue is primarily intended to break the chain of transmission, i.e., the vector control. The dengue vector control in endemic areas which are not targeted will not be sustainable and has not been able to break the chain of transmission. This may due to the method adopted not referring to the data/information vectors as well as still rely on the use of insecticides.

One of the efforts to control the vector is through cut transmission by killing adult mosquitoes quickly with insecticide application or known by the term fogging. It is still often found fogging is performed not in appropriate dose, not to the right target and not based on a scientific basis. This triggeres the occurrence of resistance in addition to the fact that some places use the same insecticide group in a long time. Insect resistance

to insecticides commonly occurs after 2-20 years of use. Cypermethrin is insecticides often used in dengue vector control programs in each district in Central Java in recent years and ironically this substance is found no longer useful as the mosquito has been resistant [3] besides to 0.8% malathion and 0.25% permethrin [4].

Kebumen and Banyumas are two districts in the southern part of Central Java province which includes using cypermethrin in the last three years. Kebumen is a county located in the lowlands and by the Indonesian Ocean, while Banyumas is situated in the highlands and bordered by the beach. Their geographical and topographical differences that allow growth, the joy of life and adaptability of mosquito Aedes aegypti can be different as well. Cypermethrin associated with the use of insecticides may have different levels of vulnerability in the mosquito Aedes aegypti in the two districts as a result of using cypermetrin continuously.

METHODOLOGY

This type of research is observational research with a cross sectional approach by conducting surveys to endemic areas of dengue fever in the district of Kebumen and Banyumas in Central Java province, Indonesia.

Samples were the Aedes aegypti obtained from the highest dengue cases in Kebumen (districts of Sempor) and Banyumas (the District of South Purwokerto). Adult mosquitoes collected by hatch (rearing) obtained through the installation of ovitrap across the two districts. The number of mosquitoes used in research is 125 each region bringing the total number of mosquitoes = 125 head x 2 areas = 250 Aedes aegypti adult female mosquitoes. Tests were carried out by using WHO standard kit equipment such as susceptibility test set consisting of three pairs of test tubes and three pairs of control tubes. Test tube comprises of a tube collector mosquito (risela oil-coated paper) and the tube contact insecticides (coated paper impregnated).

The calculation result is determined by the provision if the results obtained mosquito mortality in the control group. If it is <5%, then it is ignored. If the death of larvae in the control group is > 20%, the research is considered failed, and the test should be repeated. The percentage protection (feeding inhibition, mortality or knockdown effect) was estimated by Abbot formula as PE = (NC - NT)/NT × 100%, where NC and NT are the number of the mosquito on control and treatment, respectively [5]. The mortality rate of Aedes *aegypti* is interpreted as follows:

vulnerable: if the death of the mosquito larvae is 98-100% tolerant: if the death of larvae mosquito is 80-97% resistant: when the mosquito larvae mortality is <80%

RESULTS

The insecticides used for fogging on the location of the study are described below.

Table 1. The Insecticides Used for Fogging

No.	Location	Insecticides Group	Frequency	Duration of use
1.	Kebumen Regency	Synthetic pyrethroid	1-2 times/year	> 5 years
2.	Banyumas Regency	Synthetic pyrethroid	1-2 times/year	> 5 years

Temperature measurements are carried out every day, i.e., air temperature at the test and 24 hours after testing. Temperature measurements obtained can be seen in the table below.

Table 2. Measurements of Air Temperature

Sampel		Data Testing	Initial temperature (°C)	Temperature after 24 hours (°C)
1	Jatinegara Village	1	25	26
		2	25	26
		3	25	26
2	Karangklesem Sub-district	1	25.5	26
		2	25.5	26
		3	25.5	26

Humidity measurements were performed everyday, i.e., air humidity during testing and observation 24 hours after trial. The humidity measurements obtained can be seen in the table below.

Table 3. Humidity Measurement Results

Sample		Data Testing	Initial humidity(%)	Humidity after 24 hours (%)
1	Jatinegara Village	1	77	78
		2	77	78
		3	77	78
2	Karangklesem Sub-district	1	78	78
		2	78	78
		3	78	78

The susceptibility status of Aedes aegypti resistance to 0.05% Cypermethrin is obtained through test or susceptibility test. The resistance test data was collected from the results of Aedes aegypti mosquito count which died in the 0.05% Cypermethrin, exposure group after being observed for 1x24 hours. Aedes aegypti mosquito resistance test result in exposure group of 0.05% Cypermethrin insecticide in Jatinegara village can be seen in the following table.

Table 4. Aedes aegypti Mosquito Resistance Test Results in Jatinegara Village

No.	Samples	Mosquitos	Death	Alive	Mortality Rate (%)	Note
1	1	20	3	17	15	Resistant
2	2	20	7	13	35	Resistant
3	3	20	7	13	35	Resistant
Average		20	5.7	14.3	28.3	Resistant

From table 4 it can be seen that the population of Aedes aegypti mosquitoes in Jatinegara village, Kebumen regency with 3 times test have Aedes aegypti mosquito death rate respectively: 1st test as much as 15%, 2nd test as much as 35%, and 3rd test as much as 35% with the average percentage of deaths is 28.3%. Thus it can be said that Aedes aegypti mosquitoes in Jatinegara Village, Kebumen Regency have been resistant to 0.05% Cypermethrin insecticide.

In the control group, the test was performed using three sets of test tubes. The experimental procedure is similar to the resistance test in the exposed group. What distinguishes is in the control group it applies a non-insecticide paper. The death of Aedes aegypti mosquito in the control group can be seen in the following table.

Table 5. Resistance Test Results Aedesaegypti mosquito in the Control Group

No.	Samples	Mosquitos	Death	Alive	Mortality Rate (%)
1	1	20	0	20	0
2	2	20	0	20	0
3	3	20	1	19	5
Average		20	0.3	19.7	1.7

Aedes aegypti mosquito resistance test result in exposure group of 0.05% Cypermethrin insecticide in Karangklesem Urban Village, South Purwokerto District, Banyumas Regency can be seen in the following table.

Table 6. Resistance Test Result of Aedes aegypti Mosquito on Exposure Group

No.	Samples	Mosquitos	Death	Alive	Mortality Rate (%)	Note
1	1	20	7	13	35	Resistant
2	2	20	5	15	25	Resistant
3	3	20	2	18	10	Resistant
Average		20	4.7	15.3	23.3	Resistant

Based on Table 6, it can be seen that the population of Aedes aegypti mosquito in Karangklesem village, South Purwokerto subdistrict, Banyumas regency with 3 times test have Aedes aegypti mosquito death rate: 35% in experiment 1, 25% in test 2, and check 3 as much as 10% with the average percentage of death 23.3%. Thus, it can be said that Aedes aegypti mosquito in Karangklesem Village, District of South Purwokerto, Banyumas Regency has been resistant to 0. 05% Cypermethrin insecticide

In the control group, the test was performed using three sets of test tubes. The experimental procedure is similar to the resistance test in the exposed group. What distinguishes is in the control group it apllies a non-insecticide paper. The death of Aedes aegypti mosquitoes in the control group can be seen in the following table.

Table 7. Aedes aegypti Mosquito Resistance Test Result in Control Group in Banyumas Regency

No.	Samples	Mosquitos	Death	Alive	Mortality Rate (%)
1	1	20	0	20	0
2	2	20	1	19	5
3	3	20	1	19	5
Average		20	0.7	19.3	3.3

Based on Table 7 it can be seen that the control group mortality from Aedes aegypti mosquitoes on the 0.05% Cypermethrin insecticide resistance test in Karangklesem Subdistrict of Purwokerto Selatan District of Banyumas Regency with three times test, the control group mortality rate is 3.3%.

DISCUSSION

The result of temperature measurement shows that the temperature in the study room is 25-26 ° C. In general, mosquitoes will lay eggs at temperatures around 20-30 ° C, so it can potentially breed the Aedes aegypti mosquito [6].

The optimum temperature of mosquito breeding is between 25 ° C-27 ° C and will stop entirely at <10 ° C or> 40 ° C [7]. Thus the temperature of the room in the laboratory is still in optimum condition for the heat of Aedes aegypti mosquito development. The result of initial humidity test measurement and after observed 1x24 hour gets the result between 77-78%. The need for high humidity affects mosquitoes to find moist and wet places as a place to rest or rest. At moisture less than 60%, the age of the mosquito is short [8]. Humidity in the laboratory room is adjusted with moisture in place of mosquitoes to rest or to rest area, so that at the time of mosquito breeding and at the time of the testing process of mosquito in excellent condition and stable.

The test data of resistance with susceptibility test method was obtained from Aedes aegypti mosquito count which died on Cypermethrin 0.05% exposure group after observed for 1x24 hours. Aedes aegypti mosquito resistance test in 0.02% Cypermethrin insecticide group in Jatinegara village, Sempor sub-district, Kebumen regency with three times analysis has Aedes aegypti mosquito average percentage of death = 28.3%. Thus it can be said that Aedes aegypti mosquitoes in Jatinegara Village, Sempor Sub-district, Kebumen Regency have been resistant to 0.05% Cypermethrin insecticide.

In the control group, the test was performed using three sets of test tubes. The death of Aedes aegypti mosquitoes in the mean control group was 1.7%. Due to the control mortality <5%, it does not need to be corrected with the Abbot formula. Aedes aegypti susceptibility or resistance to Cypermethrin 0,05% in Karangklesem Village, District of Purwokerto Selatan, Banyumas Regency known that Aedes aegypti mosquito average percentage of death is 23.3%. Thus it can be said that Aedes aegypti mosquito in Karangklesem Village, District of South Purwokerto, Banyumas Regency has been resistant to Cypermethrin insecticide 0,05%.

Tests on the control group of Aedes aegypti mosquito in Karangklesem Village, District of Purwokerto Selatan, Banyumas Regency were done using three sets of the test tube. The death of Aedes aegypti mosquitoes in the control group was 3.3%. Due to the control mortality <5%, it does not need to be corrected with the Abbot formula.

This way, communities should not always use insecticides in mosquito control but advisable to control by methods of repair or to clean the environment such as eradication of mosquito nest.

Other researchers may conduct susceptibility studies of Aedes aegypti mosquitoes against other types of insecticides or similar research with different research situation to enlarge the generality.

CONCLUSION

The application of insecticides in the control of dengue vectors performed at the study sites (Kebumen and Banyumas districts) by the health authorities has found the use of synthetic pyrethroid insecticides for more than five years. This makes Aedes aegypti mosquitoes in Jatinegara village, Sempor sub-district, Kebumen regency has been resistant to 0.05% cypermethrin insecticide (average percentage of mosquito deaths test of 28.3%). Likewise, the results of mosquito susceptibility test using susceptibility test method showed that Aedes aegypti mosquito in Karangklesem village, South Purwokerto subdistrict, Banyumas district had been resistant to 0.05% cypermethrin insecticide (average of mosquito death rate percentage was 23.3%). This makes the government necessary to find an alternative to combat the mosquito as in ineffectiveness of the insecticide may be one cause affecting the transmission of dengue fever is hard to eliminate.

Conflict of Interest: The authors have no conflict of interests related to the conduct and reporting of this research.

Effectiveness of Hand Hygiene Training by Kirkpatrick Model

Widayanti

Department of Health Policy and Administration, Faculty of Public Health, Airlangga University, Indonesia

ABSTRACT

The aim of this organisational development was to improve Hand Hygiene education and training compliance in Hospital by extension, improve hand hygiene compliance. Hand Hygiene is identified as the single most important intervention in reducing the transmission of Healthcare Associated Infections (HAIs). In 2009, The World Health Organization published comprehensive evidence-based guidelines on Hand Hygiene in healthcare, which introduced a standardized approach to Hand Hygiene practice; "The Five Moments for hand Hygiene". These guidelines have been adopted by the hospital and core to our education and training programme. The model was used to guide this research. The Kirkpatrick model was employed to evaluate the hand hygiene education and training, effectiveness of training at the different levels was being evaluated through construct on the basis of literature review. For level the respondents are who had completed training 7 months earlier. The results indicated that reaction of the participants were positive for training, secondly they had applied skills and knowledge which they had learnt from training. However, advanced research is needed to asses the impact of applying hand hygiene on spread of infection in hospital patient through measuring HAIs rate in this hospital.

Keywords: *Training evaluation, Kirkpatrick model, hand hygiene compliance, HAIs*

INTRODUCTION

Nosocomial infections are a major problem faced by hospitals and they are mostly caused by hand contact. Hand hygiene is the simplest and most effective way to prevent nosocomial infections [(1)]. In accordance with Sung Chin Pan, [(19)] hand washing compliance rate is still low on health workers. An education and training program on hand hygiene is needed to provide knowledge, understanding, and improve skills for hand hygiene according to WHO's Hand Hygiene five-point guidance.

Hand Hygiene Training helps health workers to understand the knowledge and skills needed to perform their daily work by prioritizing patient safety [(14)]. By evaluating Hand Hygiene Training of Kirkpatrick's four levels model it is expected to be measured the training effectiveness, the improvement efforts can be done for the implementation of further training or as a proposal to management and organization to improve the implementation of hand hygiene so as to achieve organizational goals in accordance with key indicators that have been set.

Training and Development

Education and training is the process of adding, encouraging and updating the knowledge, skills and abilities of human resources to move towards better performance in accordance with organizational goals [(6)]. It also encourages organizational commitment, improves employee's performance to address internal and external challenges, encourages increased knowledge and improves skills, work process efficiency, problem solving development and also builds self confidence that will has impact on performance improvement [(7)].

Education and training programs should be evaluated to determine how efforts to improve the next program, to determine whether the program needs to be continued or not and to determine the performance of the education and training units and the determination of the budget [(7)].

Training Evaluation Model

Kirkpatrick Model

An easy-to-apply training evaluation model is Kirkpatrick's four levels [(10)]

a. Reaction; The measured aspect is the level of satisfaction of the training participants on the training implementation, including elements of materials, implementation, means, and instructor's ability. The material elements are divided into systematics and presentation of the material, the ease of the material to be understood, the contribution of the material in the enhancement of knowledge and insight and it can be applied to the work, and the conformity of the material with the training objectives. The implementation elements are divided into several sub-elements of conformity with the stipulated schedule, the timeliness of the training, the willingness of the committee to assist the trainees. The elements of facility are divided to be sub-elements of audio-visual or visual aid quality, consumption, seminar kits, room and room facilities (light, wide, acoustics and ventilation). Elements of instructor's ability are divided into sub-elements of material mastery, delivery techniques, how to answer questions, language and gestures. The evaluation is done by using a questionnaire that should be filled by the trainees at the end of the training session.

b. Learning; The measured aspect is the addition of knowledge and understanding level of the participants after the training. The measured result is the learning result rather than the impact on the trainees' performance. Evaluation is done by providing pre-post test at the beginning and end of the training session.

c. Behaviour; How the behaviour change occurs in each individual trainees, this means how the knowledge acquired during training can be developed into skills improvement and applied in daily work.

d. Result; It is the process of measuring how the training program has impacts on the achievement of organizational goals, as a result of improving the trainees' performance. In this case the evaluation is done by looking at the hospital key indicator that is HAIs rate.

Hand Hygiene and Healthcare Associated Infections (HAIs)

The presence of close relationship between hand hygiene compliance and reduced risk of HAIs infection [2,3]. Hand Hygiene is the foundation of the patient's safety which will always be applied with the prescribed procedures in each process of patient care. But the low compliance rates are a common problem commonly found in health care [25]. This is what causes the transmission of microorganisms that causes HAIs can not be avoided. The high compliance rates of hand hygiene and the existence of organizational policies on this matter have an impact on the decrease in hospital HAIs [3]. The key are not lies only in health workers, but also the policies and commitments of leadership.

The effectiveness of hand hygiene compliance measurements requires the same perception of hand hygiene process terminology, which includes indications, opportunities, and actions [4].

Indication is a rational principle that becomes the basis to conduct hand hygiene. The hospital should have written policy on technical and indications to conduct hand hygiene. In accordance with WHO's Manual for Observer, the definition of hand hygiene indication "is the reason why hand hygiene is necessary at a given moment". It is based on the risk of transmitting microbe from one surface to another, using terminology before and after contact. Some examples of indications for hand hygiene based on both WHO and CDC are as follows:

- Before contact with patient
- Before performing aseptic action
- After contact with blood or blood products and body fluids
- After contact with the patient
- After touching the environment around the patient

When measuring the compliance rates, it should be clear about these indications, in accordance with WHO, it was referred as "Five Moment Hand Hygiene" [1]. Opportunities represent an opportunity to perform hand hygiene in a period of time when health workers perform patient care in accordance with prescribed indications. Action shows the performance of health workers while performing hand hygiene. Every opportunity will always be followed by the implementation of hand hygiene conducted by health workers.

HAIs (Healthcare Associated Infections) are an infection that occurs during the patient receiving care at the hospital or other health facility, the infection is not found or not being in an incubation period at the time of patient's arrive. Included in this definition are infections acquired in hospital but only show symptoms

after the patient was departed from the hospital. WHO [1], Global data on HAIs is currently very limited, but it is generally mentioned that the prevalence of HAIs in developing countries is higher than developed countries (10.1% - 7.6%). The most commonly found infections are those related to the use of invasive instruments or procedures i.e. catheter associated urinary tract infection (CAUTI), central-line associated bloodstream infection (CLABSI), ventilator associated infection (VAP), and Surgical Site Infection (SSI), some include peripheral IV line Infection or Phlebitis. HAIs can be prevented by doing hand hygiene that is the key to patient-based care, because hand hygiene is the easiest, cheapest and effective procedure to prevent HAIs [2]. The research objectives are to evaluate the effectiveness of hand hygiene training with Kirkpatrick' framework including 4 levels: reaction, learning, behaviour, and results.

MATERIALS AND METHOD

Hand hygiene training evaluation was conducted in January 2018 while the Training of Infection Prevention and Control which contained Hand Hygiene material was held in May 2017. As the priority participants were the workers of Surabaya Islamic Hospital who served in high risk units such as Operation Room, Maternity Room, Haemodialysis Unit, Laboratory Unit, Radiology Unit, ICU, *Zam-zam* Room (Neonatus), Emergency Unit, Nutrition Unit, and Sanitation and Environmental Health Unit. Training location is at meeting room of Surabaya Islamic Hospital. Training was conducted for two days starting at 08.00 up to 16.00 o'clock. The numbers of trainees in the initial stage are 30 participants. The training instructor is the team of Infection Prevention and Control that has been certified in basic level of IPC training.

This study focuses on evaluation of Hand Hygiene training based on Kirkpatrick's four level model, including reaction from trainees, learning after training, behaviour change after training, and training contribution to the achievement of hospital key indicator. For level 1, evaluation was performed by filling out the questionnaire of trainees' satisfaction. Level 2 was assessed from the pre-post test of trainees based on the WHO's Hand Hygiene Knowledge Test questionnaire. For level 3, the evaluation was performed by measuring the hand hygiene compliance rate, which was assessed after 8 months post training. The training compliance rate would be compared to the unattended-training health worker. Hand hygiene compliance measurements were performed with the WHO tool, i.e. HHOT (Hand Hygiene Observational Tools), and calculated using the *Epiinfo* method. Level 4 was measured from the hospital's key indicator that is hospital's HAIs rate.

FINDINGS AND DISCUSSIONS

Effectiveness of Level 1 Reaction

In overall the training process was well organized, the weakness is only on facilities and infrastructure factors that is limited space, and training time is too short compared with the given material density.

Measurement of trainees' perception of the implementation of each element are: it is said not satisfied with the range below 50 to 60, it is said less satisfied if the range between 61 to 70, it is said satisfied if the range of values between 71 to 80, and it is said very satisfied if the range above 81 to 100.

Islamic Hospital, 2017

Effectiveness of Level 2 Learning

The measured aspect is the trainees' understanding of the training materials. Prior to the training, a questionnaire was handed out based on WHO's tool "Hand Hygiene Knowledge Test" and at the end of the training session was done post test with the same questionnaire.

From the result of pre-post test given during Hand Hygiene training, it is seen that there is an increase of knowledge from the training participants, where the knowledge is expected to increase their awareness to do hand hygiene in accordance with the established moment. With increasing knowledge it will encourage self confidence of workers to apply the learning culture gained during the training.

Table 2 The increasing result of Pre and Post test

Pre Test	**Post Test**	**Increasing**
40.2	81.73	41.57

Effectiveness of Level 3 Behaviour

The impact of hand hygiene training that has been done shows the difference in compliance rate between health workers who received training and who did not. With increased knowledge it is easier for health workers to recognize risk factors for the transmission of microbes through the hands of health workers, and disconnect the transmission chain by applying hand hygiene according to established guidelines. Increased knowledge gained during training will also encourage the self confidence of health workers to apply hand hygiene skills to their daily work according to the steps in the guidelines.

Effectiveness Measurement of Level 4 Result

Assessment of effectiveness at the previous level should be illustrated at the level 4. With the development of knowledge and skills of health workers, they have the provision to make changes in behaviour in their daily work. The HAIs rate as a key indicator of the hospital will describe the level of workers' compliance in hand hygiene, because the largest medium of microbe transmission is through the hands of health workers.

Limitations of the study are the duration of research between training programs implemented and the time of research that are only about 7 months, it can not describe the trend of HAIs rate. With sufficient knowledge of the basics of prevention of infections acquired during the training program it is expected the cases of HAIs such as SSI, CAUTI, VAP, CLABSI and Phlebitis can be found through the implementation of hospital surveillance. From the results of research, the HAIs rate is still below the standard set by the hospital that is 2% for SSI and 15% for Phlebitis.

Table 4 HAIs rate of Hospital

December	4%0	0.5%	0	0	0

Source: IPC Committee of Surabaya Islamic Hospital, 2017

CONCLUSION

The research shows that hospital workers show increased knowledge and skills after following the hand hygiene training program. Therefore, hand hygiene training program must be done continuously. It is need further research to see the impact of HAIs rate in hospitals that are closely related to the transmission of microbes that are distributed through the hands of health workers.

Quantitative Risk Assesment of Crystalline Silica Exposure in Ceramics Industry

Moch.Sahri[1], Abdul Rohim Tualeka[1], Noeroel Widajati[1]

[1]Department of Occupational Health and Safety, Airlangga University, Surabaya, Indonesia

ABSTRACT

Crystalline silica can be found in Ceramics Industry. Ceramics are basically made of clay, feldspar and silica sand. Ceramics manufacturing process starts from the processing of materials, forming, drying, burning and gazing. Crystalline silica consists of three types of quartz, tridymite and cristobalite which are distinguished by their forming temperature. Crystaline silica dust is very dangerous for health workers are exposed continuously it can cause a silicosis. Prevention and control efforts can be done one of them by conducting a risk analysis study on crystalline silica exposure. In this research will be discussed about the analysis of crystalline silica exposure into production workers in the ceramics industry.

The purpose of this study was to assess the risk level of crystalline silica due to silicosis. Subjects in this study were 47 production workers with the exposure to crystalline silica between 0,007 – 0,4 mg / m^3. From the result of risk analysis, it was found that 42,6% of workers had unsafe risk which was confirmed by radiology examination was 6,4% of workers with abnormal condition. Complaints experienced by workers include shortness of breath, cough and phlegm. Long term exposure to 5-20 years to the next tends to increase the risk of the effects caused by exposure to crystalline silica. Based on the results of this study it is recommended that decision makers take action to implement effective risk management strategies to prevent the long-term effects of crystalline silica exposure to the workplace.

Keywords: *risk analysis, crystalline silica, ceramic industry*

INTRODUCTION

Exposure to the existing hazards in the work environment in the ceramics industry most widely encountered is silica dust, total dust and heat pressure. Silica dust is the main pollutant in the ceramics industry because it is one part in the raw material. Crystalline silica is one of the most widely encountered minerals of the earth, with wide exposure in working environments and ambient environments[1]. silica belongs to Group 1 substances that are carcinogenic in humans[2]. In China, the association with silica dust exposure and mortality from all causes of respiratory illness, respiratory tuberculosis, and cardiovascular disease is significant[3]. Worldwide estimated at least two to three million workers work roughly exposed to silica each year[1]. Silica crystal dust is inhaled from the work environment can cause pulmonary fibrosis (silicosis), decreased lung function, pulmonary inflammation, and lung cancer have been associated with glomerulonephritis and disorders of the liver, spleen, and immune system[1]. The prevalence of silicosis data varies from country to country. Studies conducted in the United States show that there is 3600-7300 new cases of silicosis per year in 1987-1996[3]. Studies conducted at a cement plant found radiological silicosis suspicion of 0.5%[4] . A study conducted at one of the cement plants in West Java showed that the incidence of silicosis was 2.06% in 1990-2003[5]. A previous study showed that 32% of ceramic material samples contains free silica throughout the Taiwan[6].

Several recent epidemiological studies have shown that the present value of standard silica dust are insufficient for guidelines to protect and prevent chronic silicosis[6]. The threshold value of crystalline silica dust

Correspoding author :
Dr. Abdul Rohim Tualeka
Email : inzut.tualeka@gmail.com

in Indonesia is based on the Ministry of Manpower and Transmigration No. PER.13 / MEN / X / 2011 on the threshold value of physics and chemical factors in the workplace set at 0.05 mg / m^3 [7]. Cases of pneumoconiosis ranked first Occupational Diseases (OD) in Japan and China[8]. Based on the silicosis surveillance program in Ontario it was found that the incidence of silicosis was a significant increase in more than 8% of respondents after exposure to silica dust for 35 years [9]. The risk analysis approach is one way to determine the level of risk due to crystalline silica dust present or some future time making it possible for early prevention efforts.

METHOD AND MATERIAL

This type of research is descriptive research using quantitative analysis method. The study design used was a risk analysis method taken from risk analysis steps, risk management, and risk communication used to assess and predict the occurrence of health effects as a result the presence of a hazardous exposure to this case is exposure to crystalline silica. The design of this research is cross sectional where the environmental data collection (silica dust measurement) and taking of rontgen photo taken at same time period. The population of this study are all workers that work in the production section from the processing of raw materials to packing which amounted to 50 people. The sample of this study is the total population with the exclusion factor of workers not suffering and never exposed from tuberculosis, so the sample in this study amounted to 47 people. The measurement of crystalline silica dust in the working environment is based on NIOSH 7500 method of XRD[10].

The risk is calculated based on the amount of intake of agent entering the worker's body so that it can be known how much the risk of health effects on workers. The data and information required to calculate the silica dust intake of the worker's body is all variables in the following [11].

$$I_{nk} = \frac{C \times R \times t_E \times f_E \times D_t}{W_b \times t_{avg}}$$

Level of risk to be expressed in Risk Quotien notation (RQ). To do risk characterization is done by comparing the intake of Rfc from the agent.

$$RQ = \frac{I_{nk}}{RfD \text{ atau } RfC}$$

The Rfc value was obtained using the data onto Chen et al of 6 µg / m3 3. The Rfc unit is converted first into units of m^3 / kg / day, by multiplying the Rfc value with the adult inhalation default value of 20 m^3 / day and dividing by the default value of the adult 70 kg[14]. Risk levels are expressed in numbers or decimal numbers without units. The risk level is said to be safe whenever its intake ≤ Rfc is represented by RQ ≤ 1. The risk level is said to be unsafe when the intake values ≥ Rfc is expressed by RQ ≥ 1[15].

FINDING

Table 1. The pattern of crystal silica dust exposure in production workers

	Concentration of c-silica dust	Respiratory rate (m^3 / h)	Intake of c-silica dust (mg / m3 / day)	Risk Quostion
Mean	0,0686	0,6572	0,00192	2,2343
Median	0,0540	0,6600	0,00129	1,5017
Mode	0,0540	0,66	0,00024	0,0459
Std. Deviation	0,0704	0,0218	0,00260	3,0251
Range	0,4387	0,10	0,01668	19,391
Minimum	0,0078	0,59	0,00004	0,0456
Maximum	0,4466	0,69	0,01672	19,4365

From table 1 the research results can be seen that the concentration of crytaline silica dust at work ranged from 0.0078 - 0.4466 mg / m^3 with an average of 0.0686 mg / m^3. The average respiration rate of workers is 0.6572 m^3 / hour. Intake of silica dust based on exposure pattern and anthropometric data of worker ranged from 0,00004 - 0,01672 mg / m^3 / day with average intake 0,00192. Risk level (RQ) ranged from 0,0456 - 19,4365 with value RQ ≥ 1 equal to 42,6% from total respondent. Age of respondents in this study between 23 - 56 years with an average age of 42.38 years. The working period ranges from 2 - 25 years with an average of 18.06 years. Workers work for 8 hours per day with 1 hour break time to exit the workroom so that the effective hours of labor are in the workroom for 7 hours.

Tabel 2. Estimate the value of the risk level of chronic exposure to production workers

Duration	Risk *Quotient* (RQ)	Persentase (%)
5 year	RQ ≤ 1	51,1
	RQ ≥ 1	48,9
10 year	RQ ≤ 1	42,6
	RQ ≥ 1	57,4
I5 year	RQ ≤ 1	34,0
	RQ ≥ 1	66,0
20 year	RQ ≤ 1	29,8
	RQ ≥ 1	70,2

Tabel 2. shows that in the projection of exposure over the next 20 years an increase in the value of RQ ≥ 1 can be interpreted that there is an increased risk due to exposure to c-silica dust up to 20 years in the future.

DISCUSSION

Continuous exposure to c-silica dust can have both long-term and short-term effects[16]. The source of c-silica dust part production comes from raw materials in the form of clay and silica sand containing free silica that make ceramic to be harder and stronger[12]. The heating process in the production process to a temperature of about 1200 ^oC will also form another fraction of the more reactive c-silica dust. The level of c-silica dust has a uniform distribution throughout the workplace with an average grade of 0.068 mg / m^3. The temperature used in the production process will also affect the convection and radiation to the temperature rise of the work environment. The working environment temperature ranges from 31.3 - 36.6 ^OC which makes the c-silica dust become drier and lighter so it is easily carried by the airflow present in the work environment and can expand the spread of the dust. Silicosis is still present in workers who die affected by exposure to silica dust between 0.05 - 0.1 mg / m^3 [3]. From the result of the measurement of c-silica dust in the working environment by using personal sampler on each respondent got result that exceeds limit value based on Indonesia regulation (Ministry of Manpower and Transmigration No. PER.13 / MEN / X / 2011) amounted to 55.3%. The value of concentration is very influential on the value of intake in workers the higher the concentration of dust c-silica in the work environment the higher the value of the intake so that the value of risk will also increase[11].

Chest radiography can be used to assess the exposure of silica dust. The interpretation of the results of a thorax examination should be done using the radiographs of pneumoconiosis guidance from the ILO[13]. Based on the calculation of risk values over the next 20 years based on table 2 there is an increased risk. This happens because exposure to c-silica dust is prolonged even further if not effectively controlled[16].

CONCLUSION

From this study it can be concluded that 42.6% of respondents mempuyai unsafe risk level of exposure to c-silica dust so potentially health problems due to exposure to c-silica dust. Based on the estimated calculation of chronic exposure risk, the risk level tends to increase to the next 20 years.

Central Obesity as a Risk Factor for Hypertension in Women : in Bogor District

Melly Kristanti[1], Helda[2]

[1]Master Program in Public Health, Faculty of Public Health, University Indonesia, Campus of Depok, West Java, Indonesia, [2]Department of Epidemiology, Faculty of Public Health, University Indonesia, Campus of Depok, West Java, Indonesia

ABSTRACT

Hypertension in women is increased by 30.9% and 26.6% of central obesity in Indonesia. The purpose of this study is to study the relationship of central obesity with hypertension in women aged 18 years and over in Bogor District year 2016. This study used cross sectional design with *cox regression analysis*. The analysis is used to see how much impact of Central Obesity with hypertension incidence after backward elimination procedure test. Total sample in this study was 525 samples. Results from this study showed an influence of age > 45 years on the association of central obesity with hypertension in women with a PR of 1:56 (95% CI 1084-2120) and the discovery of potentially confounding variables which is age. The risk of central obesity with hypertension increased after controlled by age as much as PR 1:52 (95% CI 1:07 to 2:16). Central obesity affects the incidence of hypertension in women. It is suggested that all women to increase physical activity, adjusting the diet and conduct regular health checks to maintain the weight to avoid central obesity.

Keywords: *Central Obesity, Age, Hypertension, Women, Health*

INTRODUCTION

Hypertension is a global public health problem. Hypertension is often called the silent killer, because there was no physical signs of high blood pressure and there is no record of complaints in patients with hypertension.[1] According to WHO (World Health Organiation) in 2011, 1 billion people worldwide suffer from Hypertension and two thirds of them are from low and middle-income developing countries. Hypertension in women has increased around the world in this decade. Especially in Indonesia, Hypertension in women is higher than in men. [2]

Hypertension is the latest issue to be considered in the Sustainable Develompment Goals (SDGs) program. Therefore, there is Presidential Instruction No. 1 of 2017 on Healthy Living Community Movement. The purpose of this movement is to improve prevention and early detection of diseases, especially on Non Contagious Diseases in Indonesia. One way of this GERMAS program is to check blood pressure once every month at POSBINDU in every area of the first health facility in Indonesia.[3]

Central obesity mechanism for hypertension could lead to unbalanced glucose tolerance. High levels of insulin would circulate and reduce the sensitivity of insulin metabolic activity. These conditions could lead to hyperinsulinemia that affects the rise in blood pressure.[4]

Measurement of abdominal circumference can be useful for identifying population-based risk that can cause hypertension in adult women. A study revealed that an increase in the occurrence of hypertension is influenced by the increase of abdominal circumference and age in women.[5] Another study has also revealed that waist circumference may increase the risk of hypertension. Measurement of waist circumference is one step to prevent the occurrence of hypertension in Asians.[6]

There are many risk factors which caused hypertension, such as age, gender, smoking habit, physical activity, obesity and central obesity, fruit and vegetable consumption, genetic factors, and stress. Hypertension in women can lead to more serious complications than in men. Therefore there should be hypertension prevention for women, especially in women based on risk factors. In addition, hypertension in menopausal women can contribute to an increase in incidence of hypertension. This incidence has relation to the loss of estrogen and pituitary hormones because they are produced in excess, their weight gain or a combination of other influences. Moreover, in infertile women, there are some who use oral contraceptives. Oral contraceptives could cause sodium buildup, increase fluid volume / plasma, and could increase weight. The use of oral contraceptives with more than (> 50μgr) could cause hypercholesterolemia in women.[7]

Several studies conducted in Indonesia shows that central obesity has a significant relationship with hypertension in women.[8] Other studies also explain that central obesity may increase the risk of hypertension by 1.6 times compared with non-obese central ones [9]. Based on the results of the study of Obesity Association of Indonesia in 2004, the prevalence of obesity in women is higher (11:02%) than in men (9:16%).[10] Another study conducted in Bogor District in 2007 explained that abdominal circumference is one of the risk factors associated with the incidence of hypertension.[11]

Bogor District is an area that has a high prevalence of hypertension and central obesity. Prevalence of hypertension in Bogor district is 27.6% while central obesity is 24% in 2013. This study was conducted in Bogor District. However, prevalence of hypertension and central obesity in women aged 18 years and above is not known. Therefore it is necessary to conduct research related to central obesity and hypertension in women in Bogor District.

MATERIALS AND METHOD

This research is a quantitative research with cross sectional study design using secondary data of GERMAS 2016. The data is a data of Bogor District. This design observes and measures the main risk factors (central obesity) and other risk factors (age, physical activity, smoking, total cholesterol, also fruit and vegetable consumption) and the measurement of dependent variables (hypertension) at the same time. The variable in this study is limited to the variables which available in the data GERMAS 2016. Estimated minimum sample in this study is 260 samples which determined by using two sample populations / two tail with a power of 80%. The analysis uses Cox Regression analysis because the prevalence of outcome is more than 10%. Partisipant rate in this study is 100%. Samples taken were 525 samples.

It is determined as not Central Obesity when the measurement of abdominal circumference in women is < 80 cm and it is Central Obesity if the result > 80 cm.[11] The age of respondents is grouped using ROC cut off point value, if Not Risk (<45 years cut off point ROC) and Risk (> 45 years cut off point ROC). The measurement in hypertension variabel is conducted when someone has a result of systolic blood pressure ≥140mmHg and or diastolic blood pressure ≥ 90mmHg. Not hypertension if the systolic blood pressure is < 140mmHg and or tekanan diastolic blood pressure < 90mHg.[12] Physical activity is determined as Enough if the frequency is 3-5 times a week with duration of at least 150 minutes / week. However it is determined as Less activity, if it is less than 3-5 times a week with duration of less than 150 minutes.[13] A person who is exposed to secondhand smoke either as an active smokers or as a passive smokers,[14] Cholesterol levels in the blood, if the total cholesterol level > 200 mg / dL it is high whereas if the total cholesterol level <200mg / dL it is low [15] and the average consumption of fruit and vegetable intake > 5 servings per day.[16]

RESULTS

In this study a multivariate cox regression analysis was used to examine the relationship between central obesity and hypertension occurrence in women aged 18 years and over after controlled with age, total cholesterol, physical activity, fruit and vegetable consumption and smoking. In **Table 1** from 525 respondents, 49.71% women aged 18 years and over suffered from hypertension while 50.29% had normal blood pressure. In addition, women who are central obesity is recorded at 77.33% whereas there are 22.67% of those women who is not central obesity. Percentage of female respondents by age group 46-55 years at most is 29.71%. The percentage of women whose physical activity is less is 66.67% compared with the physical activity which is enough has 33.33%, the percentage of women who are active smokers or passive smokers exposed by

cigarette smoke is lower at 48.57% than unexposed or non-smokers at 51.43%, the percentage of women who consumed less fruits and vegetables is lower which is 48.57% compared with women who consumed enough fruits and vegetables has 51.43%, and the percentage of women which has a high cholesterol levels is lower at 30.67% compared with the percentage of women who have low cholesterol levels which is 69.33%.

Table 1. Frequency Distribution of Hypertension In Women

Variabel		n	%
Hypertension	Hipertensi	261	49,71
	Normal	264	50,29
Central Obesity	Central Obesity	406	77,33
	Normal	119	22,67
Age	18-25	26	4,95
	26-35	84	16
	36-45	145	27,62
	46 – 55	156	29,71
	56-65	82	15,62
	>65	32	6,10
Physical activity	Less	350	66,67
	Enough	175	33,33
Smoke	Yes	255	48,57
	No	270	51,43
Fruit Vegetable Consumption	Less	255	48,57
	Enough	270	51,43
Total cholesterol	High	161	30,67
	Low	364	69,33

Based on **Table 2**, the stratified analysis results shows that age > 45 years is at risk for the occurrence of central obesity with hypertension 1.516 times higher compared with age < 45 years that not has a strong enough risk for the occurance of central obesity with hypertension. From these results we could say that the age affect central obesity with hypertension. The prevalence of central obese women aged 45 years and over suffer from hypertension is higher at 64.44% compared with the women who is not central obese at 42.86%. Furthermore, in central obese women aged under 45 years suffering from hypertension is higher at 37.58% compared with non-central obesity at 24.29%.

Table 2. StratificationAnalysis Central Obesity with Hypertension Adjusted by Age In Women

Variabel		**Hypertension**		**PR (95%CI)**	**p-*value* Test homogenity**
		Hypertension (%)	**Normal (%)**		
Age ≥45	Central Obesity	167(64,44)	90(35,02)	1,51 (1,084–2,12)	0,98
	Normal	21(42,86)	28(57,14)		
Age < 45	Central Obesity	56(37,58)	93(62,42)	1,54 (0,97-2,45)	
	Normal	17(24,29)	53(75,71)		

Based on **Table 3** it could be seen the relationship of central obesity with the incidence of hypertension in women after being adjusted with other variables. The risk of central obesity is 1.55 (95% CI 1.09-2.20) times occurrence of hypertension in women after adjusted by age, total cholesterol, smoking, consumption of fruits and vegetables and physical activity. The result shows that age is a confounding variable against the relationship of central obesity with the incidence of hypertension. Where the risk of hypertension is higher in age compared with central obesity, age may increase the risk of occurrence of hypertension in women by 1.69 times.

Table 3. Association of Central Obesity with Hypertension in Women

Variable	Coeff	P	PR	95% CI	
				Lower	Upper
Central Obesity*	0,439	0,014	1,55	1,09	2,20
Age*	0,524	0,000	1,69	1,27	2,23
Total Cholesterol	0,113	0,399	1,12	0,86	1,45
Smoking	0,215	0,088	1,24	0,96	1,58
Consumption of fruit and vegetable	- 0,136	0,349	0,87	0,65	1,16
Physical Activity	- 0,082	0,607	0,92	0,67	1,26

PR; Prevalens Ratio, CI; Confidence Interval * P <0.0,5 test using multivariate Cox Reggresion (adjusted by covariate variable: age, total cholesterol, smoking, fruit and vegetable consumption and physical activity).

Based on **Table 4**, the relationship of central obesity with hypertension at risk of 1.52 (95% CI 1.07-2.16) times greater after controlling it with the age variable. It could be argued that women with central obsessions will develop hypertension as much as 1.52 times greater than those who are not central obesity after being controlled by age. The results of this analysis indicate that there is still a significant relationship between central obesity and hypertension in women after controlled by age.

Table 4. Final Model of Cox Regression Association Central Obesity with Hypertension In Women

Variable	p-value	PR	95% CI	
			Lower	Upper
Central Obesity*	0,017	1,52	1,07	2,16
Age*	0,000	1,73	1,32	2,28

PR; Prevalens Ratio, CI; Confidence Interval * P <0.0,5 test using multivariate Cox Reggresion (adjusted by confounding variable: age).

DISCUSSION

Analysis has been done to prove the relationship of central obesity with hypertension after controlled with covariate variables. It was revealed that the relationship of central obesity with hypertension has a significant relationship after controlled by confounding variable which is age. The effect of central obesity with hypertension after controlled by risky age was 1.52 (95% CI 1.07-2,16), while the effect of age on the relationship of obesity with hypertension is 1.73 (95% CI 1.32-2 , 28). The effect of age on the relationship of central obesity with hypertension is higher, therefore age variable is a confounding variable to the relationship of central obesity with hypertension. However, central obesity has a significant relationship with hypertension even before or after controlled by other variables, especially by the age variable. A study conducted by Jenssen explains that an increase in the age of a person, increases the risk when entering the age of 40 years to 59 years, after age of 60 years and over, the incidence of hypertension with central obesity is lower than when entering the age of 40 to 59 years. But these results explain that the increasing size of a person's abdominal circumference increases the risk of sickness in an aged person.[17]

According to Poirier measurement of abdominal circumference can prevent the risk of increased systolic blood pressure and diastolic blood pressure after adjusted by age, sex, BMI and insulin resistance intake. Previous studies have found that abdominal circumference is a major determinant of hypertension. Research conducted in a cohort study by American and Japanese people found that a person whose stomach circumference is at risk can suffer from hypertension with more than 40%. This number is higher when a person with central obesity is exposed to hypertension is women rather than men after being adjusted by age.[18] The abdominal circumference increases with age and higher at older age than younger ones. Increased abdominal circumference is higher in women which is 4.3cm per 15 years[19]

Research conducted by Snijder explains that age is one of the effect on the relationship of central obesity with the incidence of hypertension, especially in women. Women aged> 35 years with central obesity are associated with increased diastolic blood pressure and systolic blood pressure.[20] Excessive abdominal circumference and increasing age is a risk for the occurrence of hypertension. This study proved, that women who are central obesity and at age 45 years has greater risk of hypertension. The risk of central obesity in this study on hypertension after adjusted by age is still quite high.

CONCLUSION

Central obesity affects the incidence of hypertension in women. The older a person is, the greater the risk of hypertension when central obesity. It is suggested that all women to increase physical activity, adjusting their diet and conduct regular health checks to maintain the body weight, so they can avoid central obesity.

ABSTRACT

Healthy lifestyle is a major strategy to promote current and subsequent health status. Lifestyle is the way of living of individuals, families, and societies which can be healthy or unhealthy. The objective of the present study was to find out healthy promoting lifestyle level and its associated factors among the private university students in Shah Alam, Malaysia. A cross- sectional study was conducted among 500 students using convenience sampling. Self-administrated questionnaires with 52 items of health promoting lifestyle habits with 6 subscales was used. The results showed that mean score of health promoting lifestyle scale was 136.18 ± 22.48. Half of the respondents found to have normal weight (50.2%) followed by (28.4%) overweight and (12.4%) obese. The association between gender and health promoting lifestyle was significant (P<0.001). While, Body Mass Index was not significantly associated with health promoting lifestyle (P=0.837). As a conclusion, the mean score of healthy lifestyle practice was 136, prevalence of overweight and obese was (40.8%) among university students. More promotion is needed in promoting healthy lifestyle.

Keywords: *Healthy promoting lifestyle, obesity, university students.*

INTRODUCTION

Healthy lifestyle is a major strategy to promote current and subsequent health status. The aim of this study is to assess the status of health promoting the lifestyle and its determinants among university students Health promotion is a process for empowerment of individuals in order to improve their health status. The definition of an individual from health is placed in the center of individual viewpoint toward health promoting behaviour. At this level, health is defined as using some positive qualities recommended by World Health Organization. Health is the fulfillment of human potential, maintenance of balance and goal orientation in the environment [1]. Considering the changes happened in the study modes and living in campus dormitories, there is an assumption that many students may experience a wide range of unhealthy habits such as high level of fast food intake, low level of physical activity and irregular sleep, as well. Moreover, the young age of students may lead them to believe that they are in good health, and this would be a possible reason why they are not very conscious of their health behaviours [2].

Healthy life depends on many factors, including genetics, but certain habits can have a major effect. Health lifestyles are important for health and social identity, yet little is known about their development in early life [3].

The health habits of university students are a special concern, since they represent a major segment of the young population and they are at a stage of their lives during which important lifestyle modifications take place [4]. high prevalence of risk factors for chronic diseases and poor health-seeking behavior, despite accessibility and affordability to all levels of health care [5].

Based on Pakseresht et al. 2017 [6] study which measured six domains of health promoting lifestyle by using the 52-item Health Promoting Lifestyle Profile (HPLP II). Convenient sample of 343 students from the University was selected in 2013-14. While girls scored higher in eating habits and health accountability, boys did better in physical activity. However, the scores of all

these three dimensions were undesirable in both genders. Conclusion of Health Promoting lifestyle scores were undesirable in university students and significantly related to eating and physical activities. Therefore, there is an urgent need of developing program on healthy lifestyle for them.

The aim of the present study was to find out healthy promoting lifestyle level and its associated factors among the private university students in Shah Alam, Malaysia.

METHODOLOGY

A descriptive, cross-sectional study design is used in this study which was carried out from September 2016 until February 2017 in private university in Shah Alam. The sample size required for this study was 500 respondents. This calculation using the single population mean formula.

A validated self-administrated questionnaire with 52 items [7] was distributed to 500 students. The questionnaire compromised of five sections which are:

Part A: Socio-demography. Composed of five questions.

Part B: Subscales include Health Responsibility with 9 items, Physical activity with 8 items, Nutrition with 9 items, Spiritual Growth with 9 items, Interpersonal Support with 9 items, and Stress Management with 8 items. Composed of 52 questions in total.

The raw data were checked for any exclusion, legibility and consistency before being coded for analysis. For the purpose of data analysis and hypothesis testing, several statistical tests were applied using the Statistical Package for Social Science (SPSS) version 20.0. Score for overall health promoting lifestyle is calculated by the mean of the 52 items by scoring 1 (never), sometime (2), often (3), routinely (4). The maximum total score for each subscale ranged from 32 to 36 and minimum total score for each subscales ranged 0-18. Respondents independent t-tests, chi square test, one-way anova test were used to identify any statistically significant associations between explanatory independent and outcome variables.

This study has been approved by the International Medical School of the Management and Science University (MSU) Shah Alam. Respondents are entitled to choose freely to participate in the study without any coercion. The respondents were assured that participation in the survey was voluntary and all the information will remain confidential. All participants will be given written informed consent. The participants confidentially details in the questionnaire will be kept secured. Questionnaire will then be collected upon completion.

RESULTS

A total of 500 respondents who participated in this study fulfilled the criteria of inclusions and had answered the given questions with the answer of their choice.

Table 1 shows the frequency of respondents according to the gender of 500 respondents. It show the percentage of male and female was same (50%). The lowest race is India with 148 respondents (29.6%). Body Mass Index (BMI) show half of the respondents is a normal weight (50.2%). Body Mass Index (BMI) show half of the respondents is a normal weight (50.2%).

It shows physical activity is the lowest mean among six subscales with 18.64 ± 4.99. The highest mean of subscales is spiritual growth with 26.88 ± 5.91. The total score is 136.18 ± 22.48 with the maximum of total mean is 191.

Table 3 show the male are overweight and obese with 110 students (44%) compared to the female with 94 students (37.6%). The p value is not significant (p=0.145).

It shows the mean of total score health promoting lifestyle for male is higher than a female with 138.49 ± 23.45 and 133.87 ± 21.25. Moreover, there is association between gender and health promoting lifestyle with p value is significant with (p=0.021). Alternative hypothesis is accepted.

Table 5 show India has the highest mean of health promoting lifestyle among Chinese and Malay with 137.28 ± 21.07. The p value is not significant (p=0.051). There is no association between health promoting lifestyle and race. Null hypothesis is accepted

DISCUSSION

The main finding of our current study that, the mean score of healthy lifestyle practice was 136 out of 208 , prevalence of overweight and obese was (40.8%) among university students.

Our results about healthy lifestyle was better than previous study done in Guangzhou city, mainland China. The mean score for each of the six dimensions was lower than 70. Gender and grade were the factors primarily associated with health-promoting lifestyles among undergraduates [8] .

Based on (Motlagh et al. 2011) [9] , the overall health-promoting lifestyle profile had a mean of 130.31 ±19). The highest mean in the subscales was 26.03±5.04) for spiritual growth and the lowest was 16.24±4.28) for physical activity. Based on this previous study results, there are the same results according to my current research study which is female students have a low mean of total score of health promoting lifestyle of female students (136.18 ± 22.48). Also lowest subscales for physical activity (18.64 ± 4.99) with mean of female (17.43) than male (19.86) and the highest subscales also same which is spiritual growth.

Body Mass Index (BMI) in our study showed that half of the respondents is a normal weight (50.2%). Its followed by overweight with 142 respondents (28.4%), and obese with 62 respondents (12.4%). Its show the student of the not have the a good health lifestyle according to a total of the overweight and obese of students is considered high with almost half of the respondents (40.8%). Poor diet and its consequences like obesity is the common healthy problem in urban societies. Unhealthy lifestyle can be measured by BMI. Urban lifestyle leads to the nutrition problems like using fast foods and poor foods, increasing problems like cardiovascular. More promotion and campaign about awareness of obesity is needed to prevent further complication of chronic disease for example diabetes, heart disease, coronary heart disease, heart attack, high blood pressure.

According the previous study by (Najat Yahia, et al. 2008) [10], they conclude that majority of the students (64.7%) were of normal weight in Lebanese university students. It shows that the normal weight was higher than the obesity and overweight. Similar findings of prevalence of obesity among male university students were reported in recent studies. High prevalence rate of overweight and obesity was also reported in a study conducted in Kuwait University among 842 students, at 32% and 8.9%, respectively [11].

Regarding the race, Indian has the highest mean of health promoting lifestyle among Chinese and Malay with 137.28 ± 21.07. The second highest mean is Chinese with 137.21 ± 24.28. Malay has the lowest mean among the race with 134.29 ± 21.72. It is possible because of the culture and ethnics based on each race and religions. There are no comparison with previous study between health promoting lifestyles and race. But there is a previous study of Religiosity, dietary habit, intake of fruit and vegetable, and vegetarian status among Seventh-Day Adventists in West Malaysia (Tan et al. 2016) [12], Religion has been shown to be salutary on health, and a possible link between religion and positive health outcomes is diet.

Table 1: Socio demographic characteristic of the respondents

Variable	Frequency (N)	Percentage (%)

*Independent t test was performed, level of significant at p <0.05

CONCLUSION & RECOMMENDATIONS

As a conclusion, the mean score of healthy lifestyle practice was 136, prevalence of overweight and obese was (40.8%) among university students.

In view of the results, the respondents show low of health promoting lifestyle profile especially in physical activity level. On top of that, there was a significant association between gender and health promoting lifestyle. Therefore, more the project recommends plans to elevate the poor healthy lifestyles into control into high awareness and practice of health promoting lifestyle. Aggressive health promotional campaigns and social mobilization by relevant agencies are needed to increase knowledge lifestyle diseases. Emphasis should be placed on the limitations, such as seeking early step to control the lifestyles disease to be serious such as control the fast food intake and obesity. Information, education and communication materials maybe provided in areas like schools or colleges making it more accessible for the residents to obtain. Campaign and promotion of healthy lifestyle is needed. And more the physical activity event among university students recommended. In conclusion, in spite of the study and education and communication programs to identify barriers to action and to control the lifestyle and chronic diseases in future among the university student.

Call for Papers / Article Submission

The editor invites scholarly articles that contribute to the development and understanding of all aspects of Public Health and all medical specialities. All manuscripts are double blind peer reviewed. If there is a requirement, medical statistician review statistical content. Invitation to submit paper: A general invitation is extended to authors to submit papers papers for publication in IJPHRD.

The following guidelines should be noted:

- The article must be submitted by e-mail only. Hard copy not needed. Send article as attachment in e-mail.
- The article should be accompanied by a declaration from all authors that it is an original work and has not been sent to any other journal for publication.
- As a policy matter, journal encourages articles regarding new concepts and new information.
- Article should have a Title
- Names of authors
- Your Affiliation (designations with college address)
- Abstract
- Key words
- Introduction or back ground
- Material and Methods
- Findings
- Conclusion
- Acknowledgements
- Interest of conflict
- References in Vancouver style.
- Please quote references in text by superscripting
- Word limit 2500-3000 words, MSWORD Format, single file

All articles should be sent to: **editor.ijphrd@gmail.com**

Are Body Image Issues Affecting Our Adolescents? A Cross-sectional Study among College Going Adolescent Girls

Subhashini Ganesan, S. L. Ravishankar, Sudha Ramalingam
Department of Community Medicine, PSGIMSR, Coimbatore, Tamil Nadu, India

Abstract

Background: Body image relates to how people think and feel about their own body. In today's society, with the growing sense of ideal body image, adolescents try to lose or gain body weight to attain that perfect body. Body image perception is still naive, and this research will try to understand these unexplored areas, where there is paucity of body image-related studies. **Objectives:** The objective of the study is to find out the proportion of girls dissatisfied about body image, and the association of various factors with body image dissatisfaction and to ascertain the weight control behaviors adopted by adolescent college girls. **Methodology:** A cross-sectional study was done among 1200 college girls in Coimbatore. A semi-structured questionnaire was used to collect data on various factors associated with body image dissatisfaction. Body mass index (BMI) of the participants was calculated. **Results:** Body image dissatisfaction was there among 77.6% of the girls. It was found that factors such as higher BMI, sociocultural pressure to be thin and depression were all significantly associated with body image dissatisfaction. The most commonly followed weight control behaviors were eating small meals and skipping meals. Improving the appearance and body shape were the main reasons for weight control behaviors. **Conclusion:** This study establishes the fact that body image dissatisfaction is no longer a western concept and affects Indian adolescent girls to a great extent. Hence, effective interventions have to be planned to increase awareness on ideal body weight and protect our young generation from pressures of negative body image.

Keywords: Adolescent, body image dissatisfaction, body weight, college girls, weight control

Introduction

Body image relates to how people think and feel about their own body. It relates to a person's perceptions, feelings, and thoughts about his or her body and is usually conceptualized as incorporating body size estimation, evaluation of body attractiveness, and emotions associated with body shape and size.[1]

Adolescents are particularly vulnerable to body dissatisfaction due to the physiological, social, and psychological changes they are going through.[2] For adolescent girls, a range of body and social changes take place during and following puberty that can strongly influence their body image and become more pronounced by late adolescence.[3]

Perception of overweight and dissatisfaction with body size, rather than actual weight appears to be a potent force behind girls' dieting and weight control behaviors. Such behavior is related to negative physical and psychological changes and can lead to life-threatening conditions including eating disorders.[4]

With rapid economic development and affluence, there is a progressive shift toward thinness as the ideal body shape and increasing concerns about body weight leading to dissatisfaction.[5]

Factors contributing to body image problems have been studied, and biopsychosocial model of risk factors was developed by Paxton.[6] This model [Figure 1] suggests that biological factors, such as body size, together with individual psychological characteristics such as low self-esteem, depression, and perfectionism, which refers to individuals desire to attain idealistic goals without failing, social influences, and interpersonal interactions, all contributes to the development of body image.

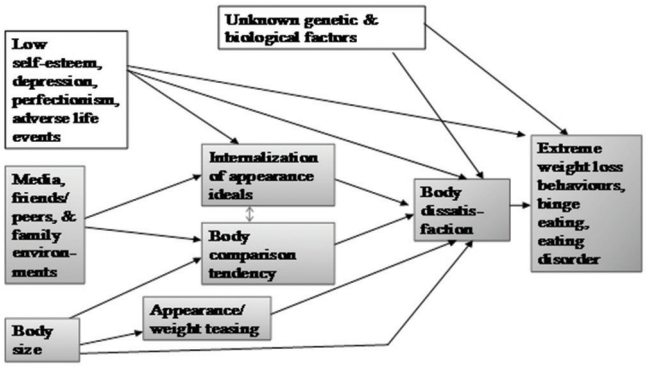

Figure 1: Biopsychosocial model of risk factors for the development of body dissatisfaction by Susan J Paxton

There is a paucity of studies in India and gaps remain in our understanding of the factors responsible for the development of attitudes and behavior related to body weight and appearance among adolescent girls.[7]

Hence, this study aimed to find out the proportion of girls dissatisfied about body image, and the association of various factors with body image dissatisfaction and to ascertain the various weight control behaviors adopted by adolescent college girls.

Methodology

This study was conducted in a college located in an urban area of Coimbatore. With an estimated prevalence of body image dissatisfaction of 33.3% from a study in Mangalore,[8] sample size was calculated to be 978, with the precision of 3.3%, and nonresponse 20%. After approval by the Institutional Human Ethics Committee, 1220 college going adolescent girls in the age group of 18–19 years, were enrolled in the study by convenience sampling. After obtaining informed consent, a semi-structured questionnaire was used to collect the data on body image dissatisfaction and the associated factors namely demographic factors, socioeconomic and media influence, sociocultural pressure, self-esteem, perfectionism, and depression. Furthermore, data regarding weight control measures adopted were collected.

Measuring body image dissatisfaction

Body image dissatisfaction of the adolescents was measured using the Stunkard silhouettes Figure Rating Scale (FRS). It includes drawing of nine silhouettes ranging from very thin (1) to very heavy (9). Students were presented with female versions of the FRS and were asked to identify the figure they currently perceived themselves with, and the figure they would wish to have. Discrepancy scores were calculated based on the difference between the actual and ideal figures chosen. Positive scores indicate a desire to be smaller, while negative scores suggest a desire to be larger. The discrepancies between the current and desired figures were interpreted as an indication of body image dissatisfaction.[9,10] Hence, participants who had discrepancies in the figures chosen were identified as having body image dissatisfaction.

Measuring factors associated with body image dissatisfaction

The factors associated with body image dissatisfaction such as self-esteem, depression, sociocultural pressure, media influence, and perfectionism were measured using previously validated questionnaires and using Likert scale ratings, and score was given.[11-15] Rosenberg Self-Esteem Scale was used to measure Self-esteem with the Likert scales ranging from strongly agree (score 1) to strongly disagree (score 4). Higher scores indicate higher self-esteem.[11] Depression was measured using Center of Epidemiological studies (CES) Depression questionnaire with Likert scale which graded from rarely to mostly with the scoring of 0–3, respectively. Score on the CES-Depression questionnaire range from 0 to 60, with higher scores indicating more severe levels of depressive symptoms.[12]

Socio-cultural pressure was measured with the pressure grading from none (score 1) to a lot of pressure (score 5). The scoring ranges from 10 to 50.[13] Media influence was measured using SATAQ 3 questionnaire with Likert scale grading of completely disagree to completely agree with a scoring of 1–5. The scoring ranges from 14 to 70.[14] Perfectionism was measured using the EDI questionnaire with Likert scale grading from always to never with score from 1 to 6, respectively. The scoring ranges from 6 to 36.[15]

The height and weight of the participants were measured and body mass index (BMI) was calculated. According to the WHO standards in our study, BMI <18.5 kg/m^2 was classified as underweight, a BMI of 18.5–24.9 kg/m^2 was considered normal, overweight is 25–29.9 kg/m^2, and obesity is ≥30 kg/m^2.[16]

The association between the possible risk factors and body image dissatisfaction was assessed by univariate analysis using Chi-square test, *t*-test, and odds ratio was estimated. Those factors found significant by univariate analysis were further subjected to multivariate logistic regression analysis to identify factors that were significantly associated with body image dissatisfaction.

Results

Majority of the study participants (60.6%) were from an urban background. About 67.5% of them belonged to Class I and Class II and 32.5% of them belong to Class III and Class IV socioeconomic status according to modified Prasad classification.[17]

Based on the BMI, about half (53.6%) of them were having normal BMI while 26.7% of them were undernourished, 15.7% were overweight, and 3.9% were obese.

The study showed that 947 (77.6%) girls were dissatisfied with their body image (95% CI: 75.2–79.9). Among the 947 participants who were dissatisfied the mean score of the perceived silhouette figure was 4.0 ± 1.5 (four corresponds to the normal range of BMI), and the mean of the chosen ideal

silhouette was 3.3 ± 0.8 (three corresponds to the lower end of the normal BMI toward the underweight range).

Table 1 shows the distribution of body image dissatisfaction based on the calculated BMI of the participants. It shows that 58.3% of the participants of normal BMI also were dissatisfied with their appearance and wanted to reduce weight. In the underweight category, 23.3% were satisfied, and 7.4% wanted to reduce their weight further showing the tendency of the college students to have a thin appearance. Tables 2 and 3 show the association of body image dissatisfaction with its risk factors by univariate analysis. Higher BMI, higher socioeconomic status, depression, increased sociocultural pressure to be thin, media influence and low self-esteem were found to be significantly associated with body image dissatisfaction.

There was no significant association with the place of residence and perfectionism.

Table 4 shows multivariate logistic regression exploring the association of body image dissatisfaction with those risk factors having statistically significant association with body image dissatisfaction by univariate analysis.

Factors such as higher BMI, higher socioeconomic status, depression, and increased sociocultural pressure to be thin were found to be significantly associated with body image dissatisfaction by multivariate logistic regression analysis.

Among the 1220 students who participated in the current study, 791 (64.8%) of them had undertaken at least one weight control measure in the past 1 year. Of which 157 (19.8%) were satisfied and 634 (80.2%) were dissatisfied with their body image.

Among the multiple options of weight control measures adopted, the most common method was taking small meals (53.2%) followed by skipping meals (42.7%). Extreme measures such as taking laxatives (5.3%) and vomiting after meals (9.7%) were also seen.

Among participants who followed weight control measures, multiple reasons were given by them, of which 61.7% gave improving the appearance and body shape as the main reason for going in for weight control measures and 33.5% said to look better in clothes.

Our study also showed that 67% of participants who were dissatisfied with their body image were adopting one or more weight control measures while in the satisfied group 57.5% have adopted weight control measures. The difference was found to be statistically significant ($P < 0.01$) with an odds ratio of 1.49 (1.13–1.97).

Table 1: Distribution of body image dissatisfaction of study participants based on calculated body mass index (*n*=1220)

BMI status (BMI in kg/m²)	Total number	Frequency of dissatisfaction	
		Increase weight	Reduce weight
Underweight (<18.50)	326 (26.7)	226 (69.3)	24 (7.4)
Normal (18.50-24.99)	654 (53.6)	84 (12.8)	381 (58.3)
Overweight (25.00-29.99)	192 (15.7)	0	185 (96.4)
Obese (≥30.00)	48 (3.9)	0	47 (97.9)
Total	1220 (100)	310 (25.4)	637 (52.2)

BMI: Body mass index

Table 2: Association of body image dissatisfaction with the risk factors (continuous variables) by univariate analysis

Factor	Mean±SD		OR (95% CI)	*P*
	Satisfied	Dissatisfied		
Media influence	37.60±8.96	40.35±8.19	1.04 (1.02-1.05)	<0.001

Higher socioeconomic status	1.28	1.06-1.54	<0.001

BMI: Body mass index, AOR: Adjusted odds ratio, CI: Confidence interval

Discussion

Our study showed that body image dissatisfaction was there in 77.6% of the adolescents. This was similar to a study done by Sasi and Maran in Chennai among adolescents above 12 years of age which showed a prevalence of 81%.[18]

Our study also showed that 23% of the underweight people were satisfied with their BMI, and among those who were dissatisfied 7.4% wanted to reduce their weight further. Similarly, 71% of the normal BMI category was dissatisfied

with their appearance of which 58.3% wanted to reduce their weight. This clearly shows the tendency for liking toward thin body shapes.

Socioeconomic status of an individual impacts their body image perceptions and satisfaction/dissatisfaction with the body. Studies have shown that body image dissatisfaction is seen more among higher socioeconomic status.[19] Our study also showed that the proportion of girls having body image dissatisfaction, who belonged to class I socio economic status are slightly higher than other classes and it was statistically significant.

Studies have also shown that urban adolescents have more body image dissatisfaction compared to rural,[20] but our study did not show any significant association.

Our study also showed that increased socio-cultural pressure, depression and higher BMI had significant association with body image dissatisfaction. Literature also shows that these factors are associated with body image dissatisfaction.[21-23]

Our study failed to show any significant association between body image dissatisfaction and media influence, self-esteem, and perfectionism which were also established in other studies.[24-26]

This study also showed that 64.8% of the college students had undertaken at least one weight control measure in the past 1 year. It also showed that girls who were dissatisfied with their appearance tend to do more weight control measures and the most common weight control measures were eating small meals, skipping meals, and avoiding certain foods. It also showed that the majority of students have cited improving the appearance and to look better in clothes as main reasons for going in for weight control measures. This was also found similar to other studies which showed that appearance was a major motivation for dieting practices.[27,28]

Our study was done in a large sample and measured the different factors which were associated with body image dissatisfaction. The study of these factors is crucial for improving our understanding of body image dissatisfaction in adolescent girls which is still naive in our cultural setup.

Limitations

Although the study area was in a college which had both self-financing and government aided divisions which brought together adolescents from different socioeconomic and cultural backgrounds, it was done in only one college - this restriction may limit the generalizability of the findings.

Conclusion

This study establishes the harsh fact that body image perceptions and dissatisfaction is no longer a western concept and affects our adolescent girls to a great extent. There is also a tendency favoring toward thin body figures which is evident in the study.

Recommendations

Effective interventions to improve awareness on ideal body weight, media literacy, and harmful effects of extreme weight control measures have to be planned, and young people both maintain a healthy body weight and are protected from the pressure of negative body image and weight control practices.

Further studies are recommended to establish the cause-effect relationship of the identified factors.

Acknowledgment

Peer Educators as Change Leaders – Effectiveness of Peer Education Process in Creating Awareness on Reproductive Health among Women Workers in Textile Industry

Suvetha Kannappan, Karthikeyan Shanmugam[1]

Department of Community Medicine, PSG Institute of Medical Sciences and Research, Coimbatore, Tamil Nadu, [1]Department of Community Medicine, Government Medical College, Palakkad, Kerala, India

Abstract

Context: India is one of the leading manufacturers of garments with roughly 80% of the workforce dominated by female migrant workers. Lack of education and access to resources in these women contribute to unsafe sexual behaviors, sometimes leading to unwanted pregnancies or sexually transmitted infections (STIs). Awareness raising, and peer education in particular, is extremely effective in addressing reproductive health issues. **Aims:** This study aims to study the effectiveness of peer health education in improving the awareness on reproductive health among women workers in textile industries. **Settings and Design:** A health educational interventional study for women in garment and spinning mills using peer education process carried out over a period of 18 months. **Subjects and Methods:** The process includes orientation to factory management, health needs' assessment, identifying health topics, peer educators' selection, peer educator trainings followed by outreach sessions, and impact measurement. The impact of peer education on reproductive health has been assessed among 597 participants from 9 factories. **Statistical Analysis Used:** Data were entered in SPSS version 24 and analyzed. Results were expressed as percentages. Chi square test was used where appropriate to find association between categorical variables. **Results:** The mean age of the workers in both the groups is 25.4 (±9.6) years and 25.1 (±8.3) years. In both the groups, most of the workers were single and more than half of them reside within the factory premises. Significant change in menstrual hygiene practices, knowledge in family planning methods, STIs, and cervical cancer has been observed following peer health education. **Conclusions:** A well-designed health educational interventional program using peer educators could be a successful approach to create awareness on sensitive topics.

Keywords: Peer health education, reproductive health, textile industry, women workers

Introduction

India has made a name for itself as a garment manufacturing center of global renown. The textiles and garments industry contributes 16.63% of India's export earnings. However, India's niche in the global garments market has been carved out at the cost of lakhs of workers in this industry's predominantly female and migrant labor force. Roughly 80% of garment workers are women between the ages of 21 and 25. Most are semi-skilled migrant workers and the sole earning members in their families.

These women workers often suffer from anemia, poor hygiene, inadequate pre- and post-natal care, sexual violence, and exposure to infections and illness. Lack of education and access to resources contribute to unsafe sexual behaviors, sometimes leading to unwanted pregnancies or sexually transmitted infections (STIs). They also contribute to high rates of malnutrition, maternal and infant mortality, and the spread of sexually transmitted and other preventable diseases such as HIV/AIDS and tuberculosis.[1]

Facility-based studies done in Chennai[2] and other parts of India[3] have shown that unwanted pregnancies among young

unmarried women are high and emphasize the need for educating them about contraceptives. Data from subnational study conducted in 2006 have shown that around 80% of young women perceive the need for family life education. The same study has shown that peers are the major sources of information regarding contraception.[4]

Awareness raising, and peer education in particular, is extremely effective in addressing reproductive health issues. Women are grateful for such education focusing on personal and family health, with information they have seldom received before. An environment focused on education rather than behavior change empowers the women to make better health choices for themselves.

Peer education typically involves training and supporting members of a given group to affect change among members of the same group. The peer education model initiated by business for social responsibility for improving health of women at factories has proven to be an effective model that encourages women to share their knowledge with other family and community members extending the benefits well beyond the factory floor.[5,6] A study conducted among women workers in garment industries has shown that peer education approach is effective in raising the awareness on STIs. The study also concludes that it is likely that the health education program may help to reduce the burden of healthcare costs to the community in the long run.[7]

This study looks into the effectiveness of peer health education in improving the awareness on reproductive health among women workers in textile industries.

Subjects and Methods

This study is part of an ongoing health education program done by the Department of Community Medicine for women workers in garment and spinning mills located within 100 kilometer radius from our institution. Pooled baseline and endline assessment data of 597 workers from nine industries which include six spinning mills and three garment factories have been analyzed for the study purpose. The study has been approved by the institution's human ethics committee.

Data were entered and analyzed using statistical package for social sciences (SPSS) version 19 (IBM SPSS statistics Company, IBM corporation). Results are presented as percentages. Chi-square test is done for statistical association wherever appropriate.

Salient steps of the health education program

As part of the program, baseline assessment is conducted by survey method using a prevalidated questionnaire among 10% of women workers chosen by simple random sampling. Health education was then conducted by peer education process. Peer educators were selected by the factory representatives(supervisory level) using the following guidelines: workers who have ability to read and write in local language, working in the factory for at least one year and having exhibited leadership skills. As a measure to ensure sustainability, nurse, female human resource (HR) representatives, and volunteers from staff level were also included. Peer educator strength in each factory ranged from 10 to 20 proportionate to the total strength of the women workforce.

Peer education process

Health education in reproductive health issues focused on menstrual hygiene and reproductive tract infections, STIs including HIV and hepatitis B, family planning and cancers. Health education sessions for the peer educators were conducted once in 2 months. Each session was conducted for over 2 h by interactive lecture aided by flip charts and videos supplemented with demonstrations where appropriate. Participatory methods such as body mapping exercise were used to teach anatomy of reproductive system. Energizers were conducted to break monotony and avoid boredom.

Following the session, peer educators conduct outreach sessions during weekends, lunch breaks, etc., for their coworkers in small groups ranging between 10 and 15. These sessions were facilitated by the HR department in coordination with the nurse. Informal discussions also took place in leisure times in the dormitories. A refresher session was conducted after a month following the main session to reemphasize the important points and clarify any doubts the peer educators might have. An endline assessment at the end of the program was done among 10% of randomly chosen workers.

Results

The pooled data of 597 female workers interviewed during baseline (316) and endline (281) assessment were included for analysis. The mean age of the workers in both the groups is 25.4 (±9.6) years and 25.1 (±8.3) years.

Table 1 shows the distribution of the female workers based on certain sociodemographic variables.

Table 1: Distribution of workers based on certain sociodemographic variables

Sociodemographic variables	Baseline (%) (n=316)	Endline (%) (n=281)
Mean age (years)	25.4±9.6	25.1±8.3
Marital status		
Single	69.3	71.8
Married	29.8	26.4
Divorced/widowed/separated	0.9	1.8
Educational status		
None	7.7	6.8
Primary	27.5	30.0
Secondary	53.8	52.5
Postsecondary	11.0	10.7
Residence		
Within the factory premises	52.2	67.3
Home outside factory	47.8	32.7

In both the groups, most of the workers were single and more than half of them reside within the factory premises.

Table 2 shows the comparison of practices during menstruation before and after intervention. A statistically significant ($P < 0.01$) improvement in frequency of changing pads has been observed before and after intervention. The results also reveal a significant ($P < 0.01$) decrease in menstrual problem-related absenteeism.

A significant increase in knowledge on awareness about family planning and its methods has been observed following the intervention [Table 3].

Knowledge regarding both HIV and hepatitis B has improved significantly among the workers, but very few women (17.1%) had awareness about hepatitis B before intervention compared to HIV where the preintervention knowledge was 74.4% [Table 4].

During baseline assessment, it was observed that only 40% women have heard of cervical cancer, and among them, only 24.6% were aware about the symptoms [Table 5]. Following health education, significant increase in knowledge has been observed.

Discussion

The mean age of the female workers in the textile industry is around 25 (±9 years). Similar age profile was observed in studies conducted among women workers in textile industries in Bangladesh and China.[8,9] Around 30% of the workers in our factories have no or limited literacy. This finding is similar to studies done in other parts of India,[10] but low literacy rate in Chinese workers is only around 2%.[9] More than half of the workers in our study population reside the dormitories within the factories. This is in contrast to situation in others places[8] where most workers come from their residence. Women of younger age together with limited literacy and being away from home warrant need for creating awareness and providing enabling environment for reproductive health issues in industries.

Peer education process is a successful method in bringing about awareness, especially in sensitive health issues. Peer educators could be powerful change agents as evidenced by interventional studies in HIV/AIDS using peer educators.[11,12] Our study has also proven that peer education process has led to significant change in knowledge and practice in reproductive health issues. A significant improvement in menstrual hygiene practices (59.7% vs. 84.2%, $P < 0.05$) and decrease in absenteeism (36.6% vs. 27.2%, $P < 0.05$) during menstruation has been observed. There is slight increase in the proportion of workers using sanitary pads, but this difference is not statistically significant. This could be due to a relatively higher proportion of workers already using sanitary pads.

Although 75% of women have heard about family planning methods, the baseline assessment findings showed that only around a quarter of them could mention few contraceptive methods. Peer educators were able to bring a significant improvement in knowledge on the different contraceptive methods (8.2% vs. 55.6%, $P < 0.05$). This is important considering the age profile of the workers and most of them being away from home. Our study has shown that peer education has been effective in bringing about a significant awareness about various contraceptive methods.

Educational intervention on STI focusing on HIV and hepatitis B has brought a significant increase in awareness, especially in hepatitis B (17% vs. 89%, $P < 0.05$). Many of the workplace based health educational interventions focus mainly on HIV[13] even though the awareness on hepatitis B is very low[14] conducted among women in reproductive age. Our study also showed that the preintervention knowledge was only 17%.

Despite being the leading cause of all cancers among women in India, the awareness of cervical cancer and its symptoms was

Table 2: Comparison of certain practices during menstruation before and after intervention

Parameters	Baseline ($n=303$) (%)	Endline ($n=279$) (%)	*P*
Frequency of changing pads more than two times a day	181 (59.7)	235 (84.2)	0.000
Absenteeism during menstruation	111 (36.6)	78 (27.9)	0.026
Use of sanitary pads during menstruation	277 (91.4)	261 (93.5)	0.748

P<0.05 is considered statistically significant

Table 3: Knowledge regarding family planning and its methods

Parameters	Baseline ($n=316$) (%)	Endline ($n=281$) (%)	*P*
Heard of family planning	231 (74.3)	257 (94.5)	0.000
Can mention at least two methods of family planning	26 (8.2)	176 (55.6)	0.000

P<0.05 is considered statistically significant

Table 4: Knowledge regarding HIV and hepatitis B

Parameters	Baseline ($n=316$) (%)	Endline ($n=281$) (%)	*P*
Heard of HIV	235 (74.4)	260 (92.5)	0.000
Heard of Hepatitis B	54 (17.1)	250 (89.0)	0.000

P<0.05 is considered statistically significant

Table 5: Knowledge regarding cervical cancer and its symptoms

	Baseline (%)	Endline (%)	*P*
Heard of cervical cancer	(n=316) 126 (39.9)	(n=281) 247 (87.9%)	0.000
Heard of cervical cancer symptoms	(n=126) 31 (24.6)	(n=247) 193 (78.1)	0.000

P<0.05 is considered statistically significant

less among our study population. Community-based studies in other parts of the country have shown even higher level of lack of awareness.[15] Our study showed a significant improvement in knowledge of cervical cancer (39.9% vs. 87.9%, $P < 0.05$), and its symptoms were brought about following health education (24.6% vs. 78.1%, $P < 0.05$).

Conclusions

A significant increase in knowledge and practice has been brought about in menstrual hygiene, family planning methods, STIs, and cervical cancer. Our study has shown evidence that peer education approach is effective in bringing about significant change in knowledge in reproductive health issues. A well-designed health educational interventional program using peer educators could be a successful approach to create awareness on sensitive topics.

A Toolkit for Strengthening Health Care Policies and Infrastructure of Industries in Developing Countries

Suvetha Kannappan, Mansi Gupta[1]

Department of Community Medicine, PSG Institute of Medical Sciences and Research, Coimbatore, Tamil Nadu, India, [1]India Representative, HER Project, Business for Social Responsibility, San Francisco, CA 94104, USA

Abstract

Background: The health risks faced by textile workers calls for a workplace health system that is comprehensive and accessible. To enhance the capacity of workplaces to strengthen their health system, a toolkit was developed by the Business for Social Responsibility (BSR), a non-profit global business network and sustainability consultancy. **Methods:** The Health System Strengthening (HSS) toolkit was designed to provide a set of tools, resources, and concrete steps for the factory management and health staff to work toward continuous improvement of their on-site health systems. It was then implemented with academic collaboration simultaneously In three factories/ in three manufacturing units/ in three workplaces in South India over 6 months to find out its usefulness as a self-reference tool for HSS. Monitoring and evaluation tools and indicators were developed based on the logic framework. **Results:** The main outcomes of the HSS pilot program include the formation of a health committee which was able to utilize the modules, perform a self-assessment of the health system, and come out with short- and long-term action plans for HSS under expert supervision and guidance. **Conclusions:** Overall, the toolkit was found to be an effective solution for HSS in industries which require expert guidance for implementation.

Keywords: Capacity building, health system strengthening, industries, toolkit

Introduction

The Indian subcontinent has seen tremendous industrial growth with the textile and garment industries contributing to 13% of the export earnings of the country.[1,2] This huge contribution from the textile industry has been the outcome of a large number of laborers involved in long hours of repetitive and monotonous work which could put them at risk of general, and occupational health problems unique to this industry.[3]

The health risks faced by the textile workers call for a workplace health system that is comprehensive and accessible. Health services that are currently offered within the workplace are underutilized as they are most often poorly equipped, lack trained staff, and have weak linkages with external healthcare providers. The existing external systems of healthcare in the private sector are either expensive or inaccessible, and on the other hand, the health services offered by the state are poorly utilized due to unfriendly timings, lack of adequate services, and facilities.[3,4]

The current health systems and services in the industries are modeled and regulated by the Indian Factories Act. The industries restrict themselves to fulfilling the requirements of the act and focus only on the basic parameters.[5] This is also partially fulfilled in most industries due to the lack of trained workforce available for providing occupational health services. Sharma *et al*.[6] identified a 50% deficiency of trained workforce for providing occupational health services in industries across India.

Saha, in his extensive review of occupational health status in India, has raised an urgent need for the development of

institutions and infrastructure of occupational health, need for spreading awareness of occupational health-related issues among all stakeholders, need to increase awareness about the concept of occupational health nursing, and to have in policy for safety, health, and environment in the workplaces.[7] Growing industrialization, changing profile of health needs of workers together with the lack of a system for providing occupational health services, calls for an urgent need to set up comprehensive and sustainable workplace health programs (WHP).[6,8,9]

To enhance the capacity of the workplaces to strengthen their health system, a toolkit was developed by the Business for Social Responsibility (BSR), a non-profit global business network and sustainability consultancy. The overall goal of the toolkit is to provide a set of tools, resources, and concrete steps for factory management and health staff to work toward continuous improvement of on-site health services. The toolkit was pilot-tested by a collaborative effort of BSR and its academic partner based in South India. They teamed previously for a health educational interventional program called 'HERproject' targeted to improve the health of female workers in the textile and garment industry.[10]

This paper explains in detail the various phases of the development and implementation of the toolkit, monitoring, and evaluation framework used, the outcomes of the pilot initiative, and the perceptions of the industries about the usefulness and challenges in using the Health System Strengthening (HSS) toolkit.

Methods

The pilot program was implemented by the academic team simultaneously in three workplaces in South India over 6 months between May and October 2017. A detailed description of the two phases of the study is given below.

Description of the phases of the program

A framework of the various components of the two phases of the study is depicted in Figure 1 followed by a detailed description of the two phases.

Phase. 1a: Development of Health System Strengthening toolkit

The HSS toolkit comprises two main components: (1) Tools for self-assessment; (2) Capacity-building resources.

Tools for self-assessment

The self-assessment component of the toolkit consists of a clinic scorecard [Figure 2] and a mapping tool. The self-assessment tool known as the scorecard was used to benchmark the workplace health system's performance. The scorecard was divided into two sections (a) on-site services and (b) workplace systems and policies.

Each indicator under these benchmarks was demarcated as basic (B), middle (M), or high (H) based on the priority level. A workplace could self-score its performance by assigning a color code based on the presence and functionality of a particular indicator, and if any improvements are necessary. A mapping tool was developed along with the clinic scorecard to help the management teams map out the external health service provisions, assess existing partnerships, and identify potential partnerships to meet the workers' needs and implementation resources.

Capacity-building resources

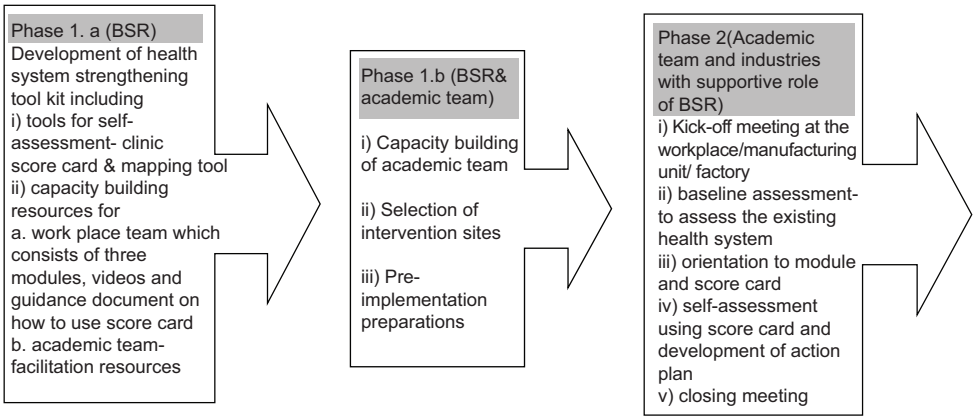
The capacity-building component of the toolkit consisted of complementary resources for the workplace team and resources for the academic team. For the workplace team, the resources included self-reference modules and videos; for the academic team, facilitation resources were provided.

Phase 1b: Capacity building of the implementing partners

Phase 1b of the program included capacity building of the implementing (academic) team, selection of the intervention site, and pre-implementation preparations.

Phase 2: Pilot testing of the health system strengthening toolkit

The second phase of the program was initiated with a kick-off meeting with the senior management. This was followed by the baseline assessment of the workplaces using qualitative methods like interviews, focus on group discussions, and observation of clinics to understand the existing health system



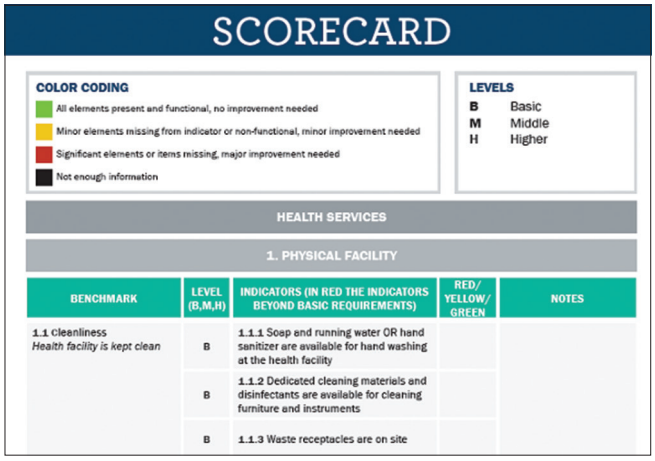


Figure 1: Framework of the phases of implementation of the program

of the factories. Following baseline assessment, a HSS team was formed at the factories and they were oriented to the modules and scorecard. The HSS team then conducted a self-assessment of the health system. The results of which were calibrated with the findings of the academic team. Short- and long-term action plans were developed by the committee based on the gaps identified. The final and crucial step was the closing meeting was attended by all stakeholders. The HSS team presented their action plans and the way forward.

Monitoring and evaluation framework

The logical model for program planning and evaluation which has been an effective tool for monitoring and evaluation of programs and interventions was used throughout the pilot of the HSS toolkit to monitor progress.[11] The summary of the various phases of the pilot program along with relevant indicators are given in Table 1.

	B	1.1.3 Waste receptacles are on site		

Figure 2: Outline of the scorecard

Results

Section 1: Profile of the factories

A total of three factories (one garment and two spinning mills) were included for the pilot study with a worker strength ranging from 600 to 2000. A majority of the workers in the garment industry were women residing within the factory premises. All the factories have a functioning clinic with a staff nurse. The spinning mill had a full-time physician and nurses working in shifts. From the "mapping exercise," it was understood that all the factories had established linkages with external service providers, both public and private. Social protection benefits covering health and accident insurance are available through the Employees State Insurance (ESI) for all permanent workers.

Section 2: Outcome of intervention of the program

Table 2 provides a summary of a few areas of improvement identified in different assessment parameters like physical infrastructure and strengthening health committee. The areas of concordance and discrepancy between the factory and academic team can also be observed from the results.

Then, a concordant list of areas for improvement was developed by the teams in all three factories, which was one of the main expected outcomes of the program. Short-term action plans focused on improving clinic facilities, strengthening biomedical waste management, and ensuring availability and displaying health education materials. Long-term plans focused on improving the physical infrastructure of the clinics,

Table 1: Summary of monitoring and evaluation framework of the Health System Strengthening toolkit pilot-based on the logic model

Phases of the model	Activities in the program	Indicators
Input (resources)	Academia team to facilitate the health system strengthening at the factories	Number and composition of members of the academic team
	Toolkit with self-assessment component and capacity-building resources	Availability of the capacity-building resources
	Implementation package	Number and expertise of the members of the health team at the factory
	Health System Strengthening Committee identified and formed at the factory level	
Process	Baseline assessment by the academia team at the factory	Report on baseline assessment
	Periodic visits by the academic team for facilitation of the toolkit, building capacity of the factory HSS committee, and overall program monitoring	Number of visits conducted by the academic team
		Strength of members from the health team attending the meetings with the academic team
Output	Utilization of capacity-building resources by the HSS Committee, especially the clinic staff at the factory	Self-assessment results on the clinic scorecard
	Self-assessment of the factory health systems using the clinic scorecard	Presentation of the short- and long-term action plans
	Identification of areas for improvement and develop short-term, medium-, and long-term action plans for the health system strengthening	Approved action plans and completion of the short-term action items before pilot closing
Expected outcome	Implement the health system strengthening measures from the action plan	Periodic self-assessment using the "scorecard'
	Functioning of a comprehensive health system at the workplace	Improved clinic attendance
	Improved access to healthcare products and services	Improved satisfaction of the workers

Table 2: Areas for improvement identified by the health team

Assessment parameters	Factory 1		Factory 2		Factory 3	
	Factory health team	External evaluation	Factory health team	External evaluation	Factory health team	External evaluation
Physical facilities products equipment materials	Need for the improvement of the clinic facilities, increase the number of health personnel, and to provide patient-waiting area		Nil		Need to strengthen clinic facilities	
Facility policies and procedures	Not identified	Need to improve disinfection protocols, develop policies for ensuring confidentiality and safety during patient care	Not identified	Infection prevention protocols not in place	Need for more insurance facilities for workers as private facilities are more utilized.	
				Need for the development of policies for regular pre-placement screening for all workers and to develop policies to address grievances of the workers' concerns for health care		
Referral and provision of care	Need to organize non-communicable disease screening program		Nil		Nil	
Education and counseling	Not identified	Need for providing health education and counseling in nutrition, hygiene, contraception, and non-communicable disease risk factors, occupational diseases	Not identified	Need for providing health education and counseling in nutrition, hygiene, contraception, and non-communicable disease risk factors and occupational health risks	Increase scope for the nurses to be involved in health management like taking an active role in committees, providing counseling services, etc.	
Management system and corporate leadership	Need to initiate and involve health committee in health planning and budgeting		Need for a health committee, written policy on health management: the hiring of workers, appraisals, promotions, etc., and streamlining of health budgeting		Need for strengthening of health committee; their roles and responsibilities, develop written policy on health management-hiring of workers, appraisal, promotions, etc., and streamline health budgeting	

*"Nil" denotes that from the assessment no area for improvement identified by the factory and academic team. "Not identified" denotes the academic team has identified gaps but the health team missed the gaps

budget reallocation, and strengthening the healthcare team, and bringing policy-level changes.

Section 3: Reaction and perception of the factory team regarding the HSS program

Table 3 is a summary of the perceptions and experiences of the factory team regarding the program in all three factories. The HSS program was a new experience for all three factories.

Discussion

The present study was piloted to develop and implement a HSS package consisting of self-assessment tools to improve the health facility and resources for capacity building of the staff in the factories and to understand the usefulness of the package for the industries. This intervention is very much needed in workplaces as only 5–10% of the industries in the developing countries have employee health services, that too, mostly restricted to the manufacturing industries.[12]

The baseline assessment using a multipronged approach helped to understand the existing health systems at the factory level and the gaps and strengths in running their health systems parallelly with the business operations. All the factories had established a good linkage with the public service providers but utilization was less due to issues in timings and having to wait for long hours. Lack of awareness regarding the benefits of ESI services and low trust levels in the government health institutions were added reasons for poor utilization of the services. Rashidha, in her study in Kerala, observed similar reasons for the average or low utilization of ESI services among the respondents.[13]

The HSS toolkit was designed as a self-reference tool for workplaces. During its pilot run, valuable insights were gained from different stages of its development and piloting. While the toolkit was well-received by all the three pilot factories, it was realized that the toolkit in itself could not be used by the factories without proper orientation and facilitation on the different components and resources through a systematic approach.

The clinic scorecard was well appreciated as an internal audit tool by the factories to track their health systems periodically.

Table 3: Perceptions and experiences of the program from the pilot industries

Components	Perceptions of team members about the program
Capacity-building resources	*"The module on budgeting was a very useful resource for us as we had no idea earlier as to what are the components of a health budget. Now, we are able to do line listing of items."* **HR Manager**
	"The toolkit will be a good resource to improve our clinics as it gives us a guideline of how a clinic should function, why and how a health budget should be planned." **General manager**
Self-assessment using scorecard	*"Scorecard was a handy tool for us to self-assess our clinic and come up with short- and long-term plans to strengthen our clinic."* **HR manager**
	"Rating Methodology-Level (B, M, H) and Red, Yellow, Green very innovative. Just by seeing the color coding, we will be able to have a clear idea of which areas to improve. " **Nurse**
	"By using this scorecard-almost everything related to dispensary like what records to maintain, what information to display in the clinic, what cleanliness measures to be followed, was covered." **Nurse**
Overall impression of health system strengthening program	*"Apart from the module, you have given such valuable health- and hygiene-related guidelines to our staff."* **Labour Welfare Officer**
	"This strengthening process will be useful for us as we are applying for OSHA certification where health system strengthening is the main component." **Senior Manager**
Change in attitude and behavior following the program	*"More involvement from the nursing staff into the HR system. She now helps us in budgeting."* **HR Manager**
	"Increased proactiveness of the nurse." **HR Manager**
	"We feel the need to strengthen ourselves in managing communicable diseases, prevent outbreaks." **HR Manager**
Outcome of the program	*"We have modified the job description of our nurse widening her scope of work."* **Senior Manager**
	"We have improved the physical infrastructure of our health center." **Nurse**
	"We have started making our budget and we already notice that there is a decrease in the cost of medicines as we used to buy unnecessary medicines earlier." **HR manager**
	"We have made a policy to send our health staff for continuous professional development programs at least twice a year" **HR manager**

The role of the standardized assessment criteria using checklists or any validated tools for the improved quality of healthcare has been emphasized by many authors.[14,15] In the first attempt, workplaces tend to score themselves higher on the scorecard, assuming they have all things in place. However, an external non-biased assessment of the workplace health systems using the same scorecard can bring out completely different results. In our pilot study, we found discordance between the factories and external agencies in identifying gaps in counseling and education and policies and procedures. This finding is not surprising considering that workplaces generally look beyond occupational safety as observed by Pescud *et al*.[16] The WHO has emphasized the role of senior management in establishing workplace health policies and the participation of employees for the proper implementation of such health policies.[17]

An important outcome from the program was a better role clarification of the occupational health nurse, commitment of the management to establish policies for ensuring the continuous professional development of the nurse. The nurses who participated in the program have expressed that the scope of their job has been widened as an outcome of the pilot and they feel that they can play a proactive role in the industry. The multidisciplinary role of the occupational health nurses and the need for strengthening their capacity has been emphasized by the WHO.[17]

Another key outcome from this pilot was the realization that workplaces are primarily preoccupied with business operations, and despite the best intentions, may lack the knowledge and skills required to strengthen healthcare support for their workforce. While the HSS toolkit is well-designed for self-reference use for factories to fill this gap, it is not a complete solution in itself. For best results, it is preferable that an expert agency facilitates this toolkit and builds the capacity of the factory management toward strengthening their health systems.

Conclusions

Conducting a self-assessment using a validated tool is an effective method for workplaces to identify the gaps in their existing health systems, and further propels them toward their next steps in making action plans for short- and long-term duration. This exercise once facilitated by an expert organization can pave the way toward a self-sustainable practice that the workplaces can periodically continue to review and strengthen their health systems. A tool that was tested in the textile industries can as well be used in any industrial setup with expert guidance.

Ethics approval

The study was cleared by the Institutional Human Ethics committee of PSG Institute of Medical Sciences and Research, Coimbatore, India.

Acknowledgments

Abstract

Background: Tobacco use has emerged as a major public health problem. But, most graduates in medical and dental schools receive limited systematic training. The objective of this education innovation project was to enhance dental undergraduate student's ability to identify tobacco users through oral manifestations and improve their counseling skills using a customized Tobacco Counseling Training Module (TCTM).

Methods: A TCTM for students of dentistry was developed using ADDIE framework as a guide. Content and construct validation of the module was done by six subject experts using Delphi technique for obtaining consensus. Pilot testing was done on 20 students of third year BDS. Pre- and post-intervention assessment of knowledge, attitude, self-confidence was done using learning outcomes questionnaire. Ability to correctly identify oral manifestations was assessed using extended item MCQs and tobacco counseling skills using a modified KEECC. The difference in mean scores were computed and subjected to further statistical analysis using SPSS version 22.

Results: There was a significant improvement in post intervention scores for mean knowledge (5.5 ± 1.4 to 13.2 ± 1.1), attitude (5.6 ± 0.9 and 8.5 ± 0.5), self-confidence (1.5 ± 0.5 and 3.1 ± 0.2), ability to correctly identify oral manifestations (5.2 ± 1.4 and 9.4 ± 0.8) and tobacco counseling skills.

Conclusion: It is possible to introduce the module in the existing curriculum and its effectiveness evaluation shows benefit in terms of Kirkpatrick's Level 1, 2, 3 (improvement in knowledge, attitude, self-confidence, ability to identify oral manifestations, and tobacco counseling skills) of training effectiveness.

Introduction

Tobacco use has emerged a major public health issue worldwide that has resulted in massive disability, disease, and death acquiring the dimension of an epidemic.[1] Smoking is a leading cause of preventable deaths across the nations. It is estimated that five million preventable deaths occur every year globally, attributable to tobacco use which is expected to double by 2020. Approximately one person dies every 6 seconds due to tobacco, accounting for one in 10 adult deaths. Nearly 80% of the more than one billion smokers worldwide live in low- and middle-income countries where the burden of tobacco-related illness and death is heaviest. Besides damaging personal health, tobacco use contributes to severe societal costs like reduced productivity, environmental damage, and poverty of the families.[2] India is the second largest producer and consumer of tobacco after China. More than one-third of adults use tobacco in India accounting for 275 million. Out of these 275 million users, 163.7 million consume smokeless tobacco, 69 million are smokers, and 42.3 million consume tobacco in both the forms.[3]

Medical and dental students upon graduation are often tasked with assisting to promote health and welfare of the population as part of the health system as well as for their individual patients. Literature suggests that most graduates in medical and dental schools worldwide receive limited training and are ill-equipped to treat tobacco dependence.[4] Although, Dental Council of India expects a dentist to identify a tobacco addict using oral manifestations and offer some basic counseling, there is lack of a structured training module in existing curriculum. Such a focused training to combat a common public health problem will also improve generic communication and health behavior counseling skill sub-components such as establishing rapport, focusing on affective behavioral issues, and cross-cultural communication. In this background, this education innovation intervention was undertaken to explore and test whether a systematic structured approach using a customized Tobacco Counseling Training Module (TCTM) will enhance dental undergraduate student's ability to identify tobacco users through oral manifestations of tobacco use and improve their skills in tobacco cessation counseling. The specific objectives of the study were:

- To do learning needs assessment by assessing the learner's pre-intervention status of knowledge, attitude, ability of undergraduate dental students to correctly identify oral manifestations and skills in tobacco counseling, and identify the gaps in knowledge and practice against recommended Public Health Service's Clinical practice guidelines by US Department of Health and Human Services for tobacco cessation counseling[5]
- To develop and validate a customized TCTM based on identified gaps in knowledge and practice and implement this intervention on a group of third year BDS students
- To determine the effectiveness of TCTM on knowledge, attitude, ability of undergraduate dental students to correctly identify oral manifestations, and their skills in tobacco counseling following its implementation.

Methods

This education innovation project was carried out over a period of one year from June 2017 to May 2018 at JSS Dental College and Hospital, Mysore. Ethical clearance was obtained from the Institutional ethics committee on 23rd February 2017. A mixed method research design was adopted. A customized tobacco cessation counseling training module for students of dentistry was developed using ADDIE framework (Analyse, Design, Development, Implement, Evaluate), which is a useful tool for building effective training and performance support.[6,7]

ADDIE step 1: Analyze (Learning needs assessment)

This was done using a combination of qualitative and quantitative research techniques. Training needs for a customized tobacco counseling module was identified using a pre-designed structured questionnaire on 10 undergraduate students, one focus group discussion (FGD) involving six interns, in-depth interview among two teaching faculty in Public Health Dentistry and four office bearers of Indian Association of Public Health Dentistry [Table 1]. FGD guide and in-depth interview guide were prepared. These were used by the principal investigator to elicit information on current practices of training students in tobacco counseling, perceived gaps in existing curriculum which needed to be addressed, the contents to be included while developing any such customized training module, method of teaching and evaluation to be adopted. The FGD and in-depth interview were audio recorded. An abridged transcript was prepared by listening to the tape of focus group and in-depth interview. Classical content analysis[8] method was used wherein we created smaller chunks of data and then placed a code with each chunk. These codes were then placed into similar groupings and counted. The frequency of each code (quantitative information) was supplemented with rich description of each code (qualitative information). Besides, five faculties in the department of public health dentistry were requested to participate in a free listing exercise where they enlisted all the important topics that in

[Downloaded free from http://www.indianjcancer.com on Wednesday, July 22, 2020, IP: 172.20.65.147]

their opinion were to be included in training module. Summary of outcomes from needs assessment using FGD and in-depth interview is captured in Table 2. Key contents suggested by faculty during free listing were identified by card pile sorting. The needs analysis revealed that tobacco related topics were taught in bits and pieces in different specialty departments in dentistry and students found it difficult to integrate and apply what is being taught during real patient encounters. It was felt that there was a need for designing a structured training module to be taught by a multispecialty team. Teaching in such module should focus on tobacco trends and patterns, role of dentists in tobacco cessation counseling, scales for assessing tobacco dependence, behavioral theories that could be adopted for counseling, clinical tips for identifying and differentiating various oral manifestations in a tobacco user and a tobacco cessation counseling framework that could be used in dental clinical setup.

ADDIE Step 2: Design (Module designing)

A framework for TCTM was designed by synthesizing inputs from learning needs assessment, free listing among faculty who suggested the contents for such module and through literature review. The module was designed to be spread over five sessions of 90 minutes each, and broad contents, structure, delivery methods, duration, assessment and feedback for each of these sessions were incorporated. The initial five modules focused on (1) global pattern, trends and impact of tobacco consumption, (2) role of health and oral health care providers in reducing the tobacco burden, (3) alarming oral manifestations suggestive of tobacco use and differential diagnosis of these manifestations, (4) introduction to behavioral theories and motivational interview, (5) tobacco counseling using "STAR with

Table 1: Training Needs Assessment: Background of participants in focus group discussion, in-depth interview and free listing

	Gender		Designation				
	Male	Female	Interns	Postgraduate students	Lecturers/Assistant professors	Associate professors	Professors and above
Focus group discussion (*n*=6)	2	4	6	-	-	-	-
In-depth interview (*n*=6)	-	-	-	-	-	2	4*
Free listing (*n*=5)	-	-	-	-	3	2	-

*Office bearers of Indian Association of Public Health Dentistry

Table 2: Training needs assessment using focus group discussion and in-depth interview: Key findings

Major theme	Responses of participants with group consensus
Current practices	"Tobacco-related topics are taught by four different specialties in dentistry They are taught in different contexts without stressing on how to assess level of tobacco dependence and counseling"
Concerns on current practices	"Although tobacco topics are taught by four specialties, we find it difficult to apply in real life (clinical practice) situations." "We find it difficult to identify a tobacco addict using oral manifestations and also to differentially diagnose the lesion in a tobacco user." "The current practice of teaching has never made us think tobacco counseling is so important and we should do this in every possible patient encounter."
Need for a customized training program	"We need some dedicated hours of training exclusively for tobacco counseling in one department by a team of specialists from these four departments." "Focus in such training program should be on most common oral manifestations in a tobacco user and tips for clinically differentiating them from other similar lesions."
Topics (contents) suggested	"We need to know all health and oral health risks of tobacco use, its burden and impact on society." "We need to know about simple chair side tools for determining tobacco addiction". "We need to understand the fundamentals in tobacco counseling; Some demonstrations on how to counsel a tobacco addict".
Recommendations for mode of teaching and student assessment	"Preferably teaching on tobacco counseling should be done in Public Health Dentistry department by a multispecialty team during clinical postings." "Interactive teaching methods should be adopted with demonstrations of counseling" "Pictures, videos and real-life examples should be used for training." "Evaluation may be undertaken using quiz, match the following, MCQs etc., for each session." "Effectiveness of training may be elicited by using a customized questionnaire on knowledge, attitude and self confidence."

5A and 5R approach" incorporated into Calgary—Cambridge communication skill framework.[9,10] This module was prepared for third year BDS students and can be implemented during clinical posting of students in Public Health Dentistry.

Addie Step 3: Development (Module development)

Development Part 1: Development and validation of content and structure of modules 1 to 5

At this stage, a trainer's (facilitator's) guide and a guide for student on each session that contained the resource material with specific learning objectives, well-defined learning outcomes, the teaching methods to be adopted, a worksheet with small group activities incorporated, mode of assessment, and session feedback were prepared. The focus areas (contents) in five sessions of TCTM have been listed in step 2 above. The fifth session focused on tobacco counseling using "STAR with 5 A and 5 R approach".[9,10] The content knowledge base for the tobacco cessation was developed from "STAR with 5 A and 5 R approach" used by US Public Health Service which is popular among public health dentists.[5] Content and context validation was done by six subject experts locally. Delphi technique was used to obtain consensus on the contents from six subject experts.[11] Summary of output from Delphi technique is shown in Table 3. TCTM was shared with six subject experts and each subject expert was requested to provide their inputs on relevance, appropriateness and applicability of contents in each session using a predesigned content validation form. The experts were requested to suggest their recommendations for modifications, deletions and addition of contents of the module with justifications. After receiving replies from each expert, a summary was prepared based on their inputs for each session and this was shared with all the experts again for them to refine it further. Based on recommendations of experts following second round of communication, a summary with explanations for inclusion of contents in each session and their relevance, appropriateness and usefulness in enhancing the knowledge, attitude, and skills related to identification and counseling was prepared. This was shared with the subject experts and they were requested to express their views and

Table 3: Summary of output from the Delphi technique

Purpose: Content and context validation of TCTM			
Number of subject experts participated: 06			
	Round 1		
Session	**Number of experts expressing their agreement with content and context of sessions**	**Number of modifications suggested for each session**	**Number of suggestions incorporated following this round**
Session 1: Global pattern, trends and impact of tobacco consumption	4	2	2
Session 2: Role of health and oral health care providers in reducing the tobacco burden	3	3	2
Session 3: Alarming oral manifestations in a tobacco user	3	3	3
Session 4: Introduction to behavioral theories and motivational interview	4	4	2
Session 5: Tobacco counseling using "STAR with 5 A and 5 R approach	5	3	2
	Round 2		
Session 1: Global pattern, trends and impact of tobacco consumption	6	None	None

Session 3: Alarming oral manifestations in a tobacco user	5	2	2
Session 4: Introduction to behavioral theories and motivational interview	4	2	1
Session 5: Tobacco counseling using "STAR with 5 A and 5 R approach"	5	1	1
	Round 3		
All the six subject experts expressed their consensus and agreement for the learning objectives, lesson plan, method of teaching adopted, activities planned, method of eliciting feedback for each session.			

[Downloaded free from http://www.indianjcancer.com on Wednesday, July 22, 2020, IP: 172.20.65.147]

refine it further to modify the same, if needed. All the six subject experts expressed their consensus on the output content at this stage.

Development Part 2: Development of module 6 (Tobacco counseling incorporated into Calgary—Cambridge communication skill framework)

When the above mentioned training modules were shared with faculty mentor who was an expert in medical education, it was suggested to incorporate contents of "STAR with 5 A and 5 R approach" into the Calgary—Cambridge communication framework[12] to enable the students to engage in deliberate practice of tobacco counseling and receive feedback to improve performance. This necessitated the inclusion of sixth session of 120 minutes into the module. Addition of sixth session into the module necessitated revalidation of contents to make subject experts understand the importance of incorporating Calgary—Cambridge communication framework. But, three out of six subject experts who validated TCTM, initially, were out of country at that time. TCTM was supposed to be implemented in the institution within a week's time according to calendar of events in the department. Conventional process of reaching consensus on inclusion of sixth session using Delphi would have taken more time with no real time interaction. So, we tried a combination of WhatsApp and mobile conference call to get all these subject experts in different time zones to discuss the project synchronously. A WhatsApp group of all subject experts and moderator was created. An article that described the process of fitting Calgary-Cambridge framework to tobacco counseling was shared in group.[1] Subject experts were requested to post their comments in the WhatsApp group after referring the article. Some experts expressed diverging opinions on inclusion of sixth session to an already validated module. To explain the rationale and to reach consensus on revised module, mobile conference call was thought about. Mobile conference call following initial discussion using WhatsApp provided quick and timely interaction on diverging opinions. Queries raised by some experts were replied by either moderator or other subject experts. We were able to arrive at consensus in 25 minutes on revised contents, teaching plan for each session and evaluation tools for all the six sessions. As a result of all these processes, "The modified CALGARY – CAMBRIDGE communication framework for tobacco counseling" was developed and is shown as Annexure 1.

ADDIE Step 4: Implementation

The module containing five sessions of 90 minutes each and an additional session of 120 minutes for deliberate practice and evaluation of tobacco counseling pilot tested on twenty students of third year BDS in May 2018 on six consecutive days during clinical postings in Public Health Dentistry. Third year BDS students were divided by institution authorities into 10 clinical batches. Each batch had approximately 10 students. Two batches were selected out of 10 batches using lottery method for this pilot study and this constituted 20% of students in the batch. The flow chart of these sessions in TCTM is attached as Annexure 2 which provides an overview of sequencing, contents and lesson plan for each session. TCTM was implemented by a multidisciplinary team comprising of faculty from Public Health Dentistry, Community Medicine and Oral Medicine. Faculty selection for the multidisciplinary team was made by HOD of Public Health Dentistry based on interest of faculty in tobacco intervention and their availability to offer training in a sustained manner for subsequent years as well. Moreover, these faculties were also suggested by interns to be included in the multidisciplinary team for training on tobacco counseling during FGD. Students and faculty orientation was conducted before initiating the training module. These sessions incorporated a combination of various teaching methods like initial brainstorming, lectures using PowerPoint, videos, experience sharing, quiz, small group activities, role playing, etc.

ADDIE Step 5: Evaluation

To evaluate the effectiveness of the intervention (TCTM), a questionnaire was developed for assessing knowledge, attitude and self-confidence in tobacco counseling. MCQs with extended items were used for assessing the ability to correctly identify oral manifestations. An initial Learning Outcomes Questionnaire (LOQ) for assessing knowledge, attitude, and self-confidence in tobacco counseling was prepared using expert inputs and literature review. This LOQ had 30 items for assessing knowledge, 15 items for assessing attitude and 10 items for assessing self-confidence. The LOQ was communicated to six subject experts along with a content validation form. Each expert was requested to rate the relevance, appropriateness and clarity of each item on a five-point Likert scale with 1 being least favorable response to 5 being highly favorable response. Fourteen items from knowledge, 5 items from attitude and 4 items from self-confidence were deleted from the original questionnaire due to redundancy, lack of relevance and appropriateness. The final LOQ had 16 items for assessing knowledge, 10 items for attitude and 6 items for self-confidence. The initial tool for assessing ability to correctly identify oral manifestations had 17 items. During

[Downloaded free from http://www.indianjcancer.com on Wednesday, July 22, 2020, IP: 172.20.65.147]

validation from six subject experts, three items were deleted due to redundancy, two for not being relevant and two for not being appropriate. Final tool had 10 extended item MCQs. Cognitive interview was conducted to assess the response process validity of these tools among ten final year BDS students. Known group validity of LOQ was assessed by using this questionnaire on three final year BDS students, three interns and three postgraduate students from Public Health Dentistry. Each correct response was given a score of one while incorrect response was scored zero. The total score for knowledge (score range 0–16), attitude (score range 0–10), and self-confidence (score range 0–6) in tobacco counseling was computed for each participant. Extended item MCQs was administered to three final year BDS students, three interns and three postgraduate students from Oral Medicine to assess known group validity. Tobacco counseling skills was assessed during role play by students in the sixth session using a modified Kalamazoo Essential Elements Communication Checklist (KEECC).[13] Here, students were divided into triads where one student acted as a tobacco user while others acted as doctor and recorder. This (formative assessment) was repeated till each student completed all three roles. However, score given by the observing trained faculty (summative assessment) was considered for statistical analysis on effectiveness of the TCTM. Reliability assessment of the tools for knowledge, attitude, self-confidence and ability to identify oral manifestations was done on 10 students using test-retest method.

Pre-intervention knowledge, attitude, self-confidence, ability to correctly identify oral manifestations and their skills in tobacco counseling was assessed before implementation of module on twenty students of third year BDS and post-intervention assessment was done following its implementation. The difference in mean scores were computed and subjected to statistical analysis using SPSS version 22 (IBM, Chicago, USA). Student and faculty satisfaction was collected using a pre-designed satisfaction survey questionnaire on 5 faculty and 20 students. Paired sample *t*-test was used for comparison between pre and post-intervention values while calculating the effect size. McNemar's Chi square test was used for comparing frequencies and percentages before and after implementation of module.

Results

Validity testing of the tool used. The scale level content validity index for evaluation tools assessing knowledge, attitude, self-confidence and ability to identify oral manifestations was 1.0. Cronbach's alpha values indicating the intra examiner reliability score for the tools evaluating knowledge, attitude and self-confidence, and ability to identify oral manifestations were 0.98, 0.96 and 0.97 respectively. In known group validity assessment, knowledge,

Table 4: Summary of validity and reliability of Learning Outcomes Questionnaire (LOQ) and extended item MCQs used for assessment of knowledge, attitude, self-confidence and identification skills

Assessment tool	Scale level content validity index/ Universal agreement (S - CVI/UA)	Intra rater reliability (Cronbach's alpha) *n*=10 participants
Learning Outcomes Questionnaire		
Knowledge (16 items)	1.0	0.98
attitude and self-confidence (10 items+6 items)	1.0	0.96
Extended item MCQs	1.0	0.97
Details of known group validity assessment for Learning Outcomes Questionnaire. (*n*=3 each from three groups)		
Outcome assessed	**Knowledge (16 items), (Mean±SD)**	**Attitude and self-confidence (16 items) (Mean±SD)**
Final year BDS students (*n*=3)	5.7±0.6	5.3±0.6
Interns (*n*=3)	7.7±0.6	6.7±0.6
Postgraduate students from Public Health Dentistry (*n*=3)	11.7±0.6	9.3±0.6
Statistical inference	*F*: 84.0, *P*: <0.001	*F*: 37.3, *P*: <0.001
Details of known group validity assessment for extended item MCQs (*n*=3 each from three groups)		
Outcome assessed	**Identification skill (10 items), (Mean±SD)**	
Final year BDS students (*n*=3)	5.3±0.6	
Interns (*n*=3)	7. 0±0.0	
Postgraduate students from Oral Medicine & Radiology (*n*=3)	8.7±0.6	
Statistical inference	*F*: 8.3, *P*: <0.001	

[Downloaded free from http://www.indianjcancer.com on Wednesday, July 22, 2020, IP: 172.20.65.147]

attitude and self-confidence, ability to identify oral manifestations scores were higher for postgraduate students followed by interns while being least for the fourth year BDS students [Table 4].

Effectiveness of the Intervention (TCTM) in terms of Student learning i.e., Kirkpatrick level 2 of Training program evaluation: This is shown by the mean knowledge score increasing from 5.5 ± 1.4 to 13.2 ± 1.1 suggesting a significant improvement (t = 16. 9, P < 0.001, Effect size: 1.33). The mean attitude and self-confidence scores at pre-intervention were 5.6 ± 0.9 and 1.5 ± 0.5 respectively and they changed to 8.5 ± 0.5 and 3.1 ± 0.2 post-intervention. The difference was statistically significant for attitude (t = 16.5, P < 0.001, Effect size: 0.52) and self-confidence (t = 13.5, P < 0.001, Effect size: 0.34). Mean scores for identification of oral manifestations at pre and post-intervention were 5.2 ± 1.4 and 9.4 ± 0.8 with the difference being statistically significant (t = 12.8, P < 0.001, Effect size: 0.98) [Table 5]. With regard to tobacco counseling skills, none of the students did well during pre-intervention assessment while it increased to six (30%) after intervention. The positive change in their communication skills was statistically significant (X^2 Value: 11.7, P value: 0.001) [Table 6].

Effectiveness of the intervention (Student and Faculty reaction i.e., Kirkpatrick level 1 of training program evaluation): All five faculty (100%) and 15 students (95%) felt that the program was very much relevant and highly appropriate [Table 7]. The faculty also offered some specific suggestions for implementation of the training module to make the program even better.

Discussion

Tobacco use has become a common contributor to premature death and disability.[14] Learning counseling skills that facilitate behavior modification is one of the essential skill expected of a competent health care professional. These behavior interventions are beneficial in changing the life course of a tobacco consumer/addict that will have several social, economic and health related benefits to the individual, family and society as a whole.[14,15]

Literature indicates that health care professionals can learn tobacco cessation counseling skills to improve patient outcomes.[16-18] Literature also suggests that there is lack of structured training program in tobacco counseling for medical and dental undergraduates in the existing curriculum.[19] Dental undergraduates are in a strategic position to identify a tobacco user through oral manifestations and offer tobacco counseling. Dental Council of India also expects a graduating dental student to undertake tobacco counseling among patients with tobacco habits. It was evident in needs assessment undertaken in the present study that the existing curriculum does not have structured training program for training dental undergraduate students in tobacco counseling. It was realized during focus group discussion among interns

Table 5: Effectiveness of the TCTM intervention (knowledge & attitude)

Outcome variable (maximum score)	Pre-intervention score mean±SD	Post-intervention score mean±SD	Tests of significance
Knowledge (16)	5.5±1.4	13.2±1.1	t: 16.9 Effect size: 1.33 P: <0.001
Attitude (10)	5.6±0.9	8.5±0.5	t: 16.5 Effect size: 0.52 P: 0.001
Self - confidence (6)	1.5±0.5	3.1±0.2	t: 13.5 Effect size: 0.34 P: 0.001
Ability to correctly identify oral manifestations (10)	5.2±1.4	9.4±0.8	t: 12.8 Effect size: 0.98 P: 0.001

Table 6: Effectiveness of the TCTM intervention (tobacco counseling skills)

Tobacco counseling skills (using role play)	Done well n (%)	Needs improvement n (%)	Not done n (%)	Total n (%)
Pre - intervention (n=20)	0 (0)	4 (20)	16 (80)	20 (100)
Post - intervention (n=20)	6 (30)	14 (70)	0 (0)	20 (100)

that some topics related to tobacco habits, pattern of tobacco use, oral manifestations in a tobacco user and brief counseling was taught by different specialty departments. But, this compartmentalized training was not useful as many of them could not connect between what is being taught and its application in their routine practice. It was apparent after needs assessment that there was a need for a customized tobacco counseling training module for dental undergraduate students to enhance their skills in the identification of oral manifestations in a tobacco user followed by counseling. Hence, in response to this need, the TCTM was developed and tested on a group of third year BDS students. In BDS curriculum specified by Dental Council of India, a dental undergraduate student enters clinical postings in third year of BDS program. We introduced TCTM of six sessions as an introductory module on tobacco counseling for students entering the clinical settings. It was evident in the literature that early training on promotion of behavior change among medical students facilitated better acquisition and application of tobacco intervention skills.[19] The early exposure resulted in promoting a sense of belonging and provided usefulness in clinical environments. Moreover, early exposure of students to TCTM was intended to create a sense of responsibility among students as soon as they enter clinicals to make them realize the importance of identifying tobacco addicts using oral manifestations and also to highlight the importance of early intervention to make these addicts quit the habit. This was somehow not given due importance while eliciting case histories of patients by dental undergraduate students as noted during needs assessment. However, the training module is designed in such a way that this foundation course of six sessions in third year will be followed by three session's module to be undertaken among final year BDS students and one hour refresher session for interns. The modules for final year BDS students and interns have been developed and validated, but, are yet to be implemented in a sequential manner by a multispecialty team. This pilot study evaluated the effectiveness of TCTM on Kirkpatrick level 1 (reaction) and level 2 (learning). Here, the evaluation of knowledge, attitude and self-confidence was done using LOQ, extended item MCQs with clinical vignettes were used to assess ability to correctly identify the images of oral manifestations projected on a screen on a random basis. Here, the counseling skills were assessed while the students practiced it through role plays. However, in final year BDS and during internship, the evaluation of counseling is proposed to be undertaken using standardized patients and real patients, respectively. The sequencing of training module initially from third year BDS and extending into their final year and internship was thought to provide reinforcement at regular intervals throughout their curriculum to achieve optimum results. The first session on global pattern, trends and impact of tobacco consumption was incorporated to provide an overview on the tobacco consumption pattern and recent statistics on tobacco usage around the world and in India. It was realized through feedback after the session that many students were not even aware about facts on tobacco presented in the session. This session was included to enhance their knowledge on tobacco burden while motivating them to consider tobacco counseling as an important aspect in their clinical practice. Second session focused on role of health and oral health care providers in reducing tobacco burden and also provided some practice on assessing tobacco dependence using Fagerstorm scale among smokers and smokeless tobacco users. The intension of this session was to make participants realize the fact that dentists are in a key position to motivate patients to quit tobacco. Third session focused on alarming oral manifestations in a tobacco user and their diagnosis. It was included to provide clinical tips for identifying oral manifestations in tobacco user and their differential diagnosis. This was also one of the skills expected to be enhanced through TCTM. Fourth session focused on introduction to behavioral theories and motivational interview. It was expressed by the students during learning needs assessment that they are not aware of any behavioral theories which they could apply for lifestyle and behavior management. This, in fact was the rationale for inclusion of this session. The session was included to provide brief overview on most commonly used theories for behavior modification in medical profession. It was felt necessary to provide some knowledge to the students on various stages of change a person goes through during behavior modification which could be applied for other clinical purposes as well. Fifth session focused on tobacco counseling using expanded Calgary - Cambridge communication skill framework. Inclusion of communication skills framework in the module was done to make students to understand the importance of communication

[Downloaded free from http://www.indianjcancer.com on Wednesday, July 22, 2020, IP: 172.20.65.147]

in motivating a person to adopt healthy lifestyle. Students expressed in their feedback that this session specifically helped them to understand the key components of communication in medical case history taking which was not known to them previously. Students expressed their willingness to adopt these key components in their routine clinical encounters as well besides tobacco counseling. The additional session of 120 minutes provided an opportunity for deliberate practice of tobacco counseling through role plays and also to evaluate student's performance in tobacco counseling in a simulated setting. Students expressed in their feedback that they enjoyed this session and also learnt their mistakes when their own batchmates identified the aspects that were done well, not done well or those that required improvement using a checklist. Besides, the feedback by faculty on individual student's performance also was appreciated by the students.

There was a significant increase in the knowledge, attitude and self-confidence of students towards tobacco counseling following implementation of TCTM. This could be attributed to focused and relevant topics being covered in one stretch by a multispecialty team. Some students have expressed in their feedback that the mode of training which included initial brainstorming, lectures, video demonstrations, experience sharing, interactive group discussion and small group activities were interesting and kept them engaged throughout the sessions. These results were similar to the findings of a study by Brown RL *et al*.[19] who in their study assessed whether a curriculum on tobacco intervention could garner student acceptance; improve relevant knowledge, attitudes, and self-confidence; and be applied in students' early clinical experience. They found significant improvement in all these attributes following implementation of Tobacco Intervention Basic Skills curriculum (TIBS). Ahmadian M *et al.* in their study compared the effectiveness of two educational methods in teaching tobacco cessation counseling (TCC) in dental practice for senior dental students.[20] They found both role play (RP) and problem-based learning (PBL) methods to be effective in enhancing the knowledge, attitude, and skill of the participants. Ability to correctly identify oral manifestations also improved significantly following implementation of training module. The session that specifically focused on clinical presentation of most common oral manifestations in a tobacco user and pathophysiology of these lesions which was taught by an expert in oral medicine was appreciated by the students. It was their perception through feedback that this session helped them in enhancing their ability to correctly identify these lesions while differentially diagnosing them. Students practiced counseling using a modified Calgary—Cambridge communication skill framework that incorporated STAR with 5A and 5R approach content for reference during deliberate practice using role plays. The counseling in practice sessions facilitated self-improvement through deliberate practice using role play in triads of students where one student acted as patient, one student as a doctor and other as an observer followed by feedback by observing faculty. This session of deliberate practice gave each student an opportunity to undertake counseling in a simulated setting. Students perceived that role play enabled them in understanding the sequence of communication contents to be followed during counseling process while they got exposed to the checklist used for evaluation during such counseling sessions. During this deliberate practice, one student who acted as evaluator was given the modified Kalamazoo Essential Elements Communications Checklist to evaluate the performance of the student who was acting as doctor. This gave an opportunity for students to understand how communication during a clinical encounter will be assessed using standard checklist. This modified evaluation checklist is attached as Annexure 3**.** It was found that their counseling skills improved with 30% of the students performing well following implementation of TCTM compared to none of the students before the intervention. Fernandes K *et al.* in their study to enhance communication skills of MBBS (Bachelor of Medicine and Bachelor of Surgery) students in counseling of tobacco users by using interactive teaching methods found role play, interactive session, anecdotes to play a vital role in improving their counseling skills.[21] Gordon JS *et al.* in their study found an innovative and interactive CD-ROM tobacco cessation training program to be effective in enhancing the knowledge level and attitudes of 47 third-year dental students and 30 dental hygiene students.[22] Faculty and students in our study also expressed complete satisfaction on the course content and method of teaching adopted. Faculty expressed their desire to incorporate this into the existing dental curriculum at the institution level. Davis JM *et al.* in their study to evaluate the effectiveness of a peer-reviewed tobacco curriculum (Tobacco Free! Curriculum) found an average increase in the amount to time spent by faculty on tobacco education. There was an increase of 85 minutes on tobacco education in dental hygiene curriculum. Besides, there was a large positive increase in the percentage of faculty members who formally assessed the use of 5As and 5Rs (21%–88%), and a dramatic increase (+100) in the percentage of faculty members who taught or included most of the 13 tobacco use cessation (TUC)

[Downloaded free from http://www.indianjcancer.com on Wednesday, July 22, 2020, IP: 172.20.65.147]

interventions content areas following the introduction of the curriculum and training program.[23] Our findings were consistent with the results of these studies and others.[24,25]

Conclusions

Using a systematic process guided by the ADDIE Framework, it is possible to design a structured learning experience (curricular module) for equipping students with skills to manage a common public health problem. TCTM was found to improve knowledge, attitude, self-confidence, ability to identify oral manifestations and tobacco counseling skills among study participants (Kirkpatrick's Level 1, 2, 3). Students and faculty expressed their satisfaction about the TCTM with some specific suggestions.

Novelty: TCTM was developed through synthesis of contents from literature review and inputs obtained from students, faculty and experts during needs assessment. TCTM was implemented during clinical training of students in Public Health Dentistry by a multispecialty team. It required six days during their clinical training which was found to be practically feasible and well accepted by students and faculty. This study also describes the process of learning needs assessment, training module design, content and process validation, and training program evaluation using the ADDIE model of instructional design. The content matter (knowledge needed in tobacco use and cessation) was incorporated into the Calgary-Cambridge Counselling framework and validated by dental experts using Delphi technique. This can be used by fellow teachers in dentistry and other health care educators as it helps students engage in deliberate practice and receive feedback on performance to sharpen and improve their tobacco cessation communication skills.

Limitation: Time constraint was a limitation as intensive training was required on six consecutive days. It may be practically difficult to apply this for each small group in an academic year. Hence, it was suggested by faculty to consider three knowledge-oriented sessions in large-group mode for all students together to be then followed up by three skill-oriented sessions during clinical postings in small groups. This will reduce the time constraint (if any) and make it more practical for its replication in other institutions for common and important public health problems. It was mentioned by interns who participated in focus group discussion during needs assessment that no customized training was undertaken with regard to tobacco counseling. Hence, we thought of comparing pre and post-intervention scores among participants who underwent training as part of evaluation. However, comparison of performance of students who underwent training against those who were not offered such training would have given us chance to compare effectiveness of the current module against traditional method. This could not be undertaken owing to the time constraints. The long-term impact will be evaluated in the future when subsequent follow up sessions are undertaken during the fourth year BDS and internship.

Way forward: This customized tobacco counseling training module for dental undergraduate students would be evaluated by incorporating this as a value addition into the existing curriculum at the level of institution before recommending this as a curriculum reform to Dental Council of India.

Acknowledgements

We express our sincere thanks and gratitude to the Principal, JSS Dental College and Hospital, Dr. Praveen Kulkarni, JSS Medical college, Faculty from JSS Dental College, subject experts and students of JSS Dental college for their support and participation in this education innovation project.

Declaration of participant consent

The authors certify that they have obtained all appropriate participant consent forms. In the form, the participant(s) has/have given his/her/their consent for his/her/their images and other clinical information to be reported in the journal. The participants understand that their names and initials will not be published and due efforts will be made to conceal their identity, but, anonymity cannot be guaranteed.

Annexure 1

MODIFIED CALGARY – CAMBRIDGE COMMUNICATION FRAMEWORK FOR TOBACCO COUNSELING

I. ESTABLISHES INITIAL RAPPORT AND BUILDS POSITIVE RELATIONSHIP

- Greets patient,
- Introduces self,
- Demonstrates respect to the patient (uses words that show care and concern, uses tone, pace, eye contact, and posture that show care and concern)

II. OPENS THE DISCUSSION ON TOBACCO COUNSELING BY ASKING RELEVANT OPEN ENDED QUESTIONS ON TOBACCO HABITS

- **Explores (Asks about)** the patient's tobacco related problems with an appropriate **opening question** (e.g., "tell me about how you got into this habit?" and what happened after that till date" or "what questions related to this habit did you hope to get answered today?")
- **Encourages patient to tell the story** of the tobacco related problem(s) from when first started to the present in own words (clarifying reason for presenting now)
- **Listens** attentively to the patient's opening statement, without interrupting or directing patient's response
- **Facilitates** patient's responses verbally and non–verbally e.g., use of encouragement, silence, repetition, paraphrasing, interpretation
- **Picks up** verbal and non–verbal cues (body language, speech, facial expression, affect); checks out and acknowledges as appropriate
- **Makes necessary notes and confirms** tobacco related information elicited and looks for further information (e.g. "Tell me about any previous attempts to quit the habit and what happened then?")

III. GATHER ADDITIONAL RELEVANT INFORMATION ON FOUR "R"S (RISKS, RELEVANCE, REWARDS AND ROADBLOCKS)

- **Asks about frequency and duration of current habit,** current habit, risks involved, relevance of quitting, rewards of quitting, and anticipated roadblocks in such quit attempts,
- **Clarifies** details as necessary with more specific questions
- **Summarizes the information** gathered and provides opportunity for patient to correct or add information

IV. ASSESSES PATIENT'S LEVEL OF ADDICTION BY USING FAGERSTORM TEST FOR NICOTINE DEPENDENCE FOR SMOKING/USE OF SMOKELESS TOBACCO

- Informs the patient about the need for filling the small questionnaire (which may take approximately two minutes).
- Administers the questionnaire after obtaining informed consent

V. ADVICES PATIENT TO QUIT THE HABIT

- Tries to communicate the necessity to quit the habit by connecting the patient's current habit and adverse impact (social, economic and health related) it can have on the entire family.
- Uses the information gathered earlier by patient on risks, relevance, rewards and roadblocks to enhance his/her existing knowledge by giving additional relevant information.
- Adopts motivational interviewing technique while giving such advices

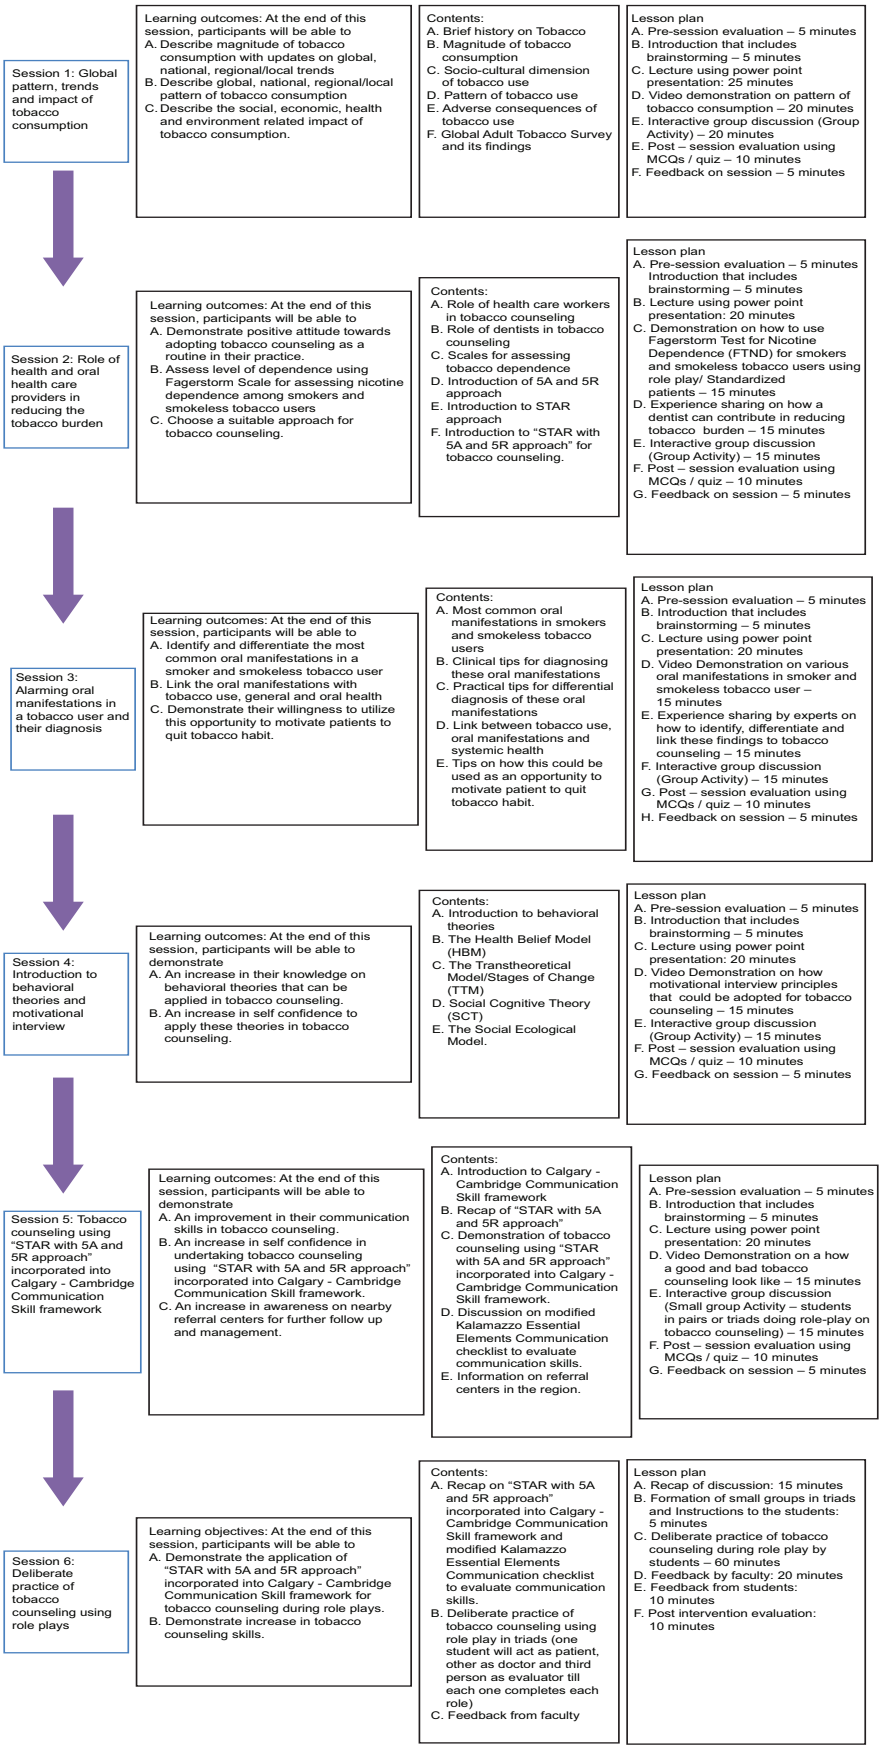
VI. ASSESSES PATIENT'S WILLINGNESS TO QUIT

- Elicits and documents the patient's willingness to quit by a question such as "what is your opinion on trying to quit the habit considering the risks and benefits of quitting and specially in the interest of your family"
- Gives opportunity to the patient to express freely without imposing

[Downloaded free from http://www.indianjcancer.com on Wednesday, July 22, 2020, IP: 172.20.65.147]

If willing to quit,

VII. ASSIST THE PATIENT IN MAKING A PLAN TO QUIT



- **Explains STAR approach to the patient**
- S- Set a quit date: Gives flexibility to the patient to decide a date preferably within the next one month
- T- Tell your friends and family: Informs the patient to tell his/her decision to quit to all family members and friends who may encourage him to do so.
- A – Anticipate adherence challenge: Tells the patient that some withdrawal symptoms like head ache, irritability, lack of attention, etc may be experienced. Motivates the patient to be mentally prepared to face these short term challenges with determination. Encourages the patient to do so in the best interest of dependent family members.
- R – Remove all tobacco products from vicinity: Informs the patient about the necessity to keep tobacco products away so that they are not easily available in times of craving.

VIII. CLOSES THE DISCUSSION WITH AN ARRANGEMENT FOR FOLLOW UP

- Tries to set a date for follow up examination even if the patient is not willing
- Tries to set a date for follow up even when patient agrees to quit by adopting STAR Approach
- Asks whether the patient has questions, concerns, or other issues
- Acknowledges patient and closes the interview by greeting the patient

[Downloaded free from http://www.indianjcancer.com on Wednesday, July 22, 2020, IP: 172.20.65.147]

Annexure 2: Flow chart of six sessions in TCTM

Annexure 3

Modified Kalamazoo Essential Elements Communication Checklist for tobacco counseling

	Done well	Needs improvement	Not done
Build a Relationship			
Greets and shows interest in patient as a person			
Uses words that show care and concern throughout the interview			
Uses tone, pace, eye contact, and posture that show care and concern			
Open the Discussion			
Allows patient to complete opening statement without interruption			
Asks "Is there anything else?" to elicit a full set of concerns			
Explain and/or negotiates an agenda for the visit			
Gather Information			
Begins with patient's story using open-ended questions ("Tell me about…")			
Clarifies details as necessary with more specific "yes/no" questions			
Summarizes and gives patient opportunity to correct or add information			
Uses an appropriate scale to elicit the level of addiction to tobacco			
Advices patient to quit the habit and assess readiness to quit			
Discuss four “R”s effectively to reinforce and enhance existing knowledge			
Motivates patient by connecting the health, social and economic impacts			
Elicits patient's willingness to quit by clarifying the doubts			
Assist the patient in making a quit plan by explaining STAR approach			
Explains using words that are easy for patient to understand			
Provide closure by arranging a follow up			
Asks whether the patient has questions, concerns, or other issues			
Acknowledges patient and closes the interview

Abstract

Background: Schools are the best setting for health promotion activities, and in India, for many, the schools are in fact the only nurturing and supportive place where they learn health information and have positive behavior consistently reinforced. Therefore, health promotion addressing the nutrition and personal hygiene habits among school children would improve health of school children and mold them into healthy productive citizens of tomorrow. **Objectives:** The objective of the study is to find the effectiveness of multi-strategic health screening cum educational intervention model in promoting the health of school children. **Methods:** A school-based intervention was designed using multi-strategic approach to promote the health of 2500 school children in 13 schools in rural Coimbatore. Logic model was used to plan the intervention, and the approach included health screening, nutrition and personal hygiene assessment and educational intervention in three phases over a period of 1 year. The multi-strategic approach comprised of approach through doctors, teachers, and through peer educators. The effectiveness of the intervention was assessed with improved nutrition and personal hygiene habits, improved body mass index status, and reduction in sickness absenteeism. **Results:** There was a significant improvement in nutrition and personal hygiene habits among school children. There was also significant reduction in the proportion of underweight category. Furthermore, a slight increase in sickness absenteeism was observed. **Conclusion:** Our study shows evidently that a multi-strategic health screening cum educational intervention model can be implemented and can be effective in bringing changes in the nutrition and personal hygiene habits thereby promoting the health of school children.

Key words: Educational intervention, health promotion, school children

Introduction

Schools have been a popular setting for health promotion activities for many years and served as the major institution in providing education and experiences that mold the young children into responsible and productive citizens.[1] School health programs and interventions are one of the most effective ways in reaching the children of that age. Well-designed educational interventions in schools can bring about awareness leading to change in attitudes and behaviors and thus promotion of healthy practices.

In India, the major health problems of school-going children are undernutrition and added to that, micronutrient deficiency, and overweight/obesity are increasing.[2] In addition, another major reason for poor health and infections among school children is the lack of awareness of the health benefits of personal hygiene. Diarrheal diseases, skin diseases, worm infestations, and dental diseases are most commonly associated with poor personal hygiene. It is also an established fact that infection and malnutrition form a vicious circle and retard children's physical development. Studies also show that repeated attacks of infections often compound the existing poor health of children, compromising children's attendance, and performance at school.[3]

Hence, from a school health perspective, the major components to be addressed to improve the health of school children are improving their nutrition and personal hygiene. By doing this, we can target the major health problems of school children namely malnutrition and infections which are the major contributors to poor health and poor academic school performance, particularly in rural areas. Literature also shows that healthy eating habits in young children may prevent various chronic health disorders in childhood and adult life, including obesity, diabetes, hypertension, cardiovascular disease, cancer, and dental caries.[4,5] School environment also provides an easily accessible setting for interventions targeting the children to promote healthy lifestyles.[6,7]

There are many studies on interventions to promote healthy behaviors among school children, and systematic reviews have shown that interventions to promote healthy eating and physical activity were the most likely to be effective.[8,9] A lot of studies have evaluated school-based interventions on a diet of which a few are from low- and middle-income countries. Review shows that the interventions that were effective are high-intensity school-based interventions which were comprehensive and multicomponent.[10]

A study done in India has shown that school-based child-to-child personal hygiene education resulted in behavior change among children.[11] Another study done among adolescent school students in North India included intervention components like nutrition education lectures, promotion of physical activity, individual counselling by a trained nutritionist, increased availability of healthier food choices in the school canteen and involvement of teachers and parents, showed effectiveness in improving the diet of school children.[12]

Studies have also shown that while it appears that parental involvement is crucial in school interventions, challenges exist for recruiting and sustaining parent involvement in school-based programs.[13]

Studies have revealed that reaching the children through peer leaders were more effective than when done through adults,[14] especially when targeting behavioral changes and draws on the credibility that young people have a rapport with their peers and provides flexibility in meeting the needs of their peers.[15,16]

Similarly, the WHO also recommends that a variety of activities promoting a healthy diet and a strong educational component are likely to be more successful among school students.[17]

Hence, this study was conducted to find out the effectiveness of a multi-strategic health screening cum educational intervention model in promoting the health of school children.

Materials and Methods

Based on the extensive review of various interventions and recommendations of the WHO as well as keeping in mind, the cultural settings and resources available, a custom-made intervention was designed to promote the health of school children, and this included the following components:

Morbidity screening and dietary and hygiene gap identification

The school children were screened for general morbidities including eye and dental examination. The morbidities were documented in the health card. The body mass index (BMI) was measured, and the WHO charts were used to grade the BMI status. Then, they were also assessed for personal hygiene habits and nutritional habits using a checklist developed based on standard recommendations. The gaps in the recommended diet and personal hygiene habits were identified. Those who needed referral were also given a referral slip.

Individual counseling of students based on individual gaps identified

The students at the end of the screening were given individual counseling by doctors on their morbidities, about the gaps in their diet and personal hygiene practices and how they can be rectified.

Modification of teaching curriculum

The heads of the schools, along with the teachers were approached, and efforts were taken to include the nutrition and personal hygiene education as a part of their routine classes in which definite hours were allotted for educating students on nutrition and personal hygiene using the tailor-made module designed using standard recommendations of the National Health Agencies.

Designing modules for dietary and personal hygiene education

The teaching module on good nutritive diet and personal hygiene was prepared based on standard recommendations and the one regarding diet-based on the Indian Council of Medical Research/National Institute of Nutrition (ICMR/NIN) recommendations for a balanced diet. We designed the module in such a way that the student's interest, i.e., their future aspirations and career choices were linked to nutrition and personal hygiene practices. How a proper nutrition and personal hygiene practices could bring them close to their aspirations. Further, the module developed was a flip chart with pictures for easy understanding and the key points to be told during the session were printed on the back side of the flip for ease of using it. Studies showed that flipchart was an effective tool in poor resource setting for health education.[18] This could capture the student's interest and be a motivation for the positive behavior changes expected in them. Based on the evidence of the impact of using posters on imparting knowledge, a poster was also given for each school that had the key points of the module.[19]

Training of teachers for communicating the health promotion messages

The teachers were given training on how effectively the tailor-made modules could be used to educate the children on nutrition and personal hygiene habits.

After the training, their sessions were observed by doctors and feedback on the same was given to the teachers to increase their effectiveness in the communication of key messages.

Selection and supervision of peer educators

The peer educators were chosen from each class with the help of teachers. The selected peer educators were motivated to teach their peers and use of the modules that would aid the diet and hygienic behavior change. The peer education sessions were supervised and feedback was given to the peer educators to improve their communication skills.

Reinforcing, cascading, and buttressing approach

The students were approached using three different approaches – through doctors, teachers, and peers.

- First was through teachers, who have good face value and rapport with the students. We involved the teachers by training them to take sessions using our module designed
- Second was through doctors and health team, the doctors did the nutrition and personal hygiene assessment and counseling. Doctors had good credibility among the students and were always looked on by the students, in this way, it motivated the students to a positive change in behavior
- Third, we also used peer approach by selecting peer leaders in school in their same class and trained peers in using the module among their peers. It gave them recognition and motivation to deliver the modules to their peers.

Assessment tools and program evaluation

The assessment tools were designed based on standard recommendations (ICMR/NIN) and were developed as a checklist in quickly identifying the gaps in the recommendations. The same was piloted, and face validation was done among the experts of community medicine. The checklist developed assessed the nutrition and personal hygiene habits of children and based on this counseling was given. The tool designed was kept simple, user-friendly and effective in quickly identifying gaps and faulty habits in nutrition and personal hygiene. We also incorporated an evaluation component in the tool by giving a scoring for the assessment done.

The intervention was designed to promote the health of school children in 13 schools in rural Coimbatore. The study was done over a period of 1 year from 2014 to 2015. The preparatory work of planning the intervention, getting approval from authorities, acquiring funding, and designing the tailor-made modules were done during March–May 2015. When the schools reopened baseline assessments were done in all 13 schools and Phase 1 extended from June to August 2014, Phase 2 visits were done during September–November 2014 and final assessments were done during Phase 3 which extended from December 2014 to February 2015. The study population included all 2500 students from the age of 6–18 years of both sexes studying in these schools. The health team consisted of doctors, postgraduate students, interns, nurses, social worker, and health assistant who participated in the intervention.

Logic model was used to plan the intervention process leading to a desired result. It also helped to set out the evaluation priorities right from the beginning of the process.

Figure 1 shows the inputs needed for the project, the various activities planned, the output expected from these activities, and finally, the impact of the project, a desired outcome of the planned intervention.

The health education intervention was done in three phases. There was an interval of 3 months in-between these three visits. The final visit and assessment were done at an interval of almost 6 months from the baseline assessment. The Institution Human Ethics Committee approval was obtained for using the data for the study.

Phase 1

During the first visit, health screening was done, and the student was also assessed for the nutrition and personal hygiene habits and based on the assessment were given individual counseling. During the same visit, the teachers were given training by the health team member on how to use the tailor-made module on nutrition and personal hygiene to deliver the health education to students.

Phase 2

During the second visit, the students were again subjected to health screening and assessment of the nutrition and personal hygiene using the checklist. Based on which individual counseling and reinforcement of corrective measures were done. In this visit, the teachers were asked to deliver the health education session to the students with the help of the module, which was supervised and feedback was given. Child peer educators were selected from their own peers in each class.

Phase 3

During the third visit, again the students were screened and assessed for nutrition and personal hygiene and counseled individually. In this visit, peer educators delivered the health education which was supervised.

The module on nutrition and personal hygiene was given to each school, and a poster of the same was also placed on prominent areas of the school premises.

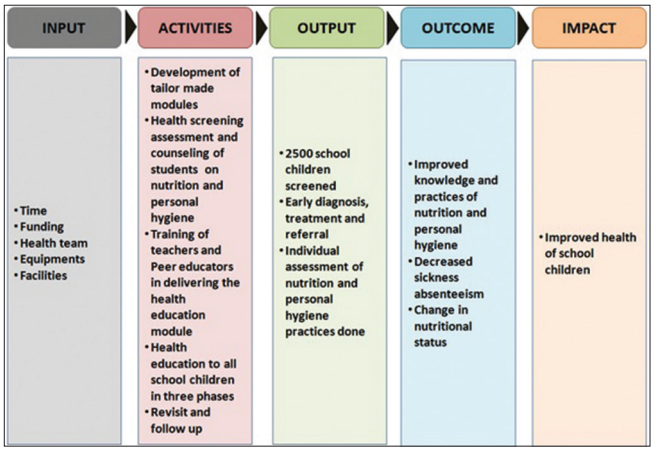

Figure 1: Logic model used in planning the intervention.

Measuring the effectiveness of the intervention

The outcome assessment indicators were chosen such that they would reflect the changes that we aimed doing this intervention. As our aim was to improve the health of school children by improving nutrition and personal hygiene practices, we chose the following indicators.

Change in the dietary and personal hygiene assessment score

The students were assessed for good nutritional intake and personal hygiene on the first visit following which a score was assigned against a maximum score of 10 each. The same was assessed at the end of the year; an improvement in score was considered improved practices of nutrition and personal hygiene.

Change in body mass index status

The BMI of school children was computed as a part of health screening so that the baseline BMI distribution could be compared with the change in the BMI distribution of the school population at the end of the intervention. Reduction in the underweight category was considered as a positive change indicating the effectiveness of the intervention.

Decreased absenteeism

This was another indicator that we chose. The days of absenteeism were noted down for each quarter; this was a proxy indicator indicating the health of school students. The mean days of absenteeism were compared using baseline and the mean days at the last quarter of the intervention. This indicator was chosen with the assumption that improved practices of good nutrition and personal hygiene would prevent most of the common communicable diseases thereby reducing sickness absenteeism.

Results

The total number of students was 2500 of which 2204 were assessed at the baseline assessment and 1836 were assessed during the final visit. The baseline (preintervention assessment) score and the postintervention score for a total score of 10, at the end of 1 year were documented.

Table 1 shows the basic characteristics of the study population; the participants belonged to the age group of 6–18 years.

Table 2 shows the pre- and post-intervention mean scores. Scoring was given on a total score of 10 each for both the nutrition and personal hygiene assessment. The difference between pre- and post-mean scores was found to be statistically significant. However, the increased figures for absenteeism shows we need to further ascertain whether the absenteeism is because of sickness or due to other extraneous reasons.

Table 3 shows the mean BMI distribution of the students, pre- and post-intervention. The BMI was calculated using the WHO standards,[20] and it was found that the difference in the distribution of BMI pre- and post-intervention was statistically significant. There was a significant reduction in the underweight category and improvement in the normal BMI category, though in the overweight and obese category there was a slight increase.

Table 1: Gender distribution of the study population at baseline and postintervention

Participants	At baseline assessment, *n* (%)	At postintervention assessment, *n* (%)
Boys	1128 (51.2)	937 (51.0)
Girls	1076 (48.8)	899 (49.0)
Total	2204 (100)	1836 (100)

Table 2: Indicators showing the effectiveness of the intervention

Indicators	Mean±SD		P
	Preintervention (*n*=2204)	Postintervention (*n*=1836)	
Diet assessment score	4.6±2.5	7.2±2.7	0.0001
Personal hygiene score	4.3±2.5	6.5±3.5	0.0001
Mean days of absenteeism	4.6±5.6	5.4±7.1	0.0001

SD: Standard deviation

Table 3: Body mass index distribution before and after intervention

BMI category	Preintervention (*n*=2204), *n* (%)	Postintervention (*n*=1836), *n* (%)	χ^2 and *P*
Underweight	505 (22.9)	356 (19.4)	77 and 0.024
Normal	1558 (70.7)	1351 (73.6)	
Overweight/obese	141 (6.4)	129 (7.0)	

BMI: Body mass index

Discussion

Our study aimed to show and share multipronged model of promoting the health of school children. The intervention was school-based in which we targeted the school children by individual counseling by doctors, health education by teachers, and also peer-led health education. The intervention had led to the improvement in the total mean score of diet and personal hygiene assessment among the students at the end of 6 months.

Our study highlights that students when individually screened for gaps in diet and hygiene and counseled for the same, the acceptance and understanding are better and when doctors themselves give the counseling, it increases the credibility of the information given. Second, we involved the teachers also who already had the confidence of the students, and so information from them would reinforce the key messages to the students even more. Third, we also chose peer educators among the same class since they would be easily accessible to their classmates and they had greater influence on their peers through peer pressure.

We also used tailor-made health education material which linked the academic performance and the career aspiration of students to their dietary and personal hygiene habits which was a motivation for the students to adapt better dietary and personal hygiene practices.

Our intervention showed that by involving the stakeholders during the planning and implementation stages, even a multipronged intervention can be implemented and can be effective in bringing changes in the diet and personal hygiene habits of school children, which was evident from the increase in postintervention behavior change scores as well as its positive health outcome reflected by the change in BMI distribution and particularly so reduction in underweight category at the end of 1 year.

Similar studies done in other places have shown that school based and peer-led programs have been successful in bringing out changes in regard to nutrition among school children. A study done in Canada also shows that peer educators models have been successful in bringing changes in elementary children also.[21] A study done in China among school adolescents have also proven to be effective in reducing sedentary behaviors in school children.[22] Systematic reviews have been done which discusses the success and failures of these models and need for further studies.[9]

Although BMI status and mean days of sickness absenteeism was taken as proxy measures, BMI status change reflected the status change of the whole study population and not necessarily the change in the individual status. In addition, mean days of absenteeism observed does not necessarily represent actual sickness since we did not insist on production of the sickness certificate. Furthermore, the increased absenteeism seen as a finding during the final impact assessment may be a confounder arising due to it being done in the festive season.

Our study also found out the practical difficulties in bringing changes in the habits of school children. Nutrition and personal hygiene habits cannot be inculcated in school children unless the resources and opportunities are provided. Parents and schools should be able to provide them with the proper nutrition, and environmental facilities and resources have to be provided for personal hygiene practices. The major drawback identified was the lack of parental involvement in the intervention, effectiveness of this intervention cannot be completely assessed unless the parents are involved.

Limitations

Our study focused on finding the effectiveness of an innovative intervention in which change in the nutrition and personal hygiene scores were taken as a main indicator. Since we could not find any existing tool that was user-friendly in assessing a large number of children in a short duration of time, we developed our own tool in the form of a checklist to assess nutrition and personal hygiene habits. The reliability and validity of this tool need to be tested. The other limitation was though our tool assessed the habits of recommended nutrition intake and personal hygiene practices the scores were self-reported, so increase in score had definitely shown knowledge increase but how far it was transformed into change in practices could not be evaluated. Another limitation of our study was due to resource constraint the individual-level data could not be compared preintervention and postintervention, we had to use aggregate data to compare scores.

Conclusion

Our study has shown evidently that this innovative model of health education where school children are intervened by individual counseling by doctors, teachers, and peer educators based health education sessions is effective in increasing the knowledge and practices of school children regarding nutrition and personal hygiene. Our evidence also showed a positive influence on the BMI of school children. Thus, this model of individual counseling involving health team, teachers, peer educators, and custom-made modules on relating nutrition and hygiene to their academic performances, aided by flipcharts and posters had created a positive impact on the ethos of the schools. Further studies with the involvement of parents and providing proper resources for aiding nutrition and personal hygiene practices are needed to study the real impact of the intervention.

Are Our Rural Adolescents Eating Healthy?: Implications for Redesigning School Health Interventions – A Cross Sectional Study in Rural Coimbatore

Subhashini Ganesan[1], Thomas V. Chacko[2], G. M. Muhammad[3]

[1]Assistant Professor, [3]Associate Professor, Department of Community Medicine, PSGIMSR, Coimbatore, Tamil Nadu, [2]Dean Medical Education and Professor, Department of Community Medicine, Believers Church Medical College and Hospital, Kuttapuzha, Thiruvalla, Kerala, India

Abstract

Background: Adolescence is a period of transition where independence in thinking and behavior is established and food choices that are made are followed for several years, and this can influence their health in adulthood. Hence, understanding the eating habits are necessary to plan effective nutritional interventions in adolescents. **Objectives:** The main objective of the study is to find out the extent of malnutrition among rural adolescents as well as evaluate their eating habits against recommended dietary food groups and to compare eating habits across gender and age groups. **Methods:** A cross-sectional study was done among 1425 adolescents from 13 rural schools from 2014 to 2015, and the variables considered in this study were age, sex, body mass index (BMI), and the eating habits of the adolescents. **Results:** Undernutrition was seen among 23% and overweight/obesity among 8% of adolescents. The habit of taking milk and milk products, fruits, and green leafy vegetables were very poor among the adolescents. Significant association was found between eating habits and BMI. Furthermore, late adolescents had better eating habits, and significant gender difference was seen in certain eating habits. **Conclusions:** The study shows that it is possible to understand the gaps in eating habits of adolescents, and this can be used to plan tailor-made nutritional interventions to adolescent groups as their eating habits are different and have long-term nutritional and health implications.

Key words: Adolescent, dietary gap assessment, faulty diet, nutritional diagnosis, school health

Introduction

Adolescence is a period of transition. The World Health Organization (WHO) defines the period of adolescents as 10–19 years of age.[1] It is a period of rapid growth and maturation in human development. It is a period where independence is established and adolescent makes choices of their own. The choices that are made are followed for several years and food habits are greatly established during this period, and this can influence their health in the adulthood.[2]

As global foods are widely marketed in low- and middle-income countries, it becomes important to understand the diet patterns and preferences.[3] In India, among adolescents, there is an increased consumption of fast foods contributing to overweight and obesity.[4] Furthermore, studies have shown that the food consumption pattern is poor among adolescents and have observed frequent consumption of energy-dense, nutrient-poor foods, and sugar-sweetened beverages, and the omission of a variety of healthy foods from their daily diet.[5]

In addition, cultural factors such as dietary practices and attitude toward food are evolving. These factors eventually influence the eating habits and today's adolescents lack proper knowledge on good eating habits and how those habits contribute toward their healthy nutritional status.

Hence, healthy eating behavior should be established in childhood and maintained during adolescence.[6] Adequate knowledge of healthy food choices and eating habits should be taught early to adolescents, as it can predispose them

to lifestyle diseases in adulthood. Adolescents should be constantly motivated, and the need of the hour is bridging the knowledge gap on healthy eating.[7]

In India, there is a paucity of information about eating habits of adolescents, and limited information is available regarding various categories of food consumed by adolescents in relation to the food pyramid, which defines and identifies the balanced diet and corresponding nutritional status of an adolescent. Moreover, this type of nutritional data is even more difficult to find among rural population in India. Also, adolescents are the most important and vulnerable segment of population who have been largely ignored, and exclusive data pertaining to adolescent health are not widely available in Indian scenario.[8]

Hence, this study aimed to measure the extent of malnutrition among rural adolescents as well as evaluate their eating habits against recommended dietary food groups and to compare eating habits across gender and age groups.

Materials and Methods

A cross-sectional study was done among adolescents from 13 schools in rural area within the Madukkarai block, Coimbatore District, in 2014–2015. Prior permission was obtained from the concerned school health authorities, and this study protocol was approved by the Institutional Human Ethics Committee. Data used in this study were collected as a part of the school health project. The variables considered in this study were age, sex, body mass index (BMI), and the various elements in the recommended food portions that constitute the eating habits of the adolescents.

This school health program was funded by Larsen and Toubro, under their corporate social responsibility scheme. The funders' interest was only on the services to the rural school children and did not have a role in the research component. The research on the data obtained was done after obtaining ethics committee clearance from our institution. All adolescents from 10 to 18 years were included in the study and students who were absent from school on the day of visit were excluded from the study.

Anthropometric measurements such as height and weight of all students were recorded. Instruments were calibrated, and the BMI was calculated based on the measured height and weight. The nutritional status of the adolescent was determined based on the WHO BMI charts available, separately for boys and girls, from 5 to 19 years.[9] The WHO chart classifies them as severe thinness, thinness, and normal, overweight, and obese based on their BMI for their particular age. A questionnaire/checklist was designed to record the daily eating habits of school children based on the recommended portions of various categories listed in the food pyramid, as recommended by the ICMR and National Institute of Nutrition (NIN).[10] Based on the above balanced diet recommendations, questionnaire was developed which assessed the daily eating habits of the adolescents.[11] The questionnaire was a simplified tool with ten items, to assess gaps in the recommended portions of food category intake, by directly asking question that checks in Yes/No terms the compliance with daily recommended intake of cereals in the three main meals, daily intake of vegetables and green leafy vegetable, daily intake of milk and milk products, habit of taking a fruit daily, and intake of protein-rich foods in daily diet. In the assessment of protein-rich food/pulses recommended, portions can also be replaced by egg or other nonvegetarian food as per recommendations.[10] Hence, this assessment includes the assessment of egg and nonvegetarian food also. Additional questions were added to assess other eating habits such as the habit of taking mid-day snacks and questions that captured certain faulty eating habits of students like habit of skipping meals, taking junk food, and eating from street shops. The scoring was also given for each student based on the Yes/No terms in the questionnaire. Each positive response had a score of 1. Total score was 10 and a score of <10 indicates the gap from the recommended portion of food, or they have a faulty eating habit. Lesser the score, more is the gap in the recommended dietary portion of food category. Each student was individually enquired about the eating habits based on the questionnaire, and individual nutrition counseling was given to students who had a faulty eating habit or not complying with the recommended dietary food group intake standards.

All quantitative values were expressed in proportions. Normality test (Shapiro–Wilk test) was done and the nutritional score followed a nonnormal distribution. The association between eating habits and gender, age, and the nutritional status was tested using Chi-square test and Kruskal–Wallis test. All statistical analysis was performed using IBM SPSS Statistics for Windows, Version 24.0. Armonk, NY: IBM Corp (24.0), $P = 0.05$ or less, were considered as statistically significant.

Results

A total of 1425 adolescents between the ages, 10 and 18 years were included for this study, of which 53.1% belonged to early adolescents (10–13 years), 39.9% belonged to middle adolescents (14–16 years), and 6.9% belonged to late adolescents (17–18 years). The mean age was 13.38 ± 2.03 years. The study participants were 753 (47.2%) males and 672 (52.8) females.

Table 1 shows that a majority (68.8%) of adolescents had a normal BMI. However, more than a quarter of them (23.2% of

Table 1: Nutritional status of adolescents based on the WHO body mass index charts

Nutritional status	Male (*n*=672), *n* (%)	Female (*n*=753), *n* (%)	Total (*n*=1425), *n* (%)
Severe thin	53 (7.9)	23 (3.1)	76 (5.4)
Thin	145 (21.6)	109 (14.5)	254 (17.8)
Normal	429 (63.8)	551 (73.2)	980 (68.8)
Overweight	28 (4.2)	38 (5.0)	66 (4.6)
Obese	17 (2.5)	32 (4.2)	49 (3.4)

students who were undernourished including thin and severely thin and 8% were either overweight or obese) need dietary and other interventions.

The nutritional status of boys revealed 29.5% were either severely thin or thin, 4.2% were overweight, and 2.5% had obesity. Among girls, 17.6% were in severely thin or thinness category, 5.0% overweight, and 4.2% had obesity. This difference between boys and girls was statistically significant ($P < 0.001$).

Figure 1 shows the percentage of adolescents taking the recommended food groups daily as per the ICMR/NIN recommendations and also certain faulty eating habits such as eating junk food, eating from street shops, and skipping meals. It shows that none of the adolescents had the habit of taking green leafy vegetables daily. Furthermore, the habit of taking fruits and milk was very poor among the adolescents, thereby putting them at risk of micronutrient and vitamin deficiency which are not picked up if we do anthropometry alone as done in most school health programs.

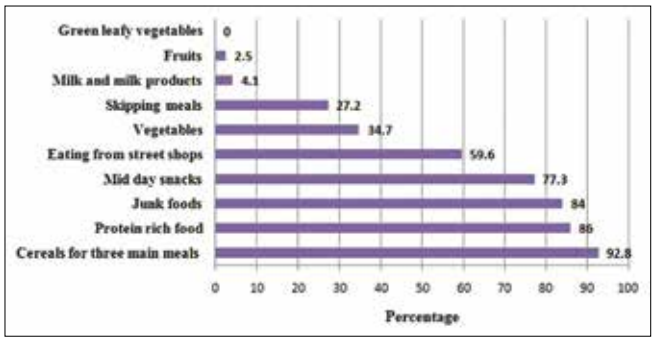

Figure 1: Pattern of eating habits among adolescents.

Table 2 shows that there is an association between eating habits and nutritional status of the adolescents. Chi-square test was used to find whether there was any significant difference in the eating habits among the adolescents of various nutritional statuses (based on BMI). Except for the habit of eating junk foods, others habits have significant association with BMI ($P < 0.001$).

Table 3 shows the difference in eating habits based on gender. Chi-square test was used to find whether there was any significant difference in the eating habits among the adolescent boys and girls. Odds ratio was also calculated. Habits of taking cereals, mid-day snacks, skipping meals, and eating from street shops showed significant difference between boys and girls.

The mean score obtained by the students on the diet assessment was compared between the age groups. Kruskal–Wallis test was used to find the statistical significance among the various age

Table 2: Association of eating habits and nutritional status of schoolchildren ($n=1425$)

Eating habits (recommended ICMR/NIN food category portion frequency)	Nutritional status (BMI categories)			χ^2	*P*
	Thin ($n=330$), *n* (%)	Normal ($n=980$), *n* (%)	Overweight/obese ($n=115$), *n* (%)

OR: Odds ratio

groups. The mean scores of early, middle, and late adolescents were 4.3 ± 1.27, 4.2 ± 1.23, and 4.6 ± 1.02, respectively. Late adolescents had a better nutritional score compared to early and middle adolescents. The difference was found to be statistically significant ($P = 0.006$).

Discussion

Our study shows that undernutrition or thinness among the rural school-going adolescents was a common problem (23.2%). Furthermore, 8% were overweight or obese and hence over a quarter of them need dietary and other interventions. The percentage of undernutrition and overweight was less in our study compared to a study done in Karnataka by Benazeera., where among school adolescents, 34% were belonging to the category of underweight, 21.33% were obese, and 10.67% were overweight.[12]

We also found that underweight was more common among boys and overweight and obesity were more among girls and hence targeted interventions for girls and boys are needed that address factors that could be different. This means further studies are needed to find out the reasons for the difference observed. A study done in Bangalore by Abraham and Anand showed similar findings among adolescent schoolchildren.[13] The study by Venkaiah *et al*. among rural adolescents in nine states also showed that underweight was more among boys than girls.[14]

Regarding eating habits, our study showed that the habit of taking green leafy vegetables daily was not there in any of the adolescents. Furthermore, the habit of taking fruits (2.5%) and milk and milk products (4.1%) was very poor. These habits were poor even in the normal BMI category. Thus, traditional school health programs that use anthropometry alone would not help identify vitamin and micronutrient deficiency unless anthropometry is combined with clinical screening for vitamin and micronutrient deficiency diseases and their contributing factors by doing a diet survey. A study done by Rathi *et al*. among adolescents in Kolkata also showed that 45% did not consume any fruit, 30% did not take vegetables, and 36% did not take milk and milk products. Our study showed that consumption was very less percentage maybe because it assessed daily habits, while the study in Kolkata showed the consumption based on the last 2 days.[5]

In our study, the eating habits of adolescents were found to have significant association with their nutritional status, except for habit of eating junk foods. Our study showed that habits like not consuming cereals for three main meals, not taking mid-day snacks, protein-rich food, and skipping meals were significantly associated with the underweight. In the overweight/obese category, factors such as milk and milk products, eating from street shops, and junk food were high, though junk food did not show any statistical significance. Similar findings were seen in a study by Amin *et al*. which showed that frequent consumption of sweets/candies and milk and milk products are associated with obesity.[15] However, even habits of eating vegetables and fruits were also high in the overweight/obese category. Since the study did not take into consideration the quantity of consumption and exact fruits and vegetables consumed, we could not comment on this. A study by Bhattacharjee *et al*. among adolescents showed that BMI correlated significantly with the dietary habits.[16] Another study by *et al*. showed that eating habits were a better predictor of BMI, especially among boys.[17]

In our study, association of gender with eating habits showed that habits such as consumption of cereals, having mid-day snacks, skipping meals, and eating from street shops showed significant differences. Habit of consuming cereals and having mid-day snacks were better among girls. A study by Rathi *et al*. also showed that females had better consumption of cereals.[5] However, higher percentage of girls had the habit of eating from street shops. This was again similar to a study which showed that significantly more mid-adolescent girls purchased from tuck shops than boys.[18] The habit of skipping meals was more common among boys than girls. Similarly, a study among Turkish Adolescents shows that one-third of the boys skip meals, while only one-sixth of the girls skip meals.[19] Furthermore, a systematic review done among young adults showed that men tend to skip breakfast more often than females, while skipping lunch and dinner was more common among females.[20]

Our study also showed that late adolescents had better eating habits as demonstrated by their higher nutritional scores compared to early and middle adolescents. The nutrition scores are least in the middle adolescents group. This might be because in early adolescents still parental influence is more as shown in a study which shows parental influences can influence the diet of the child.[21] In the late adolescence, the better scores might be because the adolescents become more aware about healthy eating, as shown in certain studies that late adolescents have better knowledge than the younger ones.[22] However, further studies are needed to establish the factors influencing their diet.

Limitations and strengths

Our study has several strengths; we have studied a large number of children in the study sample. A simple and effective questionnaire was used for identifying the gaps in the eating habits based on the standard ICMR/NIN recommendations for a balanced diet. In addition, standard methods like the WHO-developed BMI age charts were used to assess the nutritional status.

However, there were certain limitations, eating habits were assessed by self-reported data and quantitative measuring of the intake of the recommended portions of food groups was not done. We could not exclude the possibility of confounding effects by unmeasured variables such as physical activity and other comorbidities that influence the BMI. Furthermore, data did not include social factors known to affect BMI such as socioeconomic status, number of family members, and education of the mother. Although our study identified low

intake of green leafy vegetables and fruits, we had not planned to look for clinical manifestations of vitamin and micronutrient deficiencies and then look for correlation between the two. Also, since we have found that underweight was more common among boys and overweight and obesity were more among girls and hence further studies are needed to find out the reasons for the difference observed.

Notwithstanding the above limitations, our study findings show that there is scope for doing further in-depth studies to prove the preliminary findings of this study.

Conclusion

The study shows that it is possible to make a Nutritional Education Diagnosis by identifying the gaps in eating habits compared to the recommended one for school-going adolescents. This can then be used to plan tailor-made educational and nutritional programs for improving their eating habits. Using the rapid screening method used in the study, it would be relatively easy to conduct this exercise on a sample of schools in a district to capture gaps in diet at district level for conducting health education and awareness programs on nutrition for adolescents in schools at the district and using similar methods to scale it up for state-level as possibly a national-level initiative to extend school health nutritional interventions to adolescent groups, as their eating habits are different and have long-term nutritional and health implications for the population beyond adolescence.

Abstract

Due to the increasing adoption of nutrient discharge regulations, many research groups are stepping into new territory with phosphorus (P) measurements. Accurate reporting of P concentrations in effluent from novel wastewater treatment technologies is critical for protecting both environmental and human health. Analysis of P in wastewater is prone to pitfalls because of the (1) variety of chemical forms of P in wastewater (orthophosphate, condensed P, and organic P), (2) availability of different chemical assays for measuring different P forms, and (3) different conventions in the units for reporting P. Here, we present a case study highlighting how these pitfalls affect analysis and interpretation of P measurements. We show that, when used appropriately, commercially-available kits are indeed accurate tools for evaluating reactive P and total P concentrations. For both standard solutions and real wastewater, we systematically remove steps from the total P protocol to show how protocol deviations affect the results. While standard solutions are important for validating analytical methods, commercially-available wastewater standard solutions only contain P as orthophosphate (reactive P).

We therefore demonstrate options for making a mixed-P standard solution containing acid-hydrolyzable and/or organic P compounds that can be used to validate both reactive P and total P assays.

Keywords: Wastewater, nutrient pollution, standard solutions, onsite treatment, phosphorus, phosphate, non-sewered sanitation

Introduction

An intense area of research is non-sewered sanitation solutions for rural areas and low- and middle-income countries[1-14] to address the urgent need for safely-managed sanitation to improve human health and the environment.[15,16] In addition to removing pathogens and organic compounds, a key requirement of wastewater treatment is removal of nutrients including nitrogen and phosphorus (N and P) due to their potential toxic effects on aquatic environments.[17,18] The concern with P is that phosphates are limiting nutrients in freshwater aquatic environments; an overabundance can lead to decreased dissolved oxygen, accelerated eutrophication, and harmful algal blooms.[19] These algal blooms can also pose a human health risk through the production of cyanotoxins.[20] Additionally, P is a limited, valuable natural resource that should be recovered and reused.[21,22]

Nutrient discharges from inadequate onsite wastewater treatment systems are a growing concern globally and likely underreported.[16,23] Affordable and sustainable methods for effective N and P removal in decentralized treatment systems remain technologically challenging.[24,25] Recently, an international standard ISO 30500 was specifically developed to provide performance requirements for non-sewered sanitation systems[26] and sets a minimum threshold reduction of 80% for total P. As P regulations are increasingly enforced, wastewater P content will need to be regularly measured and reported as new technologies are pilot-tested.[2,14,27,28] Standardized P reporting is required to compare performance across different technologies and wastewater streams to accelerate technology adoption, yet a critical gap exists due to lack of a common set of metrics.[29] This knowledge gap in reporting metrics for P and its different chemical species is also highlighted in a recent systematic review of nutrient removal and recovery technologies by Kogler et al.[30] In reviewing 292 articles across 46 sources, Kogler et al.[30] found that removal efficiency and achievable effluent concentrations for P removal and recovery technologies are generally underreported, with only 16% of the articles reviewed giving adequate quantitative information for meaningful interpretation of technology performance.

As we embarked on the journey of adding total P to our routine testing regimen, we identified several specific points of confusion. We determined that measurement and reporting of P requires particular attention because of the (1) variety of chemical forms of P in wastewater, (2) availability of several different chemical assays for measuring different forms of P, and (3) different conventions in the units used for reporting P. Due to the interrelated nature of these topics, there is potential for inconsistencies in reporting results for P. Here, we present a case study highlighting the importance of accurate and clear reporting of P units and strict adherence to chemical assay protocols for measuring P in wastewater samples. The objective of this paper is to share our experiences in identifying and overcoming these P-related pitfalls so that others may avoid these issues in their future work. The aims of this paper include (1) determining the root cause(s) of discrepancies in P results and (2) developing new standard solution mixtures to ensure accurate analytical method implementation and data reporting.

We begin with a brief review of the forms of P in wastewater and typical units used for reporting P. We then describe our recent experiences where we identified discrepancies in P concentrations we measured using a commercially-available test kit and those measured by a third-party lab for the same

samples. Due to the transparent and productive relationship with the third party lab, we were able to identify two distinct sources of confusion as the likely reason for these discrepancies: (1) the factor of 3.066 difference in results reported as mg L^{-1} "PO_4-P" versus mg L^{-1} "PO_4^{3-}"; and (2) the omission of the digestion heating step in the total P protocol. By systematically omitting steps from the total P chemical assay procedure, we show that skipping the digestion heating step results in a significant undercounting of total P, both for standard solutions and for real wastewater samples.

To avoid these issues in future studies, regularly testing known P standard solutions to validate analytical methods and reporting methods is needed. However, we observed that the common commercially-available wastewater standard solutions only contain P as orthophosphate (reactive P). This is perhaps due to the fact that soluble orthophosphate is the majority P form in effluents from traditional wastewater treatment systems and therefore also the P form of primary concern for anthropogenic nutrient pollution.[31] However, our analysis reveals that the assumption that orthophosphate = total P does not necessarily hold for wastewater influent of novel onsite wastewater treatment technologies. We therefore believe that including acid-hydrolyzable P and/or organic P components in known standard solutions is especially important to ensure accurate reporting of novel wastewater treatment technology performance. To this end, we have prepared and validated our own standard mixtures of orthophosphate, acid-hydrolyzable P, and organic P using readily available and inexpensive chemical reagents.

Methods

Unless otherwise indicated, all glass wares used in this study were cleaned by soaking in 1:1 HCl:water (v:v), rinsing thoroughly in distilled or ultrapure water, then filling with fresh distilled or ultrapure water and storing until needed. Mean and standard deviation values for replicate measurements were calculated using Excel. Data were plotted using OriginPro 2018.

Standard solutions

A mixed-parameter quality control standard solution for wastewater was purchased (Hach, product LCA720) that features 10.0 mg L^{-1} PO_4-P in addition to ammonia, nitrate, COD, and TOC. A wastewater influent inorganics quality control standard solution was also purchased (Hach, product #2833149) that contains 10 mg L^{-1} PO_4^{3-} in addition to ammonia, nitrate, COD, sulfate, and TOC. (See Supplemental Material for details.)

The other standard solutions used to validate assay performance were prepared in-house. Phosphate stock standard solutions (PO_4^{3-} = 10 and 25 mg L^{-1}, labelled P 10 and P 25, respectively) were prepared by dissolving potassium dihydrogen phosphate (KH_2PO_4) in distilled water. Mixed standard solutions were prepared using KH_2PO_4, sodium trimetaphosphate ($Na_3P_3O_9$), and adenosine 5'-triphosphate, disodium salt (ATP), all purchased from Sigma-Aldrich (see Supplemental Material for additional reagent information).

Real wastewater samples

Effluent from a toilet was collected to serve as wastewater samples for evaluation. A women's shared toilet facility at a privately-owned textile mill in Coimbatore, India (described in a previous study) was the sample collection site.[13] The facility is used by 20 to 50 employees and features five toilet stalls equipped with Indian squat plates, each connected to cistern flush. The effluent of one of the toilets can be easily tapped into from the pipe and was diverted from its septic tank to a 200 L collection tank. After collecting all toilet effluent (containing flush water, urine, and feces) from 8 am to 5 pm local

time, the wastewater was left to settle overnight. The supernatant was collected the morning after and then the contents of the tank were homogenized by with a macerator pump (Jabsco Model: 18950, 45 lpm). Both supernatant and macerated wastewater samples were analyzed with the commercially-available test kit on the same day.

Commercially-available test kits (ascorbic acid method)

Total P (method 8190) and reactive P (method 8048) test kits were purchased from Hach and used with a Hach DR 900 colorimeter. Unless otherwise indicated, the test kits were used exactly as per the manufacturer's instructions (see Supplemental Material for more detail). Both test kits use the ascorbic acid method, are USEPA accepted for reporting wastewater analyses, and the procedures follow USEPA and Standard Method 4500-P.[32] Distilled (in India) or ultrapure 18.2 MΩ cm (in the US) water was used for dilution as necessary to bring the samples within the assay detection range. The total P test kit includes two powder pillows (potassium persulfate, PhosVer 3), a bottle of sodium hydroxide 1.54 N, and glass reaction vials containing a pre-measured sulfuric acid solution. A Hach DRB 200 digester heating block was used for the digestion step in the total P protocol. The reactive P test kit includes one powder pillow (PhosVer3) and either glass reaction vials containing a pre-measured volume of deionized water or a reusable glass sample cell (see Supplemental Material).

Third-party laboratory measurement (stannous chloride method)

Samples sent to a NABL certified laboratory (T.STANES Coimbatore) were analyzed using the Indian Standard IS:3025 part 31[33] stannous chloride method for the measurement of total P, a method essentially similar to Standard Method 4500-P.[32] According to the IS:3025 part 31 stannous chloride method, samples are decolorized by shaking with activated carbon for 5 minutes, then filtered. A phenolphthalein indicator is added to the filtered sample, and if a pink color develops, the pink color is discharged through the addition of up to 5 drops of a strong acid solution. Finally, ammonium molybdate and stannous chloride reagents are added and allowed to react for 10 minutes. The sample is then quantified spectrophotometrically at 690 nm. Fresh standard solutions were prepared by the third-party lab to calibrate their instrument upon receipt of each set of samples. Distilled water was used for sample dilution when necessary to bring the sample within the assay detection range. Analytical results from the third-party lab were reported to us in units of "Phosphorus (mg/L)."

Results and Discussion

Forms of P relevant for wastewater analysis

In aqueous solutions relevant for wastewater treatment technologies, P exists in three main forms, commonly referred to as orthophosphate, condensed phosphate, and organic phosphate (Table 1).[32] Phosphate anions can be detected colorimetrically, and chemical assays are commercially available for measuring only orthophosphate (sometimes called "reactive P"), "acid-hydrolyzable P" (orthophosphate + condensed phosphate), or "total P" (orthophosphate + condensed phosphate + organic phosphate). The specific chemical reactions responsible for the colorimetric responses have been described in detail elsewhere[32] and should be included with each commercially-available assay. Briefly, orthophosphate anions form a colored complex with a transition metal under the chemical assay conditions.

Table 1.

Common assays, with naming and unit conventions, for forms of P in wastewater analysis.[32]

Commercially-available chemical assays	"Orthophosphate" or "reactive P"	"Acid-hydrolyzable P"	"Total P" or "total phosphate"
Forms of P detected	Orthophosphate	Orthophosphate + condensed phosphate	Orthophosphate + condensed phosphate + organic phosphate
Digestion required?	No	Yes	Yes
Strong oxidant required?	No	No	Yes
Typical reported units (mg L^{-1})	PO_4^{3-} or PO_4-P	PO_4^{3-} or PO_4-P	PO_4-P or P

The color response for all the different assays is due to detection of orthophosphate. Other forms of P (condensed phosphate and organic phosphate) must first be converted to orthophosphate before they can be detected. Condensed phosphates require a preliminary acid hydrolysis step at elevated temperatures before the colorimetric response can be observed. Some organic phosphates also require addition of a strong oxidant to the acid hydrolysis step. Orthophosphate and acid-hydrolyzable P are typically reported using units of either mg L^{-1} "PO_4^{3-}" (orthophosphate) or "PO_4-P" (orthophosphate as P). Total P is typically reported as mg L^{-1} "P."

Potential Pitfall #1: Distinguishing and converting between the different units used for P reporting

Note that the "typical" reporting units in Table 1 are just a guideline. In our experience, these do not appear to be hard rules, and all three units are used for reporting all types of phosphorus data. *The units alone will not tell you which forms of phosphorus have been measured.* It is therefore important to understand what the different units mean and how they are interrelated. Some standards, such as the ISO 30500, are written as percent reduction requirements; in this case, the units in which P quantities are reported is not particularly important as long as it is internally consistent within any given study. However, P units must still be accurately and clearly reported in order to compare values across different studies and to nominal values for other discharge standards. Briefly, units of "PO_4-P" and "P" are equivalent and therefore interchangeable. "PO_4^{3-}" units are calculated differently and a mathematical conversion must be performed to compare to the other units.

Converting between values reported in the three different units requires accounting for the mass of atoms which are counted in each unit. Units of PO_4-P and P only count the 1 P atom (30.97 amu). Therefore, values reported in mg L^{-1} PO_4-P will be identical to values reported in mg L^{-1} P and no conversion is required. In contrast, units reported in PO_4^{3-} count all atoms in the phosphate anion—1 P atom (30.97 amu) and 4 O atoms (each 16.00 amu). Values reported in mg L^{-1} PO_4^{3-} can be converted to P or PO_4-P by dividing by 3.066, which is the stoichiometric ratio of the mass of the phosphate anion (1P + 4O = 30.97 + 4(16.00) = 94.97 amu) to that of a single P atom (30.97 amu). Similarly, values reported in units of P or PO_4-P can be converted to units of PO_4^{3-} by multiplying by 3.066:

$$1.000\ \text{mg L}^{-1}\text{P} = 1.000\ \text{mg L}^{-1}\ \text{PO}_4\text{–}P = 3.066\ \text{mg L}^{-1}\ \text{PO}_4^{3-} \quad \text{Eq. (1)}$$

As an example, consider the two wastewater (WW) quality control standard solutions, both purchased from Hach for use in this study. The first WW standard solution (1) is listed by the supplier as containing "10.0 mg L^{-1} PO_4-P," while the other (2) is listed as containing "10 mg L^{-1} PO_4^{3-}." It is an easy mistake at first glance to think that the phosphate concentrations of these solutions are equivalent. However, when we convert WW standard solution (1) to PO_4^{3-} units, we see that it actually contains 3 times as much phosphate: (10.0 × 3.066) = 30.7 mg L^{-1} PO_4^{3-}. To directly compare these wastewater standard solutions, we will hereafter label them as (1) WW 30 and (2) WW 10 to reflect the expected phosphate concentration in PO_4^{3-} units.

We use a commercial test kit for total P (Hach 8190) for our in-house field testing, because this field-friendly method utilizes only two small, easily-transportable pieces of equipment (the DRB 200 digester and the DR 900 colorimeter) and pre-portioned reagents in pre-measured vials and sealed "powder pillow" packets. The results for total P are displayed by the DR 900 colorimeter in units of "mg L^{-1} PO_4^{3-}." We used the WW 30 standard solution described above to validate the total P test kit, as recommended by the manufacturer. Results were obtained for samples collected in glass bottles cleaned with or without a HCl acid wash. (The acid wash is used to eliminate possible contamination from the detergent used to clean bottles, which may contain phosphate.) Figure 1 shows that all results obtained were within 15% of the expected value (n = 4; mean = 29.6 ± 4.2 mg L^{-1} PO_4^{3-}), however the variability in the acid-washed results was lower, within 5% of the expected value (n = 3; mean = 30.6 ± 1.5 mg L^{-1} PO_4^{3-}). We therefore used acid-washed containers for all subsequent measurements, including with samples sent for analysis to the third-party lab.

Open in a separate window

Figure 1.

(A) Total P test results (measured by Hach kit) for the commercially-available standard solution WW 30 and in-house prepared phosphate solutions (P 25 and P 10). Each standard solution was tested multiple times; the results of individual tests are shown as open symbols, with the mean for each column shown as a short dashed line and the expected values shown as solid horizontal reference lines. The variability in test results is highest for WW 30 measured without acid washing of glassware (diamonds, n = 4, 29.6 ± 4.2 mg L^{-1} PO_4^{3-}). The variability is similar for all three standard solutions when glassware is acid washed prior to contact with the samples (circles; WW 30, n = 3, 30.6 ± 1.5; P 25, n = 6, 25.3 ± 1.0; P 10, n = 6, 10.8 ± 1.1). Position along the x-axis is not meaningful—data points within each column are offset from one another for clarity. (B) Total P measured for identical samples tested in-house with the Hach test kit and by the third-party lab. Values for units of PO_4^{3-} are shown on the left y-axis and values for units of PO_4-P are shown on the right y-axis. Expected values are shown as solid horizontal reference lines. Values reported by the third-party lab (in PO_4-P units) are similar to those measured in-house (in PO_4^{3-} units) once the correct unit conversion is applied.

In addition to the WW 30 standard solution, we evaluated phosphate solutions prepared in-house of known concentrations (PO_4^{3-} = 10, 25 mg L^{-1}, labelled P 10 and P 25, respectively) obtained by dissolving KH_2PO_4 in distilled water. Again, these solutions gave results close to the expected values (P 10, n = 6, mean = 10.8 ± 1.1 mg L^{-1} PO_4^{3-}; P 25, n = 6, mean = 25.3 ± 1.0 mg L^{-1} PO_4^{3-}). These results confirm that solutions of KH_2PO_4 can effectively serve as standards for P in orthophosphate form, and that acid-washing of sample glassware reduces test-to-test variability in the results.

Initial reports showed different units for P analysis performed by a third-party lab, leading to a discrepancy which required further validation. Our third-party collaborator, a certified laboratory located in the same city, uses the stannous chloride method for total P measurement. This third-party lab requires a large volume (>150 mL) of sample to run their assay, thus we diluted by 5× the WW 30 standard solution prior to delivering it. We also sent for analysis a sample of the P 25 solution.

The third-party lab reported values of 10.25 mg L^{-1} for the WW 30 sample and 7.84 mg L^{-1} for the P 25 solution, both reported with units of "Phosphorus (mg/L)." Initially, we were surprised to find that the third-party lab results appeared much lower than the values we expected (30.7 and 25.1 mg L^{-1}, respectively) for the WW 30 and P 25 samples. After clarifying discussions with the third-party lab, we determined that their results were reported in "PO_4-P" units. Thus, the expected values would be 10.0 and 8.15 mg L^{-1} for units of PO_4-P, respectively, for these two samples. In Figure 1B, the results are shown for both units of PO_4^{3-} (on the left axis) and PO_4-P (on the right axis). It is clearly seen that by resolving the ambiguity of the reported units, the total P values were measured by the third-party lab within a few percent from the expected values.

Potential Pitfall #2: Omission of steps from the total P test protocols

Despite reconciling the difference in reported units between our in-house total P test results and those from the third-party lab, we noticed that there was still a discrepancy between results from the two labs when real wastewater samples were analyzed. Total P results from the third-party lab were always lower than those measured in-house, although not always lower by a consistent nominal amount or percentage. Importantly, we learned through fruitful discussions with the third-party lab that while a digestion (heating) pre-treatment step is listed in the IS:3025 protocol, digestion was not actually performed. This indicates that while the third-party lab results were accurate in determining total P content from the standard solutions (where only orthophosphate was present), their procedure will under-report the total P content for samples where condensed and organic phosphates are present (e.g., real wastewater samples from field testing evaluation of onsite treatment technologies).

The full protocol for Hach total P measurement includes a digestion step performed by heating the sample in acid at 105 °C for 30 minutes with a persulfate ($S_2O_8^{2-}$) reagent added to the solution. Heating in acid converts any acid-hydrolyzable P to orthophosphate. The addition of the strong oxidant $S_2O_8^{2-}$ ensures that organic phosphates are fully converted to orthophosphate. Figure 2 shows in-house results for two raw wastewater samples where steps from the total P protocol were systematically and intentionally omitted. Samples A and B were collected on different days from the same shared toilet effluent, and the liquid supernatant as well as a macerated sample containing higher fecal load were analyzed. The primary soluble form of P in wastewater is orthophosphate, therefore orthophosphate is expected to dominate in the supernatant fraction, while the macerated fraction is expected to contain a higher concentration of organic and condensed P forms.

Figure 2.

Comparison of total P results obtained during systematic omission of testing steps for two raw wastewater samples A and B collected from the Coimbatore field testing site. The photograph shows the typical appearance of the supernatant and macerated sample fractions. For each sample, both the macerated fraction (closed circles) and the supernatant fraction (open circles) were measured. The macerated fraction contains more fecal matter and thus a higher total P concentration. Omitting the heating step ("-heat") from the testing protocol has the largest effect on the measured total P concentration, while omitting the persulfate reagent ("-$S_2O_8^{2-}$") has a smaller effect that is most visible for the macerated fraction. Samples were diluted with distilled water by 10× to 25× to bring them within the range of the total P Hach test kit.

Figure 2 shows that omitting the heating step has the largest effect on the total P results, both for the macerated and supernatant sample fractions. Omitting the $S_2O_8^{2-}$ reagent has a measureable, but smaller, effect. When the protocol is followed fully, the total P measured for Sample A was 45.8 mg L^{-1} PO_4^{3-} for the macerated fraction and 42.2 mg L^{-1} PO_4^{3-} for the supernatant fraction. These values drop to 35.4 and 35.6 mg L^{-1} PO_4^{3-}, respectively, when the heating step is omitted. This results in an under-reporting of total P by 23% for the macerated fraction and 16% for the supernatant. For Sample B, omitting the heating step results in under-reporting of total P by 35% for the macerated fraction and 21% for the supernatant. Omitting only the $S_2O_8^{2-}$ reagent under-reported the total P in the supernatant samples by ~5%, which is similar to the test-to-test variability for standard solutions as shown in Figure 1. In contrast, omitting only the $S_2O_8^{2-}$ reagent from the macerated fraction under-reports the total P by 8% for Sample A and 18% for Sample B.

In summary, total P content in raw wastewater samples can be substantially under-reported if any step in the digestion protocol is omitted. The largest differences in total P values were found with heating and/or persulfate omission for the macerated sample fractions. This shows that the risk of P under-reporting increases as the fecal content (and thus the amount of condensed and/or organic P) increases. This is important when testing new treatment technologies, particularly those which involve novel solid/liquid separation processes, solids-settling techniques, or other methods of solids treatment where solid fecal matter is broken down and mixed with liquid effluent.

Impact of the pitfalls

While the major contribution of water soluble P in human excreta is inorganic orthophosphate, orthophosphate may not always be the sole contributor to total P in effluent from onsite wastewater treatment technologies. Raw influent of onsite wastewater treatment technologies is highly variable and impacted by many factors such as number of toilet uses, flush volume, and diet.[34,35] We suspect that concentrations of condensed and/or organic P may be significant in influent and in effluent from some technologies with novel solid/liquid separation or solids processing methods.

Our group has previously evaluated one such novel system. We reported in a previous publication total P values of system effluent of 8.3 and 21.5 "mg P L^{-1}"[5] that we now suspect were measured omitting the heating step; thereby, those values represent only the orthophosphate as opposed to the total P. In a different publication,[13] we reported values of "P," without specifying the form (which was orthophosphate) nor clarifying the reporting units (mg L^{-1} P). In another recent paper,[14] we did specify

in the methods section that both reactive P and total P were reported in units of "mg L^{-1} PO_4^{3-}." However, table columns and figure axes in that work were labelled only as "mg L^{-1}" for both reactive P and total P. For added clarity in the future, we will explicitly include the full unit "mg L^{-1} PO_4^{3-}" or "mg L^{-1} P" in all tables and figure axes, as demonstrated in the present work.

From our experiences described here, particularly those during collaboration with a third-party laboratory, we now fully appreciate how critical it is for groups working on wastewater treatment technologies to report the correct P form in clear, specific units. Our concern that inconsistencies in P reporting are widespread is further supported by a recent systematic review of the literature on nutrient removal and recovery technologies by Kogler et al.[30] In sorting reports for P removal efficiencies and effluent concentrations, three separate categories were required for reports of "TP = total phosphorus" and "PO_4 = phosphate," and "P = general phosphorus species if species was not identified clearly."[30] This review shows that there is a prevalent need to standardize quantitative performance metrics of nutrient removal and reuse technologies.

The ambiguity in reporting units introduces lingering questions of whether variable P concentrations in wastewaters across different studies is due to variability in the wastewater itself or variability in reporting and analysis methods. For example, Cid et al.[2] reported 0.64 mmol L^{-1} "PO_4^{3-} + HPO_4^{2-}" in average macerated toilet wastewater from one of their self-contained bathroom + wastewater treatment and recycling prototypes. The specific analytical method used in that work is not reported, but assuming based on the units that this represents a measurement of orthophosphate (reactive P), this would be approximately 60.8 mg L^{-1} PO_4^{3-}. This value is similar to what we report here for total P concentrations in macerated toilet wastewater, but also aligns well with our previous report of reactive P in toilet effluent.[14] Another recent study by Reynaert et al.[27] reported 36.2 mg L^{-1} average soluble phosphate "PO_4" concentration in toilet wastewater influent from a urine-diverting toilet with solids separated from the flush water. While the use of the "PO_4" unit is ambiguous, the analytical test used (Spectroquant) appears to give results in units of PO_4-P. This would indicate that the average influent concentration in this study was 36.2 mg L^{-1} PO_4-P or 111 mg L^{-1} PO_4^{3-}, and the nominal average concentration in the treated clean water tank is 25.4 mg L^{-1} PO_4-P or 77.9 mg L^{-1} PO_4^{3-},[27] which would be unable to meet water reuse or discharge standards with nominal effluent P concentration limits (eg, <1 mg L^{-1} P in India).[36]

Pitfall prevention: Preparation of mixed-P standard solutions for analytical test validation

For pitfall #1, we determined that validating test protocols and reporting units for reactive P, both in-house and with the third-party lab, can be accomplished by testing commercially-available standard solutions of orthophosphate. But what about validating methods when samples contain condensed and/or organic forms of P? Researchers should clarify the analytical methods used by explicitly stating whether samples were digested prior to analysis. For example, Chapter 4500-P in the 22nd edition of Standard Methods for the Examination of Water and Wastewater contains ten subsections detailing sample filtration pretreatments, three digestion methods, and three colorimetric methods.[32] Therefore, simply referencing "standard method 4500-P" is insufficient for determining the fraction or form of P that has been analyzed. For samples containing condensed and/or organic P, definitive confirmation that digestion has been performed requires an analytical validation step testing a standard solution of known composition. However, the wastewater standard solutions readily available for purchase only contain orthophosphate. Testing these standard solutions will not clarify whether sample digestion is performed as required to convert all P forms to orthophosphate.

We therefore set out to prepare our own in-house, mixed standard solution for validating total P testing protocols. In addition to KH_2PO_4 to provide orthophosphate, we identified two non-hazardous compounds which are readily-available and relatively inexpensive to represent condensed and organic P forms: trisodium trimetaphosphate ($Na_3P_3O_9$) and adenosine 5'-triphosphate, disodium salt (ATP). Figure 3 shows the structures of these compounds and relevant properties, such as number of PO_4^{3-} equivalents (i.e., number of PO_4^{3-} anions detected in total P test per molecule of the compound). While KH_2PO_4 will be detected in a reactive P test, $Na_3P_3O_9$ and ATP will only be detected in a total P test, as digestion is required to hydrolyze P-O and O-C bonds to release free orthophosphate into the solution.

Open in a separate window

Figure 3.

Chemical compounds used in this study to make in-house mixed-P standard solutions. KH_2PO_4 dissociates readily to give phosphate anions that are detected in reactive P tests. $Na_3P_3O_9$ and ATP each contribute 3 phosphate equivalents, but these molecules must undergo acid digestion to release phosphate anions. $Na_3P_3O_9$ and ATP are thus detected in total P tests but are not detected in reactive P tests.

Solutions were first prepared containing only KH_2PO_4, $Na_3P_3O_9$, or ATP and analyzed using total P and reactive P Hach kits (see Supplemental Material for a complete table of all solution recipes). Figure 4 shows these results by comparing samples that contain no reactive P (top; ATP only and $Na_3P_2O_9$ only) to samples with only reactive P (bottom; P 25, P 10, WW 10). For samples with no reactive P ($Na_3P_3O_9$ and ATP), the total P results match the expected values only when the heating step was included in the protocol. When heating was omitted from the protocol, both samples showed <1.5 mg L^{-1} PO_4^{3-} for the total P measurement. As expected, the reactive P test for both $Na_3P_3O_9$ and ATP measured almost zero ($Na_3P_3O_9$ = 0.34 mg L^{-1} PO_4^{3-}; ATP = 0.08 mg L^{-1} PO_4^{3-}). Standard solutions purchased (WW 10) and prepared in-house (P 25, P 10) which only contained reactive P showed no difference in the values for the total P test when steps were omitted from the protocol. As expected, the results of the reactive P test and total P test are identical for samples containing only reactive P.

Figure 4.

Demonstration of the different results obtained from total P and reactive P tests for identical samples, including tests where steps were systematically omitted from the total P protocol. Expected values are shown as horizontal reference lines (dashed lines = ATP). As expected, samples containing condensed and organic P (top, triangles) show no response to the reactive P test (shaded column). Samples containing ATP (closed symbols) and $Na_3P_3O_9$ (open symbols) are accurately measured only when the total P test has been performed according to the protocol. Eliminating the heating step ("-heat" and "-heat, -$S_2O_8^{2-}$") results in a complete failure of the total P test. Eliminating only the persulfate pouch ("-$S_2O_8^{-2}$") shows only a small effect on the total P result for ATP. In contrast, samples that only contain reactive P (bottom, circles; WW 10, shaded symbols; P 25, open symbols; P 10, closed symbols) show nearly identical results for total P and reactive P (shaded column), and omitting steps from the total P protocol imparts no effect.

We also prepared two standard solutions with mixed-P forms that could be used to validate results from reactive P or total P tests using the same solution. Figure 5 shows total P and reactive P results for a 2-part standard solution (containing KH_2PO_4 and $Na_2P_3O_9$) and a 3-part standard solution (containing KH_2PO_4, $Na_3P_3O_9$, and ATP). Both the 2-part and 3-part standard solutions give measured total P concentrations close to their expected values. When the heating step is omitted, the total P results are nearly identical to the reactive P results.

Figure 5.

Comparison of total P and reactive P (shaded column) results for two mixed standard solutions prepared in-house. The 2-part mixed standard solution (open symbols) is a mixture of KH_2PO_4 and $Na_3P_3O_9$. The 3-part mixed standard solution (closed symbols) contains KH_2PO_4, $Na_3P_3O_9$, and ATP. Expected values are shown as horizontal lines (solid lines for 2-part standard solution; dashed lines for 3-part standard solution). Measured results for both mixed standard solutions were close to the expected values. When the heating step is omitted from the total P protocol, the measured value is the same as that for the reactive P test.

The results in Figure 5 show that a 2-part standard solution of KH_2PO_4 and $Na_3P_3O_9$ is sufficient to conclude whether the digestion heating step proceeds as necessary. These chemicals are affordable and do not require any special handling or storage considerations, so a solution of these two compounds could serve as a simple, yet robust mixed-P standard solution. The ATP salt has some disadvantages compared to $Na_3P_3O_9$; it is more expensive, requires storage under refrigeration, and can have a variable water content bottle-to-bottle, making the calculation of the expected concentration slightly more complicated (see Supplemental Material).

However, there are two advantages for why some researchers may choose to include ATP in their in-house standard-solution formulation. First, as persulfate is expected to affect hydrolysis of organic P (ATP) but is not necessary for hydrolysis of condensed P ($Na_3P_3O_9$), we hypothesized that including

ATP in the mixture could validate that the persulfate reagent is included in the total P protocol. When the $S_2O_8^{2-}$ is omitted from the solution of only $Na_3P_3O_9$ or from the WW 10 standard solution (see Figure 4), the total P result does not decrease. In fact, there is a slight increase in the measured total P values (55.6 to 56.6 mg L^{-1} PO_4^{3-} for $Na_3P_3O_9$ from 9.8 to 10.0 mg L^{-1} PO_4^{3-} for WW 10), although this change is well within the test-to-test variability demonstrated in Figure 1. On the other hand, when $S_2O_8^{2-}$ is omitted from the solution of only ATP, the total P value measured decreases from 46.4 to 43.8 mg L^{-1}. Similarly, for the 3-part mixture, omitting $S_2O_8^{2-}$ gives a small decrease in total P from 50.4 to 49.4 mg L^{-1}, however, this is on the border of the test-to-test variability of 1.0 to 1.5 mg L^{-1} shown in Figure 1. If validating inclusion of persulfate is desired, increasing the ratio of ATP in the 3-part mixed standard solution may be prudent. Alternatively, a 2-part standard solution containing only KH_2PO_4 and ATP would also be suitable. The second advantage of including ATP is that it also contains N atoms (5 N equivalents per ATP molecule) and can therefore be used to validate total nitrogen digestion protocols as well. Using the Hach low range total N kit (method 10071), we measured total N concentrations of 8.9 mg L^{-1} N in the ATP only solution and 2.0 mg L^{-1} N in the 3-part standard solution, both of which are in close agreement with the expected values of 11.4 and 2.3 mg L^{-1} N, respectively.

Finally, we evaluated the stability of the in-house mixed-P standard solutions over time, with and without refrigeration of the solutions. If either the $Na_3P_3O_9$ or ATP is susceptible to degradation over time (e.g., slow hydrolysis), then the reactive P concentration of the standard solutions should increase as the samples age. Figure 6 shows reactive P values measured for $Na_3P_3O_9$, ATP, 2-part, and 3-part mixtures after ageing for several days in sealed glass bottles. Only the 3-part mixture was stored under refrigeration; the other solutions were left in the laboratory ambient (21 °C). Small increases in the reactive P concentration were observed for all three solutions stored at room temperature (0.91, 1.98, and 1.40 mg L^{-1} PO_4^{3-} for ATP, $Na_3P_3O_9$, and the 2-part mixture, respectively) for 6 to 11 days. The 3-part mixture stored for 13 days at 4 °C increased by only 0.2 mg L^{-1} PO_4^{3-}. All of these values are within the test-to-test variability of 1.0 to 1.5 mg L^{-1} PO_4^{3-}, except for the $Na_3P_3O_9$ solution, which is only slightly higher.

Figure 6.

Comparison of reactive P results for freshly prepared samples (open symbols) and the same samples after ageing for several days (closed symbols) under laboratory conditions. Samples containing ATP and/or $Na_3P_3O_9$ show very small increases in reactive P when stored at 20 °C for 6 to 11 days. The 3-part standard solution showed no increase in reactive P after 13 days when stored at 4 °C.

In summary, solutions prepared in-house with $Na_3P_3O_9$ and/or ATP are sufficiently stable for several days without refrigeration to serve as standards for validation of total P protocols. These compounds show minimal degradation once dissolved in water and stored at room temperature. The mixed standard solutions can be used in-house or sent to third-party laboratories to confirm that the total P sample digestion protocol is followed correctly.

Conclusions

Accurate and clear reporting of P in effluent from novel wastewater treatment technologies is critical for preventing eutrophication of receiving water bodies and in protecting human health. New research into methods to mitigate nutrient discharge in effluent from non-sewered sanitation systems and the adoption of nutrient discharge standards has many research groups stepping into new territory with phosphorus measurements. We have shown that commercially-available kits are accurate tools for evaluating reactive P and total P concentrations in standard solutions, and results were consistent across the two testing methods used in-house and at third-party lab once the correct unit conversion was applied. We also described options for making a standard solution containing condensed and/or organic P compounds that can be used to validate the digestion step in total P assays. We hope that the mixed-P standard solution recipes will be useful for other research groups, as commercially-available wastewater standard solutions only contain orthophosphate.

The work described here leads us to give recommendations for best practices going forward:

1) Regularly include P standard solutions of known concentration in P analyses. We advise that both an orthophosphate and organic phosphate standard solution (or a mixture) be used to validate which P assay is being used, determine the presence of a digestion step, and confirm the reported units.

2) Clearly state the fraction of phosphorus measured—reactive P, acid-hydrolyzable P, or total P—when reporting phosphorus results. Neither the units for reporting P nor a reference to "standard method 4500-P" are sufficient to convey this important information.

3) Discontinue use of the unit "PO_4-P" in reporting results, and instead only use either PO_4^{3-} or P. We think this may be the root of much confusion in the field, as (1) "PO_4-P" and "P" units are interchangeable and therefore redundant, (2) "PO_4-P" and "PO_4^{3-}" are *not* interchangeable, yet look quite similar, and (3) "PO_4-P" is not a chemically meaningful notation (see Supplemental Material for further discussion).

We hope that these recommendations will be useful and widely adopted by groups (including ours) who are adding or continuing with total P analysis as part of their routine testing.

Abstract

Preoperative prediction of morbidity in colorectal cancer (CRC) surgery helps to optimize the surgical outcome. In this study, we aim to develop a dedicated equation for predicting operative morbidity using colorectal possum scoring system and also to validate the predictive accuracy of CR-POSSUM scoring system in prognosticating actual complications. We did a retrospective analysis of 322 patients undergoing colorectal cancer surgery from a single centre in South India from 2004 to 2016. Mortality and morbidity risk factors as defined by CR POSSUM were collected from 322 patients who underwent CRC surgery and were used to derive equations to predict morbidity, and the results were compared with the observed morbidity. Logistic regression analysis was used to derive the equation. The model fit and model discrimination were analysed using the Hosmer-Lemeshow statistical test for goodness of fit, the Nagelkerke R^2 and area under the receiver operating characteristic (ROC) curve respectively. Out of 322 patients, 103 (32%) patients developed complications and 10 (3%) died due to complications. The regression equation we derived has an overall correct classification of about 70% ($P < 0.01$) with positive and negative predictive value of 60% and 73% respectively. The Hosmer-Lemeshow goodness of fit was 3.147 ($P = 0.829$), and the Nagelkerke R^2 was 17% and area under ROC as model discrimination was 71.6%. Hence, CR-POSSUM scoring which was originally used for predicting mortality risk can also be extrapolated to predict morbidity.

Keywords Colorectal POSSUM · POSSUM · Colorectal surgery · SSI · Morbidity and mortality · Prediction model

Introduction

Colorectal malignancy is the third most common malignancy among men and the second most common among women around the world [1]. Fortunately, in India, the incidence is not too high. However, the incidence has been found to be rising, with the AAR (adjusted annual incidence rate) for colon cancer in men and women being 4.4 and 3.9 per 100,000, respectively [2]. Being in a country, where people living with poor access to quality healthcare, extreme presentation like advanced stage and perforation are common in tertiary care centres [3, 4]. In such scenarios, the mortality and morbidity for the patients undergoing surgery are relatively high [5]. Complications following major surgeries will proportionately increase the hospital cost and duration of hospital stay [6]. Apart from such hardships, complications also had an adverse impact on long-term survival [7]. So in a country like India, where the spending on health by the government is low and health insurance is under-penetrated, morbidity following a major surgical procedure will further drain the already constrained resources [8]. The complication rates are not uniform and cannot be generalised, as there are certain factors, such as age, patients' co-morbidity and operative severity, influencing the outcome of surgery [9]. So, putting together these factors and assessing the postoperative outcome preoperatively will help in optimizing the available resources. In such cases, the predictive scoring has to be more accurate, and its predictive ability should

Key message: CR-Possum can be used to predict morbidity in patient undergoing colorectal cancer surgery.

be proven in multiple centres. In our study, we devised a morbidity scoring system with already established parameters in CR-Possum which influence the outcome of colorectal surgery in terms of mortality and assessed the model calibration and discrimination with statistical analysis tools.

Patient and Methods

Data of 506 patients undergoing colorectal surgery for colorectal malignancy from January 2004 to December 2017 was collected from the medical records department of a single tertiary care centre. The in-patient files were analysed and the required variables as per CR-POSSUM scoring [physiologic severity score (PSS) (age, cardiac failure if any, systolic blood pressure, pulse, urea, haemoglobin) and operative severity score (OSS) (operative severity, peritoneal soiling, operative urgency, cancer staging in Dukes)] were collected and entered in an excel data sheet. Patient files, with single missing variable, were excluded from the study. Therefore, only 322 patients with complete details were included. The dichotomous outcome of each patient, either dead/alive, with/without complication, was entered. Presence or absence of complications, such as haemorrhage, wound infection, wound dehiscence, anastomotic leak, deep vein thrombosis, pulmonary embolus, cerebrovascular accident, myocardial infarction, cardiac failure, impaired renal function and respiratory failure were also entered. Complications were also graded based on Clavien-Dindo scale of surgical morbidity, and all grades were considered. Duration of hospital stay in terms of number of days for each patient was also recorded. The study was approved by institutional ethics committee.

Statistical Analysis

The data was analysed using SPSS version 24. Mean and standard deviation were calculated for continuous variables. Chi-square test was done to check association between categorical variables. The equation to predict morbidity was derived using multiple logistic regression analysis, and the model discrimination was measured by calculating the area under ROC (receiver operating characteristic) curve. The Nagelkerke R^2 and the Hosmer-Lemeshow statistics were used for model calibration (goodness of fit). Positive and negative predictive values were also calculated. $P < 0.05$ was considered as statistically significant.

Results

Out of a total of 506 patients undergoing colorectal surgery for malignancy, 322 (63.2%) satisfied the criteria to be included in the study. Among the 322 patients, 103 (31.9%) developed complications and 10 (3%) patients died of complications. The average duration of hospital stay for all patients who underwent surgery was 15.5 days. The mean duration of in-hospital stay for patients with and without complications was 18 and 14.5 days respectively ($P = 0.01$) which was statistically significant. The proportion of patients with and without complications and in-hospital stay days are shown in Fig. 1. The summary of procedures and their associated complications were shown in Table 1. The complications rates were more in tumours located in sigmoid and rectum compared to other sites ($P < 0.05$). The complications were graded as per Clavin-Dindo classification. Wound-related complication tops the list (37%) followed by respiratory complications (18%). These are shown in Table 2. The patient's demographic characteristics and the in-hospital morbidity rates for the factors taken into consideration for CR-POSSUM scoring are shown in Table 3. Majority of the patients are in the age group less than 60 years (51%) and there is a male preponderance (61%). Table 4 summarizes the CR-POSSUM scoring system which we used for the analysis. The equation we derived using above data was $In\ (R/(1-R)) = -4.83 + 0.09(PSS) + 0.35(OSS)$($P < 0.001$). The positive and negative predictive value of the equation was 60.87% and 73.09% respectively. The overall percentage of correct classification was 70%. The goodness of fit was looked at to check whether the predicted probability was assigned accordingly to individual patient's outcome. The Hosmer-Lemeshow test statistics was 3.147 ($P = 0.829$) which was reasonably a good fit for higher the P value, more fit the model is. The Nagelkerke R^2 which was another test to check goodness of fit was fairly good (17%). Model discrimination calculated by area under ROC curve was 71.6% (Fig. 2), which was reasonably a fair discrimination. The observed and expected ratio was almost close to 1 among the different range of predictions.

Discussion

POSSUM AND P-POSSUM were original scoring systems which enumerated the mortality and morbidity in a patient undergoing major surgeries [10, 11]. These have been validated in numerous studies outside the UK, and their value in surgical audit has been proven beyond doubt [12–14]. A study conducted by the American College of Surgeons (ACS-NSQIP) in 2005 to 2006 showed that ten procedure groups among various general surgical operations accounted for 62% of complications, and colectomy was topping in the list [15]. It accounts for 24% of adverse events. CR-POSSUM, developed by Tekkis et al., a modification in the original scoring system, was designed for enumeration of mortality in patients undergoing colorectal procedures [16]. Since the mortality following colorectal surgery was brought down with

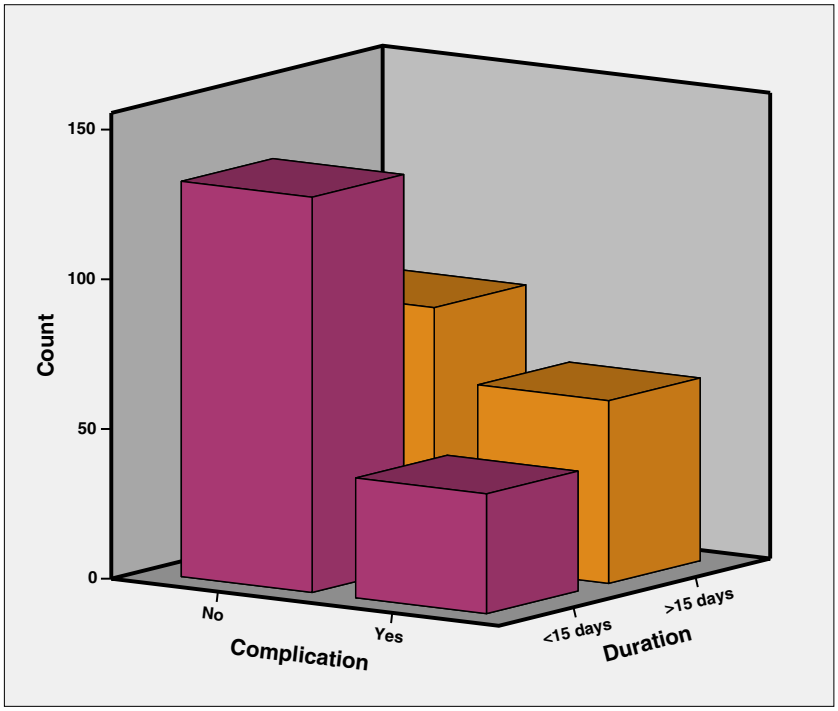

Fig. 1 Duration of hospital stay in patients with and without complications

improvement in postoperative critical care but the morbidity following such procedures especially in patients undergoing emergency surgery for perforation and obstruction was considerably high [17]. Complication rates in surgery for colorectal malignancy elective and emergency were 26 and 38% respectively. In our study, the overall complication rate was 31.9%. The original CR-POSSUM was devised by identifying odds of risk factor causing mortality. However, it was a well-known fact that mortality was the end point of severe morbidity [18, 19]. Therefore, we used the same scoring system to analyse the outcome in terms of complications in our study. The equation, though, using the same odds as for mortality did not overpredict morbidity in our study. But in the physiological severity scoring, except for preoperative cardiac status and urea level, other variables have no significant correlation

Table 1 Tumour location and procedures with in-hospital complication rates

Location of the tumour	Patients	Morbidity (%)	X^2 (P value)
Rectum	99	33(32)	14.40 ($P = 0.04$)
Sigmoid colon	77	31(30.1)

Table 3 Patient demographic and in-hospital complication rates

Variables in consideration	No. of patients $n = 322$	No. of complication (n = 103)
Age		
< 60	165 (51.2%)	50 (48.5%)
61–70	104 (32.3%)	36 (35.0%)
71–80	38 (11.8%)	11 (10.7%)
> 80	15 (4.7%)	5 (4.9%)
Sex		
Male	197 (61.2%)	65 (63.1%)
Female	125 (38.8%)	37 (35.9%)
PSS		
6 to 10	273 (84.8%)	81 (78.6%)
11 to 15	49 (15.2%)	22 (21.4%)
Operative severity scoring		
Intermediate	27 (8.4%)	8 (7.8%)
Major	228 (70.8%)	61 (59.2%)
Complex major	67 (20.8%)	34 (33.0%)
Peritoneal soiling		
None	275 (85.4%)	80 (77.7%)
Local pus	6 (1.9%)	3 (2.9%)
Faceal contamination	41 (12.7%)	20 (19.4%)
Operative urgency		
Elective	280 (87%)	81 (78.6%)
Urgent	34 (10.6%)	18 (17.5%)
Emergency	8 (2.5%)	4 (3.9%)
Cancer staging		
Dukes A, B	162 (50.3%)	43 (41.7%)
Dukes C	120 (37.3%)	42 (40.8%)
Dukes D	40 (12.4%)	18 (17.5%)

with outcome. Since wound infection and its sequelae occupy a considerable share (37%) of complications in our study, the role of physiological factors influencing the result may be less significant compared to operative severity score where later affects the outcome in terms of surgical site soft tissue infection [20]. Next common complications were respiratory (16.5%) and anastamotic leak (14.5%). Regarding mortality, CR-POSSUM observed and expected mortality ratio was 1

Table 4 Colorectal POSSUM scoring system

Score	1	2	3	4	8
Physiologic score					
Age (yr)	≤ 60		61–70	71–80	≥ 81
Cardiac failure	None or mild	Moderate	Severe		
Pulse (beats/min)	40–100	101–120	> 120 or < 40		
Systolic BP (mmHg)	100–170	> 170 or 90–99	< 90		
Urea (mmol/l)	≤ 10	10.1–15	> 15		
Haemoglobin (g/dl)	13–16	10–12.9 or 16.1–18	< 10 or > 18		
Operative severity score					
Operative severity	Minor		Intermediate	Major	Complex major
Peritoneal soiling	None or serous	Local pus	Free pus/feces		
Operative urgency	Elective		Urgent		Emergency
Cancer staging (dukes)	None or dukes A, B	Dukes C	Dukes D		

and area under ROC curve was 80% showing good model discrimination. But with low mortality rate [$n = 10$ (9.7%)] in our study, the validity of it may not be reliable.

Among the various risk factors, age and cancer staging are considered non-modifiable risk factors. The rest are modifiable risk factors and give the extent of scope to which the complications can be prevented by addressing such factors. But once patients present to tertiary centres in emergency or semi-emergency conditions, most of the risk factors will be present. Tackling such elements will be time-consuming and lead to a further chance of increasing complication [21]. Surgical site-related complications top in our study (37%) and elsewhere, as well [22]. They have an adverse impact in terms of long-term survival [23]. Since operative factors play a significant role in outcome in terms of wound infection as per our study, measures that reduce the chance of acquiring surgical site infections with high level of evidence are appropriate and timely administration of antibiotic, discontinuation of prophylactic antibiotic within 24 h of surgery, optimization of blood glucose levels and avoiding spillage of bowel contents [21]. Similar to SSIs, respiratory complication and anastomotic leak leading to deep-seated infection also affect the long-term survival [24]. PSS and OSS both play a significant role in predicting the latter two complications here. Hence tackling both physiological and operative variable assumes an important role prevention of these two problems.

CR-POSSUM, which was originally developed to predict mortality, can also be used to predict morbidity. But, there are some limitations to our study. Both CR-POSSUM and POSSUM models for mortality and POSSUM model for predicting morbidity left many variables like preoperative nutrition level, operative duration, BMI and length of preoperative stay, all of which influence the eventual outcome. These were not considered while developing the equation [21]. But these scoring systems were developed 10 and 25 years ago respectively, and many new influencing variables were found in subsequent research.

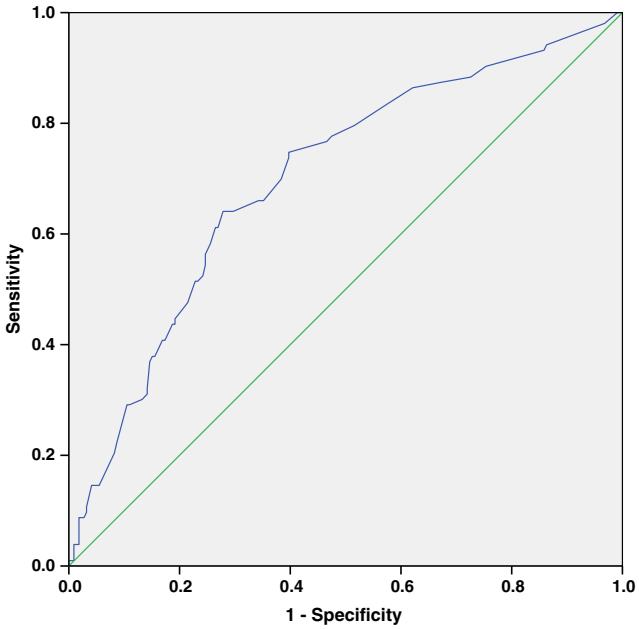

Fig. 2 Receiver operator characteristic curve (ROC) for the derived equation (Area under the curve is 71.6%)

Our results may be biased since there is a high proportion of SSI-related complication. We, therefore, validated the equation after excluding this group of patients. We excluded surgical site infection (SSI) in further analysis, to check whether physiological factors had a role in predicting non-SSI-related complications. We found that there was, indeed, a significant association ($P = 0.005$) between PSS and other non-SSI complications. The results were similar with few minor variations in predictive values. So, if a new model is developed considering the various new variables, then the predictive accuracy of such an equation can be close to reality.

To conclude, these predictive models once validated, across various centres in India, can be used as a measure of quality control in different institutions. Secondly, they can also be used to allocate resources and adequately trained professionals to deal with those patients whose expected morbidity and mortality are high.

Acknowledgements We thank our institute, its medical records and IT department for providing immense support in collecting data of the patients. We also offer special thanks to Prof. Dr. Karthikeyan of respiratory medicine department for his valuable input in design of the study. We thank Prof. Malmarugan Devanathan for his guidance in statistical analysis and make us to understand the statistical results.

ABSTRACT

Background: Inadequate breastfeeding results in hypernatremia in otherwise healthy neonates. **Objective:** This study finds out the predisposing factors and clinical outcome of hypernatremia in breastfed late preterm and term neonates. **Materials and Methods:** A descriptive study was conducted in a tertiary hospital with retrospective data from July 2013 to June 2016. Babies with serum sodium ≥ 150 mEq/L were identified. Breastfed babies with little or no formula feeds, gestational age ≥ 34 weeks, and birth weight ≥ 2000 g were included. Babies with congenital anomalies, sepsis, prior parenteral fluid therapy and renal or endocrine diseases causing fluid and electrolyte disturbances were excluded. Total weight loss > 10% or daily weight loss > 5% from the birth weight were considered as excess weight loss. **Results:** A total of 201 babies were studied. Hypernatremia was significantly more common in babies of primiparous mothers ($p < 0.01$). There was no difference in incidence between vaginal born and cesarean-born babies. Positive correlation was seen between age at presentation, percentage of weight loss ($p = 0.001$) and serum sodium ($p = 0.01$). Significantly more cases were seen in summer season ($p < 0.01$). Excess weight loss, jaundice, fever, and dehydration were the common symptoms. Complications observed were acute kidney injury, seizures, intracranial bleed, apnea, and bradycardia. Babies with complications mostly presented after 7 days of age, had > 25% weight loss and had serum sodium ≥ 170 mEq/L. There was no death. Three babies had neurodevelopmental problems on follow-up. **Conclusion:** Breastfed babies of primiparous mothers and born in summer are predisposed to hypernatremia. Babies presenting at a later age had severe weight loss, severe hypernatremia, and complications.

Key words: *Breastfeeding, Hypernatremia, Primiparity, Summer season, Weight loss*

Exclusive breastfeeding for the first 6 months of life is recommended by the World Health Organization to optimize the growth and development of the infants [1]. Breast milk in addition to nutrients provides various immunological factors that help to reduce the diarrheal and respiratory illness in children [2]. Breastfeeding is an instinct behavior and many mother-baby dyads accomplish it successfully [3]. However, some babies may not receive enough milk from their mothers due to various reasons. If breastfeeding is inadequate, then malnutrition and hypernatremic dehydration can occur in the baby [4]. Moritz *et al*. have termed this condition as "breastfeeding associated hypernatremia" (BFAH) [5].

An increase in the incidence of BFAH in otherwise healthy neonates has been observed in the past few years [5-8]. The clinical features and complications seen in these babies have been reported in various studies [9]. It has been found that daily weighing of the babies helps in the early recognition of this illness [10,11]. Thus, the discrepancy in clinical features and complications reported in various studies were probably related to weight monitoring practices and timing of presentation of the cases [10,11]. This study was planned to find out the predisposing factors and outcome of hypernatremia in breastfed late preterm and term neonates in a hospital with regular weight monitoring practice.

MATERIALS AND METHODS

This descriptive study was done using retrospective data from July 2013 to June 2016. The study was conducted in an urban tertiary care medical college hospital with an average delivery rate of 2500 per year. Exclusive breastfeeding was promoted for all babies in the hospital. The mother-baby dyads were discharged at around 72 h after normal delivery and 120 h after cesarean delivery. As per hospital protocol, all babies were weighed daily. Excess weight loss was defined as total weight loss more than 10% from birth weight or weight loss per day more than 5% of birth weight [12]. Serum sodium level was checked for babies with excess weight loss. Hypernatremia was defined as serum sodium more than or equal to 150 mEq/L. Babies with hypernatremia were treated with liberal oral feeds, intravenous (IV) fluids, and other supportive therapies. Serum sodium <150 mEq/L was considered an end point of treatment.

The Institutional Ethics Committee approved the study. Babies admitted during the study period with hypernatremia were identified from the hospital database. Their case records were scrutinized and babies who fulfilled the following criteria were included in the study: (1) Breastfed babies with little or no formula supplementation, (2) gestational age more than or equal to 34 weeks, and (3) birth weight more than or equal to 2000 g. The babies who had major congenital anomalies, blood culture positive sepsis, received IV fluids within 48 h before diagnosis of hypernatremia and renal or endocrine disorders which may affect the fluid and electrolyte balance were excluded from the study. The following data were collected: Gestational age as completed weeks, age at diagnosis as completed days, birth weight, weight at diagnosis, maternal age, obstetric details, details about baby feeding, clinical features, treatment, complications, condition at discharge, and neurodevelopment at follow-up.

The total weight loss and weight loss per day were calculated as a percentage of the birth weight. Axillary temperature more than 38°C was considered as fever. The rate of decline in serum sodium was calculated using the sodium before and after treatment and the time taken to achieve it. Acute kidney injury (AKI) was diagnosed if serum creatinine increased by >0.3 mg/dl in 24 h or if it was >1.5 mg/dl with normal maternal renal functions [13]. Jaundice treated with phototherapy was considered as significant. At the time of discharge, babies were said to have improved if their serum sodium level was <150 mEq/L and was taking feeds well. At follow-up, their neurodevelopment was said to be normal if gross motor, fine motor, language, and social milestones were appropriate for age and had no other neurological problem.

SPSS software version 24 was used for analysis. Numerical data were presented as mean±standard deviation or median±interquartile range as appropriate. Categorical data were presented as percentages and analyzed using Chi-square test. Ordinal data were analyzed with Mann–Whitney U-test or Student's t-test. Correlation was done with Spearman rank correlation coefficient where appropriate. $p<0.05$ was considered as significant.

RESULTS

There were 213 babies with hypernatremia satisfying the inclusion criteria during the study period. 12 babies were excluded due to various reasons. The remaining 201 babies were considered for analysis (Fig. 1). During the study period, there were 7613 live births, with 4570 vaginal births, and 3043 cesarean births. There were 4463 primiparous and 3150 multiparous mothers. Hypernatremia was seen in 2.4% of vaginally born babies and 3.1% of cesarean-born babies. This difference was not statistically significant. 3.1% babies of primiparous mothers and 1.6% babies of multiparous mothers had hypernatremia, and this different was statistically significant (Chi-square 16.7, $P<0.01$). All babies were born of singleton pregnancy. Most of the (80%) mothers had no problem in breastfeeding their babies (Table 1).

Serum sodium had a negative correlation with mother's age ($r=-0.23$, $p=0.01$) and baby's gestational age ($r=-0.2$, $p=0.004$). No correlation was seen between serum sodium level and birth weight. A positive correlation was seen between age at presentation and total weight loss ($r=0.65$, $P=0.001$). Serum sodium at admission had a positive correlation with age at presentation ($r=0.704$, $p=0.01$) and percentage of total weight loss ($r=0.652$, $p=0.001$). More than 50% of the cases were seen during the summer season in this study. This seasonal variation in the incidence of cases was statistically significant (Chi-square-26.9, $p<0.01$) (Table 1).

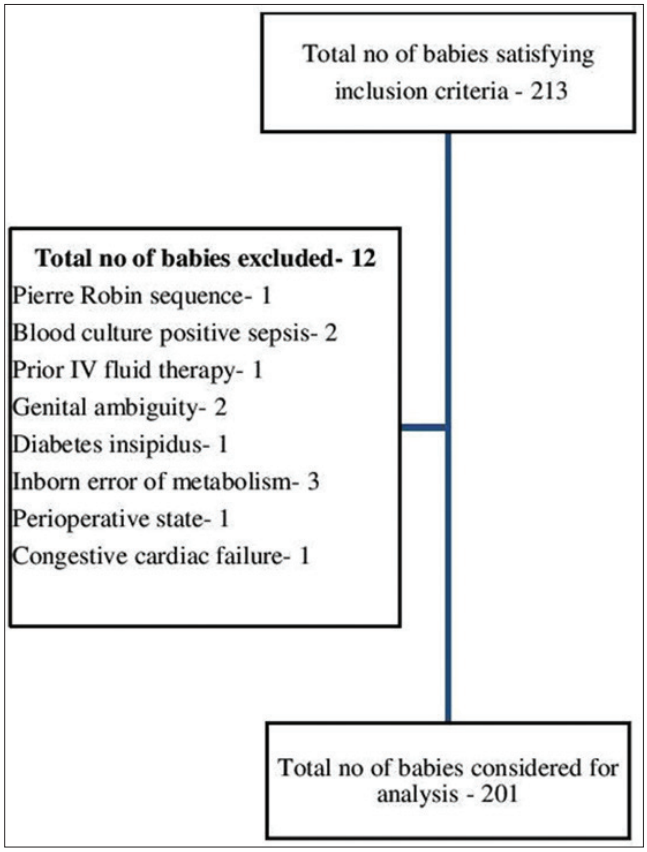

Figure 1: Flow of cases in the study

Significant jaundice was seen in 57.2% babies, but none required exchange transfusion. Phototherapy (median duration 24 h) before the onset of hypernatremia was given to 26 babies. Other common clinical findings observed were fever (33.8%) and dehydration (17.4%). No symptom other than excessive weight loss was seen in 21.4% of babies. Severe hypernatremia with serum sodium ≥170 mEq/L was seen in only five babies, and all other babies (98%) had moderate hypernatremia (serum sodium 150–169 mEq/L). About 89% of babies improved after treatment and got discharged. There was no death in the study population (Table 2). The babies who improved had a median birth weight of 3000 g (2800–3300), median admission weight of 2700 g (2460–2930), and median discharge weight of 2800 g (2540–3070).

Five babies (2.5%) had complications during the course of hypernatremia. One male baby with serum sodium of 151 mEq/L had apnea after vomiting of feeds and developed aspiration pneumonia. He improved with mechanical ventilation and antibiotics. All other four babies presented after 7 days of life

Table 1: Baseline characteristics of hypernatremic babies

Characteristics	Observation
Median maternal age (years) (n=183)*	26.9 (23-29)
Number of babies born to primiparous mothers	138/188 (73.4%)
Number of babies born to cesarean mothers	108 (53.7%)
Number of mothers reported problem in breastfeeding	42 (20.1%)
Male to female ratio	1.34:1
Median gestational age (weeks) (n=189)*	38 (37-39)
Median age at diagnosis (days)*	3 (2–18)
Number of babies presented on 2–3 days age	161 (80.1%)
Median birth weight (g)*	3080 (2810-3410)
Median weight at diagnosis (g)*	2710 (2470-3020)
Median daily weight loss (%)*	3.9 (3.3-4.7)
Median total weight loss from birth (%)*	11.3 (10-12.8)
Number of babies with 10–15% weight loss	139 (69.2%)
Season and number of babies admitted	
a. March to June (Summer)	103 (51.2%)
b. July to October	40 (19.9%)
c. November to February (Winter)	58 (28.9%)
Number of babies on exclusive breastfeeding	177 (88.1%)

*Median (IQR). IQR: Interquartile range

Table 2: Clinical features and outcome of hypernatremic babies

Characteristics	Observations
Median serum sodium at diagnosis (mEq/L)*	153 (151–155)
Serum sodium range and number of babies	
a. 150–159 mEq/L	184 (91.5%)
b. 160–169 mEq/L	12 (6%)
c. ≥170 mEq/L	5 (2.5%)
Mean time to normalize serum sodium	
a. 150–159 mEq/L (n=161)	17.8 h
b. 160–169 mEq/L (n=12)	26.6 h
c. 170–179 mEq/L (n=3)	48.8 h
d. ≥180 mEq/L (n=2)	71.3 h
Outcome	
a. Improved	178 (88.6%)
b. Left against medical advice	23 (11.4%)
Neurodevelopment problem at follow-up	3/154 (1.9%)

*Median (IQR). IQR: Interquartile range

with weight loss more than 25% of birth weight and severe hypernatremia (serum sodium ≥170 mEq/L). Complications observed were AKI (4), seizures (2), apnea (2), intracranial hemorrhage (1), and bradycardia (1). Peritoneal dialysis was done for one baby with AKI. No baby had peripheral or cerebral vessel thrombosis. Neurosonogram done for one baby with seizures showed increased white matter echogenicity. Another baby with seizures had normal neurosonogram. The treatment and outcome details of babies with severe hypernatremia are given in Table 3.

Follow-up details were available in 154 cases (76.6%) for a median duration of 1.5 months (0.5–11 months). Three babies had abnormal neurodevelopment. One female baby with serum sodium 150 mEq/L had a prolonged period of jaundice requiring phototherapy for 9 days. At follow-up, she had a global developmental delay with a seizure disorder. One male baby with serum sodium 150 mEq/L was found to have hyperactivity and aggressive behavior at 3 years. Neuroimaging was not available for these two babies. Another female baby had severe hypernatremia with AKI, seizures and normal neurosonogram in the neonatal period; and on follow-up at 1 year was found to have left hemiparesis and magnetic resonance imaging of the brain showed chronic infarct in right front parietal region and white matter changes in subcortical and deep cerebral white matter.

DISCUSSION

In this study, we have found BFAH to be more common among babies of primiparous mothers. Although breastfeeding is an instinct behavior, mothers have to learn the technique and need social support to successfully breastfeed their babies [3]. Systematic review on BFAH has found cesarean delivery, primiparity and absent previous breastfeeding experience as risk factors for BFAH [9]. However, there was no difference between cesarean babies and vaginally born babies in this study. Similarly, two studies had found no significant difference in mode of delivery among hypernatremic babies compared to control group [5,14].

It is stated that the parents of hypernatremic babies have poor recognition of their baby's illness [7,15]. About 80% of our baby's mothers have not felt any problem with their baby's feeding behavior. Excess weight loss gave a clue to identify these cases early. Thus, majority of our cases were identified at an early age, had less severe weight loss and less severe hypernatremia. Many studies report that babies presenting at a later age have higher weight loss and more severe hypernatremia [16,17]. Hence, daily weighing of babies along with appropriate lactation support during the first 4–5 days of life has been suggested for early detection of BFAH [10,11,18]. The seasonal variation in the incidence of hypernatremia was reported in some studies [12,19-21]. This was attributed to excess insensible water loss due to the hot climate in summer and overuse of room heaters in winter [9,21]. In this study, we have found significantly more number of cases during the summer season. This seasonal variation may be related to hot environmental temperature during summer seen in Tamil Nadu state of India where the study was done.

At admission, jaundice, fever, and dehydration were common symptoms in our study population. Lavagno *et al*. through systematic review have found jaundice, poor feeding, and dehydration each seen in about 45% of all reported cases [9]. Yang *et al*. have showed that percentage of weight loss within first 3 days of life has a positive correlation with jaundice at 72 h after birth in healthy term breastfed babies [22]. The hypernatremia and the resultant hyperosmolar state may damage the blood–brain barrier and facilitates bilirubin entry into nervous tissues at

Table 3: Clinical features and outcome of babies with severe hypernatremia

Gestational age (weeks)	Birth weight (g)	Total weight loss (%)	Day of diagnosis	Maximum Sr. sodium (mEq/L)	Complications	Treatment	Time to correct Sr. sodium (h)	Outcome at follow up
40	2700	25.9	12	182	Seizures, AKI, apnea, bradycardia	½ DNS+oral feeds; peritoneal dialysis; anticonvulsant	57	Normal
40	3630	14.3	4	173	Nil	½ DNS	43	Normal
37	2510	37.5	18	174	AKI, cerebral hemorrhage	NS bolus, ½ DNS	69.75	Normal
36	3060	27.5	8	173	AKI	½ DNS+oral feeds	33.5	Normal
Term	2700	24.1	17	186	AKI, seizures	NS bolus, DNS, ½ DNS; anticonvulsants	85.5	Left hemiparesis

AKI: Acute kidney injury

lower serum bilirubin level [5,23]. This has to be considered in one baby with neurodevelopmental impairment in our study who had hypernatremia and prolonged jaundice. About 20% of our babies had no symptoms at admission except for excess weight loss. Similarly Uras *et al*. and Korgali *et al*. have found that 14% and 2.4% of their hypernatremic babies were asymptomatic at admission, respectively [24,25].

Four out of five babies with severe hypernatremia had neurological and/or renal complications. Similarly, Ahmed *et al*. have found that babies with AKI presented at a later age, had higher weight loss and higher serum sodium [26]. However, less number of babies in this study had complications compared other studies [5,8,9,20,25-27]. This may be due to earlier age at presentation and a lesser degree of hypernatremia seen in the large proportion of babies in our study. There was no death in our study population and on follow-up only three babies had a neurodevelopmental problem. Mortality rate of 1-5% has been reported by various authors [8,26-28]. Koklu *et al*. have reported neurodevelopmental impairment in 47.8% cases [27]. Similarly, a high rate of neurodevelopmental impairment is also reported by Bolat *et al*. and Ergenekon *et al*. [29,30]. This emphasizes the need for formal neurodevelopmental follow-up of hypernatremic babies.

In this study, we have reported the correlation of serum sodium level with various other clinical parameters in babies with BFAH. Our study has the following limitations due to retrospective nature of the study: Some data were incomplete and long-term formal neurodevelopmental assessment was not done. Our study was hospital based, and many babies had a less severe degree of hypernatremia with fewer complications. A larger scale prospective study with neurodevelopmental follow-up is needed to have a clear understanding of the risk factors, complications and long-term effects of BFAH.

CONCLUSION

Breastfed late preterm and term babies born to primiparous mothers and born in summer season have predisposition to develop hypernatremia. These babies commonly presented with excess weight loss, jaundice, fever, and dehydration. Babies presenting beyond 7 days of age and with more than 25% weight loss are likely to have severe hypernatremia. Neurological complications and AKI were common complications observed with severe hypernatremia. These babies are at risk of neurodevelopmental impairment. Prospective study with long-term follow-up is needed.

Abstract

Context: Highest intensity of soil-transmitted helminthiasis (STH) is seen among school age children. **Aims**: The aim of this study is to find out the prevalence and factors associated with soil-transmitted helminthic infection among school age children (5–14 years) in a rural area of Coimbatore district. **Settings and Design:** The study was conducted in the field practice area of the Rural Health Training Centre (RHTC) Vedapatti, Coimbatore. RHTC caters to a total population of 23,841 distributed in 14 villages. After getting ethical clearance, five of the 14 villages of Vedapatti were selected by the cluster sampling method. Totally, 819 participated in the survey conducted between November 2015 and July 2016 in the field practice area. **Subjects and Methods:** Structured questionnaire was used to collect the information. Consent from parents and assent from child were obtained. Totally, 610 gave one adequate stool sample. Early morning samples were collected and transported to the laboratory within four hours. Formal ether concentration method was performed, and examination was done. **Statistical Analysis Used:** Data analysis was performed with the SPSS version 19 software. The prevalence is expressed in percentage with 95% confidence interval (CI). Univariate and multivariate analyses were performed. Strength of association was expressed in terms of odds ratio (OR) and adjusted OR with 95% CI. $P < 0.05$ was considered as statistically significant. **Results:** The prevalence of STH was 7.70% (95% CI: 5.58–9.82). *Ascaris lumbricoides* was highly prevalent 6.9% (4.89%–8.91%) followed by Hook worm 0.7% (0.04%–1.36%), and *Trichuris trichiura* 0.2% (0.15%–0.55%). Mulitivariate logistic regression analysis showed that pucca houses offered protection against STH. **Conclusions:** The prevalence of STH in a rural area of Coimbatore is 7.7% (95% CI: 5.58–9.82), and is continuing as a public health problem.

Full Text

Introduction

The soil-transmitted helminthes causing major illness among human beings include Ascaris lumbricoides, Trichuris trichiura, Necator americanus, and Ancylostoma duodenale.[1] STH are considered neglected tropical diseases.[2] STH affects more than one fourth of the world's population, and it is reported more in tropical and subtropical areas.[3] The greatest number of cases are occurring in sub-Saharan Africa, the Americas, China, and East Asia.[4] In India, the reported prevalence of STH infection can be striked out varied from 7.8% to 92.6%.[5],[6],[7],[8],[9] The reported prevalence varies according to the place and time of the study conducted.

The highest intensity of soil-transmitted helminthes occur in school age children.[10] Children do not fully understand the connections between illness and behavior.[11] It has been demonstrated that children often than adults tend to go barefoot, resulting in more contact with soil, and fail to use sanitary facilities even when they are present.[12] STH infections are considered an important cause of sickness absenteeism. They are accounting for loss of 12.3% and 11.4% of disability adjusted life years in girls and boys, respectively.[13] Over 270 million preschool-age children, and over 600 million school-age children live in areas where sanitation is poor and these parasites are intensively transmitted.[14] In India, more than 241 million children are at the risk of parasitic worm infections. Ministry of Health and Family Welfare, Government of India launched the National Deworming Day (NDD)[15] on Feb 10, 2015. NDD aims to de-worm all children between the ages of 1–19 years. The tablets were supplied to children through government, government-aided and private schools, and Anganwadi centers.

When regular deworming is accompanied by appropriate sanitation and hygiene activities designed to prevent re-infection, a long-term impact can be achieved. Epidemiological studies are needed to identify the risk factors which may represent critical control points. There is no recently published article on the prevalence of soil-transmitted helminthes in Coimbatore, where open-air defecation is a common practice. As per the 2011 census, 46% of the households in Coimbatore district lack toilets. Hence, this cross-sectional study was proposed and conducted with the objective of finding the prevalence and risk factors associated with soil-transmitted helminth infections in school age children (5–14 years) in a rural area of Coimbatore district.

Subjects and Methods

The study was conducted in the field practice area of the Rural Health Training Center (RHTC) Vedapatti, Coimbatore. RHTC caters to a total population of 23,841 distributed in 14 villages.

of Thondamuthur and Madukarai block of Coimbatore district. The total number of school-aged children (aged 5–14 years) is 3266.

Ethical clearance was obtained from Institutional Human Ethics Committee, in 2014. The sample size was calculated to be 819 assuming 34.5% as prevalence, relative precision of 15%, design effect of 2, and nonresponse rate of 20%.[16] Five out of 14 villages were selected by the cluster sampling method. House-to-house survey was conducted in the five villages during November 2015–July 2016. All school-age children (aged 5–14 years) who were permanent residents of Vedapatti field practice area of RHTC were included in the study. Children who were not available on three visits within a week time were excluded from the study.

At the home setting, after getting consent from the parent and assent from the child any one of the parents of the child was interviewed in the evening hours of the day. A structured questionnaire was used to collect the information on demographic, socioeconomic, and environmental information such as availability of type of drinking water and availability of functioning sanitary toilet. Few questions were asked regarding the knowledge and attitude of the parents on STH. Respondent was asked to give comment on the personal hygiene practices of child such as washing hands with soap before taking food and after defecation, eating fallen foods on the floor, wearing foot wear outside the house and intake of de-worming tablets in the past 3 months. Observations were also made regarding the personal hygiene of the children related to STH such as clipped nails. Knowledge and attitude score was generated from the correct responses for the knowledge and attitude questions. The correct responses were given a score of one, and maximum score one could get was nine. Score five and above was considered as adequate knowledge and attitude score.

At the end of survey, a screw-capped plastic container with the identification of the child was given to collect the stool sample of the child on the next morning. Instructions regarding stool collection were given. The stool samples were collected and transported to microbiology laboratory within 4 h of sample collection. Stool samples were examined by saline wet mount and iodine wet mount.[17] Iodine preparation was done for the better visualization of morphological details of ova. All samples were re-examined after concentrating with WHO recommended.[18] Formalin-ether sedimentation method.[19] To reduce the human error, duplicate slides (both direct and after concentration method) were prepared from each sample and the slides were read by two different microbiologists and the opinion of chief microbiologist was considered as final.

Analysis

Data entry was made in the Microsoft Excel software in codes and analysis was done with SPSS-19 (IBM, Armonk, New York ,United States) computer package. The presence of ova of A. lumbricoides, Trichuris trichiura, N. americanus, and A. duodenale was considered as the dependent variable. The prevalence is expressed in percentage with 95% confidence interval (CI). Univariate analysis and logistic regression were performed to find the associations between the independent variables and dependent variables. Strength of association was expressed in terms of odds ratio (OR) and adjusted OR with 95% CI and $P < 0.05$ was considered as statistically significant.

Results

The results of this study are based on 610 children, who gave one adequate stool sample. Totally, 819 children participated in the survey; hence, the nonresponse rate was calculated as 25.52.

The distribution of the study population and their risk factors is shown in [Table 1] and [Table 2]. The mean age of the study population was 8.92 ± 2.68. Among them, children below 10 years (58.5%), female participants (52.1%), belonged to families with members four and above (54.92%), children living in kutcha and semi-pucca houses(80%), and children belonged to low socioeconomic status (52.3%) Class IV and V according to the modified Prasad classification were found in majority. Illiteracy was found among 20.2% of mothers. Open air defecation was found among 33.4% of the children. Regarding the toilet usage, only 50.7% of the children were using the toilets in the home. Around 66% did not wash their hands with soap before taking food. Moreover, 44.6% did not wash their hands with soap after defecation. Around 63% children regularly used foot wear and around 70% of the children had trimmed nail during the visit. Nearly half of the parents of children had adequate knowledge on STH. Only 59% reported intake of de-worming tablets in the past 3 months.{Table 1}{Table 2}

The prevalence of STH among 610 children who had given one adequate stool sample and whose parents participated in survey was 7.70% (95% CI: 5.58–9.82). Among all STH, A. lumbricoides was highly prevalent 6.9% (95% CI: 4.89%–8.91%) followed by Hook worm 0.7% (0.04%–1.36%), and Trichuris trichura 0.2% (0.15%–0.55%).

There was no significant association found between STH and factors influencing STH by univariate analysis. However, when all independent variables were subjected to multivariate logistic regression analysis, only pucca houses offered protection OR: 0.34(95% CI: [0.10–0.91]) against STH.

Discussion

Relatively high nonresponse rate (25.52%) was noted in this study. It is also evident from a similar study by Shubha and Fatima[20] that surveys involving bio samples shows high nonresponse rate (30.9%) when compared to simple questionnaire-based surveys.

The prevalence of STH in the study population is 7.7% (95% CI 5.58–9.82%). The results of the current study were less than other studies conducted in the nearby areas.

The explanations for the low prevalence are more number of risk group (29.13%) were found among the nonresponders compared to younger children (22.72%, P = 0.02). The study results were based on single stool sample, modified formol-ether concentration (FEC) method with low sensitivity (63.1%)[21] which could have estimated the low prevalence. The other probable explanations are Mass Drug Administration (MDA) under NDD[15] might have changed the scenario.[5],[6],[7],[8],[9] However, there are no sufficient data from to compare prevalence before de-worming in this area to support this statement. Coimbatore first round of NDD was just completed and second round was on-going at the time of the survey (2016-Feb). Kattula et al.[8] also explains the reason for the low prevalence of STH (7.8%) in Vellore area is due to Albendazole supplied in MDA along with diethylcarbamazine since 2004 Deworming using albendazole rapidly declines the overall prevalence of STH, and this is evident from Mani et al.[22] study on efficacy of albendazole in Tamil Nadu. However, there are other studies reported with a higher prevalence in the nearby areas. Kaliappan et al.[23] explains the reason for the increased prevalence (39%) in Thiruvanamalai District in the year 2013 could be due to five stool samples collected among tribal population where open-air defecation and bare foot walking were common practice. Ragunathan et al.[16] explains the reason for higher prevalence (34.56%) reported in Pudhucherry, a coastal area using FEC method in year 2006 is due to poor hygienic practices of the participants.

This study showed the most common soil-transmitted helminth as A. lumbricoides with the prevalence of 6.9% (95% CI: 4.89%–8.91%) followed by Hook worm 0.7% (95% CI: 0.04%–1.36%) and T. trichura 0.2% (95% CI: 0.15%–0.55%). In general studies showed that A. lumbricoides and T. trichura were more common among urban children and hookworm infestation among rural children.[24]

Regarding the factors influencing STH pucca houses offered protection OR: 0.34(95% CI: [0.10–0.91]) against STH, by multivariate analysis. A cross-sectional study by Kattula et al [8].showed that children living in Hut/Kutcha houses are at higher risk for STH.

Kattula et al.[8] also showed that children of more than 10 years of age, living in households without toilet, open air defecation, unhygienic practices like keeping untrimmed nails are important risk factors for STH. Kattula et al.[8] showed that the consumption of deworming tablets offered protection. However, there was no significant association noted in this study. This is a cross-sectional study; hence, the cause-effect relationship cannot be determined and is the major limitation of this study. Moreover, the other limitations are as follows: the study results were based on single stool sample which could have estimated the low prevalence. The newer techniques with higher sensitivity would have given higher prevalence. Sample size was not adequate to comment on factors influencing STH.

Conclusion

The prevalence of STH in a rural area of Coimbatore is 7.7% (95% CI: 5.58–9.82), and is continuing as a public health problem. Open-air defecation is a biggest concern (33.4%), hence, more private, public toilets should be built in this area. The children should be trained to use toilet facilities either private or public. It is very important to raise the awareness about these infections; hence, parents of children with inadequate knowledge should be given health education. When regular deworming is accompanied by appropriate sanitation and hygiene activities designed to prevent reinfection, a long-term impact can be achieved.

ABSTRACT

Background: Working women are constantly facing the problems of role conflict or dual role. Due to role conflict, there are reports of psychological distress, mental tension, anxiety, etc, which affect the psychological well being of working women. Due to outside work, they have psychological problems such as anxiety, stress, burn out, fatigue, etc. This way, the mental health status of working women is neglected and hence, the present study **aims** to assess the psychological wellbeing of women in an industrial setup. **Methods:** A cross sectional study was done among women workers of 18 years and above. A standardized questionnaire was used to collect data. The data was analyzed using SPSS version 24. A total of 136 participants completed the study. **Results:** Present study showed that majority of the workers (67%) had low level of psychological well-being. **Conclusion:** Women workers have low level of psychological well-being and further studies are needed to understand factors influencing it.

Key Words: Psychological well-being, Women workers, Garment industry.

INTRODUCTION

"The mind is everything. What you think you become." – Buddha

According to the World Health Organization (WHO), mental health includes "subjective well-being, perceived self-efficacy, autonomy, competence, inter-generational dependence, and self-actualization of one's intellectual and emotional potential, among others". WHO further states that the well-being of an individual is encompassed in the realization of their abilities, coping with normal stresses of life, productive work and contribution to their community. [1]

Psychological well-being is a very subjective term meaning contentment, satisfaction with all elements of life, self-actualization (a feeling of having achieved something with one's life), peace and happiness.[2]Psychological well-being is defined as the presence of psychological and social skills and abilities that contribute to optimal functioning in daily life. [1]

The concept of mental health is inextricably linked to that of psychological well-being. A comprehensive model developed by C. Ryff provides an integration of different viewpoints. It encompasses six inter-related psychological dimensions: positive evaluation of one's self (Self-Acceptance), a sense of continued growth and development (Personal Growth), the belief that life is purposeful and meaningful (Purpose in Life), the possession of quality relations with others (Positive Relations with Others), the capacity to manage effectively one's life (Environmental Mastery), and a sense of self-determination (Autonomy). Lack of psychological well-being has been found to be a risk factor for depression. [3]

Garment workers around the world, especially those involved in tailoring, are predominantly women. The Indian garment industry is dominated by women workers and 80% of them are young women between 21-25 years. [4]

The workplace is one of the key environments that affect our mental well-being and health. It is difficult to quantify the impact of work alone on personal identity, self-esteem and social recognition; most mental health professionals agree that the workplace environment can have a significant impact on an individual's mental well-being. [5]

Working women have many problems such as career related problems, social problems such as domestic violence, health problems such as psychological distress due to role conflict, mental stress, tension, anxiety, physical health problems such as Anemia, arthritis, etc.

As discussed above, due to outside work, they have psychological problems such as anxiety, stress, burn out, fatigue, etc. This could lead to neglect of mental health. Hence this study is proposed with the objectives of

assessing the psychological well-being of women workers in garment industries and to find out its association with socio demographic factors.

MATERIALS & METHODS

A cross sectional study was conducted in a selected garment industry in Tirupur district of Tamilnadu state. This factory is mainly involved in manufacture of garments for export. Majority of the workers are unmarried women.

Sample size: Based on 63.5% prevalence of moderate level of psychological well-being study done by K.S.Velmurugan, Dr.K.Maheswari, in Tiruchirappalli [6] sample size was calculated as 136.

Inclusion criteria: There were 200 women workers above 18 years in our study factory. Prestuctured and pre validated questionnaire was administered to 136 women workers who were selected by simple random sampling.

Study tool: Carl Ryff's 18 item psychological well-being questionnaire translated into local language was used capturing various dimensions: autonomy, environmental mastery, personal growth, positive relations and self-acceptance, purpose in life. These items were measured using Likert scales of 1 to 6, with 1 indicating strong disagree and 6 indicating strong agree. The maximum score for psychological well-being that could be obtained under each dimension is 18.The maximum score that could be obtained for overall psychological well-being is 128.

Data collection: Data collection was done using the above tool as self administered questionnaire. Data entry and analysis was done using Statistical Package for Social Sciences (SPSS) version 24. The data were analyzed by using mean, standard deviation and two-way analysis of variance (ANOVA) and p <0.05 was considered statistically significant.

Ethical Issues: Approval for the study was obtained from the Institutional Human Ethics Committee of PSG Institute of Medical Sciences and Research.

RESULTS

A total of 136 participants completed the survey. The study participants were in the age group of 18 to 25 years. The participants were representative of different sections of the factory with majority (45%) being tailors. The demographical details of the participants are shown in Table1.

Table 2 shows the mean scores of the participants under each dimension of psychological well-being. For all dimensions the mean score was 12 and below which indicates low psychological well-being. The findings indicated that workers scored high in personal growth (M= 12.02, sd= 4.05) and least in environmental mastery (M=10.10, sd=4.05).

Table 1: Demographic details of the participants

Demographic factors	Percentage
Age	
Below 20 years	58%
Above 20 years	42%
Education Qualification	
High school	48%
Hr.sec.school	40%
Diploma	4%
Graduate	8%
Work experience	
Below 1 year	57%
Above 1 year	43%
Type of family	
Nuclear family	73%
Joint family	27%
Residence	
Hostel	97%
Day scholar	3%

Table 2: Overall level of workers Psychological well-being

Indicators of Psychological well-being	Mean±SD
Autonomy	11.50±3.39
Positive relations	11.92±2.37
Self-acceptance	10.13±3.52
Environmental mastery	10.10±4.05
Purpose in life	11.66±2.24
Personal growth	12.02±4.05
Total score	67.36±13.20

Table 3: Association of various factors with psychological well-being

Socio economic Factors	Total score of Psychological well-being (Mean±SD)	p value
Age		
Below 20 years	67.69±12.74	0.728
Above 20 years	66.89±13.91	
Education Qualification		
High school	68.39±13.26	
Hr.sec.school	67.59±13.14	
Diploma	68.20±14.06	0.241
Graduate	59.63±11.84	
Work experience		
Below 1 year	67.02±12.26	0.733
Above 1 year	67.81±14.46	
Type of family		
Nuclear family	67.02±13.00	0.625
Joint family	68.27±13.84	

Table 3 shows the association of various demographic variables with psychological well-being. Age was categorized less than 20 and more than 20, also between various educational level and work experience of at least a

year and whether they belonged to nuclear or joint family. The findings indicated that there is no significant difference between demographic factors like age, education and years of education with psychological well-being.

DISCUSSION

The present study showed that overall psychological well-being of women garment workers was low (mean value 67.36). In garment industry women workers work for longer hours (10 hours). Also due to high production pressure, hourly targets are set for workers. Staying away from family and having long working hours could be reasons which need to be explored.

Our study findings revealed relatively higher score for personal growth compared to other dimensions. It indicates that women workers had more positive feelings towards their continued development and ready to experience new challenges in life. Similarly, a study done on 2015 showed that a high score in personal growth and positive relations subscales. [7]

The result of present study concurs with a similar study done in Perambalur which showed that women in higher age have low psychological well-being. In our study there is no significant difference between workers age & their psychological well-being. But a woman with higher age shows low psychological well-being. In the same study it was found that women with more work experience had higher psychological wellbeing. In our study though not significant the mean score was comparatively higher among women with more work experience. [6]

In our study we couldn't find out any reasons for poor psychological well-being. Instead, we say above mentioned reasons could be the reason for poor psychological well-being. The present study concurs with a similar study, done in Mysore where the mean score for psychological well-being was 193. [8]

Conclusion and way forward

From the study we conclude that psychological well-being is low among women workers. Management should develop policies for addressing mental health issues and creating access to counseling services.
Though quantitative analysis did not reveal statistical association between psychological well-being and demographic profile, further qualitative studies would help in better understanding the factors influencing psychological well-being.

Received January 25, 2017

In India, research prioritization in Maternal, Newborn, and Child Health and Nutrition (MNCHN) themes has traditionally involved only a handful of experts mostly from major cities. The Indian Council of Medical Research (ICMR)-INCLEN collaboration undertook a nationwide exercise engaging faculty from 256 institutions to identify top research priorities in the MNCHN themes for 2016-2025. The Child Health and Nutrition Research Initiative method of priority setting was adapted. The context of the exercise was defined by a National Steering Group (NSG) and guided by four Thematic Research Subcommittees. Research ideas were pooled from 498 experts located in different parts of India, iteratively consolidated into research options, scored by 893 experts against five pre-defined criteria (answerability, relevance, equity, investment and innovation) and weighed by a larger reference group. Ranked lists of priorities were generated for each of the four themes at national and three subnational (regional) levels [Empowered Action Group & North-Eastern States, Southern and Western States, & Northern States (including West Bengal)]. Research priorities differed between regions and from overall

Supplementary material available from *http://www.ijmr.org.in/article.asp?issn=0971-5916;year=2017;volume=145;issue=5;spage=611;epage=622;aulast=Arora*

national priorities. Delivery domain of research which included implementation research constituted about 70 per cent of the top ten research options under all four themes. The results were endorsed in the NSG meeting. There was unanimity that the research priorities should be considered by different governmental and non-governmental agencies for investment with prioritization on implementation research and issues cutting across themes.

Key words Child health - Child Health & Nutrition Research Initiative - Indian Council of Medical Research - INCLEN - maternal health - Maternal, Newborn, and Child Health and Nutrition - newborn health - nutrition - research priority setting

National Steering Group[18]

Reang Kamal, Agartala; Mavalankar Dileep, Ahmedabad; Nandan Deoki (Late), Allahabad; Dhanya Kumar BN, Divakar Hema, Rao Veena S, Bengaluru; Sivadas Aswathi, Bhubaneswar; Jain Vanita, Chandigarh; Bansal Pankaj K, Iyyanar N, Chennai; Dholakia NB, Gandhinagar; C Sarala Rajyalakshmi, Guntur; Bhatnagar Shinjini, Chandy Thomas, Sharma Rekha, Reddy KS, Zodpey Sanjay, Gurugram; Deka Hitesh, Guwahati; Bansal CP, Gwalior; Laxmaiah A, Hyderabad; Prasad Nupur, Jaipur; Bhatti MH, Jammu; Awasthi Shally, Lucknow; Bavdekar Sandeep, Begkoyian Genevieve, Krishna Vandana, Mumbai; Purwar Manorama, Nagpur; Arora NK, Arora Rashmi, Awin Narimah, Bagchi Kunal, Baswal Dinesh, Bhan MK, Bhatla Neerja, Bhushan Himanshu, Chaturvedi Sanjay, Chaudhury RR (Late), Chopra Nandita, d'Silva Angela, Das JK, Dasgupta Rajib, Deb Sila, Desiraju Keshav, Dhamija NK, Francis Paul, Elliott Marshall, Goswami Kiran, Gupta Anuradha, Gupta Piyush, Haldar Pradeep, Vijay Raghavan K, Kannan Evelyn P, Kant Lalit, Kapil Umesh, Kathuria Ashi, Katoch VM, Khera Ajay, Kiran Usha, Kriplani Alka, Kumar Harish, Kumar Rajesh, Kumar Rakesh, Kumar Sanjiv, Malhotra Manisha, Mathur Prashant, Mehta Jayshree, Mehta Rajesh, Mishra CK, Mor Nachiket, Mozo Victor A, Mundol Hisham, Mukherjee Shirshendu, Narain Prem, Patwari Ashok K, Paul Vinod K, Prabhakar PK, Pradhan Anju, Prasad Jagdish, Rai Sanjay K, Raina Neena, Ramachandran Prema, Ramji Siddharth, Rasaily Reeta, Rathore AS, Roy Malabika, Sankar Rajan, Seda Sheila, Seem Tarun, Shah Dheeraj, Sharma Ashutosh, Sharma Bhanu P, Shreeranjan, Sidhwa Xerses, Singh Gayatri, Singh Lakhwinder P, Singh Shalini, Sood Bulbul, Swaminathan Soumya, Ramasami T, Talwar KK, Tandon Rajiv, Thavaraj Vasantha, Toteja GS, V Somasundaran, Verma IC, New Delhi; Kumar Sanjay, Patna; Jog Pramod, Pune; Amandeep Garg, Shimla; Subba Namita H, Sikkim; K Rajamohanan, Nair MKC, Prathapan P, Thiruvananthapuram.

Research Sub-Committee[18]

Visaria Leela, Ahmedabad; Maitra Nandita, Baroda; Kodkany BS, Belagavi; Kurpad Anura V, Murthy Nirmala, Raj Rebecca K, Bengaluru; Dwivedi Rashmi, Kanani Shubhada J, Bhopal; Mohanty Aswini, Bhubaneswar; Nahrel Rakesh, Bilaspur; Jana Narayan, Burdwan; Singh Karanjit, Chandigarh; Kumar Rathna, Vijayakumar, Chennai; Kowsalya S, Coimbatore; Kumar Ashok, Darbhanga; Pradhan PM, Gangtok; Agarwal Veena, Gwalior; Prakasamma M, Shamanna BR, Hyderabad; Sharma Yashpal, Jammu; Baroovah Basanti, Jorhat; Prabhu Radhabai, Kancheepuram; Das Indranil, Kolkata; Das Vinita, Hashmi Gulfam, Jain Neera, Srivastava Niraj M, Lucknow; Chhatwal Jugesh, Ludhiana; Gupta Abhilasha, Meerut; K Sheela, Meghalaya; Daver Rekha G, Dwivedi Laxmi K, Madan Jagmeet, Mumbai; Patel Archana B, Mundle Shuchita, Nagpur; Agarwal Ramesh K, Anand VK, Bhandari Nita, Chowdhury Dipa N, Chhabra Sheena, Das Abhijit, Deka Deepika, Dubey AP, Ghosh D, Ghosh Sandip, Gogoi Aprajita, Jain Shikhar, Kalaivani K, Khan ME, Khanna Rajesh, Kumar Sanjiv, Malhotra Sudhansh, Malhotra Sunita, Mathai Saramma T, Mathur Arvind, Menon Purnima, Puri Seema, Sagar Karan S, Tripathi Reva, Singh Arun K, Vir Sheila C, New Delhi; Jampa Lobsang, Papum Pare; Kumar Sanjay, Patna; Bhat B Vishnu, Chathurvedula Latha, Srinivasan S, Puducherry; Vaidya Umesh, Pune; Daripa Tapan K, Raipur; Pandey Sharat, Sharma Arun K, Ranchi; Abraham Alice, Shillong; Bhat Sharif, Srinagar; Krishnaswamy Kamala, Hyderabad; Chandran Anil, Jain Naveen, Elizabeth KE, Remadevi S, Thiruvananthapuram; Iyenger Kirti, Udaipur.

Nation-wide Network[18]

Names of participants in the Nation-wide Network are provided in Supplementary Table I (available on *http://www.ijmr.org.in/articles/2017/145/5/images/IndianJMedRes_2017_145_5_611_215547_sm6.pdf*) and also on *www.inclentrust.org*

Prioritization of research options in health is essential to plan for achieving efficient and impactful investment of limited resources against a large number of competing research options[1]. There is an increasing need and effort to set research priorities in health in a systematic way using a sound and transparent methodology and through engagement of the various key stakeholder constituencies[2,3]. Research priority setting (RPS) in India has traditionally been guided by a small group of experts, mostly identified from major metropolitan areas of the country. Subsequent to India's impressive yet inadequate improvement towards achieving Millennium Development Goals (MDGs) 1, 4 and 5, an expert group had convened on May 23, 2011 at the Indian Council of Medical Research (ICMR) Headquarters in New Delhi to discuss RPS. The participants observed that evidentiary gaps in the country impeded informed action in Maternal, Newborn, and Child Health and Nutrition (MNCHN) themes, and that an inclusive and transparent method should be adopted to decide the national research agenda. The agenda so developed should also identify areas for innovation and strategies to improve deliverability, efficiency, scalability and sustainability of existing interventions, avoid common blind spots in MNCHN research (*e.g*., still birth & neonatal health) and engage the multiple stakeholder constituencies including end users of any funded health research activity. This led to the formalization of the ICMR-INCLEN collaboration for undertaking the national RPS exercise for MNCHN using the Child Health and Nutrition Research Initiative (CHNRI) methodology. Since 2006-2007, the CHNRI priority setting methodology has been increasingly acknowledged as a flexible yet systematic priority-setting method for ranking competing research options using an objective, quantified and inclusive approach[2-7]. The method is opined to be effective at the national level where the results derived from inputs from national stakeholders can have a direct and prominent impact on the research investment policy[8]. As a major conceptual advancement, this method ranks the broadly defined competing research options that not only generate new knowledge but also synthesize evidence for efficient implementation of what is already known[9]. The ranking of these research options employs 'crowdsourcing' through the engagement of a wide range of stakeholder constituencies with due cognizance of their core expertise. The various dimensions of the research priorities are carefully examined by the experts using a predefined context and set of strictly defined scoring criteria. The collective optimism of the stakeholders, which can be considered as the 'wisdom of the crowd', helps in identifying research priorities through a democratic method of scoring, weighting and ranking of competing research options[1,5].

National Research Priority Setting (RPS) exercise for Maternal, Newborn, and Child Health and Nutrition (MNCHN)

The protocol was reviewed and approved by the Independent Institutional Ethics Committee of INCLEN, and the exercise was undertaken between 2012 and 2016. The context, in which the research priorities were identified in this exercise, are provided in Box 1.

The exercise was woven around four key structures, namely, the National Steering Group (NSG), the Thematic Research Subcommittees (RSCs) constituted for each of the four MNCHN themes (112 experts in India were identified based on active contribution to contemporary research), the Nation-wide Network for Crowdsourcing (experts of various disciplines related to MNCHN with due attention to regional representation

Box 1. Context of the Indian Council of Medical Research-International Clinical Epidemiology Network (ICMR-INCLEN) National Research Priority Setting Exercise for maternal, newborn, child health and nutrition

Purpose: Priority setting in maternal, newborn, and child health and nutrition for efficient and rewarding investment in research using a systematic, transparent, inclusive and consultative method.

Geography: India (National) and three regional levels *viz*., Empowered Action Group (EAG) & North-Eastern States, Southern & Western States, and Northern States & West Bengal.

Target population: Women of reproductive age (15-49 yr); pregnant women, newborns (0-28 days), under-five children (0-59 months) and children (up to the age of 18 yr).

Major areas of concern for research: Conditions that together contributed to at least 75% of the mortality and morbidity burden in Maternal, Newborn, Child Health and Nutrition in India during 2012-2013 as per the available evidence and expert opinion.

Time frame: 2016-2025.

Stakeholder constituencies (public and private sectors, health and non-health sectors): Researchers, professionals, public health functionaries, policy makers, communities and their leadership, civil society and donor agencies.

Translation and implementation context: Public and private health systems of India and their existing as well as future policies and programmes.

Source: Ref. 11, reproduced with permission with minor modifications

from 256 institutions) and the Larger Reference Group (LRG) (84 members group) constituted with Central and State policy decision makers, politicians and bureaucrats from key ministries, MNCHN programme managers, eminent researchers and representatives from research funding organizations. The list of participants in the Nationwide Network is provided in Supplementary Table I (available at *http://www.ijmr.org.in/articles/2017/145/5/images/IndianJMedRes_2017_145_5_611_215547_sm6.pdf*). [The list of all participants in the exercise with respective institutional affiliation is available on *www.inclentrust.org*].

The NSG for the exercise, co-chaired by the Secretary, Department of Health Research (DHR) and Director General (DG)-ICMR and the Executive Director of The INCLEN Trust International, was formed with key officials from concerned Ministries, namely, Ministry of Health & Family Welfare (MoHFW) (National Health Mission, Child Health, Maternal Health and Nutrition Divisions, Directorate General of Health Services and DHR-ICMR), Ministry of Women and Child Development [Integrated Child Development Services (ICDS), Food and Nutrition Board] and Ministry of Science and Technology (Department of Biotechnology, Department of Science & Technology). There was a wide range of invited subject experts, Central and State programme managers, national and international donors and multilateral agencies, who were members. Two NSG meetings were organized, one at the initiation of the exercise to ratify the context and protocol (April 18, 2013) and second, at the conclusion for reviewing and endorsing the findings (February 4, 2016).

The Thematic RSCs contributed to research ideas in the first round of crowdsourcing, helped in refining and consolidating the ideas into research options, finalizing the scoring criteria, participated in second round of crowdsourcing for scoring the research options and presented the results to the NSG for ratification.

The Nationwide Network of experts participated in the first and second round of crowdsourcing for pooling of research ideas and scoring the research options, respectively.

The LRG assigned relative weights to the five scoring criteria, namely answerability, relevance, equity, innovation and out-of-the-box thinking and investment on research.

The exercise was centrally coordinated by the RPS Management Team at the Executive Office of The INCLEN Trust International, New Delhi.

The RPS Management Team established a national network of 1066 experts from institutions across India during 2012-2013. During the same period, it completed an extensive review of literature (research, academic and policy documents) on burden of diseases of MNCHN in India and presented the summary to the NSG at its first meeting. The NSG decided that topmost causes collectively accounting for at least 75 per cent of mortality and morbidity burden (Areas of Concern) for each of the RPS themes so identified shall guide pooling of research ideas and subsequent framing of research options for priority setting. Between September and December 2013, 3498 research ideas were pooled from the nationwide network using custom-designed online software (1st round of crowdsourcing). The participation rate was 42.3 per cent [of the 1178 experts contacted (1066-national members and 112-RSC members), 498 experts contributed research ideas]. Several of these research ideas were narrations comprising more than one research idea spanning across themes, areas of concern and domains. With the help of RSC members (January 2014-February 2015), these were split and refined into 4003 research ideas that were further consolidated into 373 research options (Maternal: 122, Newborn: 56, Child: 101 and Nutrition: 94) (*http://inclentrust.org/inclen/?page_id=8666*). Five criteria (answerability, relevance, equity, innovation and out-of-the-box thinking and investment on research) were identified and defined for scoring the research options (March-June 2015) (Box 2). This was done through a comprehensive review of criteria that had been used in previous exercises at national and global levels and iterative discussion with RSC members and national and international CHNRI experts (University of Edinburgh, Johns Hopkins Bloomberg School of Public Health and the WHO).

Scoring of the research options was done independently by 893 experts (of the 1536 experts approached; Participation rate: 58.1%) using a customized online (*SurveyMonkey.com*) platform (July-October, 2015) (2nd round of crowdsourcing). The scores obtained by the research options were adjusted with criteria weights as assigned by the LRG (November, 2015-January, 2016) as per standard CHNRI data analysis practices[10]. The Average Expert Agreement (AEA) was also calculated for each research option score. The detailed methodology and process adopted for this priority setting has been published

Box 2. Criteria used for scoring the research options

Answerability: Can the research be done through ethical, transparent, well-designed, 'do-able' studies with the existing local and national capacities and or by strengthening the existing capacities through regional or global collaboration?

Relevance: Is it likely that the research would address a high burden condition and critical gap in knowledge?

Innovation and out-of-box thinking to resolve complex and refractory challenges: Does the new research have the potential for transformative change in the health system/ health care?

Equity: Is it likely that the research product will address the differences in health and nutrition that are systematically associated with social, cultural and economic hierarchies, ethnicity, gender, environment and geographic disadvantages, thereby reducing inequities?

Investment on research: Is it likely that the potential impact and benefits of the new knowledge on health/ nutrition will outweigh the considerations of investments on research?

Source: Ref. 11, reproduced with permission

elsewhere[11]. The research options were categorized into four domains; description, discovery, delivery and development.

In addition to national priorities, the States and Union Territories in the country were grouped into three subnational regions to obtain regional priorities [Empowered Action Group (EAG) and North-Eastern States, States in Western and Southern India and States in Northern India (including West Bengal)] (Fig. 1).

The number of scorers ranged between 60 and 96 scorers across each region and theme. Therefore, four priority lists were obtained for each theme: one national and three regional priority lists. The NSG reviewed and discussed the ranked list of priorities and made focused observations on the patterns of research that had evolved as priorities and the possible interlinks between the priorities identified. It also discussed other potential priority research options that might not have made it to the topmost priority list. This helped enrich the structuring of the national research agenda and identify the way forward.

Outcome of the research priority setting (RPS) exercise in the four themes

About 43 per cent of all the research options scored pertained to the delivery domain and required implementation research methodology (Fig. 2). It was observed that in each of the four themes, a large

Fig. 1. Geographical context of the ICMR-INCLEN National Research Priority Setting Exercise for Maternal, Newborn, and Child Health and Nutrition (2016-2025) (Map courtesy: *www.mapsofindia.com* modified with permission).

proportion (70%) of the top ten prioritized issues were dealing with delivery domain of research and implementation of programmes. Amongst the top ten priorities identified at national level, delivery domain research options accounted for 80 per cent in maternal health, 70 per cent in newborn health, 60 per cent in child health and 70 per cent in nutrition themes. Significant differences were also observed between national and regional research priorities for all the four themes. The AEA was very high for the top ten priorities of research in the four themes both nationally and regionally. There were research options in the top ten regional priorities under various themes that did not figure in the national priority list. The Table enlists the top ten priorities identified under each theme by the exercise at the national level. Top ten priorities and their scores along with the national and region-specific ranks are provided in Supplementary Table II (available at *http://www.ijmr.org.in/articles/2017/145/5/images/IndianJMedRes_2017_145_5_611_215547_sm7.pdf*). Key priority research options under each MNCHN theme are summarized below.

Maternal health

The network indicated the need for developing and evaluating screening checklists and management algorithms for severe acute maternal morbidities (SAMMs), near-miss events, high-risk pregnancies,

Table. Top ten priority research options in maternal, newborn, and child health and nutrition themes at national level

Theme	Rank	Research option
Maternal Health	1	Development and validation of algorithms for prevention, early detection and management of severe acute maternal morbidities and near-miss events in resource-constrained settings
	2	Strategies to improve quality of care during childbirth in the public health system, for example, medical practices, LSCS, active management of third stage of labour, EmOC, biophysical profiling for foetal assessment, application of epidural anaesthesia during delivery; beneficiary counselling and communication inside the labour room
	3	Early identification, referral and management of high-risk pregnancies (having maternofoetal morbidities including IUGR, stillbirths and preterms) at all levels of health care
	4	Introduction of a validated and cost-effective cancer screening programme of reproductive system for women in the community and health facilities
	5	Improving EmOC services [*e.g*., risk prediction, identification and communication; prompt referral; service availability (safe transportation, skilled personnel, capacity, logistic, blood storage); accountability; innovations]
	6	Assess blood transfusion needs, current availability and delivery mechanisms of blood for pregnant women based on PHC and CHC catchment areas in the context of prevailing burden of severe anaemia and post-partum haemorrhage
	7	Implementation research for effective delivery of evidence-based care protocols/algorithms for prevention and management of post-partum haemorrhage at different levels of care
	8	Improving maternal death audits, protocols and practices in the public health care system (body handling, support to family, communication, autopsy, death audit and causality ascertainment)
	9	Process and impact evaluation of public health programmes targeted for adolescents (ARSH, AFHS, RMNCH+A, RTI/STI screening services) in urban and rural areas
	10	Develop and validate a self-assessment check list for pregnant women to identify warning signs and need for care seeking
Newborn Health	1	Designing and evaluating curriculums for skill building and their retention for health personnel involved in newborn care in the community and at various levels of health care system (*e.g*., training in identification of warning signs, safe injection practices, administration of oxygen therapy, *etc*.)
	2	Engaging and empowering family members and community in the care of newborn (including family centred care): barriers, strategies to overcome, impact, cost-effectiveness
	3	Identifying appropriate and effective strategies (messages and channels of communication) to promote community awareness on newborn care practices and social mobilization for early healthcare seeking (including utilization of existing nutrition and health services) to prevent adverse outcomes
	4	Low cost, feasible, portable technological innovations in equipment to improve capacity (diagnosis, identification and management) and outreach for foetal & neonatal care (especially, LBW, preterm: CPAP, surfactant therapy, *etc*.,) at various levels of the health system and their impact evaluation
	5	Improving the implementation (service availability, quality, programme management and referral chain robustness) of neonate centric programmes and services (RMNCH+A, JSSK, NSSK, IMNCI & F-IMNCI, SNCUs, *etc*.)
	6	Implementation of an integrated and comprehensive maternal and newborn healthcare package for delivering continuum of care: barriers, strategies to overcome, need for governance modification, maternal and newborn outcomes
	7	Strategies to scale up home-based newborn care: Role assignment and rationalization for frontline workers, barrier identification and mitigation, cost-effectiveness, impact

Contd...

Theme	Rank	Research option
	8	Strategies for social, economic, skill and knowledge empowerment of women and its impact on newborn, child and women's health
	9	Establishing an innovative framework of monitoring and supervision with in-built mechanism of accountability to improve performance of frontline workers and health personnel involved in neonatal care (*e.g*., physical supervision; engaging PRIs and clients; use of ICT, telemedicine, maternal health)
	10	Development and validation of protocols for the management of pregnant women at risk of pre-term delivery, in the healthcare system [*e.g*., nutritional, pharmaceutical (steroids, betamimetics, progesterone, nitroglycerine patches, prophylactic antibiotics, *etc*.), surgical, exercise and lifestyle counselling]
Child Health	1	Develop locally relevant cost-effective strategies to expand the coverage of UIP by reaching segments of populations that are traditionally left out (address system 1 and community-Level 2 challenges) (*i*) VPD epidemiology, system capacity, cold chain, safety surveillance; (*ii*) Hesitancy, dropout, outreach strategies, KAP of care provider, community and clients
	2	Improving administrative data quality and strengthening data-driven child health programme monitoring, action and accountability at PHC and district levels (*e.g*., line listing of households with children with NDD, use of ICT, develop novel indicators)
	3	Development and validation of low-cost technologies for screening, referral and management of childhood pneumonia and ARI in the community and at various levels of health care (*e.g*., maternal health, point-of-care diagnostics & therapeutics, management protocols, *etc*.)
	4	Strategies to promote WASH practices in the community to improve child health and nutrition
	5	Development of cost-effective, feasible, validated point-of-care diagnostics for malaria in children for use at community and different levels of healthcare
	6	Development of evidence-based guidelines for rational use of antibiotics for childhood morbidities in India: choice of antibiotic; route and delivery systems (*e.g*., nebulizers); duration of therapy; monitoring criteria; adjunct therapies
	7	Development of an integrated child health programme for improving quality of life of children: challenges and barriers; strategies to overcome; feasibility across the country; effectiveness, cost-effectiveness
	8	Establishing an effective and sustainable vaccine preventable disease surveillance programme (especially, measles and rubella, pneumonia and diarrhoea) in India [*e.g*., defining syndromes (fever and rash) and programme thresholds, forging PPPs, building upon polio infrastructure, using technology (maternal health, GIS, *etc*.)]
	9	Identifying cost-effective strategies for supplementation of micronutrients and probiotics to prevent and control childhood diarrhoea, pneumonia and other infections
	10	To establish nationwide multicentric antimicrobial surveillance and antibiotic stewardship programme for infectious morbidities during childhood
Nutrition (Maternal and Child)	1	Identify and evaluate strategies to promote healthful lifestyle (physical activity and diet behaviour) in children through school and home-based interventions
	2	Determine characteristics of mother friendly work place policies and governance framework that enable optimal care and nutrition of pregnant and lactating women and their children: identify barriers and challenges to implement (*e.g*., financial security and compensation for loss of pay; crèches at workplaces; provision for breast milk expression and storage for working mothers)
	3	Process, impact and economic evaluation of NRCs for management of severely malnourished children (*e.g*., quality of care and client satisfaction; implementation gaps and challenges, reasons for underutilization and relapse; IEC to mothers during stay and at discharge; impact assessment, effectiveness of the RUTF used in NRCs and plausibility of indigenous preparation with the help of SHGs)

Contd...

Theme	Rank	Research option
	4	Identifying strategies for engaging the male partners, families and communities to improve the nutrition of women of reproductive age group and under-five children
	5	Process, impact, and economic evaluation of community-based management of childhood malnutrition (including SAM): role, effectiveness and accountability of various stakeholders (including frontline workers)
	6	Impact and economic evaluation of WASH practices in the community on the nutrition of women and children
	7	Cost-effective strategies to improve the quality, quantity and coverage of food supplements provided under the Mid-Day Meal Programme to improve the nutritional status of school-going children
	8	Determining optimal growth trajectory of LBW (preterm, SGA) babies: nutrient and calorie requirements; strategies to minimize, mitigate development of chronic diseases
	9	Development and popularisation of improved varieties of traditional food items rich in micronutrients (*e.g.*, iron rich millets): adoption of viable business models and modifying value and supply chains
	10	Strategies to overcome barriers and improve implementation of WASH practices in the community with particular focus on poor, socially disadvantaged groups

AFHS, Adolescent Friendly Health Services; ARI, Acute respiratory infections; ARSH, Adolescent reproductive and sexual health; CHC, Community Health Centre; CPAP, Continuous positive airway pressure; EmOC, Emergency obstetric care; F-IMNCI, Facility-based Integrated Management of Newborn and Childhood Illnesses; GIS, Geographic information system; ICT, Information and communication technology; IEC, Information, education, communication; IMNCI, Integrated Management of Newborn and Childhood Illnesses; IUGR, Intra uterine growth restriction; JSSK, *Janani Shishu Suraksha Karyakram*; KAP, Knowledge, attitude and practice; LBW, Low birth weight; LSCS, Lower segment cesarean section; NDD, Neuro-developmental disorders; NRC, Nutrition rehabilitation centres; NSSK, *Navjaat Shishu Suraksha Karyakram*; PHC, Primary Health Centre; PPP, Public private partnership; PRI, *Panchayati Raj* Institutions; RMNCH+A, Reproductive maternal newborn child and adolescent health; RTI, Reproductive tract infections; RUTF, Ready-to-use therapeutic food; SAM, Severe acute malnutrition; SGA, Small-for-gestational age; SHG, Self help group; SNCU, Special Newborn Care Units; STI, Sexually transmitted infections; UIP, Universal Immunization Programme; VPD, Vaccine preventable diseases; WASH, Water, sanitation and hygiene

post-partum haemorrhage, stillbirth, eclampsia and cancers. Development of point of care diagnostics and technological solutions for SAMMs, perinatal hypoxia and foetal distress were ranked as high priorities. Research on strategies to empower families and women for better self-care and timely care seeking, and skill enhancement (including role rationalization, task shifting and sharing) along with accountability of health providers at different levels were scored as important priorities. Process and impact evaluation of existing maternal health programmes to improve outcomes, developing implementation strategies to improve the quality of different aspects of maternal care in health system and expanding their coverage were considered important research areas. Development of pharmaceutical protocols for prevention and clinical management and novel technological solutions for identifying SAMMs, epidemiology of stillbirths and expanding coverage of reproductive tract infection (RTI)/sexually transmitted infection programmes and specific studies on symptomatic and asymptomatic RTI and its impact on stillbirth, low birth weight (LBW), intrauterine growth restriction (IUGR) and abortions were scored as important regional priorities.

Newborn health

Newborn health priorities included strategies to improve delivery and quality of care of newborn health-oriented programmes; skill and capacity enhancement of service providers including pre-service changes in the curriculum with in-built mechanisms of accountability; empowering mothers, families and communities to improve care seeking and quality of care in home environments; multicentric antimicrobial surveillance and antibiotic stewardship programme; development of point-of-care diagnostics/biomarkers for improving neonatal outcome, particularly for LBW neonates (preterm and IUGR) and neonatal sepsis; use of information and communication technology and utilization of m-Health to improve access to newborn care.

Child health

Six areas emerged prominently within child health: (*i*) issues related to coverage of Universal

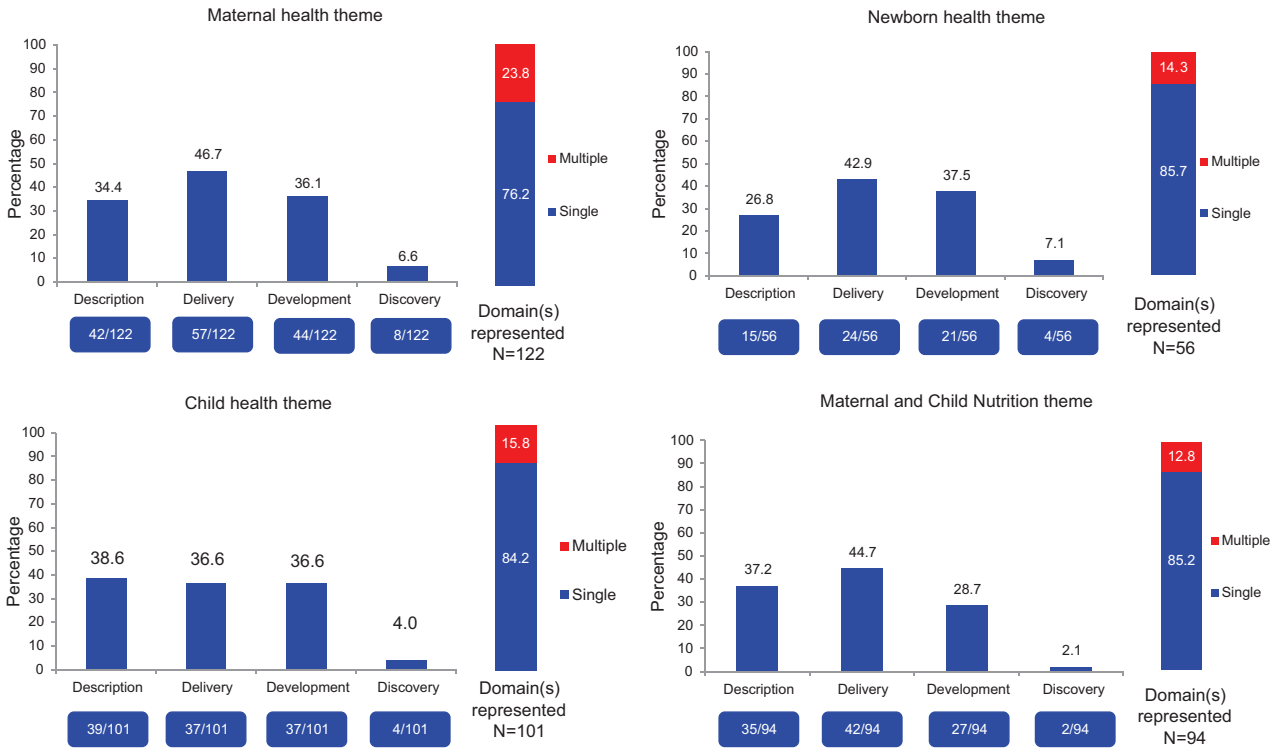

Fig. 2. Distribution of the research options in maternal, newborn, and child health and nutrition themes across the four domains of research.

Immunisation Programme (UIP) and surveillance for vaccine preventable diseases; (*ii*) point-of-care diagnostics; (*iii*) use of technology and development of biomarkers for the screening, referral and management of common childhood illnesses, namely, diarrhoea and acute respiratory infections (ARIs) along with improved control and management of malaria; (*iv*) rational use of antibiotics; (*v*) early childhood risk factors of adverse metabolic outcomes in later life, namely, obesity and metabolic syndrome; and (*vi*) water and sanitation hygiene (WASH). Operational and implementation research to effectively deliver different child health interventions in an integrated manner, including improving administrative data quality for decision-making, achieving Indian Public Health Standards at facilities, engaging community and its resources for better care seeking and care at home, strengthening curriculums for skill building and retention of personnel, was another area that scored high at both national and regional levels.

Maternal & child nutrition

Creation of mother friendly environments was an interesting and important priority to address issues of maternal and child nutrition. Research options that addressed the issues related to chronic diseases (*i.e.,* lifestyle behaviour modification interventions, point-of-care diagnostics and biomarkers for metabolic syndrome and nutrition of women around conception to prevent foetal programming and consequent risk for foetal origin of adult diseases) also scored high. Research options for enhancing skill of care providers and empowerment of families and communities including behavioural change communication were prioritized as was observed for other thematic areas. Research options around WASH (environmental and water hygiene) were scored high by experts across the country. Importantly, these research options were seen across all four themes. Research options to explore the performance and impact of various nutrition and food supplementation programmes (including community-based management of childhood malnutrition, midday meal, ICDS and food items provided under National Food Security Programme), improvement of administrative data quality for decision-making and the multisectoral governance of agriculture-nutrition-health nexus were prioritized at both national and regional levels. Anaemia (including issues related to absorption of nutrients), growth trajectory of LBW and breastfeeding were important cross-cutting areas for both mother and child perspective and were scored high.

The LRG had assigned the highest weight to the scoring criterion of 'relevance' and the lowest weight to 'investment in research'. The relative weights assigned to the five scoring criteria by different categories of members within the LRG did not vary significantly.

Discussion

The NSG strongly endorsed the research priorities identified by the exercise as appropriate for investment by different science and research departments of the Government of India and other national and international donor agencies and academic institutions over the next decade. It felt that the research agenda established with this exercise was in alignment with the national programme for achieving the recently enunciated health-related Sustainable Development Goals (SDGs) and will facilitate in accomplishing the unfinished agenda of the MDGs.

The exercise engaged experts who were well dispersed across the country. Thus, for the first time, regional MNCHN research priorities could be identified. In all the four thematic areas, there were differences between the top ten national and regional priorities. This observation made it imperative to take cognizance of the unique research needs of the regions. Although not part of the current project, the NSG suggested that a systematic effort must be made to determine factors that could explain differences in national and subnational (regional) priorities. The States falling under the three regions vary in terms of their health infrastructure, programme implementation and governance, development indicators and availability of baseline information on various health indicators. This may to some extent, explain the differences in the emerging research priorities. Better understanding of these factors will be important to design need-based research programmes and policies for different parts of the country. There are significant rural and urban differences for the health challenges and these have assumed greater significance in the light of rapid urbanization in certain parts of the country. The rural-urban divide will also have to be kept in mind when decisions on research investments are made.

In addition to the top priorities identified by the exercise, the NSG highlighted some more areas of research in MNCHN themes that deserve investment. These included role of environmental exposures in the occurrence of neurodevelopmental disorders such as autism; early childhood care and stimulation for improving cognitive outcomes; better description of childhood cancers and their risk factors; unsafe abortions; innovations to solve the 'nutrition enigma'; factors interfering with iron absorption in both women and children; impact of fluoride on health and nutrition of women and children; micronutrient deficiencies and occurrence of congenital birth defects (*e.g*., neural tube defects with folic acid deficiency); research into processes and strategies to make multisectoral governance for human nutrition workable and effective and technology innovation for developing better tools of nutrition assessment.

As part of Infant and Young Child Feeding and Complementary Feeding research agenda, NSG has also suggested that it is important to innovate strategies to promote breastfeeding; innovation is also needed in the development of low cost nutritious and healthy processed foods that require minimal cooking, are prepared from indigenous raw material and are appropriately fortified. This is important in the context of giving relief to severely time-constrained mothers who have now entered the workforce in a considerable way. Legislations affecting women and child health and nutrition are an important aspect to consider when research programmes and investment decisions are made. NSG suggested that researchers and funding agencies should work with Food Safety and Standards Authority of India in MoHFW to better understand regulatory issues related to food processing and related nutritional impacts.

Adolescents constitute almost 25 per cent of the Indian population. They suffer from several health problems that have been hitherto neglected. The foundation of several chronic diseases in the form of exposure to risk factors is laid during the adolescent years. NSG advised that adolescent-related research options were culled from the four themes and put forward separately with a caveat that scorers did not have an opportunity to see all the options in this section together. These have been put together in Supplementary Table III (available at *http://www.ijmr.org.in/articles/2017/145/5/images/IndianJMedRes_2017_145_5_611_215547_sm8.pdf*). However, as adolescent health was not stated as a theme on its own for prioritization, the research options that were chosen from within the other sections may not reflect the true priorities in adolescent health. An independent exercise may be undertaken where adolescent health is given a focus (One example where a gap can easily be seen is interventions to target adolescent boys or interventions looking at accidental

injury or drowning which carry a huge burden in this age group).

The NSG acknowledged implementation research as an important area for consideration. This necessitates bridging the 'disconnect' between the research community, the policy and programme makers, implementers and the communities to achieve the desirable impact. Implementation research involves behavioural changes of health providers, and this cannot be overlooked. Some of the prioritized implementation research options can also help the national and State administrators to either commission research studies or decide to reset the way, in which the health system is working. This will also provide an opportunity for re-engineering health systems and programmes to improve their efficiencies: by dropping redundant programmes and/or making way for newer, refined and 'need of the hour' programmes. As a cross-cutting research priority, the NSG strongly pitched the imperatives of improving the quality of administrative data for better use in decision-making at ground level.

The NSG members observed that several of the priority research issues were cross-cutting and common across the four themes; these should be brought together as common research agenda for MNCHN. This will make the research investment efficient and effective by addressing more than one theme at a time and also align the research projects with the national goal to achieve universal healthcare in India. As a follow up on this suggestion, the investigator team has prepared a separate list of cross-cutting research options [Supplementary Table IV (available at *http://www.ijmr.org.in/articles/2017/145/5/images/IndianJMedRes_2017_145_5_611_215547_sm9.pdf*)]. Similarly, as technology has cross-cutting usage, another list of research options related to research on the use of technology for health has been prepared for consideration by agencies with mandate to exclusively fund such research [Supplementary Table V (available at *http://www.ijmr.org.in/articles/2017/145/5/images/IndianJMedRes_2017_145_5_611_215547_sm10.pdf*)].

The NSG strongly advised that the DHR and other science ministries along with MoHFW should make efforts to pool resources for addressing priority research issues and also encourage national and international agencies to come together to invest strategically for greater and faster impact. The NSG has suggested that a number of research issues have the ability to be 'game changers' for the health systems, and for the health and nutrition of mothers and children, in general. These can be systematically identified and taken up in a mission mode by science ministries and donor agencies as per their own prioritization and investment policies. Recognizing the challenges of programme delivery in the context of weak infrastructure, national policymakers and programme planners have already identified north-eastern States and EAG States for the focus of several developmental schemes including health and nutrition (*http://nhm.gov.in/nhm/nrhm.html*). To further accelerate the developmental process, region-specific research agenda should become natural corollary. Health is a State subject in India and implementation of research issues can be integrated with the programme monitoring and evaluation frameworks existing therein. The research agenda could be accomplished in an accelerated manner and effectively with multistakeholder and multi-agency engagement through a broader convergent innovation coalition that will add to existing sectoral and cross-sectoral capacity for science, social sciences, economics, technology, innovation, strategy and policy to achieve better health and nutrition for mothers and their children in India.

Conclusion

It was concluded that the logical way forward for this exercise would be to take up these research priorities with different governmental and non-governmental agencies for investment. Various government and non-governmental funding agencies were requested to now re-align their investment with these priorities to achieve better health and nutrition for women and children of India effectively and efficiently. Further, bridging the gap between researchers and programme implementers at the grass root level would be essential along with decentralization of strategies to have State and possibly, district centric solutions for the betterment of health and nutrition scenario in India. In view of the predominance of delivery and implementation research identified as priority in all thematic areas, it was suggested to explore the possibility of supporting such research projects from the programme funds.

Acknowledgment

This exercise was co-funded by the ICMR, the CHNRI Secretariat and the INCLEN Trust International, New Delhi. The team is grateful to the experts from different parts of India for their enthusiastic participation in this exercise and kind support. The teams thank Drs Geeta Chibber, Meenu Maheshwari, Manish Singh Chundawat, Kriti Agarwal, Sarvshri Amit K Sagar, Gaurav Banyal

and Chandan Singh from INCLEN Executive Office, for their assistance during various phases of the exercise. PREVALENCE OF DEPRESSION AND ITS ASSOCIATED FACTORS IN ADULTS WITH DIABETES MELLITUS: A CROSS-SECTIONAL STUDY IN A TERTIARY CARE CENTRE

Shweta Paulraj[1] , Senthil Rajasekaran[2] and Anil C Mathew[3]

[1,2] Department of Endocrinology, [3]Department of Community Medicine, PSG Institute of Medical Sciences and Research, Coimbatore, India

ABSTRACT

The prevalence of Diabetes Mellitus has been rising steadily owing to several factors such as sedentary lifestyle, obesity and an aging population. The prevalence of diabetes is predicted to double globally from 171 million in 2000 to 366 million in 2030 with a maximum increase in India with up to 79.4 million individuals in India. Depression occurs frequently with diabetes but there are not many studies in India to estimate its prevalence and associated factors. This study was done with the aim of estimating the prevalence of depression among diabetes patients using the validated Patient Health Questionnaire-9 and also its associated factors. A cross sectional study was done on 100 consecutive patients with Diabetes Mellitus (both type 1&2) attending the Outpatient Endocrinology clinic from September 2015 to November 2015. The Patient Health Questionnaire diagnostic algorithm was used to identify major depression. The covariates studied were age, gender, duration of diabetes, presence of hypertension and glycaemic control. Chi-square test was done to find the association of demographic and clinical characteristics of depression. Multiple logistic regressional analysis was done to identify the statistically significant variables. The prevalence of major depression was found to be 35%. People with hypertension were found to have a significantly higher prevalence of depression (adjusted odds ratio=3.02, 95% CI: 1.17 to 7.7, P=0.022). Also, employed people were at a lower risk for depression when compared to the unemployed /retired population (adjusted odds ratio=0.319, 95% CI: 0.11-0.85, P=0.023).Interestingly age, duration of diabetes and glycaemic control were not significantly associated with depression. Over one-third of the patients with diabetes mellitus had depressive symptoms. The prevalence varied by demographic and clinical characteristics.

KEYWORDS

Diabetes, Depression, Patient Health Questionnaire- 9, Hypertension.

1. INTRODUCTION

The prevalence of Diabetes Mellitus has been rising steadily owing to several factors such as sedentary lifestyle, obesity and an aging population. The prevalence of diabetes is predicted to double globally from 171 million in 2000 to 366 million in 2030 with a maximum increase in India with up to 79.4 million individuals in India.[1]

Depression occurs frequently with diabetes and has been found to be associated bidirectionally with diabetes mellitus.[2,3] However, it was observed that the reported prevalence in the studies varied tremendously in terms of definition, study design, source of subjects, time frame and measurement methods.[4-6] Moreover, with the predicted rise of diabetes in India, and risk factors

for depression such as low socioeconomic status, financial constraints being rampant here it is quintessential to establish regional studies as a guideline to aid in a holistic patient approach. [7]

Apart from this, most of these studies used self-administered questionnaires which cannot directly establish a diagnosis of depression. [4,5,6,8] Standard interviews, such as the Structured Clinical Interview for DSM Disorders (SCID)[9] and the Composite International Diagnostic Interview (CIDI) [10] can yield a clinical diagnosis according to the Statistical Manual of Psychiatric Disorders, 4th edition (DSM-IV) [11] ; however, lengthy assessments and high costs preclude the extensive use of such structured diagnostic interviews in large population-based surveys.

The Patient Health Questionnaire (PHQ) can establish provisional diagnoses of major and minor depression as well as evaluate the severity of depressive symptoms. [12] ; The PHQ-9 diagnosis of major depression yielded acceptable sensitivity and specificity. The present study aims to estimate the prevalence of depression among diabetes patients using the validated Patient Health Questionnaire-9 and its associated factors.

The variables taken into consideration for association with depression in this region include age, gender, duration of diabetes, glycaemic index and presence of hypertension . This stems from previous studies which show significant correlations between the above variables and depression[6,13,14]

2. MATERIALS AND METHODS:

This study is a cross-sectional study on 100 consecutive patients presenting at a tertiary care centre, aged >18yrs diagnosed with Type 2 diabetes mellitus by a certified Endocrinologist. The study was carried out after obtaining institutional ethics committee clearance. Written informed consent was obtained from the study participants and the PHQ-9 questionnaires were distributed. Those subjects that couldn't read were assisted in filling the questionnaires by an interpreter (Figure 1). During multivariate analysis we have combined the scores 0-9 (none, minimal and mild depression categories) as "no major depression" and scores of 10-27 (moderate, moderately severe and severe categories) as " major depression".[15,16]

Patients with complications from diabetes (retinopathy, neuropathy, nephropathy), previous history of mental illness, previous illnesses known to increase a risk for depression (CAD,CVA), and patients already on antidepressants for other symptoms were excluded from the study.

The demographic variables considered were age, gender, duration of diabetes, glycaemic index and presence of hypertension. Age was measured in completed years. Duration of diabetes and glycaemic control were taken from the patients' case records. Hypertension was defined in the study as systolic BP level of ≥140mmHg and diastolic BP of ≥90mmHg, or current treatment for hypertension with prescription medication. [17,18]

Data were analysed using SPSS(19). Chi-square test was done to find the association of demographic and clinical characteristics of depression. Further, multiple logistic regressional analysis was done to identify the statistically significant variables. *P* value of <0.05 was considered as statistically significant

PATIENT HEALTH QUESTIONNAIRE (PHQ-9)

NAME:_____ DATE:_____

Over the last *2 weeks*, how often have you been bothered by any of the following problems?
(use "✓" to indicate your answer)

	Not at all	Several days	More than half the days	Nearly every day
1. Little interest or pleasure in doing things	0	1	2	3
2. Feeling down, depressed, or hopeless	0	1	2	3
3. Trouble falling or staying asleep, or sleeping too much	0	1	2	3
4. Feeling tired or having little energy	0	1	2	3
5. Poor appetite or overeating	0	1	2	3
6. Feeling bad about yourself—or that you are a failure or have let yourself or your family down	0	1	2	3
7. Trouble concentrating on things, such as reading the newspaper or watching television	0	1	2	3
8. Moving or speaking so slowly that other people could have noticed. Or the opposite — being so figety or restless that you have been moving around a lot more than usual	0	1	2	3
9. Thoughts that you would be better off dead, or of hurting yourself	0	1	2	3

3. RESULTS:

Among the 100 patients studied, 35 were found to have major depression (Figure 2). In the univariate analysis, those who were having hypertension and those who were unemployed were significantly associated with depression (P<0.05). In the multiple regression analysis(Table I), people with hypertension were found to have a significantly higher prevalence of depression (adjusted odds ratio=3.02,95% Confidence Interval :1.17 to 7.7,P=0.022) (Figure 3).Also, employed people were at a lower risk for depression when compared to the unemployed /retired population(adjusted odds ratio=0.319,95% Confidence Interval :0.11-0.85,P=0.023) (Figure 4) that bar graph has nothing written on x axis. Interestingly age, duration of diabetes and glycaemic control were not significantly associated with depression.

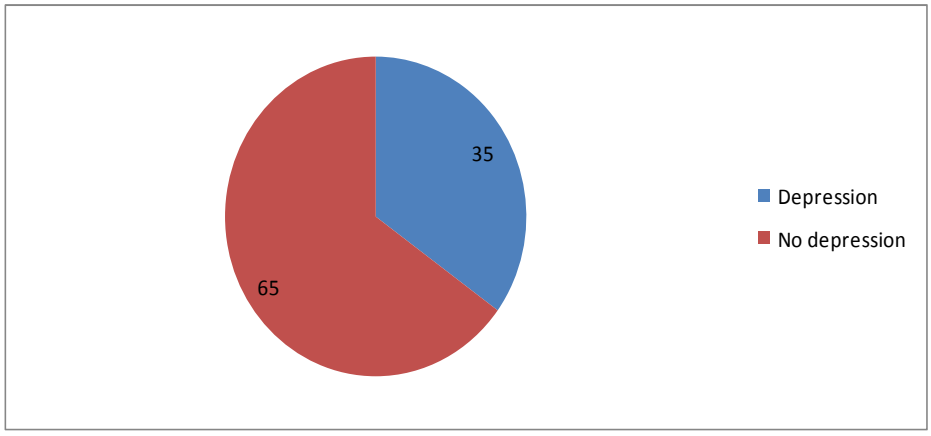

Figure 2. Percentage of patients with and without depression among the study group.

4. DISCUSSION:

In the present study the prevalence of depression among patients with diabetes mellitus was found to be 35% which was slightly smaller than the prevalence in a study conducted by Joseph N et al., in an adjoining area that reported a prevalence of 45.3%.[13] It was also found to be more than twice as common as depression in the general population of our region.[7,19]

This leads us to ask the more imposing question, “Why is depression more prevalent in people with diabetes mellitus?”. The study by Talbot F et al., suggested that the extent to which diabetes intrudes in life, rather than diabetic complications per se or personal control, is a key factor in

relation to depressive symptomatology in individuals with diabetes. [20]In an animal model, Wang and colleagues demonstrated that experimentally induced type 1 diabetes impairs hippocampal neurogenesis, which may contribute to diabetes-related depression.[21] Another study demonstrated decreased plasma brain-derived neurotrophic factor (BDNF) in patients with type 2 diabetes compared to controls, which has been hypothesized to play a role in learning and memory and has also been implicated in the pathogenesis of depression.[22]

Among the risk factors, depression was found to be significantly associated with hypertension. This is in line with the findings of Saeed AK et al., where the prevalence of depression in hypertensive people with diabetes mellitus was 57% whereas in people with diabetes alone it was 40%. (P is less than 0.05). [23] There are also other studies which showed that depression is common in patients with uncontrolled hypertension irrespective of presence of diabetes and may interfere with blood pressure control. [24, 25] Studies have shown that plasma noradrenaline, as an indirect marker of sympathetic tone, was elevated in patients with essential hypertension.[26] There is also reported evidence showing abnormal autonomic nervous system function in depression, specifically regarding increased sympathetic activity and poor vagal control. Several studies have examined cerebrospinal fluid (CSF), plasma or urinary levels of norepinephrine (NE) and its major central nervous system metabolite, 3-methoxy-4-hydroxyphenylglycol (MHPG). Plasma NE and/or MHPG levels have been reported to be elevated in depressive patients.[27,28] Thus, the existing relationship between hypertension and depression by itself could have contributed to the statistically significant presence of depression among hypertensive people with diabetes mellitus.

Also, we found that depression among diabetes was significantly associated with employment status with a higher prevalence in the unemployed population. This is in line with other studies which showed a higher prevalence of depression in the unemployed population. [13,29,30] The unemployed individuals lack sociological functions such as time structure, status and identity, social contacts, participation in collective purposes and regular activity which could predispose them to depression.[30]

A methodological innovation of our study was the application of the PHQ-9[12] which was developed for clinical use, scoring each of the DSM IV criteria on grades from 0-3 based on the frequency of the symptoms[31] Scores of 20-27,15-19,10-14,5-9 and 1-4 represent severe, moderately severe, moderate, mild and minimal depression respectively. [11]

Our results indicate that a substantial number of people with diabetes are at an increased risk of having major depression, and those who care for patients with diabetes should routinely screen them for major depression using the PHQ-9 or other such instruments. Among the umpteen methods to screen for depression, the PHQ-9 is a promising tool with its ease of administration, convenient scoring system, brief and simple questions. Most importantly, the use of PHQ-9 can serve in comparisons of depressive symptomatology on an international basis given its worldwide validation. [32,33]

This study has some limitations. The study was conducted in a tertiary care hospital, so a possible selection bias cannot be excluded. This could be because the patients coming to the tertiary care hospital belong to the relatively higher socioeconomic status of the community. A large sample community based study could throw more light on this relationship. Since this study is a cross-sectional study, temporal relationship between depression and diabetes cannot be determined.

5. CONCLUSIONS

Over one-third (35%) of the patients with diabetes mellitus had depressive symptoms. It is widely associated with unemployment and co-existent hypertension in this population.

This emphasizes that the mind/body dualism is a false dichotomy and there is an increasing need to integrate mental health services in these patients. We recommend routine screening of diabetic patients with PHQ-9 to identify those at risk as it is a quick and easy tool to identify depression and refer patients appropriately for further counselling and support.

In addition, the issue of depression in association with socioeconomic factors such as unemployment is to be addressed by the health policy to aim for an overall betterment of the welfare of the people in this region.

ACKNOWLEDGEMENTS

My sincere thanks to my Guides, Dr. Senthil Rajasekaran and Dr. Anil Mathew stood by my side and helped me carry out this research perfectly at each and every step. I would also like to thank the Department of Endocrinology and Community Medicine, and all the supporting staff for their help. Finally I wish to thank the study participants for sparing their valuable time and for providing the information which enabled us to complete our research.

ABSTRACT

Aim: The aim of the study was to examine the association of consumption of tea with the risk of type 2 diabetes mellitus. **Methods:** A case control study was conducted at PSG Hospitals between 1st June 2017 and 1st July 2017. All those who had newly diagnosed type 2 diabetes mellitus and attended Department of Endocrinology for follow-up visit were the cases and the relatives accompanying them without the history of diabetes mellitus were the controls. Tea consumption and other dietary factors were elicited. The mediating factors studied were age, sex, Body Mass Index (BMI), educational levels, smoking status, alcohol consumption, family history of diabetes mellitus, potassium intake, magnesium intake and use of statins. **Results:** After adjusting the potential confounders, tea consumption was inversely associated with risk of type 2 diabetes mellitus with odds ratio of 0.652 (95% CI = 0.43 – 0.98). The association was also observed with participants who consumed tea 3 or 4 cups per day compared to those who did not drink tea on a daily basis (odds ratio = 0.368, 95% CI = 0.14 – 0.96). However, the association was not observed among those who take 5 or more cups of tea per day (odds ratio = 0.328, 95% CI = 0.06 – 1.60).**Conclusion:** Our findings suggest that consumption of 3 to 4 cups of tea per day has a decreased risk of type 2 diabetes mellitus. The results from our study also suggest that adjusting for mediating factors did not alter the results and hence other unknown factors may explain inverse relation between tea consumption and type 2 diabetes mellitus. Further studies are warranted.

Keywords: Tea consumption, type 2 diabetes mellitus, chocolate consumption, potassium intake

Introduction

The prevalence of type 2 diabetes mellitus has increased dramatically in the past decades [1, 2].

The majority of cases of diabetes mellitus could be prevented by changes in life style. However, the association of tea consumption with the risk of type 2 diabetes mellitus is not entirely clear. Few studies found an inverse association between tea intake and type 2 diabetes mellitus, while few other studies did not observe an association between tea consumption and risk of type 2 diabetes mellitus [3-6].The underlying mechanism regarding the relation between tea consumption and type 2 diabetes mellitus is also

unclear. Several components of tea have been suggested as possible causal factors [7].Magnesium plays a role in regulating insulin action and is inversely associated with insulin sensitivity and type 2 diabetes mellitus. Potassium intake has also been associated with reduced risk of diabetes mellitus [8].So far; there is no conclusive evidence about whether these factors explain the association of tea intake and type 2 diabetes mellitus. Besides these, earlier studies have not accounted for the effect of long term medication such as statin use which may confound the results. Therefore the present study is aimed to investigate the association of tea consumption with the risk of type 2 diabetes mellitus adjusting for multiple covariates.

Materials and Methods

Study population and design

A case-control study was conducted at PSG Hospitals. All those who have newly diagnosed in the past 1 year as type 2 diabetes mellitus and attending the Department of Endocrinology for follow up between 1stJune 2017 – 1st July 2017 were considered as cases. Controls were those who accompany them and do not have history of diabetes mellitus. We then retrospectively evaluated their food practices and other demographic information.

General assessments

The general assessment survey was conducted at the outpatient Department of Endocrinology, PSG Hospitals, Coimbatore. The general questionnaire contained questions on demographic characteristics. Body weight (in kg) and height (in meter) were also measured. However in few cases, we were not able to measure height. Food intake was assessed using a validated Food Frequency Questionnaire in this population and from this magnesium intake and potassium intake were estimated. The questionnaire also asked about smoking status, practice of alcohol intake, whether previously diagnosed as diabetes mellitus, other medical histories and medications taken. The information on baseline consumption of coffee, tea and other beverages were also collected. We also collected the data about consumption of chocolates, since chocolates are also a source of caffeine.

Statistical analysis

To examine the association between tea consumption and incidence of type 2 diabetes mellitus, we used four logistic regression models. In the first model, odds ratio and 95% confidence intervals for type 2 diabetes mellitus were calculated against a reference group of low consumers adjusted for age (continuous) and gender (male/female). A second logistic regression model corrected the other known diabetes mellitus risk factors which include smoking status (present/absent), BMI, education attainment (classes up to 12th standard/college and above), family history of diabetes mellitus (present/absent); alcohol intake (gm. per week). Body mass index was calculated by the formula, body weight (kg) divided by the square of the body height in meter. A third model corrected for coffee (considering the fact that those who drank a lot of tea tend to drink less coffee and vice versa) and chocolate consumption. Mediating factors were included in the final model. The mediating factors considered were daily intake of magnesium and potassium, which were elicited from their food consumption practices and the effects of long term medications particularly the use of statins[9].

Results

The study included 150 cases and 150 controls. Baseline characteristics of the study participants among cases and controls were presented in Table 1. Most of the demographic factors were comparable between cases and controls. However cases were having slightly older age compared to controls. Family history of diabetes mellitus and level of education was higher among cases compared to controls. In the multivariate regression model, odds ratio shows that the participants who drank more tea had a significantly decreased risk of diabetes mellitus compared with those who do not drink tea on a daily basis (odds ratio = 0.652, 95% CI = 0.43 – 0.98). On further analysis, it was observed that the participants who consumed 3 or 4 cups of tea per day had a decreased risk of type 2 diabetes mellitus compared to those who do not drink tea on a daily basis (odds ratio = 0.368, 95% CI = 0.14 – 0.96) (Table 3) with no significance in analysis of trend (Figure 1). The reduced risk was not observed among those who take 5 cups or more tea per day (odds ratio = 0.328, 95% CI = 0.06 – 1.60)

Discussion

Several studies have investigated the association between tea consumption and type 2 diabetes mellitus[10-14]. Some of these studies did not find any association, while other studies observed an inverse association between tea consumption and type 2 diabetes mellitus. Another study found an association only for green tea and not for black tea. However, our study strongly support the findings of the recent meta-analysis[11] which concluded that consumption of 4 cups of tea per day may lower the risk of type 2 diabetes mellitus, but a reduced risk was not observed for 1 to 2 cups per day. In addition, we also observed that the reduced risk was not observed for those who take more than five cups of tea per day. This is perhaps due to the reduced sample size in this group.In univariate analysis, we observed an inverse association between potassium intake and the risk of type 2 diabetes mellitus. In our study, intake of magnesium and potassium were included in the final model to assess whether these factors mediated the observed association between tea intake and type 2 diabetes mellitus, but none affected the association. Hence, results from our study suggest that other factors may be more important to explain inverse relation between tea consumption and type 2 diabetes mellitus. Tea contains flavonols and flavones are antioxidants. Antioxidants may reduce the amount of reactive oxygen species, which activate stress-sensitive pathways. These pathways can lead to insulin resistance, impaired insulin secretion and beta cell dysfunction. Our study has several limitations, first we relied on self-reported tea consumption and therefore misclassification may have occurred. Second, we relied on self-reported information on non-diabetic status among controls. Third, we could not assess the influence of physical activities due to some practical reasons. The strengths of this study are a large number of covariates studied and extensive information on diet of the participants.

In conclusion, the results from our study suggest that consumption of 3 to 4 cups of tea per day has a decreased risk of type 2 diabetes mellitus. Further large scale prospective studies can provide more information in this field.

Acknowledgement

The authors are extremely thankful to Dr. S. Ramalingam, Dean, PSG Institute of Medical Sciences and Research for permitting us to do the study. We are thankful to Dr. S.L. Ravishankar, Professor and Head of the Department of Community Medicine for his continuous support to conduct the study. We are also grateful to Ms. B Divya, Senior Dietitian, Department of Dietary for her valuable support in estimating the magnesium and potassium

intake using the dietary history of the participants. We do not have any conflict of interest and not received any research grants for this study.

Abstract

Background and Aim:

The incidence of heart failure (HF) is rising to epidemic proportions in developing countries like India. A lack of adequate Indian studies underscores the importance of pursuing research into HF in an Indian population. G protein-coupled receptor kinase 5 (*GRK5)* Gln41>Leu (rs2230345) polymorphism was reported as a genetic modifier associated with survival in HF patients. A prospective study was conducted to investigate the association of *GRK5* Gln41>Leu polymorphism with response to β-blocker therapy in Indian HF patients.

Methods:

HF patients (*n*=584) were recruited for the study. The patients were genotyped by tetra-primer based allele specific polymerase chain reaction and confirmed with Sanger sequencing. The HF patients were evaluated for *GRK5* gene expression and followed up for ~3 years. Drug dosages, cardiac output and hospitalization-free survival were evaluated as study outcomes. HF subgroups (i.e. systolic or diastolic dysfunction, biventricular dysfunction and pulmonary artery hypertension) were also analyzed in association with hospital-free survival.

Results:

HF patients showed genotype frequencies of AT (15%) and TT (1%). AT/TT genotype carriers showed downregulated *GRK5* gene expression and significant reduction in carvedilol drug dosage (p=0.0001). Moreover, AT/TT genotype carriers on β-blockers showed improved ejection fraction from 27% to 36% (p=0.0007) and increased hospitalization-free survival in comparison to other HF patients. HF patients with AA genotype showed an increased rate of hospital admission in comparison with patients with the AT/TT genotype. HF subgroups with the AT/TT genotype showed an increased hospitalization-free survival versus subgroups with the AA genotype.

Conclusions:

GRK5 Gln41>Leu polymorphism in response to β-blocker therapy improved cardiac function in HF patients.

Relevance for Patients:

This study presents a comprehensive clinicofunctional pharmacogenetic characterization of *GRK5* Gln41>Leu polymorphism in a cohort of Indian HF patients. *GRK5* Gln41>Leu polymorphism can confer improved cardiac function and reduce hospitalization, thus improving the quality of life in HF patients.

Keywords: β-blocker, genotype, GRK5, heart failure, India, polymorphism

1. Introduction

Heart failure (HF) is a major, multifactorial global health disease affecting approx. 6.5 million adults/year in the United States [1] and 491,600 – 1.8 million individuals/year in India [2]. The common etiologies of HF are coronary artery disease, hypertension, valvular heart disease, arrhythmia, dilated cardiomyopathy, infection, and inflammation [3]. Other risk factors include hypertension, ischemic heart disease, obesity, Type II diabetes mellitus, and rheumatic heart disease [2]. Growing evidence show that mortality rates as a result of HF are higher in Indian patients than in western countries with death records of 0.1-0.16 million individuals/year in India [4].

The use of beta (β)-adrenergic receptor (β-AR) antagonists continues to be the standard treatment for HF [5] and has effectively reduced mortality and morbidity rates over the past decade. β-AR, a G protein-coupled receptor expressed by cardiomyocytes has been documented as important for effective cardiac function [6]. Many studies have shown that elevated activation of β-AR results in abnormal β-AR signaling which leads to the pathogenesis of HF [7,8]. Therefore, much of the therapeutic drugs like β-blockers that target the β-AR, antagonize catecholamine-stimulated β-AR signaling [6] and have resulted in increased survival of HF patients.

As a regulator of β-AR signaling, G protein-coupled receptor kinases (GRKs) act by phosphorylating the activated β-AR, leading to receptor desensitization and diminished β-AR signaling [9]. Overexpression of GRK5 and GRK2 contribute to dysregulation of β-AR by excess desensitization and

is also considered a hallmark of HF pathology [10]. Therefore, genetic polymorphisms in β-AR regulator genes may influence HF outcome. One such functional polymorphism being *GRK5* Gln41>Leu (rs2230345, c.122A>T, p.Q41L) in the *GRK5* gene. This nonsynonymous single nucleotide polymorphism (SNP) in the noncatalytic regulatory domain is prevalent in African Americans and confers a gain-of-desensitization function akin to the effects of β-blockade in cells. This polymorphism, however, did not alter the risk of HF but facilitated β-blocker response and reduced death [11,12].

We conducted a prospective study in a cohort of Indian HF patients to investigate the association of *GRK5*Gln41>Leu polymorphism in relation to β-blocker therapeutic response. The hypothesis behind this study was that as GRKs impose β-AR blockade by desensitization, the presence of genetic GRK variants might alter the outcome in HF patients. Therefore, the main aim of this study was to identify *GRK5* variants and to study their response to β-blocker treatment which might allow curtailing β-AR blocker usage in these selected patients to avoid potential harmful effects.

2. Materials and Methods

2.1. Study population

The study was conducted in multispecialty, tertiary care hospital. This prospective study recruited HF patients (n=584) with systolic or diastolic dysfunction, dilated cardiomyopathy or biventricular dysfunction (BVD) that attended the in- and outpatient cardiology clinic in our hospital. The study was initiated after obtaining the institutional ethics committee approval and getting informed consent from the patients. The HF patients considered for this study were diagnosed following the Framingham criteria [13]. The Framingham criteria for HF diagnosis should include either two major criteria or one major and two minor criteria. The major criteria included acute pulmonary edema, cardiomegaly, hepatojugular reflex, neck vein distention, paroxysmal nocturnal dyspnea or orthopnea, pulmonary rales, and third heart sound (S3 gallop rhythm). The minor criteria included ankle edema, dyspnea on exertion, hepatomegaly, nocturnal cough, pleural effusion, and tachycardia (heart rate >120 beats/min). Healthy controls (n=60) without any comorbidity were recruited for gene expression studies.

Stage-appropriate medications given to HF patients included diuretics, angiotensin-converting enzyme (ACE) inhibitors or β-blockers or angiotensin receptor blockers (ARBs) alone or in combination. If needed, mineralocorticoid receptor antagonists and hydralazine were also included. β-blockers were determined by the treating physicians (60% carvedilol, 17% metoprolol, 12.5% nebivolol, and 10.5% bisoprolol) and defined as continuous therapy for at least 6 months. β-blocker dosages were monitored during the follow-up period. Initial dosage refers to the dosage administered at the start of the β-blocker therapy after the diagnosis of HF. The final dosage refers to the dosage followed at the last follow-up time. The number of hospitalizations was monitored for each patient and the follow-up data were collected for 3-7 years. The mean follow-up duration was 3.7 years and 3.5 years for the β-blocker group and non-β-blocker group.

2.2. Clinical and echocardiography assessment

A complete resting two-dimensional and M-mode echocardiography color flow and spectral Doppler as well as annular tissue Doppler imaging data were obtained from the subjects using a Philips IE33™ ultrasound system (Philips Medical Systems, Eindhoven, The Netherlands). Standard two-dimensional parasternal short-axis and apical 2- and 4-chamber views were recorded. Left ventricular (LV) ejection fraction (EF) was calculated using the Teichholz formula. Mitral Doppler signals were recorded in apical 4-chamber view and early diastolic mitral inflow peak velocity (E), late diastolic mitral inflow

peak velocity (A), and E/A ratio were calculated. Thus, confirmation of HF in patients was determined on clinical and echocardiography assessment. Echocardiographic parameters were measured according to current recommendations [14].

2.3. Genotyping

Blood samples from the patients were collected by venipuncture in EDTA coated vials and immediately aliquoted and frozen at −80°C. Genomic DNA was isolated using EZ-10 spin column blood genomic DNA purification kit (Bio Basic Inc., Markham, Ontario, Canada). *GRK5* (c.122A>T, p.Q41L) polymorphism was screened and confirmed through in-house developed tetra-primer based allele specific polymerase chain reaction (PCR) and confirmed with restriction fragment length polymorphism (RFLP) method and Sanger sequencing. PCR reaction mixture containing 100 ng of DNA, Taq polymerase mix (Ampliqon, Odense, Denmark), primers for tetra primer PCR (35nM GRK5F primer: 5'- GAAGGCTGTGGTCTAGTCTAGGGGAACAG - 3'and GRK5R primer: 5'- TTGATTAGCAAAAAGGTCAGCCTGGAGC - 3', 45nM SNPTF primer: 5' - TGGCTAATGTGAGGGAAC - 3'and SNPTR primer: 5' -TGTGTGAAGACCTCCGA - 3') or primers for RFLP method (50 nM BSRF primer: 5'- CTACAGCCCGTCCCTCTGT - 3'and BSRR primer: 5' - GCAAAAAGGTCAGCCTGGAGC - 3') were subjected to thermal cycling (Eppendorf, Hamburg, Germany). For RFLP, PCR product was digested using 1.5 units of *Bsr*I (New England Biolabs® Inc., Ipswich, Massachusetts, USA) as per manufacture instructions. The genotype was identified for tetra-primer PCR (AA: 580 bp and 225 bp, AT:580 bp, 380 bp and 225 bp, and TT:580 bp and 380 bp) and RFLP method (AA:202 bp and 179 bp, AT:381 bp, 202 bp and 179 bp, and undigested TT:381 bp) with these banding patterns after resolving on the gel.

2.4. Quantitative PCR (qPCR)

RNA was isolated from the HF patients and unaffected controls using the Aurum™ total RNA mini kit (Bio-Rad, Hercules, California, USA). The RNA was qualitatively verified on denaturing formaldehyde 1.2% agarose gel electrophoresis. Using 1 μg of RNA, respective cDNAs was synthesized using iScript™first strand cDNA synthesis kit (Bio-Rad, Hercules, California, USA). qPCR was carried out to compare *GRK5* gene expression in HF cases and healthy controls using relative quantification with β-actin as reference gene. PCR mixture of 20μL contained 2X SYBR green (Sso Advanced universal SYBR® Green supermix, Bio-Rad, Hercules, California, USA), 50 nM of forward and the reverse primer of the respective gene, cDNA template corresponding to 1 μg RNA and nuclease free water. The primers used were GRK5 FP (5' - ACCTGAGGGGAGAACCATTC - 3'), GRK5 RP (5' -TGGACTCCCCTTTCCTCTTT - 3'), ACTIN FP (5' - TCCCTGGAGAAGAGCTACG - 3'), and ACTIN RP (5' - GTAGTTTCGTGGATGCCACA - 3'). Reaction included an initial denaturation of 95°C for 3 min followed by 45 cycles of 95°C for 30 s, 60°C for 30 s, 72°C for 45 s, and a melt curve analysis (65 – 95°C) was performed at the end of 45 cycles. Normalized fold expression was calculated using $2^{-\Delta\Delta Ct}$ method.

2.5. Variables

In this study, the independent variables were age, sex, and socio-demographic data. Covariates were (EF%), comorbidities, use of β-blockers, and use of other medications. The covariates adjusted for hospital-free survival analysis were age, sex, EF%, and comorbidities.

2.6. Statistical analysis

Student *t*-tests (paired and unpaired) and Chi-square tests were used to assess significant differences in variables between the groups, drug dosages, genotype classes, gene expression, and EF%. Continuous variables are expressed as mean ± standard deviation (SD). Fischer's exact test was carried out to compare cardiac output between groups. Hardy-Weinburg equilibrium was assessed to compare predictions with that of the obtained results. Kaplan–Meier curves were also constructed to plot the percentage of survival of patients. Comparisons of overall survival were performed using a log-rank (Mantel-Cox) test. All the statistical analyses were carried out using GraphPad Prism software version 5.0 Windows (GraphPad Software, San Diego, California, USA).

3. Results

3.1. Clinical and demographic characteristics of the HF patient cohort

The HF patient cohort (n=584) was considered for the study after clinical and echocardiographic assessment. Table 1 shows the clinical and demographic characteristics of the HF patient cohort. The HF patients were categorized into β-blocker group and non-β-blocker group. There was no statistically significant difference in variables such as age, sex, body mass index, and hemodynamics between the two groups. BVD (24%; p=0.002) and LV diastolic dysfunction (32.8%; p=0.002) were observed as statistically significant HF characteristics in the β-blocker group. Dilated cardiomyopathy (54%; p=0.0002) was observed as statistically significant HF etiology in the β-blocker group versus the non-β-blocker group whereas rheumatic heart disease (8%; p=0.0001) and coronary artery disease (44%; p=0.0001) were significantly higher in the non-β-blocker group. Type II diabetes mellitus (60%; p=0.0001) and its associated disorders were significantly frequent in the non-β-blocker group whereas systemic hypertension (42%; p=0.002) and dyslipidemia (25%; p=0.002) were higher in the β-blocker group. Approximately 52% of the patients were on β-blocker therapy. Among the medications administered, 38% of the HF patients received ACE inhibitors, 20% ARBs, 70% diuretics, 35% digitalis glycosides, 22% statins, and 19% anticoagulants.

Table 1

Clinical and demographic characteristics of the HF patient cohort

Variables	HF patient cohort (*n*=584)	
	β-blocker group (*n*=304)	Non-β-blocker group (*n*=280)
Mean Age±SD (years) (range)	60±10 (24 – 89)	59±11 (25 – 90)
Males (%)	73	73
Mean body mass index (kg/m^2) (range)	22 (19.5 – 24.5)	23.5 (21.1 – 26.5)
Mean follow up time (years) (range)	3.7 (3 – 7)	3.5 (3 – 7)

3.2. GRK5 Gln41>Leu polymorphism in HF patient cohort

GRK5 Gln41>Leu polymorphism was screened by in-house developed tetra-primer based allele specific PCR and reconfirmed with RFLP and the Sanger sequencing method (Figure 1). Genotype distribution was in agreement with the Hardy-Weinberg equilibrium (p=0.595). The genotype (84% for AA, 15% for AT, and 1% for TT) and allele frequencies (0.916 for A allele and 0.084 for T allele) of *GRK5* Gln41>Leu polymorphism in the HF patient cohort is presented in Table 2. On comparing the genotype frequencies, AT genotype was more prevalent in the β-blocker group (19%) compared to the non-β-blocker group (10%) (p=0.011). The unaffected healthy controls were also screened for this polymorphism. The genotype and the allele frequencies of the healthy controls (Supplementary Table 1) did not differ significantly from the HF cases (p=0.94 for genotype frequency, p=0.82 for allele frequency) ensuring a lack of association of this polymorphism with development of HF.

Figure 1

Genotyping of GRK5 Gln41>Leu polymorphism. Tetra-primer based allele specific polymerase chain reaction (A) results on showing banding pattern for Gln/Leu heterozygous AT genotype (lane 2: 580 bp, 380 bp and 225 bp), Leu/Leu homozygous TT genotype (lane 3: 580 bp and 380 bp), Gln/Gln homozygous AA genotype (lanes 4, 5: 580 bp and 225 bp). RFLP (B) results showing banding pattern for Gln/Leu heterozygous AT genotype (lanes 2, 3: 381 bp, 202 bp and 179 bp), Leu/Leu homozygous TT genotype (lane 4: 381 bp) and Gln/Gln homozygous AA genotype (lanes 5, 6, 7: 202 bp and 179 bp). Lanes 1a, 1 b: 100 bp DNA ladder (Biobasic, Canada). Sanger sequencing results of Gln/Gln homozygous AA genotype C), Gln/Leu heterozygous AT genotype (D) and Leu/Leu homozygous TT genotype (E).

Table 2

GRK5 genotype and allele frequencies in the HF patient cohort

Genotype	HF patients (n=584), n (%)	HF patients (β-blockers) (n=304), n (%)	HF patients (non-β-blockers) (n=280), n (%)	p-value
AA	493 (84)	244(80)	249(89)	0.011
AT	85 (15)	57 (19)	28 (10)	
TT	6 (1)	3 (1)	3 (1)	
Allele				0.07
A	535 (91.6)	273 (90)	263 (94)	
T	49 (8.4)	31 (10)	17 (6)	

Results were expressed as n (%) for genotype and allele distribution. $\chi 2$ test was significant for genotype frequency and not significant for allele frequency between β-blocker group and the non-β-blocker group.

As the frequency of homozygous TT genotype was low, we intended to divide the HF patients into two group, those having AA genotype alone (AA genotype group) and those with AT and TT genotype (AT/TT genotype group), to study the influence of *GRK5* Gln41Leu (rs17098707) polymorphism on response to β-blocker therapy in the HF patients.

3.3. Downregulated GRK5 expression among the GRK5 Leu41 variants (AT/TT genotype)

The *GRK5* gene expression was evaluated among different groups of HF patients. The gene expression among The AT/TT genotype carriers showed a downregulated *GRK5* expression than AA genotype carriers among β-blockers and non-β-blockers. For gene expression analysis (Figure 2), healthy controls (n=60) were included for comparison. The β-blocker AT/TT group (n=60) showed a 0.5135±0.1593-fold decrease in gene expression and the β-blocker AA group (n=60) showed a slightly but significant upregulated pattern of 1.752±0.0.2775 gene expression (p<0.0001). On comparing the non-β-blockers, there was a significant difference in the gene expression (p<0.0001) between the AT/TT group (n=31, 0.5507±0.1322) and the AA group (n=60, 1.681±0.2688).

Figure 2

GRK5 expression among different groups of HF patients. β-blocker AT/TT group versus β-blocker AA group (p<0.0001), non-β-blocker AT/TT group versus non-β-blocker AA group (p<0.0001) along with healthy controls (HC) were analyzed for _GRK5_ normalized gene expression. Student's _t_-test was used to compare the groups.

3.4. Improvement in the EF of the GRK5 Leu41 variants (AT/TT genotype)

The EF% is the measure of LV systolic function and cardiac output. Among the β-blocker group (29±4.8%) and non-β-blocker group (41.5±2.3%), the mean EF% remained significantly varied (p=0.0286). The EF% of the patients before and after pharmacological treatment was recorded and improvement in their cardiac output was compared among the groups (Figure 3). The increment in the EF% after treatment was considered as an improvement in cardiac output. About 56% of HF patients on β-blockers and 41% on non-β-blockers showed improvement in their EF% (p=0.0004; Figure 3A). As expected, 71% of the *GRK5* Leu41 variants (AT/TT genotype) showed remarkably higher cardiac output (p=0.0001; Figure 3A) versus those with *GRK5*Gln41 (AA genotype, 45%). Since the non-β-blockers had HF preserved EF, only the β-blocker group having HF reduced EF was considered for further analysis. When the HF patients with different genotypes in the β-blocker group were compared it was evident that those with the AT/TT genotype (83%) improved significantly (p=0.0001; Figure 3B) compared to those with the AA genotype (49%).

Figure 3

Percentage improvement in cardiac output among the cohort of HF patients. The percentage of HF patients improved among β-blocker and non-β-blocker groups (p=0.0004) and different genotype groups of *GRK5* (p=0.0001) (A). The percentage of HF patients improved among β-blocker group with different genotypes (p=0.0001) (B). Fischer's exact test was carried out for analysis.

The improvement in cardiac output was compared among the HF patients in β-blocker group with different genotypes (Figure 4). EF% has improved from 25.2±1.041% to 28.2±0.7638% among the AA group (p=0.0091) and 27.4±1.021% to 36±1% in the AT/TT group (p=0.0007).

Figure 4

Improvement in ejection fraction in HF patient cohort. The improvement in EF% in HF patients with different genotypes of β-blocker group was measured. AT/TT group (p=0.0091) improved significantly in comparison with the AA group (p=0.0091). Paired t-test was carried out for computing p-values.

3.5. GRK5 Leu41 variants (AT/TT genotype) show decrement in β-blocker drug dosage

Among the β-blocker group (n=304), 60% of the HF patients were treated with carvedilol, 17% with metoprolol, 12.5% and 10% with nebivolol and Bisoprolol, respectively. The initial and the final drug dosages over the follow-up period were noted and analyzed. Initial dosages administered at the start of the β-blocker therapy and final dosages followed at the last follow-up were noted. There was a statistically significant reduction in carvedilol drug dosage in the overall β-blocker group when the initial (11.2±7.7 mg) and final drug dosages (10.2±7.1 mg) were compared (p=0.0114; Figure 5A). Furthermore, the drug dosages remained unchanged in the AA genotype group (p=0.8211; Figure 5B) when the initial (11.06±7.3 mg) and final (11.1±7.4 mg) drug dosages were compared. Interestingly, there was a statistically significant reduction in the drug dosage in the AT/TT genotype group (p=0.0001; Figure 5B) when the initial (11.6±9.2 mg) and the final (6.4±4 mg) drug doses were compared. Thus, the *GRK5* Leu41 variants in the homozygous and heterozygous forms were associated with a lower dose of β-blockers.

Figure 5

GRK5 Gln41>Leu polymorphism influences β-blocker (carvedilol) drug dosage. Carvedilol drug doses were reduced in the overall β-blocker group (p=0.0114) (A). The drug doses remained unchanged in the AA genotype group (p=0.8211), whereas in the AT/TT genotype group there was a significant reduction in the drug dosage (p=0.0001) (B). Paired t-test was used to compare the drug doses between groups.

3.5. Reduced event of hospitalization among the GRK5 Leu41 variants (AT/TT genotype)

The HF patients were followed-up for ~3 years (40 months) after the initiation of pharmacological treatment. The influence of β-blocker therapy and *GRK5* genotype on hospitalization-free survival of HF patients was studied through Kaplan–Meier survival curves (time-to-event analysis). When the overall HF patients administered with β-blockers and non-β-blockers were compared for hospital-free survival, the patients on β-blockers showed higher survival than the non-β-blockers (hazard ratio [HR]: 1.167, 95% confidence interval [CI]: 0.325 – 2.008, log-rank $p<0.0001$; Figure 6A). The same was found when the overall HF patients with AA and AT/TT genotypes were compared; the presence of AT/TT genotype reduced the risk for hospitalization (HR: 0.8387, 95% CI: 0.07042 – 1.607, log-rank $p<0.0001$; Figure 6B). On further analysis of the HF subgroups, β-blocker AT/TT group versus β-blocker AA group, it was found that the presence of AA genotype increased the risk for hospitalization (HR: 1.143, 95% CI: 0.4337 – 1.852, log-rank $p<0.0001$; Figure 6C) even under the influence of β-blocker therapy. When non-β-blocker AT/TT group versus non-β-blocker AA group was analyzed, AA genotype increased the risk for hospitalization (HR: 1.364, 95% CI: 0.7020 – 2.025, log-rank $p=0.0003$; Figure 6C). In the β-blocker AT/TT group versus non-β-blocker AT/TT group analysis, the use of non-β-blockers increased the risk for hospitalization (HR: 1.067, 95% CI: 0.463 – 1.670, log-rank $p=0.0231$; Figure 6C). As expected, when β-blocker AA group versus non-β-blocker AA group was analyzed, the presence of AA genotype and use of non-β-blocker therapy increased the risk of hospitalization (HR: 1.273, 95% CI: 0.441 – 2.104, log-rank $p<0.0001$; Figure 6C).

Figure 6

Influence of β-blocker therapy and *GRK5* genotype on hospital-free survival of HF patients. HF patients were stratified by β-blockers usage (β-blockers ($n=304$); non-β-blockers ($n=280$); $p<0.0001$) (A). HF patients were stratified by *GRK5* Leu41 carrier status (AT/TT genotype) (GRK5 AA group ($n=493$); *GRK5* AT/TT genotype ($n=91$); $p<0.0001$) (B). β-blocker treated subjects and non-β-blocker subjects stratified by *GRK5* Leu41 carrier status (AT/TT genotype) (β-blocker AA group ($n=244$); β-blocker AT/TT group($n=60$); non-β-blocker AA group($n=249$); non-β-blocker AT/TT group ($n=31$) (C). Log-rank test (Mantel-Cox) test was utilized for comparisons of survival curves.

The overall HF patients were subdivided based on HF characteristics such as systolic dysfunction ($n=218$), diastolic dysfunction ($n=150$), BVD ($n=114$), and pulmonary artery hypertension (PAH) ($n=102$). The groups were compared for hospitalization-free survival. The patients with PAH showed higher survival and patients with systolic dysfunction showed the lower survival than the other groups (log-rank $p=0.02$; Figure 7A). When the subgroups with systolic dysfunction and diastolic dysfunction were compared with *GRK5* polymorphism genotypes (AA and AT/TT), it was evident that the HF patients with AA genotype under both the subgroups indicated the lower hospitalization-free survival than the HF patients with AT/TT genotype under both subgroups (log-rank $p=0.0002$; Figure 7B). When the subgroups with BVD and PAH were compared with *GRK5* polymorphism genotypes (AA and AT/TT), it was evident that the HF patients with AA genotype under both the subgroups indicated lower hospitalization-free survival than those with the AT/TT genotype under both subgroups (log-rank $p=0.0051$; Figure 7C).

Figure 7

Influence of *GRK5* genotype on hospital-free survival of HF patient subgroups. HF patients were stratified by HF characteristics systolic dysfunction (*n*=218); diastolic dysfunction (*n*=150); BVD (*n*=114); PAH (*n*=102); *p*=0.02) (A). HF patients with systolic and diastolic dysfunction were stratified by *GRK5* Leu41 carrier status (AT/TT genotype) (systolic dysfunction AA group (*n*=193); diastolic dysfunction AA group (*n*=128); systolic dysfunction AT/TT group (*n*=25); diastolic dysfunction AT/TT group (*n*=22); *p*=0.0002) (B). HF patients with BVD and PAH were stratified by *GRK5* Leu41 carrier status (AT/TT genotype) (BVD AA group (*n*=90); PAH AA group (*n*=82); BVD AT/TT group (*n*=24); PAH AT/TT group (*n*=20); *p*=0.0051) (C). Log-rank test (Mantel-Cox) test was utilized for comparisons of survival curves.

To compare the frequency of hospital admissions between the genotype groups within a month, the rate of hospital admission/month was compared (Figure 8). From the results, it was evident that the HF patients in the AA group (0.0769±0.003; *n*=493) were significantly more frequently ($p<0.0001$) admitted in hospital than the AT/TT group (0.0409±0.004; *n*=91; Figure 8A). Among the β-blocker group, HF patients with the AA genotype (0.0790±0.005; *n*=244) were significantly more frequently admitted in the hospital than the AT/TT variants (0.0374±0.005; *n*=60; *p*=0.0002). Among the non-β-blocker group, HF patients with the AA genotype (0.0749±0.005; *n*=249) had more hospital admissions compared to the AT/TT variants (0.0477±0.008; *n*=31) although not statistically significant (*p*=0.0674; Figure 8B).

Figure 8

Comparison of frequency of hospital admission between the genotype groups. The AA group of HF patients (*n*=493) had more hospital admissions than the AT/TT HF group (*n*=91; $p<0.0001$) (A). Among the β-locker group, HF patients with the AA genotype had more frequent hospital admission than the AT/TT variants (*p*=0.0002) (B). A similar trend was observed among the non-β-blocker group but the results were no statistically insignificant (ns). β-blocker AA group (*n*=244); β-blocker AT/TT group (*n*=60); non-β-blocker AA group(*n*=249); and non-β-blocker AT/TT group (*n*=31). Student's *t*-test was used to compare the gr.

4. Discussion

Genetic polymorphisms impact HF outcomes. One such polymorphism is *GRK5*Gln41>Leu (A>T), which was proven to have a role in promoting β-AR desensitization [11]. Our results show that HF patients with *GRK5* Leu41 variant in its homozygous and heterozygous forms show decreased events in hospitalization and specifically respond to β-blockers and require reduced β-blocker drug dosage in comparison to *GRK5* Gln41 carriers. Moreover, *GRK5* Leu41 variants in combination with β-blocker therapy showed improved cardiac output.

The *GRK5* genotype frequencies in this study (AT/TT15% and TT1%) were comparatively lower than that reported in African Americans (AT/TT39% and TT6%) [15]. The T allele frequency in our study (0.084) was lower than African Americans (0.23) [15] but, higher than that found in the Chinese population (0.009) [16] and Caucasians (0.017) [17]. As GRK5 is highly expressed in myocardium [18], and given its established role in cardiac failure pathology [10], this prompted our group to examine and evaluate *GRK5* expression in a cohort of Indian HF patients. GRK5 is reportedly overexpressed in HF conditions and could attenuate cardiac burden in response to adrenergic surge [19,20]. In view of this, a slight upregulation observed in *GRK5* expression in a subpopulation of HF patients could be expected. However, gene expression was downregulated in the AT/TT subset of HF patients in our study. A possible reason could be that the role of overexpressed GRK5 in β-AR desensitization is compensated by the allelic variation, bringing about an augmented desensitization, thus attempting to regulate *GRK5* expression for better cardiac performance. Interestingly though inhibiting GRK5 expression restores the cardiac muscle damage incurred during HF [21]. These observations support the fact that *GRK5* Leu41 variant confers protection from congestive HF [22].

Human and rodent data have proven that *GRK5*Leu41 protected against death or cardiac transplantation [11]. Coinciding with these data, our study reaffirms that the *GRK5*Leu41 allele improved quality of life, promoted hospitalization-free survival of South Indian HF patients. Independently, both the administration of β-blocker therapy and the presence of Leu41 allele yielded a positive outcome on hospitalization-free survival. The Leu41 allele carriers among the different HF subgroups showed increased hospitalization-free survival in comparison to Gln41 carriers. The previous reports support the fact that Indians are highly sensitive to β-blockers [23] and also speculated that polymorphic variations in β-AR gene in Indians [24] might be the reason for higher sensitivity [25]. Our data indicate that the prevalence of *GRK5* gene polymorphisms in Indian HF patients and its role in cardiac failure might be the reason for responders to β-blocker treatment. In response to β-blocker treatment, *GRK5*Leu41 allele carriers (AT/TT genotype) showed better hospital-free survival than *GRK5* Gln41 allele carriers (AA genotype) and β-blocker naïve *GRK5*Leu41 and Gln41 allele carriers. This observation was also reported in a study where HF patients with the Gln41Leu genotype had reduced hospitalization rates (18.6%) [26]. These results also justify the continued use of β-blockers as standard therapy for cardiac failure and their benefits over other pharmacological interventions [27-29]. Interestingly, it was found that although Leu41 carriers among African Americans survived better than Gln41 carriers, they exhibited a reduced response to β-blockers [11,17] such as atenolol [30]. Another study among African race demonstrated that Leu41 impacted negatively on survival of HF patients, but the effect seemed to be stabilized upon β-blocker usage. In other words, Gln41 carriers survived better in the presence and absence of β-blockers [15].

The Leu41 allele seemed to act as a genetic β-blockade [11], promoting reduced dependency on β-blockers for improvement in HF patients. Although β-blocker has been validated as a lifesaving drug in HF, in view of its adverse effects such as HF deterioration, hypotension, and impaired left atrial function [31,32], minimizing its usage is recommended. In our study, the presence of Leu41 allele has helped in curtailing the dosage of carvedilol during the course of treatment and reduced the frequency of hospital admission compared to the Gln41 allele. Carvedilol, a nonselective β-blocker with better efficacy than other β-blockers [10,33] was used in 60% of the HF patients in this study. The usage of β-blockers has substantially improved the LV systolic function by increasing the EF in 56% of HF patients in this study. Literature also supports the usage of β-blockers in recovering from LV systolic dysfunction [34]. The improvement in EF was pronounced in *GRK5* Leu41 variants compared to Gln41 carriers and this observation coincided with another study reporting *GRK5* polymorphism having a

positive effect on systolic HF after β-blocker therapy [16]. Taken together, these data present convincing evidence that the Leu41 allele and β-blocker therapy synergistically work to stabilize cardiac function in Indian HF subjects.

Ethical Approval

Human samples to carry out the study were obtained following informed consent of patients according to the Declaration of Helsinki and its later amendments or comparable ethical standards. Research involving humans was authorized by the Institutional Ethics committee from PSG Institute of Medical Sciences and Research, Coimbatore, Tamil Nadu, India.

Acknowledgments

The authors gratefully acknowledge Dr. Thiagarajan Sairam, Seetha Arunachalam, Ranjani S, Brindha A and Madhu Elango for their technical contribution towards this study.

Appendix

Supplementary Table 1

***GRK5* genotype and allele frequencies in the HF patients and healthy controls**

Genotype	HF patients (*n*=584), *n* (%)	Healthy controls (*n*=400), *n* (%)	*p* value
AA	492 (84)	340 (85)	0.94
AT	86 (15)	56 (14)	
TT	6 (1)	4 (1)	
Allele			
A	535 (91.6)	368 (92)	0.82
T	49 (8.4)	32 (8)	

Results were expressed as *n* (%) for genotype and allele distribution. χ^2 test was non significant for genotype and allele frequencies between HF patient cohort and healthy controls group.

Conflict of Interest

The authors declare no conflict of interest.

[2]Professor of Biostatistics, PSG Institute of Medical Sciences and Research, Coimbatore, India

Abstract

Purpose: The study aims to assess the emergence of deafness, blindness, cerebral palsy, and mental retardation among very low birth weight (VLBW) infants, aged 21-24 months.

Methods: A study was conducted with a total of 123 premature Saudi infants, who were recruited from King Khalid University Hospital. The association among demographic factors and neurodevelopmental morbidities were identified with the help of regression analysis.

Results: A significant relationship between deafness and cerebral palsy was found. However, there was no significant relationship between retinopathy of prematurity and intraventricular hemorrhage. Furthermore, maternal education plays a positive role in the neurodevelopment of preterm newborns.

Conclusion: This study has concluded that there has been significant relationship between cerebral palsy and deafness in preterm infants with very low birth weight. On the contrary, there was no significant relationship found between intraventricular hemorrhage and retinopathy of prematurity.

Keywords: Blindness, Cerebral Palsy, Deafness, Neonatal Care, Neonatal Morbidity

Introduction

The primary cause of neonatal morbidity and mortality is the preterm birth of an infant [1]. Developments in perinatal care have enhanced the chances of survival of preterm low birth weight infants of gestational age of less than 25 weeks. Although, the survival rate has increased, the chances of neonatal morbidity and neurodevelopment impairment have also augmented and increased. On the other hand, the lower the gestational age and the birth weight of the preterm infant; the higher the infants' likelihood of suffering from major neonatal morbidity [2].

The disabilities occur due to the improper development of the infant or poor functioning of nervous system. The limitations that are manifested during infancy or early stage of childhood include cognition, vision, behavior, and hearing. There are the modalities that these disabilities are traced in the early stage of neurodevelopment. However, the cognitive disabilities among infants and children includes mental retardation as well as it further leads to the learning disabilities. Moreover, distress and chronic stress usually leads to psychological changes, which further result in causing physical distress, psychiatric disorder, and psychological distress [3].

Early years of childhood are important for language development and communication because during this time the brain is at its highest capacity to go about structural changes in regard to external stimulation and is termed as neural plasticity [4]. According to American Academy of Pediatricians (AAP), there are 2% to 3% of infants with developmental disabilities. In most of the cases, no definite cause is ever found. Intellectual disabilities can be further classified as mild, moderate, severe, and profound; and this is done on the basis of various intellectual disabilities. Mental disability is usually result of genetic disorders; for instance, Down syndrome. In case of infants, the genetic disorders are usually detected at an

early stage. It is due to certain physical or facial characteristics that alert the parents or the clinician.

Experts, who are always associated with disabled children, believed that in such cases early intervention pays off immensely [5]. Not much work has been done in order to investigate the outcome of early intervention for children, who are deaf and blind. However, various studies illustrated that, the early identification and intervention for hearing loss, proved out to be beneficial for infants as it enhances their language skills [6]. Continued ill-health of the mother can lead to further morbidities or disabilities and can negatively impact baby's health. Whereas, these complications and consequences are not much focused upon in various countries in low-income countries. Families situated in Middle Eastern regions complaint about isolation and lack of community resources to help them in improving their child's abilities. One of the main reasons behind the lack of awareness or medical care is that there are no health professionals or researchers available in such regions. In most cases, these disabilities also come forward due to the mother's depressive state [7].The aim of the present study is to assess the relationship between Retinopathy of Prematurity and Intraventricular hemorrhage as well as the relationship between deafness and cerebral palsy.

Methods

A total of 123 premature Saudi infants, with birth weight less than or equal to 1500 grams & gestation less than equal to 32 weeks were recruited. These infants that were chosen for the study were from the King Khalid University Hospital in which these premature infants were delivered. The study was approved from the ethics committee. The analysis was done on the basis of neurological and developmental assessment, along with medical and social history. It was done in order to determine functional and neurodevelopmental outcomes among infants. The neurologic examinations were performed by certified physicians, who had been well trained in this department. The neurological assessment included the evaluation of strength reflex, angles as well as posture. The demographics include age, gender, and gestation age and body weight. The factors examined included were maternal education, birth weight, early-onset sepsis, late-onset sepsis, grades 3 to 4 IVH/PVL, Bronchopulmonary Dysplasia (BPD), Retinopathy of Prematurity (ROP), Hypoxic Ischemic Encephalopathy (HIE), Persistent pulmonary hypertension (PPHN), Patent ductus arteriosus (PDA).

During the first four weeks of life, Intraventricular hemorrhage (IVH) is usually detected by head ultrasound during first four weeks of life. Moreover, it is graded in accordance with Papile's classification. Periventricular echogenicity, which is noticed on the head ultrasound and is performed at any time during the NICU stay, is known as Preventricular Leucomalacia (PVL). Retinopathy of Prematurity (ROP) is detected during routine retinal examination. Furthermore, Patent Ductus Arteriosus (PDA) is established through an echocardiography with signs of left-to-right shunting. Bronchopulmonary Dysplasia (BPD) refers to the requirement of oxygen at 36 weeks, corrected age.

Table 1: Gestational Age of the study participants

Gestational age	Number	Percent
26	3	2.4
27	6	4.9
28	25	20.3
29	23	18.7
30	36	29.3
31	14	11.4
32	11	8.9
34	3	2.4
35	1	0.8
38	1	0.8
Total	123	100

The data were analyzed to evaluate the impact of morbidities on various neurodevelopmental disabilities like blindness, deafness, cerebral palsy (CP) and mental retardation (MR). Severe mental retardation syndrome includes optic atrophy, microcephaly, that further results in impaired vision, defect in hearing, seizures, restricted movements of large joints and spasticity. The study examined the influence of maternal education and early intervention on BINS at 21 to 24 months infants. Maternal education is considered as one of the strongest determinants that ensures infant survival in developing countries. The statistical analysis was done to assess maternal education and its association with disabilities. BINS was classified into two different groups. First group was low and the other group was taken as moderate (Mod) and high. However, 'Low' illustrated that no further follow-up is required; whereas, 'high' suggested that further developmental testing is necessary. Descriptive statistics were calculated using mean and standard deviation. Spearman rank correlation analysis was done to find the correlation between Retinopathy of Prematurity and Intraventricular hemorrhage. Chi square test was done to find the association deafness and cerebral palsy. $P<0.05$ was considered as statistically significant (Table 2).

Table 2: Association between Deafness and CP

	CP (No)	CP(Yes)	Total
Deafness (No)	120(98.4%)	2(1.6%)	122
Deafness(Yes)	0 (0.0%)	1 (100%)	1
Total	120	3	123

Results

The total number of neonates who were examined in the study were 123. Out of the total, newborn females totaled 53 (43.1%). The mean (SD) of the gestation age in weeks was 29.65 (1.82). Amongst the total number of neonates, the lowest gestational age of preterm infants was 26 weeks and the highest gestational age was 38 weeks. Apart from this, the premature neonates that had a gestational age of 28 weeks were 25 (20.3%) infants. Similarly, the preterm neonates that had a gestational age of 30 weeks were 36 (20.3%) infants and were the highest number of infants in that particular classification group (Table 1). Among the 123 mothers, 85 (69.1%) were educated. The

correlation between ROP and IVH was examined and found that spearman, s rho r=0.145 p=0.109 which is not statistically significant.). The association between Deafness and Cerebral Palsy was found to be statistically significant

(Chi-square=40.38, P<0.001)

Discussion

The results revealed that there is significant relationship between Deafness and Cerebral Palsy. However, there was no significant relationship between Retinopathy of Prematurity (ROP) and Intraventricular hemorrhage (IVH). The results are consistent with the study conducted by Neubauer et al. (2008), in which it was discovered that the proportion of disabilities has increased with decreasing gestational age of the newborn. Infants having high grade intraventricular hemorrhage, neonatal seizures, necrotizing enterocolitis and bowel perforation were at a significant risk for developing and enduring major impairment [8].

In a study conducted by Wilson-Costello et al. (2007), modern therapies that were incorporated with regard to low birth weight infants were compared to traditional therapies that were provided to low birth weight infants in the previous two decades. The comparison features were the rate of survival and death with and without impairment and the therapies that were provided. The population comprised of 496 low birth weight infants born (2000-2002), 1749 neonates that were born (1982-1989) and 233 newborns born (1990-1999). The findings revealed that between 1990 and 1999, survival rate has increased from 49% to 68%, but so did neonatal morbidity. Therefore, it leads to survival without impairment as well as survival with impairment [9].

The therapy modification between 2000-2002 included a reduction of postnatal steroid use. Apart from this, antenatal steroid use was increased. It was observed that there were no changes in the rate of lung disease. In addition, there was found to be a decrease in morbidities; such as, severe intraventricular hemorrhage (IVH) and early-onset sepsis (EOS) and late-onset sepsis (LOS). With therapeutic care, the rate of neurodevelopmental impairment has reduced from 35% to 23%. More specifically, the rate of cerebral palsy reduced from 13% to 5%. It was concluded that there was significant reduction in the neurodevelopment impairment in neonates with very low birth weight between 2000-2002 as compared to a decade early. The improved outcomes and the increase in the survival rate of newborns with low birth weight were due to modern therapies that were being provided. These included both perinatal and neonatal factors. However, despite the use of postnatal steroids, the lung condition of the infants showed no improvement [10]. Many studies revealed that maternal education has a positive impact on neurodevelopmental outcome among very low birth infants. The results conducted by Voss et al. (2012) revealed that the maternal educational background was directly associated with the intellectual growth of pre-term infants. Low maternal educational background was connected to reduced composite intelligent quotient of pre-term kids, who were between the ages of 10-13 years old during the study [11-14].

Conclusion

The preterm birth of an infant can be the cause of neonatal morbidity and mortality. Preterm neonates with a very low birth weight have an increased risk of suffering from neurological, sensory, development, and functional morbidity. The neurodevelopment of all very low birth weight newborns must be monitored and the relevant therapies must be incorporated to ensure and optimize their survival. Some morbidities are directly associated with long-term outcomes of the development of preterm infants. This study has concluded that there is a significant relationship between Deafness and Cerebral Palsy in infants. On the contrary, there was no significant relationship found between Intraventricular hemorrhage (IVH) and Retinopathy of Prematurity (ROP). Additionally, maternal education played a significant role in the development of preterm newborns. However, more studies must be conducted in relation to preterm babies and neonatal morbidity and mortality to get further insights into the causes of morbidities, suffered by preterm babies with very low birth weight.

Physical properties of menstrual hygiene waste as feedstock for onsite disposal technologies

Sarani Sasidaran, Prateek Kachoria, Antony Raj, Sudha Ramalingam, Brian R. Stoner, Katelyn L. Sellgren and Sonia Grego

ABSTRACT

Onsite incinerators offer a promising solution to the challenges of menstrual waste disposal, particularly in institutional settings. However, thermochemical processes are well known to depend on the nature of the feedstocks and their moisture content (MC). An analysis is presented of the physical properties of menstrual waste as potential feedstock for onsite incinerators. Waste was generated in three institutional settings – from women of wide age range and from people with different socioeconomic backgrounds such as workers and students. Over 10 separate collections, 613 discarded menstrual pads were obtained with over 93% of the waste representing commercially disposable pads and less than 7% of the waste appearing to be homemade cloth pads. A surprising finding of this study was that a significant fraction of the commercially disposed pads (23–37%) had a large wet weight (over 20 g) which was associated with MC exceeding 50 wt%. This high MC was attributed to the practice of washing the pads prior to disposal, and it was much higher than what is standard for thermal processing. These data suggest that testing protocols for menstrual waste incinerator technology performance should include an evaluation of the effects of higher MC, unfolded pads, and occasional cloth pads.

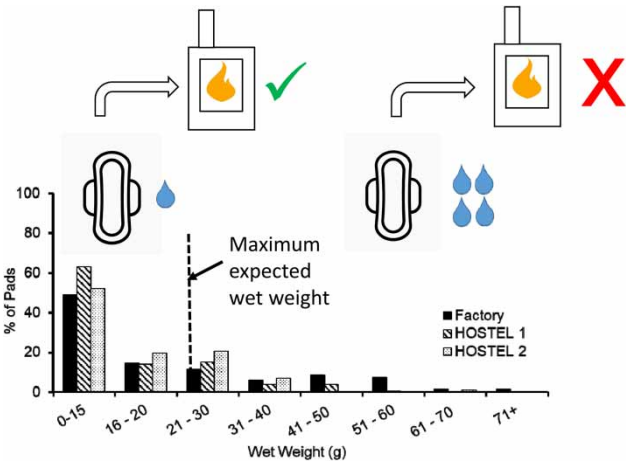
HIGHLIGHTS



- Menstrual waste consists mainly of commercially disposable pads (93% or more) and of homemade cloth pads (6–7%).
- This study found that nearly a third of commercial pad waste had a wet weight of over 20 g, which was associated with moisture content (MC) exceeding 50 wt%.
- High MC waste is attributed to the practice of washing pads prior to disposal.
- Moist waste may result in pollutant emission and incomplete processing by onsite incinerators.

GRAPHICAL ABSTRACT

INTRODUCTION

Menstrual hygiene is an essential aspect of sanitation for women and girls, which is often neglected in sanitation program implementation in low- and middle-income countries, yet is critical for women's health and dignity as well as environmental safety (Sommer *et al.* 2013; Tilley *et al.* 2013).

A body of research has shown that the lack of access to proper menstrual hygiene management has a negative impact on women's health (Balamurugan & Bendigeri 2012; Das *et al.* 2015) and women's participation in education and the workforce (Bodat *et al.* 2013; Sommer *et al.* 2016).

Challenges related to menstrual health and hygiene (MHH) in low- and middle-income countries are related to both access to safe sanitary products and safe disposal options at the household and community levels (Elledge *et al.* 2018).

The most used menstrual products are absorbents such as sanitary pads, tissue paper (disposable, one-time use) and cloth, typically homemade (Elledge *et al.* 2018). Cloth pads are the traditional and cheaper option, while disposable sanitary pads are increasingly available, especially in urban environments, and considered as aspirational products (van Eijk *et al.* 2016). Statistical associations have been reported between the use of disposable sanitary pads and younger age, higher social class, and urban residence (Elledge *et al.* 2018); however, affordability represents a major constraint (Crofts & Fisher 2012).

Disposal of used sanitary pads is a critical element of the MHH value chain. Cloth pads are cheaper and environmentally less polluting, but cleaning is challenging since it requires access to water, privacy and drying in the sun for its disinfecting effect, as opposed to a hidden drying area utilized for a sense of shame (van Eijk *et al.* 2016). Disposable pads offer convenience of use and are considered as aspirational products for women and girls; however, they present a solid waste challenge. A woman will have an average of 459 periods over her lifetime and dispose of 125–150 kg of sanitary waste (Bharadwaj & Patkar 2004).

The lack of disposal solutions leads to negative health outcomes, e.g. infrequent pad changes during school (Singh & Bhardwaj 2017) as well as environmental issues. Where solid waste management is not available, disposal practices for sanitary pads include throwing them in the open where they can contaminate water bodies, burning (in an open pit), burying them (whether waste is compostable or not), or flushing in the toilet, where they cause clogging and impair the biological degradation of human waste in sanitation systems (Path 2017).

In addition to the lack of sanitation infrastructure, menstruation is associated with stigma and taboos such as the perception of impure or shameful processes leading to restrictions of women's activities during menstruation

Downloaded from http://iwaponline.com/washdev/article-pdf/11/3/474/889950/washdev0110474.pdf
by guest

and secrecy around menstrual fluid management (Sommer *et al.* 2013; Garg & Anand 2015). Importantly, cultural beliefs and taboos, in addition to convenience and information, contribute to the selection of disposal method (e.g. bury or burn) and to practices such as washing pads before disposal (Ali & Rizvi 2010; Sommer *et al.* 2013).

Onsite incineration is an option for managing the disposal of menstrual waste to achieve both pathogen and volume reduction, thus alleviating the environmental problems associated with improper disposal. Small-scale incinerators placed within a toilet facility may provide an effective and discrete way of disposing menstrual absorbents, align with decentralized waste treatment practices, and are well suited for institutional settings such as schools and worksites (Elledge *et al.* 2018).

Concerns in regard to the adoption of incineration are related to negative health and environmental impacts associated with the release of pollutants and toxic emissions as well as incomplete waste processing (Sommer *et al.* 2013); in the past decade, poor design and insufficient operation and maintenance have resulted in negative experiences for people (Tilley *et al.* 2013).

The Government of India has promoted the adoption of incineration for menstrual waste as part of its Swatch Bharat (Clean India) mission (2018). In India, menstrual waste volume is significantly high, with an estimated 121 million women disposing of 113,000 tons of menstrual hygiene waste (12.3 billion pads) annually (Path 2017). A number of programs implemented to increase access to sanitary pads have been successful in achieving widespread adoption recently, with an estimated 98% urban women using them (Dixit *et al.* 2016) and 64% of women in low-income areas gaining access to such pads (Garikipati & Boudot 2017). It is estimated that over 50 suppliers on the Indian market sell sanitary pad incinerators in institutional settings, with the majority being electric incinerators processing batch sizes as small as 10 pads (Bill & Melinda Gates Foundation 2021). The Government of India has classified sanitary pads as solid waste (SWM 2016), with associated emission thresholds for incineration, and since 2016 has stipulated the manufacturers of sanitary napkins to, among other things, provide wrappers for used sanitary napkins. However, lack of oversight and enforcement of regulations remains a concern for menstrual waste incineration (Elledge *et al.* 2018).

To our knowledge, there are no published reports on the performance of menstrual waste incinerators on the Indian market nor is there any information that includes the details of operation with actual menstrual waste.

Thermochemical processes such as incineration are well known to depend on the nature of the feedstock and its moisture content (MC). A very low MC is advantageous to incineration, and, to give some examples, the maximum MC allowed for thermal processes including incineration has been reported to be <15% (Burguete *et al.* 2016; Eke *et al.* 2019), while municipal solid waste thermal processes operate at no more than 20–25% moisture (Dong *et al.* 2016). In general, a higher MC can result in higher pollution and incomplete treatment (Youcai *et al.* 2004).

In order to enable the evaluation of menstrual pad incinerators based on realistic feedstock characteristics, this paper characterizes the physical properties of menstrual waste in the context of feedstocks for incineration. We collected and characterized menstrual waste from women's bathrooms from three institutional sites in India, and this paper reports our findings on the nature of the waste and its physical parameters: wet weight and MC.

MATERIAL AND METHODS

Site characteristics and study population

Menstrual waste was collected from three sites in the city of Coimbatore, India, between September 2019 and March 2020. All sites were communal women's toilet facilities: a private textile factory and two student residence halls in an educational institute, Hostel 1 and Hostel 2. The collection of pads was carried out by the caretakers (custodian or janitor) of each facility. The caretakers received an orientation about the purpose of the project prior to the beginning of the study and wore personal protective equipment (masks and gloves).

Site 1: The private textile factory site is a shared toilet for live-in and day workers. According to the warden, the number of users ranges between 20 and 50 women

Downloaded from http://iwaponline.com/washdev/article-pdf/11/3/474/889950/washdev0110474.pdf
by guest

between 18 and 50 years of age. The facility has five toilet stalls, with a dedicated lidded bin for menstrual waste disposal. After an accumulation period of 2–3 weeks, the five bins were collected by the caretaker by placing the waste in one larger disposal bag and delivered to the investigators for analysis. Five separate collections were used for this study, yielding a total of 304 pads.

Site 2: Hostel 1 is a multistorey building housing approximately 900 female students, estimated to be between 23 and 30 years of age. Each floor contains a toilet facility with 25 individual toilet stalls. Each stall has a dedicated lidded bin for menstrual waste (Figure 1(a)). Caretakers empty the waste bins daily. Standard disposal operations involve the caretaker collecting the contents of all individual bins from one floor into one large disposal bag. In order to preserve the contents of each bin and prevent clumping of the pads, black garbage liner bags were provided to the caretakers the day before collection and placed in each bin. Black liners containing at least one pad were delivered to the investigators (Figure 1(b)). Four separate collections were carried out at this site for one or more floors for a total of 47 bags.

Site 3: Hostel 2 is a multistorey building housing approximately 350 female students, estimated to be between 23 and 30 years of age. Each floor contains a toilet facility with 10 individual toilet stalls. One waste bin is shared between two toilet stalls. The janitors empty the individual waste bins daily into one large disposal bag per floor, similar to hostel 1. Black garbage liners for the bins were provided to the caretakers the day before collection. After 1 day, liners containing at least one pad were delivered to the investigators. One collection was carried out at this site for a total of 24 bags.

Menstrual waste physical analysis

Analysis began the same day menstrual waste was received from the caretakers. Metal tongs were used to sort the waste into individual pads. For each pad, its type was recorded as either commercially disposable cellulose or homemade cloth (Figure 1(c)). Commercial pads were further analyzed for disposal shape and assigned one of the following categories: unfolded, rolled up/crumbled, or stuck together. Pads that were stuck together due to exposed adhesive liners were recorded as such and not analyzed further. Additional information collected from commercial pads included the presence of wings and additional coatings, as determined by a different color of the substrate material. Cloth pads were homemade and nonuniform in size; therefore, we recorded the length, width, and layers of cloth of the pad.

In a fume hood, an analytical balance was used to record the wet weight for all individual pads received. A subset of approximately 15–18 pads from each collection was further evaluated for MC analysis. Pads were assigned to three weight categories based on wet weight: low (5–20 g), medium (21–40 g), and heavy (>41 g). The pads for MC measurements were randomly selected in quantities proportional to their number in each of the three weight categories.

MC was calculated using the conventional formula $\%\ \mathrm{MC} = (W_{\mathrm{wet}} - W_{\mathrm{dry}}/W_{\mathrm{wet}})*100$, where W_{wet} is the wet

Figure 1 | (a) Photograph of a bathroom stall with individual waste bins. (b) Waste bin bag liner as received. (c) Disposed of homemade cloth pad. (d) Individually labeled commercial pads in a dry oven for moisture measurement.

by guest

weight and W_{dry} is the dry weight. Pads were placed inside a vented hot air oven whose temperature did not exceed 100 °C (typically 55 – 70 °C) (Figure 1(d)). The drying temperature is lower than the standard value of 105 °C because of the limited temperature control capability of the oven. By drying at 55–70 °C, we ensured that no temperature swings exceeded 105 °C, which would cause mass loss to volatilization, and thus, we obtained an accurate dry weight value at the cost of longer drying times. The weight of the pads was recorded over multiple days until it did not change more than 4% from prior measurement, thereby providing the dry weight value. After the completion of analytical characterization, all specimens were discarded as biohazardous waste.

Ethics

PSG IMSR's Institute Human Ethics Committee (IHEC) reviewed and approved the study as exempted (2018/Appr/Exe/017). Duke University IRB determined the study to be non-human subject research.

RESULTS AND DISCUSSION

A total of 613 discarded menstrual pads were collected over multiple collections from three institutional sites, a factory and two residence halls from an institution of higher education (Hostels 1 and 2). Two types of menstrual waste were observed: commercially disposable cellulose pads and homemade cloth pads. The overwhelming majority (≥93%) of the pads collected from the three sites were commercially disposable pads, and of these, a large majority had wings or some type of cellulose coating as detected by different colored pad material. Homemade cloth pads were found in waste in two of the three sites, namely, the factory and Hostel 1. Results over multiple collections at the same sites were consistent over time. Table 1 summarizes the

results of the physical analysis of the disposable commercial pads for all collections.

Properties of commercial pads

There was a difference in the manner of disposal across sites, with the pads at the factory site being largely disposed of as unfolded, while at the hostels, we observed a mix of unfolded and rolled up, often wrapped by a piece of newspaper. We note that India being a country with a washing culture, bathrooms do not feature toilet paper, which is commonly used as a wrapper prior to disposal in other geographies. Unfolded pads are likely to stick to each other and form clumps that may be problematic for incineration, cause them to stick to surfaces, or be improperly positioned inside the incinerator.

The number of clustered pads was higher at the factory site than at the hostels due, in part, to both the manner of collection and the adoption of liner bags for the menstrual waste bins at the hostels.

The wet weight of the pads had a similar median value consistent across sites (median wet weight between 13.9 and 15.8 g); however, the range was very broad, from 5.7 to 89 g. The dry weight of the pads had median values 7.6–8.9 g and ranged between 4.7 and 14.1 g, consistent with typical ranges for different commercial pad sizes.

Commercial pads are designed to absorb typically 5 ml and, in some models, up to 10 ml of liquid (Fraser *et al.* 2001). Given that blood density is slightly more than water (1.06 g/ml), we estimate that blood adds 5–10 g to the dry weight of pads. Using the largest dry weight measured, for pad, of 14 g, we estimate 14 g (pad) +5 g (blood) ~ 20 g as the maximum weight of used pads (dashed line in Figure 2), being aware that in some cases we may observe 14 + 10 = 24 g.

Figure 2 shows the wet weight distribution of the pads, indicating that approximately half of the collected waste was below 15 g, with the majority below the expected maximum weight of 20 g. However, a long distribution tail of wet weights higher than 20 g was recorded for all three sites, particularly at the factory site, where as many as 37% of the pads were heavier than 20 g. Weights are plotted against measured MC in Figure 3. The data show that, consistently across the three sites, heavier wet pads feature very high MCs reaching 80–90%. The dotted line at 50% MC

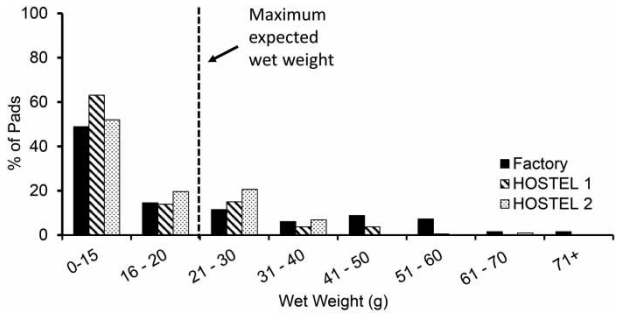

Figure 2 | Wet weight distribution of commercial pads shown as a percentage of the total number of pads from each site.

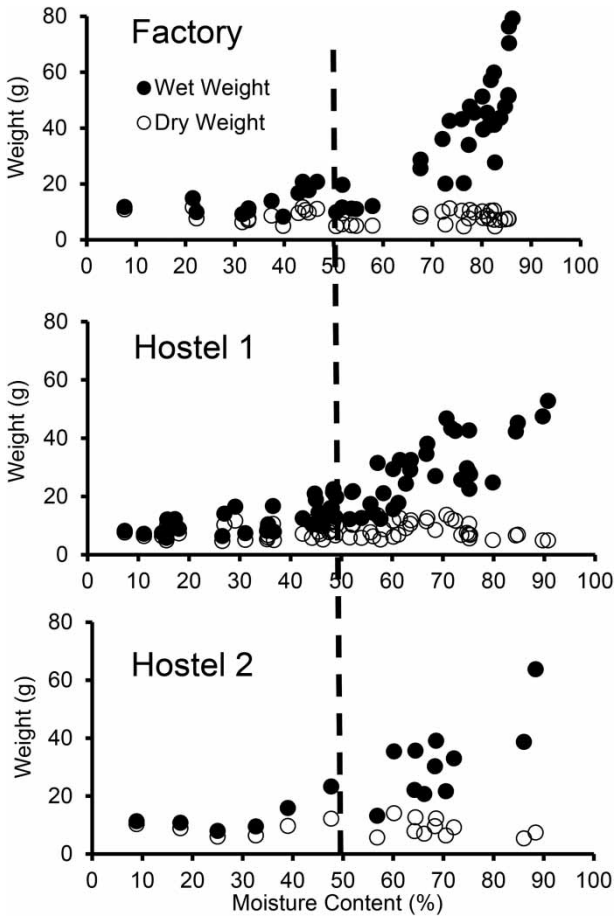

Figure 3 | MC results: wet and dry weights are reported by site. The dashed line represents 50% moisture, the expected upper limit for moisture for used menstrual pads.

corresponds to an 8 g dry pad receiving 8 ml of blood. This is expected to be an upper limit for MC for two reasons: (1) the typical volume of blood for pad rarely exceeds 5 ml and (2) in this study, drying of the pad can occur during

by guest

the time between disposal and collection (time lag = 1 day for hostels, 1–2 weeks for the factory site). Yet, the measured moisture values are too high to be consistent with moisture from menstrual blood alone. While we did not conduct chemical analysis on the liquid, we note that since India has a washing culture, a tap with water per personal wash is available in each of the toilets included in this study. Thus, we infer that wet heavy pads derive from the practice of washing them prior to disposal (Ali & Rizvi 2010; Sommer *et al.* 2013). This practice is associated with the concept that menstrual blood is impure and the belief that others should not see it, and also possibly with a lack of awareness on proper disposal practices (Garg & Anand 2015).

While MC was not measured for all pads (wet weight was measured), all pads in Figure 3 whose wet weight exceeded 20 g had a MC exceeding 50% (dotted line). Thereby, a significant portion of disposed pads (23, 28 and 37%) with wet weight above 20 g were estimated to have a MC ranging from 50 to 90%. Such high moisture levels could be problematic for thermal processing because they significantly exceed the optimal 15–25% feedstock moisture (Dong *et al.* 2016; Eke *et al.* 2019).

Properties of cloth pads

Out of the 613 pads collected in this study, 33 were homemade cloth pads. We note that since the cloth pads are reusable, the low fraction of disposed cloth pads does not represent an indication of how prevalent their use is. It is, however, an indication that the menstrual pad incinerator should be evaluated for its ability to process feedstock that contains a percentage of cloth material that has been reused multiple times.

Figure 4(a) illustrates the distribution of wet weight of cloth pads. Higher weights were observed particularly at the factory site, where cloth as long as 88 cm and as wide as 38 cm was folded in layers to serve as a pad (for reference, the length and width of a typical commercial pad product is 25 cm length × 7.2 cm width). The MC of the homemade cloth was, however, narrower than that observed for the commercial pads and ranged between 16 and 40%. Also, the MC was not associated with wet weight, with some of the heavy pads consisting of a larger quantity of material. A possible explanation for the difference in MC between cloth and commercial pads is the fact that commercial cellulose pads are designed to absorb liquid and, therefore, when washed, retain a large amount of liquid, while cloth pads can dry more easily after disposal.

Comparison with prior studies

Prior studies of menstrual waste are based on surveys, and only a few of them address specific questions on disposal practices that are relevant to our physical assessment results.

A key finding of this study is that a significant fraction of the commercial pads (23–37%) was associated with a high MC consistent with washing prior to disposal.

Prior literature that investigated reproductive tract health included questions about the pad material type and the frequency of personal washing. Within the studies that included details on menstrual hygiene material, the topic of pad washing emerged in the context of cloth pads and their reuse (Omidvar & Begum 2010; Das *et al.* 2015), while separate studies addressed the topic of pad disposal, with no mention made on washing (Wagh *et al.* 2018). Combining

questions on both washing and disposing, a study in Pakistan reported that as many as 60% of the respondents washed and discarded cloth pads; however, there was no explicit question about the washing of disposable pads (Ali & Rizvi 2010). We identified one publication (Kumar & Srivastava 2011) that, while reporting on social restrictions and taboos around menstruation, found that the majority of girls from residential areas in a city in India used disposable pads and that 25% of them washed such sanitary napkins after using them and then disposed them. This observation of washing sanitary napkins prior to disposal is consistent with the high MC in waste that we measured.

Another finding of our work is that a large portion of the pads are disposed of unfolded and, therefore, not wrapped in any paper or plastic. This result is not reflected in prior literature, because the question whether pads are wrapped prior to disposal was not directly asked. In Nayak *et al.* (2017), 98% of the respondents described the material selected to wrap pads (either paper or plastic), and only 1% of the surveyed women did not respond to the question. In Dipali *et al.* (2009), the questionnaire asked about the material the pad was disposed in, not whether it was wrapped; thus, no information on unfolded pads was captured. This difference between our findings and prior reports on this matter highlights the complementarity of physical assessments and surveys in the study of behavior and practices.

CONCLUSIONS

We investigated the physical properties of menstrual waste as feedstock for incinerators that represent an attractive solution to the challenges of menstrual waste disposal, particularly in institutional settings.

Menstrual waste was generated by women of different ages (18–50 years) and different education/income (workers vs. college students), yet consistent outcomes were observed across the two groups. The use of commercial cellulose pads was prevalent at all sites (>93%), in agreement with recent reports (Dixit *et al.* 2016; Garikipati & Boudot 2017). In two out of three sites, 6–7% of the waste consisted of homemade cloth pads, suggesting that a menstrual pad incinerator technology will encounter multiple types of feedstock. The commercial pads were disposed both unfolded or folded, indicating that the incinerator configuration should be robust with respect pad insertion and positioning inside the unit; folded pads were not wrapped in manufacturer-provided wrappers, despite country regulations and standard use instructions.

A major finding of this study was that a significant fraction of the commercial disposed pads (23–37%) had a large wet weight (over 20 g), which was associated with MCs exceeding 50%. This MC is much higher than ideal for thermal processing (<25%) and can be quite problematic for typical incinerators, leading to incomplete combustion and increased hazardous air emissions. We infer that the MC is due to the practice of washing pads before disposal, a practice that has been reported in washing cultures. While this study on menstrual waste in India is limited to three sites, hundreds of pads were collected in repeated collections over periods of months, and the results were consistent across collections. These findings suggest that further research is needed to fill the knowledge gap on practices in menstrual disposal and that testing protocols of disposal technologies should include an evaluation of the effects of high MC, unfolded pads, and occasional cloth pads on waste processing performance.

ACKNOWLEDGEMENTS

This work was supported by the Bill & Melinda Gates Foundation through grant no. INV-001513 to Duke University and through the STeP project (contract service agreement ID 43951). We thank the caretakers of the three facilities for supporting the waste collection and gratefully acknowledge the analytical support of this study by Ms Viswa Barani and Mr Praveen Rosario.

Abstract

Background: Adolescence is a period of transition where independence in thinking and behavior is established and food choices that are made are followed for several years, and this can influence their health in adulthood. Hence, understanding the eating habits are necessary to plan effective nutritional interventions in adolescents. **Objectives:** The main objective of the study is to find out the extent of malnutrition among rural adolescents as well as evaluate their eating habits against recommended dietary food groups and to compare eating habits across gender and age groups. **Methods:** A cross-sectional study was done among 1425 adolescents from 13 rural schools from 2014 to 2015, and the variables considered in this study were age, sex, body mass index (BMI), and the eating habits of the adolescents. **Results:** Undernutrition was seen among 23% and overweight/obesity among 8% of adolescents. The habit of taking milk and milk products, fruits, and green leafy vegetables were very poor among the adolescents. Significant association was found between eating habits and BMI. Furthermore, late adolescents had better eating habits, and significant gender difference was seen in certain eating habits. **Conclusions:** The study shows that it is possible to understand the gaps in eating habits of adolescents, and this can be used to plan tailor-made nutritional interventions to adolescent groups as their eating habits are different and have long-term nutritional and health implications.

Key words: Adolescent, dietary gap assessment, faulty diet, nutritional diagnosis, school health

Introduction

Adolescence is a period of transition. The World Health Organization (WHO) defines the period of adolescents as 10–19 years of age.[1] It is a period of rapid growth and maturation in human development. It is a period where independence is established and adolescent makes choices of their own. The choices that are made are followed for several years and food habits are greatly established during this period, and this can influence their health in the adulthood.[2]

As global foods are widely marketed in low- and middle-income countries, it becomes important to understand the diet patterns and preferences.[3] In India, among adolescents, there is an increased consumption of fast foods contributing to overweight and obesity.[4] Furthermore, studies have shown that the food consumption pattern is poor among adolescents and have observed frequent consumption of energy-dense, nutrient-poor foods, and sugar-sweetened beverages, and the omission of a variety of healthy foods from their daily diet.[5]

In addition, cultural factors such as dietary practices and attitude toward food are evolving. These factors eventually influence the eating habits and today's adolescents lack proper knowledge on good eating habits and how those habits contribute toward their healthy nutritional status.

Hence, healthy eating behavior should be established in childhood and maintained during adolescence.[6] Adequate knowledge of healthy food choices and eating habits should be taught early to adolescents, as it can predispose them

to lifestyle diseases in adulthood. Adolescents should be constantly motivated, and the need of the hour is bridging the knowledge gap on healthy eating.[7]

In India, there is a paucity of information about eating habits of adolescents, and limited information is available regarding various categories of food consumed by adolescents in relation to the food pyramid, which defines and identifies the balanced diet and corresponding nutritional status of an adolescent. Moreover, this type of nutritional data is even more difficult to find among rural population in India. Also, adolescents are the most important and vulnerable segment of population who have been largely ignored, and exclusive data pertaining to adolescent health are not widely available in Indian scenario.[8]

Hence, this study aimed to measure the extent of malnutrition among rural adolescents as well as evaluate their eating habits against recommended dietary food groups and to compare eating habits across gender and age groups.

Materials and Methods

A cross-sectional study was done among adolescents from 13 schools in rural area within the Madukkarai block, Coimbatore District, in 2014–2015. Prior permission was obtained from the concerned school health authorities, and this study protocol was approved by the Institutional Human Ethics Committee. Data used in this study were collected as a part of the school health project. The variables considered in this study were age, sex, body mass index (BMI), and the various elements in the recommended food portions that constitute the eating habits of the adolescents.

This school health program was funded by Larsen and Toubro, under their corporate social responsibility scheme. The funders' interest was only on the services to the rural school children and did not have a role in the research component. The research on the data obtained was done after obtaining ethics committee clearance from our institution. All adolescents from 10 to 18 years were included in the study and students who were absent from school on the day of visit were excluded from the study.

Anthropometric measurements such as height and weight of all students were recorded. Instruments were calibrated, and the BMI was calculated based on the measured height and weight. The nutritional status of the adolescent was determined based on the WHO BMI charts available, separately for boys and girls, from 5 to 19 years.[9] The WHO chart classifies them as severe thinness, thinness, and normal, overweight, and obese based on their BMI for their particular age. A questionnaire/checklist was designed to record the daily eating habits of school children based on the recommended portions of various categories listed in the food pyramid, as recommended by the ICMR and National Institute of Nutrition (NIN).[10] Based on the above balanced diet recommendations, questionnaire was developed which assessed the daily eating habits of the adolescents.[11] The questionnaire was a simplified tool with ten items, to assess gaps in the recommended portions of food category intake, by directly asking question that checks in Yes/No terms the compliance with daily recommended intake of cereals in the three main meals, daily intake of vegetables and green leafy vegetable, daily intake of milk and milk products, habit of taking a fruit daily, and intake of protein-rich foods in daily diet. In the assessment of protein-rich food/pulses recommended, portions can also be replaced by egg or other nonvegetarian food as per recommendations.[10] Hence, this assessment includes the assessment of egg and nonvegetarian food also. Additional questions were added to assess other eating habits such as the habit of taking mid-day snacks and questions that captured certain faulty eating habits of students like habit of skipping meals, taking junk food, and eating from street shops. The scoring was also given for each student based on the Yes/No terms in the questionnaire. Each positive response had a score of 1. Total score was 10 and a score of <10 indicates the gap from the recommended portion of food, or they have a faulty eating habit. Lesser the score, more is the gap in the recommended dietary portion of food category. Each student was individually enquired about the eating habits based on the questionnaire, and individual nutrition counseling was given to students who had a faulty eating habit or not complying with the recommended dietary food group intake standards.

All quantitative values were expressed in proportions. Normality test (Shapiro–Wilk test) was done and the nutritional score followed a nonnormal distribution. The association between eating habits and gender, age, and the nutritional status was tested using Chi-square test and Kruskal–Wallis test. All statistical analysis was performed using IBM SPSS Statistics for Windows, Version 24.0. Armonk, NY: IBM Corp (24.0), $P = 0.05$ or less, were considered as statistically significant.

Results

A total of 1425 adolescents between the ages, 10 and 18 years were included for this study, of which 53.1% belonged to early adolescents (10–13 years), 39.9% belonged to middle adolescents (14–16 years), and 6.9% belonged to late adolescents (17–18 years). The mean age was 13.38 ± 2.03 years. The study participants were 753 (47.2%) males and 672 (52.8) females.

Table 1 shows that a majority (68.8%) of adolescents had a normal BMI. However, more than a quarter of them (23.2% of

Thin	145 (21.6)	109 (14.5)	254 (17.8)
Normal	429 (63.8)	551 (73.2)	980 (68.8)
Overweight	28 (4.2)	38 (5.0)	66 (4.6)
Obese	17 (2.5)	32 (4.2)	49 (3.4)

students who were undernourished including thin and severely thin and 8% were either overweight or obese) need dietary and other interventions.

The nutritional status of boys revealed 29.5% were either severely thin or thin, 4.2% were overweight, and 2.5% had obesity. Among girls, 17.6% were in severely thin or thinness category, 5.0% overweight, and 4.2% had obesity. This difference between boys and girls was statistically significant ($P < 0.001$).

Figure 1 shows the percentage of adolescents taking the recommended food groups daily as per the ICMR/NIN recommendations and also certain faulty eating habits such as eating junk food, eating from street shops, and skipping meals. It shows that none of the adolescents had the habit of taking green leafy vegetables daily. Furthermore, the habit of taking fruits and milk was very poor among the adolescents, thereby putting them at risk of micronutrient and vitamin deficiency which are not picked up if we do anthropometry alone as done in most school health programs.

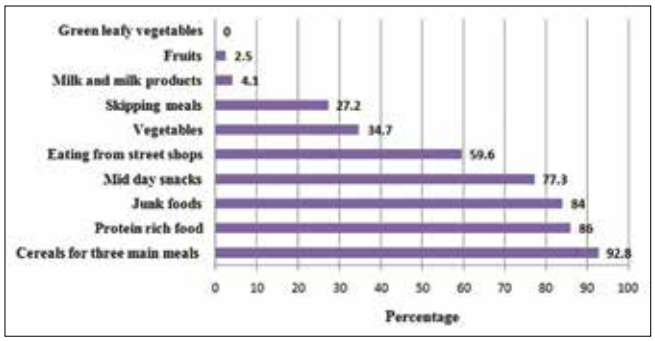

Figure 1: Pattern of eating habits among adolescents.

Table 2 shows that there is an association between eating habits and nutritional status of the adolescents. Chi-square test was used to find whether there was any significant difference in the eating habits among the adolescents of various nutritional statuses (based on BMI). Except for the habit of eating junk foods, others habits have significant association with BMI ($P < 0.001$).

Table 3 shows the difference in eating habits based on gender. Chi-square test was used to find whether there was any significant difference in the eating habits among the adolescent boys and girls. Odds ratio was also calculated. Habits of taking cereals, mid-day snacks, skipping meals, and eating from street shops showed significant difference between boys and girls.

The mean score obtained by the students on the diet assessment was compared between the age groups. Kruskal–Wallis test was used to find the statistical significance among the various age

Table 2: Association of eating habits and nutritional status of schoolchildren ($n=1425$)

Eating habits (recommended ICMR/NIN food category portion frequency)	Nutritional status (BMI categories)			χ^2	*P*
	Thin ($n=330$), *n* (%)	Normal ($n=980$), *n* (%)	Overweight/obese ($n=115$), *n* (%)

OR: Odds ratio

groups. The mean scores of early, middle, and late adolescents were 4.3 ± 1.27, 4.2 ± 1.23, and 4.6 ± 1.02, respectively. Late adolescents had a better nutritional score compared to early and middle adolescents. The difference was found to be statistically significant ($P = 0.006$).

Discussion

Our study shows that undernutrition or thinness among the rural school-going adolescents was a common problem (23.2%). Furthermore, 8% were overweight or obese and hence over a quarter of them need dietary and other interventions. The percentage of undernutrition and overweight was less in our study compared to a study done in Karnataka by Benazeera., where among school adolescents, 34% were belonging to the category of underweight, 21.33% were obese, and 10.67% were overweight.[12]

We also found that underweight was more common among boys and overweight and obesity were more among girls and hence targeted interventions for girls and boys are needed that address factors that could be different. This means further studies are needed to find out the reasons for the difference observed. A study done in Bangalore by Abraham and Anand showed similar findings among adolescent schoolchildren.[13] The study by Venkaiah *et al*. among rural adolescents in nine states also showed that underweight was more among boys than girls.[14]

Regarding eating habits, our study showed that the habit of taking green leafy vegetables daily was not there in any of the adolescents. Furthermore, the habit of taking fruits (2.5%) and milk and milk products (4.1%) was very poor. These habits were poor even in the normal BMI category. Thus, traditional school health programs that use anthropometry alone would not help identify vitamin and micronutrient deficiency unless anthropometry is combined with clinical screening for vitamin and micronutrient deficiency diseases and their contributing factors by doing a diet survey. A study done by Rathi *et al*. among adolescents in Kolkata also showed that 45% did not consume any fruit, 30% did not take vegetables, and 36% did not take milk and milk products. Our study showed that consumption was very less percentage maybe because it assessed daily habits, while the study in Kolkata showed the consumption based on the last 2 days.[5]

In our study, the eating habits of adolescents were found to have significant association with their nutritional status, except for habit of eating junk foods. Our study showed that habits like not consuming cereals for three main meals, not taking mid-day snacks, protein-rich food, and skipping meals were significantly associated with the underweight. In the overweight/obese category, factors such as milk and milk products, eating from street shops, and junk food were high, though junk food did not show any statistical significance. Similar findings were seen in a study by Amin *et al*. which showed that frequent consumption of sweets/candies and milk and milk products are associated with obesity.[15] However, even habits of eating vegetables and fruits were also high in the overweight/obese category. Since the study did not take into consideration the quantity of consumption and exact fruits and vegetables consumed, we could not comment on this. A study by Bhattacharjee *et al*. among adolescents showed that BMI correlated significantly with the dietary habits.[16] Another study by *et al*. showed that eating habits were a better predictor of BMI, especially among boys.[17]

In our study, association of gender with eating habits showed that habits such as consumption of cereals, having mid-day snacks, skipping meals, and eating from street shops showed significant differences. Habit of consuming cereals and having mid-day snacks were better among girls. A study by Rathi *et al*. also showed that females had better consumption of cereals.[5] However, higher percentage of girls had the habit of eating from street shops. This was again similar to a study which showed that significantly more mid-adolescent girls purchased from tuck shops than boys.[18] The habit of skipping meals was more common among boys than girls. Similarly, a study among Turkish Adolescents shows that one-third of the boys skip meals, while only one-sixth of the girls skip meals.[19] Furthermore, a systematic review done among young adults showed that men tend to skip breakfast more often than females, while skipping lunch and dinner was more common among females.[20]

Our study also showed that late adolescents had better eating habits as demonstrated by their higher nutritional scores compared to early and middle adolescents. The nutrition scores are least in the middle adolescents group. This might be because in early adolescents still parental influence is more as shown in a study which shows parental influences can influence the diet of the child.[21] In the late adolescence, the better scores might be because the adolescents become more aware about healthy eating, as shown in certain studies that late adolescents have better knowledge than the younger ones.[22] However, further studies are needed to establish the factors influencing their diet.

Limitations and strengths

Our study has several strengths; we have studied a large number of children in the study sample. A simple and effective questionnaire was used for identifying the gaps in the eating habits based on the standard ICMR/NIN recommendations for a balanced diet. In addition, standard methods like the WHO-developed BMI age charts were used to assess the nutritional status.

However, there were certain limitations, eating habits were assessed by self-reported data and quantitative measuring of the intake of the recommended portions of food groups was not done. We could not exclude the possibility of confounding effects by unmeasured variables such as physical activity and other comorbidities that influence the BMI. Furthermore, data did not include social factors known to affect BMI such as socioeconomic status, number of family members, and education of the mother. Although our study identified low

intake of green leafy vegetables and fruits, we had not planned to look for clinical manifestations of vitamin and micronutrient deficiencies and then look for correlation between the two. Also, since we have found that underweight was more common among boys and overweight and obesity were more among girls and hence further studies are needed to find out the reasons for the difference observed.

Notwithstanding the above limitations, our study findings show that there is scope for doing further in-depth studies to prove the preliminary findings of this study.

Conclusion

The study shows that it is possible to make a Nutritional Education Diagnosis by identifying the gaps in eating habits compared to the recommended one for school-going adolescents. This can then be used to plan tailor-made educational and nutritional programs for improving their eating habits. Using the rapid screening method used in the study, it would be relatively easy to conduct this exercise on a sample of schools in a district to capture gaps in diet at district level for conducting health education and awareness programs on nutrition for adolescents in schools at the district and using similar methods to scale it up for state-level as possibly a national-level initiative to extend school health nutritional interventions to adolescent groups, as their eating habits are different and have long-term nutritional and health implications for the population beyond adolescence.

Since January 2020 Elsevier has created a COVID-19 resource centre with free information in English and Mandarin on the novel coronavirus COVID-19. The COVID-19 resource centre is hosted on Elsevier Connect, the company's public news and information website. Elsevier hereby grants permission to make all its COVID-19-related research that is available on the COVID-19 resource centre - including this research content - immediately available in PubMed Central and other publicly funded repositories, such as the WHO COVID database with rights for unrestricted research re-use and analyses in any form or by any means with acknowledgement of the original source. These permissions are granted for free by Elsevier for as long as the COVID-19 resource centre remains active.

Abstract

Covid-19 disease caused by SARS-CoV-2 is still being transmitted in developed and developing countries irrespective of healthcare setups. India with 1.3 billion people in the world is severely affected by Covid-19 with 11.3 million cases and 157 000 deaths so far. We have assessed the

mismatches in WHO recommended rRT-PCR assays primer and probe binding regions against SARS-CoV-2 Indian genome sequences through in-silico bioinformatics analysis approach. Primers and probe sequences belonging to CN-CDC-ORF1ab from China and HKU-ORF1b from Hong Kong targeting ORF1ab gene while NIH-TH-N from Thailand, HKU-N from Hong Kong and US-CDCN-2 from USA targeting N genes displayed accurate matches (>98.3%) with the 2019 novel corona virus sequences from India. On the other hand, none of the genomic sequences displayed exact match with the primer/probe sequences belonging to Charité-ORF1b from Germany targeting ORF1ab gene. We think it will be worthwhile to release this information to the clinical and medical communities working in Indian Covid-19 frontline taskforce to tackle the recently emerging Covid-19 outbreaks as of March-2021.

Keywords: Covid-19, Primer and probe mismatches, rRT-PCR, Indian SARS-CoV-2 genome sequences

1. Introduction

Covid-19 pandemic disease is caused by novel Severe Acute Respiratory Syndrome corona virus 2 (SARS-CoV-2) worldwide. The virus has transmitted to both developed and developing countries irrespective of the healthcare setups [1]. Diagnosis of Covid-19 disease is vital to detect the infected individuals in community regarding quarantine and treatment, where real-time Reverse Transcription Polymerase Chain Reaction (rRT-PCR) is employed to detect the presence of viral pathogen in swab samples collected from Covid-19 suspected patients [2]. The virus has a strong transmission potential and caused Covid-19 outbreak in several countries throughout the world. Prompt and early detection of SARS-COV-2 through rRT-PCR is essential for the disease control strategies planned by national healthcare agencies and Government programmes. To date, there are several rRT-PCR protocols developed by different nations and approved by WHO. SARS-CoV-2 is a RNA virus having the potential to evolve rapidly through high mutation rates [3]. Since its first outbreak in December 2019 in Wuhan province of China it rapidly circulated throughout the world with accumulation of nucleotide polymorphisms in the genomes of SARS-CoV-2 strains [[4], [5], [6]].

Mismatches in the primer and probe regions of SARS-CoV-2 strains may lead to their diminished ability binding to corresponding template DNA molecules during the initial steps of PCR reactions. Mutations in the primer and probe regions have been shown to affect the sensitivity of PCR reactions in case of other viral infections such as human immunodeficiency virus (HIV), Hepatitis B virus (HBV), H1N1 virus and dengue [[7], [8], [9], [10], [11], [12], [13]].

India being the second most populous country in the world severely affected by Covid-19 and as of 10-March-2021, 11 244 786 cases and 157 930 deaths has been reported in India since its first Covid-19 case reported on 30-January-2020 [14]. With 1.3 billion people living in diverse states of different culture and health care inequalities, early detection of SARS-CoV-2 infection with robust diagnostic tests are in great demand to control the disease transmission. Previous studies reported the mismatches in primer probe regions of Covid-19 PCR primers used the sequences representing SARS-CoV-2 strains from different countries, nevertheless there are no studies focusing on the SARS-CoV-2 genomes from Indian Sub-Continent. In this study, we evaluated mismatches in PCR primers against SARS-CoV-2 genomes from India through in-silico bioinformatics analysis approach [15,16].

2. Materials and methods

Briefly, a total of 3765 whole genome sequences of SARS-CoV-2 strains isolated from India were retrieved in FASTA format from GISAID (Global Initiative on Sharing All Influenza Data) database submitted as on January 30, 2021 (Supplementary Table 1) [17]. Further search criteria employed for collecting the sequences from the database is as follows: (i) “hCoV-19” was selected under virus name (ii) “Human” was selected under host name (iii) location was selected “Asia/India” (iv) complete genomes alone were included (>29000 bp length) and (v) high coverage genomes alone were considered (low coverage entries i.e. >5% Ns were excluded). The collected individual FASTA sequences were then merged as a single FASTA file along with the inclusion of the complete genome of Wuhan-Hu-1 as reference genome in 29903 bp length (NCBI Reference Sequence: NC_045512.2). Primers and probe sequences were collected and shortlisted from the recommended protocols in the literature and from WHO website (Table 1) [18]. A detailed protocol is presented as in supplementary file 1.

Open in a separate window

Table represents the Forward primer (F), Reverse primer (R) and Probe (P) sequences, their corresponding position in relation to Wuhan SARS-CoV-2 reference Genome, followed by the number of sequences exhibiting exact match. Sequences with variance of at least 0.5% might decrease the efficiency of primers and probes

binding to the corresponding template DNA sequences. About 324 sequences submitted between November 25 2020 to November 30 2020 displayed misalignment with the reverse primer and therefore they have been omitted from the study. * - Range of melting temperature is provided in case of degenerate nucleotide

A large-scale multiple sequence alignment (LS-MSA) was carried out for the given FASTA files using MAFFT (Multiple Alignment using Fast Fourier Transform) v.7 tool available online (https://mafft.cbrc.jp/alignment/server/) [25]. MSA was carried out with the following options, (i) "Allow unusual symbols", (ii) "same as input" for nucleotide sequence direction, (iii) "Aligned" output order and (iv) "Auto" strategy. The aligned sequences were then downloaded and visualized using AliView program [26]. Sequences representing from forward primer initial nucleotide to reverse primer end nucleotide regions were trimmed from rest of the whole genome alignments and saved separately as FASTA files. Variability within primer-probe sequences were estimated as described elsewhere [16]. Briefly, positional nucleotide numerical summary (PNNS) and entropy was calculated using PNNS (http://entropy.szu.cz:8080/EntropyCalcWeb/pnns) and entropy calculator (http://entropy.szu.cz:8080/EntropyCalcWeb/) available in Alignment Explorer respectively [27]. Further, sequence stratification of primer-probe alignments was carried out using SequenceTracer module in Alignment Explorer with the segregation of sequences into discrete groups of identical sequence variants along with their frequency for each primer/probe. During the execution of the program, sequences with stretches of NNNs and ambiguous sequences in the alignments were excluded from the study. For the removal of extremely low prevalent variants and sequencing errors in the data, a threshold of at least 0.5% incidence of variation was considered as meaningful and those sequences alone were further considered for analysis [16]. Finally, the melting temperature (Tm) of the original primer/probe sequence against the variant sequences was calculated after mapping the whole genome sequences against the same. Since the length of primers included in this analysis is > 13 nucleotides, the following formula was applied for calculating the melting temperature $Tm = 64.9 + 41*(yG + zC – 16.4)/(wA + xT + yG + zC)$ where w, x, y, and z are the number of A, T, G, and C nucleotides, respectively [28].

3. Results

In this study, whole-genome sequences of SARS-CoV-2 strains isolated in India were obtained from GISAID database and their sequence similarity against various primers/probe employed in detection assays recommended by WHO were investigated (Supplementary Table 1). Variations in sequences were identified after performing multiple sequence alignment with MAFFT and visualized using Entropy Calculator and Sequence Tracer. The obtained Results were segregated into distinct groups based on the nucleotide variations. As described earlier [16], to avoid considering mismatches raised due to sequencing errors, a threshold value of ≥0.5% was set, where only sequences showing variation frequency above this limit were considered further. Non-informative sequences were segregated separately as outgroups. Outgroup 1 included sequences having "*n*" in them while incomplete/short sequences were categorized as 'Outgroup1/2'. Targets with missing or no sequences were excluded from the data processing. The remaining sequences alone called as 'informative sequences' were considered for further analysis. These informative sequences were divided into two groups namely 'perfect matches' and 'mismatches'.

Among the assays targeted against N region of SARS-CoV-2 genome, NIH-TH-N from Thailand displayed highest accuracy with 98.35% of genome sequence matching exactly with corresponding primers and probe (Table 1). This was followed by both US-CDC-N-2 from USA and HKU-N from

Hong Kong with 98.3% sequences displaying exact matches. Primers and probe sequences employed in NIID-JP-N assay from Japan displayed exact matches with 3691 (98.03%) SARS-CoV-2 whole genome sequences. The assay US-CDC-N-1 from USA had exact match with 3449 (91.6%) sequences. It had two significant single nucleotide mutations at 28312th position showing mismatch (C28312T) with 194 (5.15%) sequences at probe binding region and 28299th position showing mismatch (C28299A) with 20 (0.53%) sequences in the forward primer binding region. It also showed two insignificant consecutive nucleotide change CA to TT (C28315T and A28316T) of 4 (0.1%) sequences at the probe binding region. Among the assays targeting N gene, CN-CDC-N were found to be least specific. About 2043 (54.26%) sequences displayed exact matches with sequences and probe involved in CN-CDC-N assay while 1471 sequences (39.07%) displayed significant trinucleotide variation (GGG→AAC) in the forward primer region starting at 28881st position and significant single nucleotide mismatch with 45 (1.19%) sequences at forward primer region (C28887T) (Supplementary Fig. 1).

Other assays targeting the ORF1ab and E genes were also analyzed for their exact match accuracies between genomic sequences and primer/probe region. Among the assays targeting ORF1ab genes, HKU-ORF1b assay primers and probe sequences displayed exact matches with 3707 (98.46%) sequences. It is to be noted that the primers and probe used in HKU-ORF1b assay from Hong Kong were found to have degenerative nucleotides (Y=C/T, W = A/T and R = A/G). Further, primers and probe employed in CN-CDC-ORF1abassay had exact matches with 3710 (98.53%) SARS-CoV-2 genome sequences (Table 1). None of the sequences exhibited exact match with the primers and probe involved in Charité-ORF1b assay from Germany. Among 3620 (96.15%) sequences, a significant single nucleotide mutation (C/G15516T) was detected. Both the forward and reverse primers of Charité-ORF1b assay contained degenerative bases (R = A/G in forward primer, S = G/C, Y=C/T in reverse primer) like HKU-ORF1b assay. These bases are included to increase the binding specificity of primers and probes. A single assay targeting the E region, Charité-E, was also evaluated for the alignment accuracy between primer/probe and genomic DNA sequences. About 3667 (97.39%) of sequences exhibited exact matches with SARS-CoV-2 whole genome sequences while 139 (3.691%) of sequences were omitted from analysis as ‘outgroups’ (Supplementary Fig. 1). It is generally recommended that the range of hybridization temperature of the primer/probe sets should be less than 10 °C. In our study we found that 4 primer/probe sets namely, US-CDC-N1/USA, US-CDC-N2/USA, CN-CDC-ORF1ab/China and Charité-ORF1b/Germany were deviating from the prescribed threshold hybridization temperature. Mutations in the primer/probe binding regions in US-CDC-N1/USA and Charité-ORF1b/Germany assays further increased the hybridization temperature range (Table 1).

Overall, the primers and probe sequences belonging to CN-CDC-ORF1ab from China and HKU-ORF1b from Hong Kong targeting ORF1ab gene while NIH-TH-N from Thailand, HKU-N from Hong Kong and US-CDC-N-2 from USA targeting N genes displayed accurate matches (>98.3%) with the 2019 novel corona virus sequences from India. On the other hand, US-CDC-N-1/USA and CN-CDC-N/China primers and probes targeting N gene of SARS-Co-V2 Indian genome sequences displayed only 91.6% and 54.26% respectively. Interestingly, none of the genomic sequences displayed exact match with the primer/probe sequences belonging to Charité-ORF1b from Germany targeting ORF1ab gene.

4. Discussion

Reliability in detection of diagnostically important viruses has been a major concern prevailing for decades in the field of virology. Specific binding of primers and the probes to the gene targets must be achieved to obtain the PCR gene products. Single or multiple nucleotide changes in primer and/or

probe binding sites inside the specific gene of interest would result in poor specificity of the primers and/or probes for the test being conducted. This study was conducted to re-evaluate the specificity of primers and probes for reported Indian sequences of 2019 novel Corona virus (SARS-CoV-2). Although more than 25 primer-probe sets are available in the literature, out of them only seven assays showed significant variations at the defined threshold [16]. Hence, specificity was evaluated only for the primers and probes described in different CDC (Center for Disease Control and Prevention) protocols published in the WHO website [18]. Though similar studies have been carried out previously, a data bias has been observed with respect to either geographical locations or fewer samples. In general, most whole genome SARS-CoV-2 sequences that are deposited in the databases are from locations that have an easy access to genome sequencing facilities or from the place of outbreak. Similarly, another study reported the sequencing and depositing the first set of whole genome sequences of SARS-CoV-2 from India, after the isolation and culturing of viral particles from two positive cases with a travel history to Wuhan, China [29]. Since then more than 1000 sequences from India have been deposited to GISAID. Given the fact that corona viruses undergo mutation at moderate rate compared to other RNA viruses, a timely reassessment of the primer/probe sequences employed in the detection of SARS-CoV-2 becomes necessary. The work design and tools employed in this work requires minimal *insilico* infrastructure and bioinformatics skills which except for sequence alignment skills. The same strategy has been successfully applied in the assessment of primer/probes involved in the detection of Influenza A and SARS-CoV-2 viral genomes.

Through stringent data selection parameters and assigning a threshold value of 0.5% as significant nucleotide variation detection parameter, none of the assays displayed exact accuracy with the SARS-CoV-2 sequences obtained from India. Major of the Results obtained were in contrast with the results obtained from studies involving genomic sequences from other countries. A study carried out by Khan and Cheung (2020) demonstrated that primer/probe sequences belonging toUS-CDC-N2, NIH-TH-N, NIID-JP-N, HKU-N, CN-CDC-ORF1ab, HKU-ORF1b and Charité-E displayed 100% accuracy with around 17000 SARS-CoV-2 whole genome sequences collected around the world [16]. Another similar study carried out by Vogels et al., 2020, indicated that the primer/probe sequences belonging to US-CDC-N1, US-CDC-N2 and Charité-E displayed 100% accuracy with around 992 whole genome sequences deposited in GISAID [30]. Previous studies on the genome wide analysis of SARS-CoV-2 strains at a global scale indicated that the single nucleotide transitions act as the major mutational type and on that basis the strains have been classified into three major clades. Further, amino acid changes were also observed in the proteomes of SARS-CoV-2 at a varying rate across six continents. Based on the rates of observed mutations per sample analysis, it has been shown that genomic sequences from India possess relative higher value at 8.40 against Germany (6.09) and Italy (5.92) [31]. Recently, a detailed phylogenetic analysis of SARS-CoV-2 genome sequences Indian origin carried out by Banu et al., 2020 indicated the presence of a distinct clade unique to India, named as clade I/A3i [32]. This cluster is characterised by a core set of 4 genetic variants and at a nucleotide substitution rate of 1.1×10^{-3} variants per site per year. The variations in the clade I/A3i were predominantly observed in the E and N genes compared to S gene (prevalent in the A2a cluster). All these observations validate the result that was obtained in this study. The SARS-CoV-2 sequences obtained from India represent a geographically unique cluster with a differential mutation patterns occurring across the genome compared to other clades across the globe. Therefore, the mutations occurring in the target regions where primer/probe sequences from the assays would bind eventually hamper the successful amplification of the genes during RT-qPCR resulting in possible false-negatives.

Accuracy of some of the assays observed in this study is in accordance with the previously published Results. For instance, CN-CDC-N assay from China targeting N gene displayed an accuracy of 54.26% which was comparable with 81.2% and 87.3% obtained by Khan & Cheung (2020) and Vogels et al.

(2020) respectively [16,30]. Similarly, none of the genomic sequences displayed exact match with the primer/probe sequences belonging to Charité-ORF1b from Germany targeting ORF1ab gene. The presence of a degenerative nucleotide (S) was found to be detrimental because of the presence of T in the corresponding position. This could be due to be fact that primers were designed earlier in the outbreak based on the sequences from SARS-CoV and bat-SARS-related CoV genomes. Therefore, removing this degeneracy would help improve the detection limit of this assay. On the contrary, the presence of degenerate bases in both primers and probe sequences involved HKU-ORF1b assay has proved beneficial, turned out to be one of the most accurate assays investigated in the study. We would like to point out that a mere single nucleotide mutation in the genomes would not have serious ramification in the successful amplification of the targets. Mismatches located within 5 bp from 3′ end of the primers and in the probe regions are known to have serious implications in the amplification of targets while mismatches at any other position are well tolerated [33]. In our study, we could identify a single assay US-CDC-N1 containing mismatch in the 3′ end probe region. In the light we recommend using this primer in RT-qPCR assays with caution.

5. Conclusion

In this study, we have analyzed the binding accuracy of various primers and probes involved in commonly employed RT-qPCR assays for the detection of SARS-CoV-2. We could find that US-CDC-N-1from USA, CN-CDC-N from China, and Charité-ORF1b from Germany contained one or another mismatch, either in primer or probe sequences. The Results obtained in this study indicate that separate strategies, unique to specific geographical locations should be developed in the containment of pandemic. Given the number of available SARS-CoV-2 whole genome sequences in the database, novel primers with a higher accuracy could be developed. Further, this study provides an *in silico* template for re-assessing the diagnosis of COVID-19 through RT-qPCR.

ABSTRACT

Background: Globally, malnutrition among school age children is a major public health concern. The objectives of the study were to determine the prevalence of under nutrition (thinness and stunting) among children aged 6 to 14 years in a rural area of Coimbatore district; to determine the socio-demographic factors influencing under nutrition (thinness and stunting) among these children.
Methods: A community based- cross sectional study was conducted from December 2015 to July 2016 in the field practice area of PSG Rural Health Training Center Vedapatti. Out of the 14 villages in this area, five villages (clusters) were selected by cluster sampling. Data was collected from 702 children aged 6 to 14 years in these five villages using a structured questionnaire. Z score was used to calculate nutritional status. Thinness is defined as the BMI for age (BAZ) <-2SD.Stunting is defined as the Height-for-age (HAZ) <-2SD.The association of Thinness with socio-demographic factors were studied by univariate analysis. The association of Stunting with socio-demographic factors were studied by univariate analysis and logistic regression analysis.
Results: The prevalence of Thinness was 15.5% (95%CI: 12.82% to 18.18%) and that of stunting was 18.8% (95%CI: 15.91% to 21.69%). In univariate analysis there was no statistically significant association between thinness and socio-demographic factors. Stunting showed statistically significant association with educational status (illiteracy) of mothers and working mothers in logistic regression analysis.
Conclusions: The current study revealed that undernutrition as indicated by thinness and stunting was prevalent to some extent among these children. Stunting was significantly higher among those children whose mothers were illiterate and working. Health education and encouraging working mothers will help to solve this.

Keywords: Thinness, Stunting, BAZ, HAZ, Coimbatore

INTRODUCTION

Globally, malnutrition among school age children is a major public health concern. More than 200 million school age children are stunted and underweight and if no action is taken and at this rate, about one billion school children will be growing up by 2020 with impaired physical and mental development.[1-5]

Malnutrition is the underlying cause of one third of the 7.6 million child deaths each year before their fifth birthday. Meeting this challenge is doubly urgent because among children who survive, chronic malnutrition causes devastating and irreversible damage.[6] Lack of nutritious food, coupled with infection and illness, means their bodies and brains don't develop properly and at least 170 million children are affected by stunting.[7,8] Conditions of

early life (from conception to two years) provide the foundations for adult life. Vicious interactions between malnutrition, poor health, and impaired cognitive development set children on lower development paths and lead to irreversible changes.[9]

The prevalence of malnutrition among children in India is highest in the world. Malnutrition in school going children is responsible for 22% of the country's burden of disease. Recent reports showed that Tamil Nadu has shown gains in terms of reduction of the problem of malnutrition, but it still has a high percentage of malnourished children.[11] However, there are only a few studies regarding under nutrition among children aged 6 to 14 years reported from Coimbatore. Hence this study was undertaken to estimate the prevalence of under-nutrition in the rural field practice area of the Department of Community Medicine of PSG Institute of Medical Sciences and Research, which will help in devising suitable strategies to reduce this problem in this area.

Objectives

The objectives of this study are to estimate the prevalence of under nutrition (Thinness and Stunting) among children aged 6 to 14 years in a rural area of Coimbatore district and to determine the socio-demographic factors influencing under nutrition (Thinness and Stunting) among children aged 6 to 14 years in a rural area of Coimbatore district.

METHODS

Field practice area of PSG Rural Health Training Center, Vedapatti containing 14 villages was selected for this study. Totally 2985 children of 6 to 14 years (School age children) were living in these 14 villages. The sample size calculated was 702, assuming prevalence of undernutrition as 29%, absolute precision of 5%,design effect of 2, and non response rate of 10%.[12,13] Five out of the 14 villages (clusters) were selected by cluster sampling. A community based- cross sectional study was conducted from December 2015 to July 2016 in these five villages, and data was collected using a structured questionnaire.

All the school-age children (aged 6–14 years) who were permanent residents in these five villages were included in this study. School- age children (aged 6–14 years) who were absent for 3 visits within a week were excluded. The number of children included in this study was 702. Ethical clearance was obtained from Institutional Human Ethics Committee, PSGIMSR. Informed consent from parent and assent from the child were obtained.

Age of the child, sex of the child, total number of family members, type of house, educational status of the mother, occupation of the mother, educational status of the father, occupation of the father, socio economic status (modified Prasad's classification), were the socio- demographic factors were considered as independent variables. Thinness and stunting were considered as dependent variables.

Standing height was measured (to 0.5 cms) using stadiometer, without shoes, the child standing erect and looking straight so that the inferior orbital margin and the tragus of the ear fall in a horizontal plane parallel to the ground. An electronic weighing scale was used to measure the weight in kilograms. The scale was calibrated. Zero error was checked, children were without shoes, in shirt and trousers or skirt. The weighing machine was placed on a firm and flat ground. Weight was recorded to the nearest 100 grams. The same balance was used throughout the study. Body Mass Index, and Height for age were expressed in standard deviation units (Z scores) from reference median as recommended by 2007 WHO growth reference for (5-19 years). The calculation for Modified Prasad's classification was done using the multiplication factor as 57.07 and Consumer Price Index for Industrial Workers (November 2015) in Coimbatore area as 250.[14] Age of the child was calculated from the date of birth to number of completed years of the child.

Thinness is defined as the BMI for age (BAZ) <-2SD. Stunting is defined as the Height-for-age (HAZ) <-2SD.

The various Interpretation of cut-offs of (BAZ)[15] are:

Overweight: >+1SD (equivalent to BMI 25 kg/m^2),
Obesity: >+2SD (equivalent to BMI 30kg/m^2),
Thinness: <-2SD, Severe thinness: <-3SD
Interpretation of cut-offs for (HAZ) are:
Stunting: HAZ <–2 Z score, or <3rd percentile
Severe stunting : <-3 Z score

All the data collected was entered with MS Excel and imported to WHO Anthro software. Z score was arrived by Anthro+ package using WHO standards for nutritional status classification. The output of Anthro was analyzed with SPSS version 19. Prevalence was expressed in percentage with 95% confidence intervals (CI). Distribution of Socio-demographic factors of the study participants were expressed in percentage. The association of thinness with socio-demographic factors was studied by univariate analysis. The association of stunting with socio-demographic factors was first studied by univariate analysis and those factors found significant were subjected to logistic regression analysis.

RESULTS

A total of 702 children aged 6 to 14 years residing in the five villages were studied. Majority of the participants were female children, belonged to nuclear families and low socio economic status. Regarding educational status, 19.5% of mothers and 17.7% of fathers were illiterate. We found 36.8% mothers were home makers.

Table 1: Association of thinness with socio-demographic factors by univariate analysis.

Factors	Category	Thinness		Unadjusted odds ratio (95% confidence interval)	P value
		Yes	No		
		N (%)	N (%)		
Age in years	Age less than 10	54 (15.6)	292 (86.4)	1.01 (0.67-1.52)	0.52
	Age 10 and above	55 (15.4)	301 (84.6)	1	
Sex	Female	50 (13.5)	321 (86.5)	0.72 (0.48-1.08)	0.07

Table 3: Association of stunting with socio-demographic factors by logistic regression analysis.

Factors	Category	Adjusted Odds Ratio (95% CI)	P value
	Illiterate	1.609(1.02-2.55)	0.04*
	Literate	1	
Mother's occupation	Not working	0.624(0.41-0.95)	0.03*
	Working	1	
Socio economic status (modified Prasad Scale)	Lower SES (Class IV,V)	1.460(0.97-2.20)	0.07
	High SES (Class I,II,III)	1	

(*p<0.05 statistically significant).

The overall prevalence of Thinness (including severe thinness) and stunting (including severe Stunting) as 15.5% (95%CI: 12.82% to 18.18%), 18.8% (95%CI: 15.91% to 21.69%) respectively.

The nutritional status based on BAZ Score shows that thinness was noted among 11.4% of the children and 4.1% were severely thin. Over weight was noted among 7.3% of the children and obesity was noted among 3.8%. The nutritional status based on HAZ Score showed that. Stunting was noted among 13.8% children and 5% children were severely stunted

There was no statistically significant association between the socio-demographic factors and thinness by univariate analysis as shown in Table 1. Table 2 shows the association of stunting with socio-demographic factors by univariate analysis. Educational status of mother (illiterate), working status of mother (non working) and low socioeconomic status were significantly associated with stunting by univariate analysis. However other demographic factors showed no statistical significance**.** The factors which were significantly associated with stunting by univariate analysis were subjected to logistic regression analysis and the results in Table 3 showed that educational status and working status of mothers are significantly associated with stunting. However, low socioeconomic status showed no statistically significant association with stunting in logistic regression analysis.

DISCUSSION

The overall prevalence of thinness in the current study was 15.5%. This finding is similar to that found in a cross sectional study conducted by Vinoth et al during 2013 in Southern part of India among school children of age (9-17 years), based on WHO-BAZ scores in which the prevalence of thinness was reported to be 13%. However, a higher prevalence was reported in few other studies.[16] Bose et al did a cross sectional study in 2007 among Bengalee Hindu children aged 6-14 years and showed the prevalence of thinness as 23.1%.[17] Anjum et al conducted a cross sectional study in Kashmir in 2008 among 5-14 year old children and reported 29% prevalence for thinness.[18] Chakraborty et al conducted a cross sectional study among 5-10 year old school children of Nandigram in 2003 and showed the prevalence of thinness was 62.9%.[19] Sameena et al conducted a cross sectional study in Aligarh in 2010 among 6-12 year old children and found a very high prevalence of thinness of 79.4%.[20]

The overall prevalence of stunting in our study was 18.8%. This finding is similar to that found in certain other studies conducted in India. The cross sectional study conducted by Vinod et al reported the prevalence of stunting as 19.8%.[16] Bose et al showed the prevalence of stunting as 17.2%.[17] Ruchika et al conducted a cross sectional study from Allahabad and reported a prevalence of 17.3% for stunting among children of 7-10 years age group.[21] Chowdhary et al from West Bengal conducted a cross sectional study among the 442 Santal children of Puruliya district of West Bengal aged 5-12 years and reported the prevalence of stunting as 17.0%.[22] Bandopadyay et al conducted a study in Navinagar Mumbai among school children (aged 5 to 17 years), and reported the prevalence of stunting as 16.8%.[23] A higher prevalence (40.4%) of stunting was found in a cross sectional study conducted by Hasan et al in Bangalore in 2010 among 6-14 year old children.[24] However Anjum et al found a lower prevalence (9.25%) for stunting.[18]

Regarding the various factors influencing thinness, none of the socio-demographic factors included in our study was found to have a statistically significant association with thinness. However, Vinod et al found that factors like literacy level of the mothers, occupational status of the mothers and socio economic status had a statistically significant association with thinness.[16]

Regarding the various factors influencing stunting, we found a significantly higher prevalence among those children whose mothers were illiterate. This may be due to lack of awareness of mother regarding nutritional status of her children. Srivastava et al showed that mother's education was found to be a strong predictor of child nutritional status.[1] Those children whose mothers are working were also found to have more stunting and the probable explanation is that working mother often finds less time to care for her children. Srivastava et al showed that children of nonworking mothers have better nutritional status than children of working mothers.[1] However, Sameena et al reported higher prevalence of stunting among children whose mothers were not working.[20] Mukherjee et al reported no significant relationship between the working status of mothers and prevalence of malnutrition in their study children.[25]

Our study has certain limitations. This study being a cross sectional study, the existence of a cause-effect relationship cannot be inferred. Regarding the factors influencing thinness and stunting, only socio-demographic factors were looked into in our study.

CONCLUSION

The current study revealed that under-nutrition as indicated by thinness and stunting was prevalent to some extent among the children aged 6 to 14 years in this rural community. It was observed that stunting was significantly higher among those children whose mothers were illiterate and working. Health education is to be given to mothers to create awareness about the problem of under-nutrition including its reduction and working mothers to be encouraged to pay more attention towards the health of their children.

ABSTRACT

Background: New innovations in technology produce large opportunities in communication, information and social interaction. The excess in unwanted use of internet by people led to internet addiction. Psychological, environmental and socio demographic factors in the lives of college students may leave them disproportionately vulnerable to internet addiction. **Aims and objectives:** This study was conducted with objectives to determine the prevalence of internet addiction among medical and health science students and its socio demographic correlates. **Material and methods:** This cross sectional study was conducted on medical and health science students at PSG Institute of Medical Sciences and Research and PSG College of Physiotherapy, Coimbatore. A total of 490 students were selected by simple random sampling. Validated internet addiction scale was used to assess the internet addiction. **Results:** Of the 490 students studied, 140(28.5%) students were having internet addiction. The factors associated with internet addiction were gender(males) ($p<0.01$) and those take frequent junk food ($p<0.001$).**Conclusion:** We had observed a high prevalence of internet addiction in medical and physiotherapy students. So strategies for controlling internet addiction is mandatory for healthy and safe use of internet, particularly students studying at professional colleges.

Key Words: Internet addiction, Medical students, Internet addiction score, Young's internet addiction scale, Likert scale

INTRODUCTION

The prevalence of internet addiction has increased dramatically in these decades. The majority cases of internet addiction could be prevented by changes in lifestyle[1]. Many studies have reported that internet addiction is more common in men than women[2]. Globally, about half of the population are using internet through smartphones. In developing countries like India, population using internet increases rapidly from 5 million in 2000 to 137 million in 2012[2]. A research conducted by Indian Market Research Bureau in June 2013, indicates that the internet usage in India has gone up with more and more internet users using the internet on a regular basis[2]. Nearly 71%of the world internet users are constituted by young people aged 15-24[3].

The rapid expansion and proliferation of the internet has provided better opportunities for communication, information and social interaction[2]. Internet technology was originally designed to facilitate communication and research activities, however the dramatic increase in the use of internet in recent years has led to internet addiction which is classified into a disorder by WHO[4-6]. After effects of internet addiction includes the impairment of academic performance, psychological wellbeing and interaction with family members, depression, anxiety, sleep disorders and dissociative experience. Studies were also shown that younger internet users were more at risk of becoming internet addicts than older users[5]. Psychological and environmental factors in the lives of college students may leave them disproportionately vulnerable to internet addiction[6]. Although there were studies reported on the association of socio demographic and clinical factors associated with internet addiction among college students, the relationship between dietary behaviour and lifestyle factors such as regular exercise, place of origin, education of parents on internet addiction among college students is unclear and more studies are needed.

The aim of the study is to assess the prevalence of internet addiction and its association with socio-demographic and lifestyle factors among medical and health sciences students.

MATERIAL AND METHODS

Study location and design: This cross sectional study was conducted at PSG Institute of Medical Sciences and Research, Coimbatore and PSG College of physiotherapy, Coimbatore during April to July 2019. The study got

approval from Institute Human Ethics Committee and the consent of college and students were procured before the start of the study.With an expected prevalence of internet addiction of 50% and with 10% allowable error of the prevalence, 95% confidence limits and 20% non-response,the required sample size is 500. To meet the required sample size, 50% of the students from each batch (first year, second year, third year and forth year) were selected by Simple Random Sampling Technique. Informed consent was obtained from each study participant and administered a semi structured questionnaire as the study tool. Thus a total of 490 study participants were recruited from both the colleges.

The study tool has two parts. Part A consisted the socio demographic and lifestyle factors include year of the study, gender (male, female),regular exercise(yes, no),frequent junk food consumption (yes, no), residence(home, hostel, others), origin(city, town, village, others), father's education(below undergraduate, under graduate, postgraduate, others), mother's education(below undergraduate, under graduate, post graduate, others) and gadget(desktop, laptop, mobile, others).

Part B is the validated internet addiction questionnaire to measure internet addiction. The scale comprises of 20 questions, each questions had score ranging from 0-5(0=never, 1=rarely, 2=occasionally, 3=frequently, 4=often, 5=always)[7]. Based on these total scores, participants were classified as: normal user (score as: <50) and addicted user (score as:>=50).

The data were analyzed using SPSS version 24. Socio demographic variables and patterns of internet use have been described by frequency tables. The prevalence of internet addiction was described in terms of percentage. The descriptive statistics were calculated based on mean, standard deviation for quantitative variables and percentages for categorical variables. The association between internet addiction and socio demographic variables was assessed using Chi-square test and then performed a Multiple Logistic Regression analysis with internet addiction as dependent variable and independent variables including several socio demographic and life style factors.In all calculations, p value less than 0.05 was considered as statistically significant.

RESULTS

A total of 490 students were studied and there were 197(40.2%) males and 293(59.7%) females. 120 students were from 1st year, 134 students were from second year, 132 students were from third year and 104 students were from final year. Out of 490 students studied, 140 (28.5%) students were having internet addiction(Table 1). It was observed that males were reported more internet addiction than females (p<0.001).Students consuming junk food frequently were also more addicted than who were not frequently consuming (p<0.001)(Table 2). In the Multivariate analysis gender(males)(p<0.001) and those frequently consuming junk foods (p<0.001) were significantly associated with internet addiction(Table 3).

Table 1:Distribution of the students studied

Year of study	College of physiotherapy			College of medicine			Total

DISCUSSION

Internet addiction has been found important as a new and increasing global problem. The consequences of Internet addiction has a huge impact on students, physically and mentally,including changing the lifestyle in order to spend more time on the internet, neglecting their own health, avoiding of major life activities, reducing the social relations, ignoring the family and friends[8-10]. The prevalence of internet addiction varies from 2% to 18% worldwide and from 0.3% to 11.8% inIndia[3,11-17].The world has witnessed an explosive growth of internet users; globally more than half of the population is using the internet[18-20]. Internet user population has increased from 360 million in December 2000 to 2.4 billion in June 2012[2]. In Asia it has grown from 114 million internet users on December 2000 to 1.07 billion in June 2012[2].

Gender has a statistically significant association with internet addiction in this study. The finding has been corroborated by many previous researches explained this gender difference with a reason that males involve more in online activities such as gaming, gambling, pornography etc.[2,10-19]. In general, men are more likely to enjoy searching for information of personal interest other than the requirements of work [20-23]. Men seemed to enjoy interactive online games more than women,which draw upon power and dominance. Men seem to enjoy the aspects of violence and dominance in such interactive games[24-27].Cyber sex is another area men seemed more attracted to than women. In general, men were more openly drawn to the sexually explicit material accessible through the internet[28-30].

One of the more important finding that is revealed through our study is that junk food addicts are more likely to be internet addicts than normal people. Previous studies do not give us any effective results on the relation of junk food consumption and internet addiction. These junk food are nutritionally poor and this is universally recognized as they have very little or no vitamins, minerals and proteins and rather have a high content of salt sugar and calories that can lead to numerous health conditions when ingested in large quantities. Though it is universally accepted that these "junk food" cause numerous health issues both on a short term and long term basis, a large population of people have been found addicted to it[31-34]. The brain has perceives the food we eat in an unique way. Evolution has been a major contributor in the fact that the entire human race as a whole are more likely to ingest carbohydrates and fats when compared to vitamins, minerals and proteins as it provides an immediate energy supply and contributes to increased blood sugar levels but due to the increasing sedentary lifestyle of people, this is leading to be a major risk factor. It has been demonstrated that when some food is ingested and it reaches the GIT, impulses are immediately sent to the brain. A vast segment of nerve supply is found connecting the brain and CNS to the gut[31]. In the brain exists a pathway called the reward pathway, the reward pathway involves several parts of the brain, the ventral tegmental area (VTA), the nucleus accumbens, and the prefrontal cortex. When activated by a rewarding stimulus (e.g., food, water), information travels from the VTA to the nucleus accumbens and then up to the prefrontal cortex. It has been found that the gastrointestinal tract sends signals to the brain's reward circuits every time junk food is consumed. In the presence of calories in the gastrointestinal tract triggers the release of dopamine, the major chemical transmitter acting on the reward circuitry.A particular lipid messenger in the gut, known as oleoylethanolamine (OEA), controls the brain's perception of reward value when it comes to food.[31] A recent study byTellez, et al.found that the brain's reward circuitry is highly sensitive to the energy content of foods, independent of sensory properties such as flavour[31]. It means that calorie sensing in the gastrointestinal tract is an important

activator of this brain's reward circuitry, and thus can cause alterations in gastrointestinal physiology. Thus the consumption of junk food leads is presumed to trigger the reward circuitry of the brain and found to have same effect on the reward circuitry just like addictive drugs like cocaine and heroin. Brain's reward circuitry was active in people those frequently consuming junk food, which make them vulnerable to internetaddiction[31-36].For susceptible people, eating junk foods can lead to full-blown addiction, which shares the same biological basis as addiction to abusive drugs.

Our study has some limitations. First, the prevalence of internet addiction is difficult to establish accurately because of limitations related to the population screened, the unwillingness of subjects to participate and unreliability on the history of internet usage revealed by study subject and hence its accuracy is unknown. Second, we have not collected the information from the students studying at Government colleges. Third, since the students were asked to report details of exposure and use to internet, recall bias cannot be ruled out. Another limitation of the study is that since there was self-reporting of data and hence social desirability bias can also be present.

Despite these limitations, our study has several strengths.The main strength of the study includes scientific selection of variables.We have selected students from various classes and that also selected both from medical and allied health sciences students. Thus we studied a heterogeneous representation of college students.Sampling bias has always been a major drawback of many of the earlier studies.This study has tried to minimize this bias by not sending the questionnaire by email or group networks instead the investigators went to the class and collected the required information. We have used a validated questionnaire and questionnaires were answered anonymously and the investigators were kept away from the classrooms where information was being collected.

Conclusion

In conclusion results from our study suggest that internet addiction was observed in one third of thesubjects. The explosive growth of the internet in the last decade had a huge impact on communication and inter-personal behavior. The present study unfolds that internet addiction in the majority of medical students is a dark reality that recovers timely remedial action of detection of internet addiction therefore assumes greater importance in professional institutions such as medical colleges. It is essential to develop strategies for the prevention of internet addiction. As an emerging global issue, awareness should be created among the students to reduce the occurrence of internet addiction behaviour and for promoting their healthy growth[33-37].Further analysis of internet addiction with usage patterns will be reported in a subsequent paper.

Prevalence and correlates of anemia among women in the reproductive age (15–49 years) in a rural area of Tamil Nadu: An exploratory study

A. Jenit Osborn, G. M. Muhammad, S. L. Ravishankar, Anil C. Mathew

Abstract:

BACKGROUND: Anemia is a major public health problem among reproductive-aged women in India. Despite many programs implemented for decades to fight anemia, still the prevalence of anemia is high because its associated factors vary among different regions. This exploratory study was carried out to find the prevalence of anemia and factors influencing it among nonpregnant reproductive-aged women (15–49 years) in a rural area of Coimbatore.

MATERIALS AND METHODS: The study was conducted in the field practice area of Rural Health Training Centre, PSG IMSR, Coimbatore, during March 2016 to August 2016. Participants were recruited by two-staged random sampling method and 426 participants were enrolled. A predesigned semi-structured questionnaire was used to collect the data pertaining to the factors influencing the prevalence of anemia, and their hemoglobin level was measured using a hemoglobin photometer. The data were analyzed using SPSS-24. (IBM Corporation, SPSS Inc., Chicago, IL, USA) Univariate analysis was done using Chi-square test and the strength of association was estimated by odds ratio. Those factors which were found to be significant by univariate analysis were further subjected to multivariate logistic regression analysis. $P < 0.05$ was considered statistically significant.

RESULTS: The prevalence of anemia was estimated as 64.8% (95% confidence interval: 60%–69%). Significant predictors for anemia among the study participants were less frequent intake of green leafy vegetables (adjusted odds ratio [AOR] = 3.65, confidence interval [CI]: 2.17–6.12), low socioeconomic status (AOR = 3.36, CI: 1.93–5.84), illiteracy (AOR = 3.09, CI: 1.09–5.24), birth spacing <2 years (AOR = 2.49, CI: 1.19–5.25), excessive menstrual bleeding (AOR = 2.27, CI: 1.09–4.76), and inadequate knowledge regarding anemia (AOR = 2.03, CI: 1.19–3.44).

CONCLUSION: Anemia is still prevalent in high magnitude in reproductive-aged women, and measures to prevent and control it are not optimum. Hence, its multifactorial determinants have to be addressed to alleviate its burden.

Introduction

Anemia is a major public health problem, affecting 24.8% of the global population. The prevalence of anemia is disproportionately high in developing countries compared to developed countries due to poverty, illiteracy, inadequate dietary intake, certain infectious diseases, frequent pregnancy, and poor access to health services. The most vulnerable groups affected by anemia are children, adolescent girls, and women in the reproductive age, especially pregnant women.[1] Anemia can reduce the quality of life, leading to a substantial economic

How to cite this article: Osborn AJ, Muhammad GM, Ravishankar SL, Mathew AC. Prevalence and correlates of anemia among women in the reproductive age (15–49 years) in a rural area of Tamil Nadu: An exploratory study. J Edu Health Promot 2021;10:355.

burden on the affected individuals and their families, communities, and societies.[2] According to the Fourth National Family Health Survey (NFHS-4), 54.4% and 56.9% of women of reproductive age are found to be anemic in rural areas of India and in Tamil Nadu, respectively.[3] Anemia is found to be more prevalent among reproductive-aged women in India, and it poses a significant morbidity risk, particularly among reproductive-aged women. Despite the fact that anemia is largely preventable and easily treatable if detected in time, it still continues to be a common cause of morbidity and mortality and is considered a silent killer.[4] This nutritional disability in the life of women will have adverse consequences on the developmental stages of the next generation and can have long-term impact and thus leave a perpetual effect.[5] The WHO recommends local studies for each region to provide baseline information for designing prophylactic and therapeutic strategies to control this problem.[4] Most of the studies carried out in different parts of the country are either hospital-based studies done among pregnant and lactating mothers or college/school-based studies done among adolescent girls, there is a scarcity of community-based studies among nonpregnant reproductive-aged women. Social, cultural, economic, and dietary features vary widely across India and hence the factors influencing anemia also vary based on the geographical location. Though the accurate data on the prevalence of anemia is essential to determine public health measures, in reality, accurate data are scarce in the study area, which impedes anemia preventive strategies. Identifying the local determinants and risk factors of anemia will help to plan for appropriate package of services to reduce the risks of morbidity and mortality associated with anemia and is one of the priorities for safe motherhood initiative.

Materials and Methods

Study design and setting

A community-based cross-sectional study was done in the rural field practice area of PSG Institute of Medical Science and Research, Coimbatore, during March 2016 to August 2016. The conceptual framework adopted in this study explains the possible causes of anemia and the interconnectedness of these factors in predisposing a woman to become anemic [Figure 1].[6]

Study participants and sampling

With an estimated prevalence of 55.4% from NFHS-4[3] study and 5% allowable error, and 20% nonresponse rate, the sample size was estimated as 480. The study participants were selected by two-staged random sampling method [Figure 2]. In the first stage, three villages were selected randomly from 14 villages. In the second stage, the required sample numbers were selected from three villages by probability proportional to the size of the villages. Individual participants from each village were chosen by SPSS-generated random numbers. Women in reproductive age group (15–49 years) who are permanent residents for at least 1 year were included, whereas pregnant women, those not willing to participate in the study, and absence at home on three visits were excluded from the study.

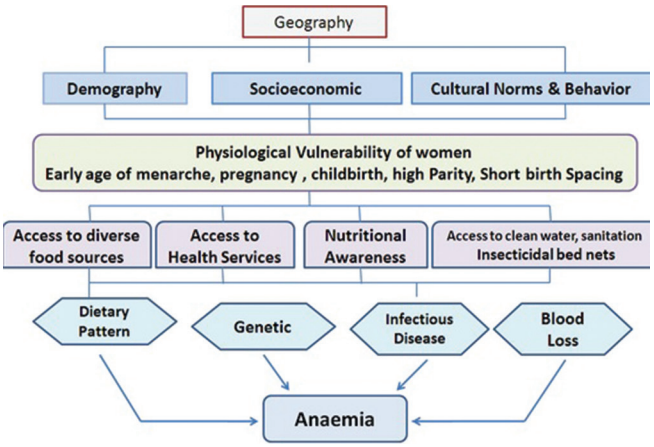

Figure 1: Conceptual framework for anemia among reproductive age women

Data collection tool and technique

After obtaining informed consent, a predesigned semi-structured questionnaire was used to collect the data pertaining to the factors influencing the prevalence of anemia namely demographic factors, socioeconomic, environmental factors, reproductive, and menstrual factors. Socio-economic status was assessed using Modified Prasad Classification. Knowledge was assessed by a series of twelve questions on causes, symptoms, complication, and prevention methods, and a scoring system was given and those who scored more than 50% were considered having adequate knowledge on anemia. Sixteen iron-rich food items were considered in our study based on the iron content given by the National Institute of Nutrition.[7] Height and weight were measured according to the WHO standard procedure,[8] and confidentiality of the study participants was ensured. Hemoglobin level was measured from capillary blood obtained by finger prick using a hemoglobin photometer, which is a reliable method in field surveys.[9] The sensitivity and specificity for the hemoglobin estimation by this photometer is 94.1% and 95.2%, respectively.[10] The Haemoglobin photometer was checked each day morning prior to data collection with the control microcuvette given along with the instrument by the manufacturer for the purpose of internal validation of the instrument. After every seventy samples examined by the photometer, the instrument was tested for reliability using same blood samples,

and it was also externally validated in the Pathology Laboratory of PSGIMSR using the Beckman Coulter LH 450 method. Difference in the value of hemoglobin was found to be in the range of 0.3–0.6 g/dL.

Ethical consideration

The study was carried out in accordance with the ethical standards of PSGIMSR Institutional Human Ethics Committee (IHEC – Proposal Code – 14/075), and the Ethical Principles for Medical Research was followed.

Operational definition

The WHO criteria for diagnosis of anemia in nonpregnant women with hemoglobin level <12 g/dL were used in this study. Grading of anemia was done on the basis of cutoff values: mild anemic (hemoglobin [Hb]: 11–11.9 g/dL), moderate anemic (Hb: 8–10.9 g/dL), and severe anemic (Hb: <8 g/dL).

Statistical analysis

Data were analyzed using SPSS-24. The prevalence of anemia was estimated with 95% confidence interval (CI). The associations between independent variables and hemoglobin level were tested using Chi-square test and the strength of associations was obtained using odds ratio. The variables which were found to be statistically significant in univariate analysis were further subjected to multivariate logistic regression analysis. $P < 0.05$ was considered statistically significant.

Results

Of the selected 480 women of reproductive age, 37 of them did not participate due to fear of finger prick, 7 of them were pregnant, and 12 of them were not present in their house during three visits and hence excluded from the study. A total of 426 nonpregnant women in the reproductive age group were enrolled in the study.

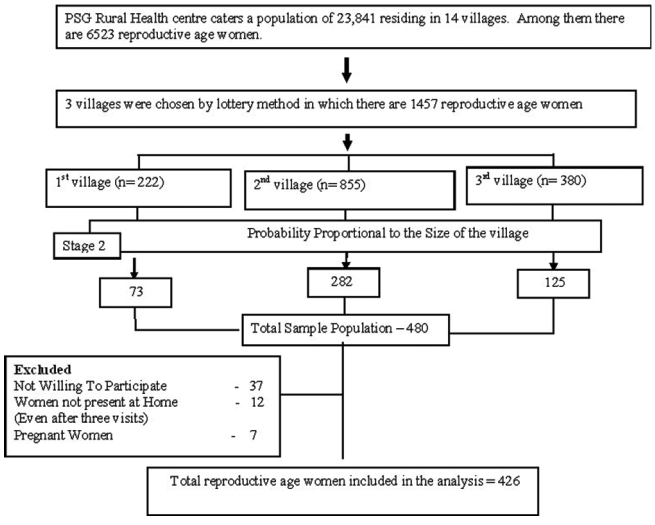

Figure 2: Flow diagram showing the sampling procedure

The demographic profile of the study participants is shown in Table 1. 18.8% of the study participants were in the age group of 25-29 years, 26.7% had education up to high School, higher proportion (63.8%) of the study participants were not working and majority of them (92.7%) belonged to Hindu religion. 71.6% of the participants were residing in a nuclear family and 37% of them belonged to low-socio-economic class (Class IV and V).

Table 2 shows the reproductive characteristics of the study participants. Nearly 75.6% of them have attained menarche before the age of 14 years, and 79.6% of the participants were married. Among those who were married, 25.7% of them got married before the age of 18 years, 9.6 % of them have more than 2 children, 28.6% have a history of abortion, and 8.3% of the individuals are currently using IUD. Among 218 people having two children and more, 45.4% had birth spacing <2 years. 10 participants had hysterectomy done, and 19 of them have attained menopause. Of the remaining 397 participants,

IUD=Intrauterine device

21.2% of them had irregular menstrual cycle and 19.5% of the individuals had excessive menstrual bleeding.

Regarding the environmental factors, only 64.3% of them were having toilet facility in their homes, 20.4% of them were having the practice of open-air defecation, and the rest were using community toilets. Almost 5.9% of the participants had the habit of barefoot walking, 8.2% of them had a history of passing worms in the stool, and 20% of them did not have the habit of washing hands with soap after defecation.

Regarding knowledge, 49.1% of them had adequate knowledge regarding anemia – its cause, symptoms, methods to prevent anemia – and knowledge regarding iron-rich foods. Almost 87.3% of the participants were on mixed diet and 40.1 of them have the habit of taking coffee along with food. Nearly half (48.6%) of them were having normal body mass index (BMI), while 19% of them were undernourished and 32.4% were overweight/obese. The mean BMI of the study participants was 23.03 ± 4.71 kg/m^2.

Prevalence of anemia

The prevalence of anemia among the study population was 64.8% (95% CI: 60–69). The mean hemoglobin of the study participants was 11.34 ± 1.63 g/dL. Out of the 276 anemic women, 55.07% of them were mildly anemic, 35.15% were moderately anemic, and 9.78% of them were severely anemic.

Factors influencing prevalence of anemia

The contributing factors associated with anemia in descending order as revealed by multivariate logistic regression [Table 3] were intake of green leafy vegetables (GLVs) (<2 times weekly), socioeconomic status (class IV and V), illiteracy, birth spacing <2 years between last two pregnancies, excessive menstrual bleeding, and inadequate knowledge regarding anemia. Factors such as open air defecation habit, history of passing worms in stool, not washing hands with soap after defecation, attained menarche <14 years of age, irregular menstrual cycle, following vegetarian diet, those having the habit of drinking coffee along with food, those having low BMI, intake of whole grains and mutton less frequently, which were found to have a significant association on univariate analysis did not show a significant association with anemia in the multivariate logistic regression analysis. There was no significant association between anemia and type of family, habit of barefoot walking, marital status, age at marriage <18 years, age at first child birth <19 years, having more than two children, current IUD usage, and other iron-rich foods.

Discussion

Anemia is largely preventable and easily treatable if the local determinants are identified. The WHO and UNICEF therefore reemphasize the urgent need to combat anemia and stress the importance of recognizing its multifactorial etiology for developing effective control programs.[11] Our study showed the prevalence of anemia to be 65% (95% CI: 60%–69%), which is 10% higher compared to NFHS-4[3] survey. According to the WHO, if the prevalence of anemia at community levels is more than 40%,[1] it is considered a problem of high magnitude.

Out of the 276 anemic women, majority of them were mild to moderately anemic and only few of them were severely anemic, which was consistent with that of other studies.[12,13] Hence, its prevention is essential for child

survival and safe motherhood.[14] The identified anemic women were referred to the Rural Health Training Centre for further management. Data from the National Nutritional Monitoring Bureau Surveys[5] show that Indian women have a sustained low intake of iron, which may be due to various reasons such as economic, social, and lack of empowerment.

In our study, we identified six factors which had a significant association with anemia. The mean

hemoglobin level of significant predictors for anemia in the current study is shown in Figure 3. The first risk factor which was found to have statistical significant association with higher risk of anaemia was the intake of GLV. The study participants who took GLV less than twice a week had three times higher risk of becoming anaemic and this finding was also observed in other studies.[15,16] GLV is a good source of iron, and inadequate intake of GLV is one of the important causes of anemia. It is followed by socioeconomic status which had an inverse relationship with anemia. This finding is consistent with that of other studies.[17-19] Poor socioeconomic status is known to be associated with a number of factors such as high parity; short birth interval; poor diet, both in quantity and quality; lack of awareness regarding health and nutrition; a high rate of infectious diseases and parasitic infestations; as well as limited access to medical attention.[12]

The current study reveals the fact that illiterates have about three times higher risk of becoming anemic. Similar findings have been observed in other studies.[20,21] Better educated women enjoy the privilege of higher paying jobs and live in better environment, which will have a positive influence on their nutritional status. In our study, another factor associated with anemia is birth spacing, which is a similar observation in other studies also.[22,23] Repeated pregnancies at short interval deplete the iron stores, thereby leading to anemia, which depict the need for contraception education.[24]

Excessive menstrual bleeding is said to be present when a woman has long duration of menstruation (>5 days) or if there is passage of clots during the menstrual period. In the present study, those with excessive menstrual bleeding had two times higher risk of anemia. Similar findings have been observed in other studies.[19,23,25] We also observed that there was a significant association between inadequate knowledge regarding anemia and risk of anemia, which was similar to the findings of other studies.[26,27] Due to lack of adequate knowledge on anemic causes, ill effects, and preventive measures, incorrect choice of food can lead to nutritional deficiency,

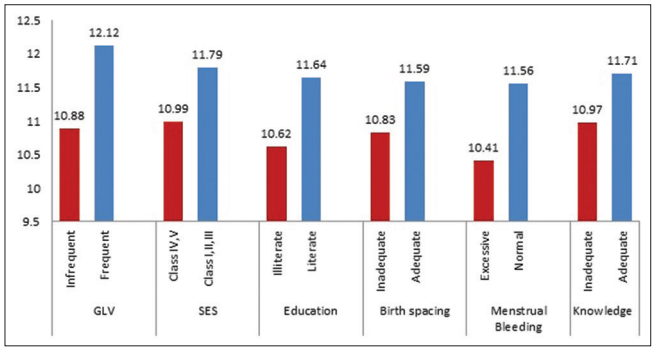

Figure 3: Mean hemoglobin levels of significant predictors for anemia in the current study

making them more prone to become anemic. No significant association was found between hemoglobin concentrations and anthropometric measurements, which was similar to that of another study.[28] Other demographic, reproductive, and socioenvironmental factors did not show a significant association with anemia.

India was the first developing country to commence a National Anaemia Prophylaxis Programme during the 4th five-year plan in 1970, providing iron and folic acid supplementation to all pregnant women and children with an aim to reduce the prevalence of anemia to below 25%.[29] The current study highlights that anemia still remains a public health issue of great magnitude among nonpregnant reproductive-aged women, even after nearly 50 years into the program. Women of childbearing age are at risk of anemia not only throughout their reproductive years but also during pregnancy. Measures to prevent and control anemia so far have largely been ineffective, hence strategies to combat anemia, therefore, should address all the causal factors and focusing our thrust on iron supplementation alone may not be able to provide the much-desired effect because the pathogenesis of anemia is multifactorial. First, the system of periodic screening for anemia among women of childbearing age should be developed and it should be considered one of the important primary healthcare activities at the center. Second, an IEC program to change knowledge, attitudes, household dietary practices, and kitchen garden activities is required to effect positive changes in consumption patterns, thereby improving the nutritional status. Economic empowerment of women can be attempted by organizing the women to form a self help group in order to carry out small scale business and thereby paving a way for small income. Optimal birth spacing (Minimum two years) should be enforced and the reproductive aged women should be made assertive to it.

Further studies are needed to determine the specific types of anemia and the quantum of dietary intake of iron, thereby giving a better insight into the situation.

Limitation

The study has few limitations. Because it is a cross-sectional study, cause–effect relationship cannot be determined. Dietary history was limited to self-reported food frequency, hence the quantum of dietary intake of iron could not be ascertained and confirmation of worm infestation by stool examination was not possible due to operational difficulty.

Conclusion

Anemia has been recognized as a public health problem for many years, but only little progress has been made in its control. The best predictors of anemia in descending order are intake of GLVs (<2 times weekly),

socioeconomic status (class IV and V by the Modified Prasad classification), illiteracy, birth spacing <2 years between last two pregnancies, excessive menstrual bleeding, and inadequate knowledge regarding anemia. Hence, to alleviate anemia burden, measures such as economic empowerment, improvement in awareness regarding anemia, dietary practice of taking frequent GLVs and making it easily available, and contraceptive education should be provided by an integrated multifactorial and multi-sectorial approach.

Abstract

Introduction: India is the first country to implement National Family Program in 1952. Acceptance of contraceptive methods is influenced by various factors at the individual, family, and community level with their roots in the socioeconomic and cultural milieu of Indian society. This study was carried to find the contraceptive prevalence rate among eligible couples as well as to find the factors influencing it in a rural area of Coimbatore. **Methodology:** The study was carried out using the data extracted from the family health survey conducted by trained field staff for the purpose of furnishing details regarding people residing in the field practice area of Rural Health Training Centre (RHTC), Vedapatti located in Coimbatore district after obtaining Institutional Human Ethical clearance. All eligible couples were included for the study. Contraceptive prevalence is expressed in percentage with 95% Confidence interval. Univariate analysis (Chi-square test) was done to find the association between contraceptive acceptance and independent variables. Strength of association is determined by odds ratio with 95% Confidence Interval (CI). $P < 0.05$ was considered statistically significant. **Results:** Contraceptive Prevalence Rate among eligible couples was found to be 75% (95% CI: 73.6–76.4). Most commonly used method among the study participants was tubectomy (81.6%), followed by condoms (11.4%), intrauterine devices (6.3%), and oral contraceptive pills (0.7%). Higher age of the women, religion, educational status of the women, socioeconomic status, working status of the women, number of living children, age at the time of marriage, and age at the time of first child birth were found to have statistical significant association with higher usage of contraception. **Conclusion:** The contraceptive prevalence rate was found to be higher in this study population and multiple factors were influencing the contraception usage among the eligible couples.

Keywords: Contraceptive prevalence, eligible couples, rural population

Introduction

Population explosion has been the major problem of India since Independence.[1] Considering the consequences, population stabilization has been identified as an essential prerequisite for the economic development of the nation resulting in improved quality of life.[2] India became the first country in the world to formulate National Family Planning Program in 1952, with the objective of "reducing birth rate to the extent necessary to stabilize the population at a level consistent with requirement of national economy."[2,3] As per the projections by United Nations, India will become the most populous country by the year 2045. One of the important components of family planning program management is to assess the potential demand for contraceptive services so as to mitigate the adverse impact of population growth.[4] Family planning can reduce maternal mortality by reducing the number of pregnancies, abortions, and the proportion of births at high risk.[5]

How to cite this article: Osborn JA, Rm S, Karthikeyan S, Ravishankar SL. A study on contraceptive prevalence rate and factors influencing it in a rural area of Coimbatore, South India. J Family Med Prim Care 2021;10:2246-51.

Many empirical studies have shown the acceptance of contraceptive methods is influenced by various factors operating at the individual, family, and community level with their roots in the socioeconomic and cultural milieu of Indian society.[6] The contraceptive prevalence rate is "the percentage of women of reproductive age (15–49 years) who are married or in a union: Who are currently using, or whose sexual partner is currently using, at least one contraceptive method, regardless of the method used".[7,8] Contraceptive prevalence rate serves as a proxy measure of access to reproductive health services and is an indicator of health, population, development, and women's empowerment[7,8] that are essential for meeting many of the Sustainable Development Goals (SDG), especially the child mortality and maternal health related goals.[8]

If the population has ready access to good quality services at affordable cost, it will be possible for them to meet all their needs, achieve the desired family size, and enable the country to achieve population stabilization rapidly.[1,9] Majority of India's population (about 70%) live in the rural communities[9] but majority of the health facilities are concentrated in the urban localities leading to a disparity in access to health care. Contraceptive use is influenced by a wide range of factors including demographic, social, and economic characteristics.

There is paucity of community-based rural studies with regard to contraceptive usage. Identifying the prevalence of contraceptive usage and the local determinants could help to plan strategy and make necessary recommendations that would help improve utilization of family planning services. Hence, this study was carried out to determine the contraceptive prevalence rate among eligible couples as well as to study the association of selected social, economic and demographic factors with contraceptive usage in a rural area of Coimbatore.

Methodology

The study was carried in accordance with the ethical standards of PSGIMSR Institutional Human Ethics Committee and Ethical Principles for Medical Research was followed. The Ethics committee approval was obtained prior to carrying out the study. Date of approval : 18/12/2019. The Institute permission was obtained prior to carrying out the study. In the current study, the data were extracted from the family health survey conducted by trained field staff for the purpose of furnishing details regarding people residing in the field practice area of Rural Health Training Centre (RHTC), Vedapatti, a rural area of Tamil Nadu located in Coimbatore district. The RHTC caters to 14 villages with a population of 25,886.

Sample size was calculated based on NFHS IV report- Contraceptive Prevalence Rate of rural Tamil Nadu was 52.3%.[10] Using the formula, $n = 4\,pq/d^2$ where P is 52, q is 100-52, that is, q = 48 and d is the relative precision (5% of p), the sample size required was estimated to be 1,477. Though the required sample size was only 1,477, all 4,438 eligible couples in the field practice area were included for the current study and their data was analyzed.

Various demographic, social, and economic factors like age of women, number of children, age at marriage, age at first child birth, religion, caste, family type, educational status of husband and wife, working status of women, socioeconomic status classification (based on Modified Prasad classification - Class I – ≥Rs. 6,414; Class II – Rs. 3,207–6,413; Class III – Rs. 1,924–3,206; Class IV – Rs. 962–1,923, and Class V - ≤Rs. 961) were included in the study.

Statistical analysis

Data was entered in Microsoft excel and analyzed in SPSS 20.0 version Univariate analysis (Chi-square test) was used to find out the association between the independent variables and the dependent variable. Odds ratio was calculated with 95% Confidence Interval (CI) to find the strength of association. $P < 0.05$ was considered as statistically significant.

Results

Total number of eligible couples enrolled in the study was 4,438.

The demographic profile of the participants is shown in the Table 1. Majority of the participants (41.3%) were in the age group of 35–49 years, 96.3% of women were Hindus. Majority of married women (70.4%) were living in nuclear families, 64% were

Table 1: Demographic profile of the study population

Variable	Number (*n*=4438)	Percentage
Age of Women (completed years)		
15-24	1196	27.0
25-34	1408	31.7
35-49	1834	41.3
Religion		
Hindu	4276	96.3

Number of Living Children		
No child	443	10
One child	777	17.5
Two child	2841	64
≥3 children	377	8.5
Age at the Time of Marriage		
<18 years	1152	26
≥18 years	3286	74
Age at the Time of First Child		
<18 years	957	21.6
≥18 years	3481	78.4

having two children, 26% of the women in the study population got married before completion of 18 years and 21.6% women delivered a baby before completion of 18 years.

Table 2 shows that most of the eligible couples were educated up to middle school. Female literacy rate was 84.8%, whereas male literacy rate was 87.3%. Higher proportion (37.4%) belonged to Class IV socioeconomic class and 31.4% women were employed with salary.

Out of 4,438 eligible couples studied, 3,328 were current users of contraception at the time of the survey. Hence, the Contraceptive Prevalence Rate was 75% (95% CI: 73.6–76.4%) in this study population. Table 3 shows the various family planning methods adopted by the eligible couples. Most common preferred method was tubectomy (81.6%), followed by condoms (11.4%), intrauterine devices (IUDs) (6.3%), and oral contraceptive pills (OCPs) (0.7%).

Table 2: Education status and socio-economic class of the study participants

Variable	Number (*n*=4438)	Percentage
Educational status of Women		
Illiterate	675	15.2
Primary	698	15.7
Middle	1237	27.9
High school	688	15.5

Class III	1333	30.0
Class IV	1660	37.4
Class V	338	7.6
Working status of women		
Working	1394	31.4
Not working	3044	68.6

Table 3: Various family planning methods adopted by eligible couples

Family Planning Method Adopted	Number (Percentage)
Tubectomy	2717 (81.64)
Condom	378 (11.36)
Intra Uterine Device (IUD)	210 (6.31)
Oral Contraceptive Pill (OCP)	22 (0.66)
Vasectomy	1 (0.03)
Total	3328 (100)

The demographic factors influencing the contraception acceptance is shown in Table 4. The significant predictors for contraceptive acceptance are higher age of women, those who are having two living children, women who are married after 19 years of age, and those who had given birth to first child after 19 years of age.

The social and economic factors influencing the contraception acceptance is shown in Table 5. Factors like higher educational level of women, working women, and higher socioeconomic class are significantly associated with adoption of any of the contraceptive method.

Discussion

Contraceptive use and unmet need for family planning are keys to understand profound changes in fertility pattern and also helps to improve reproductive health. By understanding the concept of unmet needs, the gap between women reproductive intentions and contraceptive behavior can be understood. In this study, Contraceptive Prevalence Rate among eligible couples was found to be 75%, which is higher than studies reported by NFHS IV (52.3%),[10] Patel AA (55.3%),[11] Singh *et al.* (68.4%),[1] Makade *et al.* (68.4%),[12] and Gupta *et al.* (71.1%).[13] The contraceptive acceptance is quite high among the study population.

Most common method followed by the eligible couples was permanent method, that is, tubectomy (81.6%) which is higher than other studies by Shree *et al.* (70.9%),[14] Patel AA, *et al.* (33.7%),[11] and Nanda *et al.* (30.5%).[15] In our study, 11.4% couples use condoms which is similar to study done by Chandra *et al.* (11.7%)[3] and higher than Nanda *et al.* (5.1%).[15] Usage of IUDs was 6.3% which is lower than study done by Nanda *et al.* (45.8%)[15] and Shree *et al.* (11.3%).[14] Another important finding as that only one male individual has undergone vasectomy. This clearly portrays that even though permanent sterilization method in male (i.e., vasectomy) is an easier procedure and has lesser postoperative symptoms the responsibility for birth control still traditionally rests with the woman since she has to undergo the physical and psychological burden of unplanned pregnancy.

In our study, contraception usage showed significant association with higher age of the women, religion, education of the women, higher socioeconomic class, working status of the women, presence of two living children, age at the time of marriage as well as first child birth more than 18 years of age. There was no significant association with type of family, educational status of husband and caste.

In this study, the usage of contraception was significantly higher among those who were aged 35–49 years. The contraceptive acceptance was three times higher than those of aged 15–24 years, probably these couples would have completed their family. Similar findings were reported by Patel AA,[11] Valekar SS, *et al.*,[16] and Prateek *et al.*[2] wherein women of age group 35–49 years are using better contraception. The

contraceptive usage was significantly low (34.5%) among Muslims than Hindus (75.3%) but the proportion of Muslims was low in this study. This result was consistent with other studies like Singh AK, *et al.*[1] and Chandra *et al.*[3] The reason for lower usage of contraception among the Muslim couples could be because of religious and cultural beliefs on contraception. Hence, religion still plays a predictor role on deciding the choice of contraception.

Education of women leads to a greater awareness and a significant effect on family planning behavior and use of contraception. Our study revealed significantly higher usage of contraception among literates when compared with the illiterates. The literates will be able to understand the pros of contraceptive usage which could have brought the behavioral change. This result was consistent with studies done by Singh AK, *et al.*[1] Patel AA,[11] Gupta *et al.*,[13] Kumar N, *et al.*,[17] and Oppong FB, *et al.*[18] Improving education status can pave way to delay a women's marriage age, she will be able to seek a job and can help to change the attitude toward birth spacing and family size and empowers women to make a better decision.

In our study, contraceptive use was significantly higher among working women as they are more likely to be educated and their socioeconomic status is supposed to be better than the non-working women. Working women are likely to be more knowledgeable; would have wide exposure to media and social contacts which can influence their contraceptive behavior. This finding was similar to study done by Mukherjee *et al.*[19]

In the present study, it was found that as the socioeconomic status decreases, the usage of contraception also decreases. Contraception usage is significantly higher among class I when compared to Class V. This may be due to the fact that the higher socioeconomic status individuals have better accessibility and availability of contraception and they have better awareness regarding contraception. Similar finding was reported by Prateek *et al.*[2]

Number of living children had a significant impact on contraceptive usage. Those women who had completed their family by getting at least two children (small family norm) are using contraception higher than others. This may be due to the fact that many couples decided to complete their family with two children and also female sterilization (after institutional deliveries) was emphasized for women after they bear two children. Government policies and advisory of two child norm and benefits announced could have favored contraception acceptance by these couples. This finding was consistent with study done by Singh *et al.*[1] Shree *et al.*[14] Valekar SS, *et al.*,[16] and Gothwal M, *et al.*[20] Contrastingly, it was also found contraceptive usage was higher among those having two children compared with couples having three or more

Middle	1241 (75.5)	403 (24.5)	0.93	0.74-1.17	0.5
High school	431 (76.1)	135 (23.9)	0.96	0.73-1.28	0.79
Higher secondary	225 (72.3)	86 (27.7)	0.79	0.57-1.10	0.14
Graduate	496 (74)	174 (26)	0.86	0.66-1.13	0.26
Socio Economic Status					
Class I	247 (79.9)	62 (20.1)	1		
Class II	608 (76.2)	190 (23.8)	0.80	0.57-1.12	0.18
Class III	998 (74.9)	335 (25.1)	0.75	0.54-1.02	0.06
Class IV	1261 (76)	399 (24)	0.79	0.58-1.08	0.13
Class V	214 (63.3)	124 (36.7)	0.43	0.30-0.63	<0.001
Working status of women					
Not Working	2190 (71.9)	854 (20.1)	1		
Working	1138 (81.6)	256 (18.4)	1.73	1.48-2.03	<0.01

children. This could be due to the fact the need for contraception is not well appreciated by these couples.

Age at the time of marriage and age at time of first child birth also showed significant association with contraceptive usage. Those women who got married or gave birth before the age of 18 years used less contraception when compared with those who got married or gave birth to child after the age of 18 years. This may be because the former individuals are less aware of the contraceptive methods and their maturity levels are not favorable. Hence delaying the age of marriage of women as well as delaying the age of first child birth more than 18 years could have a positive impact on contraceptive acceptance. But studies by Prateek *et al.*[2] and Valekar SS, *et al.*[16] did not show significant association between contraception usage and age at marriage or age at first child birth.

Our study did not reveal association of contraception use and educational status of husband. This result is consistent with study done by Valekar SS, *et al.*[16] But studies by Prateek *et al.*[2] and Shree *et al.*[14] has shown association between educational status of husband and contraception usage. The current study did not show significant association of contraception use with caste and type of family, but a study by Nanda *et al.*[15] has shown significant association of contraception with caste and studies conducted by Singh *et al.*[1] and Valekar SS, *et al.*[16] has shown individuals in nuclear family are accepting the family planning methods higher than those in extended family.

This study has few limitations because other confounders which can influence the contraceptive prevalence like knowledge about contraception, sex preference, female autonomy, and unmet needs of contraception were not studied. Despite the data being retrieved from the routine family health survey, the reliability of the data is not a major concern as it was collected by trained field workers for purpose of family health survey.

Conclusion and Recommendation

From our study, it is obvious that the contraceptive prevalence was high among the study population and epidemiological factors like higher age of the women, religion, education of the women, higher socioeconomic class, working status of the women, presence of two living children, age at the time of marriage, as well as first child birth more than 18 years of age are influencing the contraception acceptance. Measures to sustain the gains of the family planning program should be given priority to sustain population stabilization and to achieve Net Reproductive Rate of one. Hence, on the first-hand targeted health awareness among those who are not using contraception could help to bring about a behavioral change so contraception usage can be maximized. Secondly, outreach contraceptive services should be intensified and expanded for easy access without fear of stigma by the society. Thirdly, reproductive health programs and policies should adequately involve men, by encouraging and motivation to adopt vasectomy as an easy method of family planning.

Acknowledgements

The authors appreciate and thank the efforts put forth by the medical officers and field staffs who worked in the Rural Health Training Centre for carrying out the family health survey in the field practice area.

Abstract

Background: HIV-positive patients are at a greater risk for developing oral health problems, making them potentially susceptible to nutritional deficiencies, decreased adherence to treatment, and failure of highly active antiretroviral therapy. Their oral health needs are unmet due to a lack of awareness, social stigma, and other factors. The primary care workers (PCWs) are the first point of contact for health issues of these patients. **Aim:** The aim of the study was to assess the effectiveness of the educational intervention for the PCWs on oral health. **Materials and Methods:** This interventional pilot study was conducted at two residential centers for HIV patients in Mangalore. The participants included 15 PCWs working at these centers. An educational module was prepared as the intervention that included dental conditions that could compromise oral health, oral manifestations of HIV, and oral health care. A structured questionnaire was administered to the PCWs before the intervention, immediately after the intervention, and at 3 months. The PCWs were required to routinely examine the HIV patients for any dental or oral health problems and refer them to the dental hospital for treatment. The Statistical Package for the Social Sciences 20.0 software (Chicago. IL, USA) was used for analysis. $p < 0.05$ was considered statistically significant. Repeated measures analysis of variance and Chi-squared test were used for data analysis. **Results:** 73% of the caretakers had no training in oral health care. Analysis of the mean scores revealed a statistically significant improvement ($p < 0.05$) in their knowledge and skills from 2.53 ± 1.3 to 7.57 ± 1.2. There was also a statistically significant increase in the number of referrals to the dental hospital. **Conclusion:** Educating the PCWs showed positive outcomes enabling patients' access to regular professional oral health care, thus improving their quality of life.

Keywords: HIV, oral health, primary care workers

Introduction

HIV-related oral lesions are found in 30%–80% of HIV-infected individuals, and most often are the first clinical sign of the infection. While the presence of certain oral lesions might suggest an HIV infection, a few others might even signal the progression of the disease.[1] The oral manifestations of HIV are xerostomia, salivary gland disorders, oropharyngeal candidiasis, hairy leukoplakia, Kaposi's sarcoma, warts, recurrent aphthous ulcers, neutropenic ulcers, etc.[2] The dental conditions include dental caries, periodontal diseases, and tooth loss.[3,4] With the introduction of highly active antiretroviral therapy (HAART), there has been a significant decrease in the occurrence of the more severe types of oral lesions, but there is also an increase in frequency of the more common lesions such as candidiasis and periodontitis as compared to the noninfected individuals. Studies have shown that HIV patients are more susceptible to oral lesions and harmful dental conditions than otherwise healthy individuals.[5] These conditions are a risk factor for nutritional deficiencies as they affect mastication, swallowing, and other oral functions. They are also a potential barrier to adherence to treatment and have been shown to be associated with an increased risk of progression of HIV disease, severe immune deterioration that could lead to increased mortality.[6] These conditions have a physical, social, and psychological impact on the patients which is detrimental to their well-being and impairs their quality of life.[7] The oral

and dental needs are unmet in HIV patients due to a lack of awareness on oral health and available services, late diagnosis, social stigma, and poverty.[8] Oral health is most often neglected as it is not given utmost priority. It is therefore vital that the oral health status of these patients is regularly monitored and treatment guaranteed.

Collaborations with various professions are the need of the hour in the current health care scenario to improve health outcomes. With regard to people living with HIV, an interprofessional teamwork has the potential to bring about a significant change in their overall health and well–being, leading to a better quality of life. The dental professionals primarily work to prevent and treat oral and dental diseases. However, the HIV patients might not be able to avail of their services due to their perceived barriers. The primary care workers (PCWs) play a crucial role by complementing the health-care system. They generally are at ideal positions and the first point of contact for health issues of patients and therefore can play a pivotal role in oral health promotion. The PCWs comprise doctors, nurses, pharmacists, counselors, and care takers who regularly tend to the patients. However, in order to facilitate oral health promotion, they themselves need to have adequate knowledge about the oral manifestations of HIV and its management. The primary objective of this study was to develop an oral health-care module and evaluate its effectiveness among the PCWs in promoting oral health among HIV patients. The secondary objective was to explore if this training model led to an increase in the number of patients seeking oral health care. Althrough this project, we strived to enable HIV patients overcome their barriers and ensure accessibility to oral health care by educating the PCWs.

Materials and Methods

This educational interventional study was carried out as a pilot initiative among PCWs of two HIV residential centers of Mangalore, housing 75 HIV-positive individuals. The PCW team included nurses, counselors, pharmacist, caretakers, and volunteers. The study was approved by the Institutional Human Ethics Committee (DCGI Reg. No. ECR/348/Inst/KA/2013). The study was explained to the participants, and written informed consent was obtained from them.

Module development and validation

A team comprising dental professionals (prosthodontists and dental public health Specialists) and physicians was formed to prepare the module for the intervention. The team together finalized the topics to be included in the module. Key areas included normal anatomy of oral cavity, general oral health, oral manifestations of HIV, early recognition of the lesions, harmful dental conditions, their management, documentation of cases, and diet. The module was tailor-made for ease of use for the PCWs that included illustrations using simple language. This was also translated to Kannada, which is the local language. The topics and content of the module were reviewed by five subject experts and a consensus was arrived at.

Health education of primary care workers and HIV patients

A training session was conducted for the PCWs by interactive lectures aided by video projector and demonstrations. A PowerPoint presentation was prepared to facilitate the intervention. It contained simplified text and images of lesions such as oropharyngeal candidiasis, linear gingival erythema, salivary gland enlargement, aphthous stomatits, oral hairy leukoplakia, and dental conditions such as dental caries, missing teeth, periodontitis, and dental fluorosis. They were also taught oral hygiene procedures and diet recommendations. The interventions were carried out both in English and in Kannada.

Following the training, the PCWs were expected to periodically conduct oral examinations of the patients, refer them for treatment, ensure that they are under the care of dental professionals, and also encourage them to follow dentist's recommendations. Referral cards were provided to the PCWs for referrals to the dentist.

A health education session was also conducted for the HIV-positive patients to enable them to perform self-examinations and identify the lesions in their oral cavity so as to report them to the PCWs.

Data collection and analysis

A preintervention baseline assessment was done for the PCWs, using a structured questionnaire. The questionnaire included sociodemographic information of the PCWs (age, gender, educational qualifications and employment status, years of experience, and past training in oral health), as well as their knowledge on oral health such as symptoms and clinical appearance of the lesions, preventive measures, and diet. There were eight questions on sociodemographic characteristics, nine questions on knowledge, and four questions on beliefs. The questionnaire was administered in English as well as Kannada to facilitate the workers who were not fluent in English. The PCWs were given an opportunity to clarify any doubts with the questionnaire. The participants completed the questionnaire in 30 min, following which the educational intervention was performed.

Posttest questionnaire was administered immediately after the intervention and after 3 months. Referrals were assessed by the number of patients visiting the dental hospital, confirmed by clinical data mentioned on the referral cards. Data were analyzed using the SPSS software, Version 20.0 (Chicago. IL, USA). The changes in the mean score pre- and post-intervention were assessed using the repeated measures analysis of variance.

Results

Fifteen PCWs completed the questionnaire. All of them were females between the age group of 20–65 years. A majority of them (80%) were educated beyond the 12th grade. Nearly 73% of the workers had not received any previous training on oral health care. All the PCWs believed that oral health

[Downloaded free from http://www.jiaphd.org on Tuesday, April 6, 2021, IP: 244.52.167.49]

is important for HIV patients. They also agreed that regular screening is necessary, and it is important to seek dental treatment for dental problems. However, 20% did not believe that poor oral health could compromise nutrition. The responses showed that they had poor baseline knowledge. The pretest showed a mean knowledge score of 2.5 ± 1.3. The mean score immediately after intervention was 5.8 ± 1.2 and after 3 months was 7.2 ± 1.2. Repeated measures analysis of variance showed a statistically significant difference between the scores ($p < 0.05$), [Table 1].

There was a 36% increase in the number of patients diagnosed and referred to the dental hospital pre- and post-intervention at 3 months. This increase was statistically significant as shown by the Chi-squared test [Table 2].

Discussion

Oral diseases cause pain, discomfort, altered taste, and a burning sensation. Dental conditions such as decay, periodontitis, and loss of teeth can affect mastication, swallowing, and speech.[9] Although the overall incidence of oral lesions has significantly reduced due to HAART, the prevalence is still high in patients in developing countries and vulnerable age groups due to the various risk factors involved.[6]

The current study aimed to improve the oral health-related outcomes of HIV-positive patients through an educational intervention targeted at improving the knowledge and competencies of the PCWs. Before the study, discussions with the PCWs and also with a few patients had revealed that patients suffered from stigma associated with their illness, which along with a lack of awareness and low socioeconomic status, prevented them from seeking dental treatment. They also disclosed the problems they faced regarding accessibility to oral health care.

This study helped to empower the PCWs with knowledge related to oral health and also improve their skills in educating patients to ensure that their oral health care needs are met. Kolisa and Ayo-Yusuf[7] in their study have stated that the nontrained care givers are less likely to provide advice on oral hygiene. Educational interventions do improve the caregivers' knowledge of oral lesions and their beliefs about oral care. Therefore, they can efficiently complement the health-care system.

This study was conducted at two residential centers for HIV patients. Most of the patients were school-going children below the age of 18 years. A majority of the children were orphans and completely dependent on the PCWs for all their needs. It was seen that there was not much of an emphasis on oral health due to ignorance as well as inaccessibility to oral health-care facilities.

The PCWs who took part in the study were co-operative and willing to conduct periodic oral examinations. Regular visits and telephone reminders by the dentists also motivated them to perform their duties. The model proved to be an effective method for oral health-care promotion. It improved the knowledge of the PCWs significantly. Ever since this model has been introduced at the HIV centers, there has been a regular stream of HIV patients visiting the dental hospital to avail dental treatment. This study shows results similar to a study that had been conducted by Koyio *et al*.[10] on the community and professional health-care workers in Nairobi. They too showed that the training programs significantly increased the primary and community health workers' knowledge, recognition, and management of oral lesions in HIV patients.

This is a pilot study, and the sample is limited to 15 PCWs. However, the positive outcome with this study shows that this model can be implemented on a larger scale so as to benefit a wider population of the HIV patients.

Conclusion

Despite the limitations of the study, this model shows that this model has the potential to benefit a larger number of HIV patients through its implementation to a larger group of PCWs in other centers. The PCWs have shown improved competencies with regard to diagnosing harmful oral and dental conditions and timely referrals to the dental hospital, therefore leading to an increased awareness among HIV patients about their oral health status. The patients can overcome the stigma in seeking treatment and improve their oral health-related quality of life. The study also suggests that an effective interprofessional collaboration can be developed between the dentists and the PCWs for the benefit of the patients.

Parental Satisfaction with Pediatric Day-Care Surgery and its Determinants in a Tertiary Care Hospital

Cenita James Sam, Pavai A. Arunachalam, Sivamani Manivasagan[1], T. Surya

Department of Pediatric Surgery and [1]Department of Community Medicine, PSG Institute of Medical Sciences and Research, Coimbatore, Tamil Nadu, India

ABSTRACT

Objective: The objective is to assess the level of parental satisfaction of pediatric day-care surgery and its different determinants.

Materials and Methods: This is a descriptive study performed in a tertiary care hospital in India among parents of pediatric day-care surgery patients from June 2013 to March 2015. The core questionnaire for the assessment of patient satisfaction for general day care (COPS-D) was used. Variables related to surgery, overall satisfaction, one open-ended question, and socio-demographic data were also collected. Calculated sample size was 121.

Results: The mean and standard deviation of parental satisfaction were estimated in eight domains of day care (COPS-D) using Likert scale 1–5. Preadmission visit had a mean of 4.63 (0.52), day of surgery 4.65 (0.58), operating room 4.76 (0.51), nursing care 4.46 (0.79), medical care 4.89 (0.48), information 4.51 (0.68), autonomy 4.64 (0.56), and discharge 4.50 (0.72). In elder children, there was less satisfaction on the information and discharge domains. Overall satisfaction was good in 88% of patients and was less than satisfactory when they had significant pain.

Conclusion: Perception of quality of pediatric day-care surgery was assessed with a questionnaire and was found to be good. Variables related to surgery such as pain may be included in the questionnaire for assessing satisfaction in the day-care surgery.

Keywords: *Day-care surgery, parental satisfaction, pediatric day-care surgery, quality in day-care surgery, quality of care, variables related to day-care surgery*

Introduction

Day-care surgery is being practiced worldwide. For a child, it gives quicker return to a familiar home environment without compromising the safety of the child. This is an efficient way of reducing the costs and waiting time, maximizing the use of resources, and avoiding an unnecessary stay in the hospital.[1] Day-care surgery ranges from 20% to 68% of surgery being performed in various pediatric surgical units.[2] This is possible due to the advanced medical technology and a better understanding of what can be performed safely in a day.[3] Effective preoperative assessment and preparation with protocol-driven discharge are fundamental for safe day-care surgery.

Quality and safety in health care are of paramount importance.[4] The WHO has emphasized the importance of the patient's perspective in the evaluation of health-care delivery. After providing infrastructure and proper personnel to assure quality and safety, it is important to assess the services using a structured patient's satisfaction questionnaire. Measuring satisfaction is problematic as the evaluations are personal and subjective.[5] Expressed satisfaction reflects the patient's knowledge and expectations than the quality of the service received.[6] However, monitoring user satisfaction is important for quality care assessment and benefits patient care if their feedback influences subsequent service delivery.

Two groups of determinants of satisfaction were distinguished in reviewing literature: those relating to the characteristics of respondents and those relating to health service delivery features. The patient's expectation is an important determinant among individual factors.[7] Care process is an important determinant regarding health delivery system.[8] Other determinants specific to day-care surgery are postoperative complications, postoperative pain, waiting time before surgery, readmission, and the clinical outcome.[3]

The different approaches to measure the patient satisfaction are based on health service attributes, holistic approach, expectation-based surveys, and those evolved from economic theory.[5,7] Among these, holistic approach includes all important determinants of patient satisfaction.[7] The patient satisfaction surveys using validated instrument should be able to measure the structure, process, and outcome of a health-care system.[9,10] The patient satisfaction score is indispensable to the assessment of quality.[8,11]

In different countries, systems are established to monitor the performance of health-care institutions using a framework of structure, process, and outcome indicators.[12] The aim of our study was to assess the level of parental satisfaction with pediatric day-care surgery and to find out the different determinants that influence the parental satisfaction.

Materials and Methods

This is a descriptive study conducted in PSG Institute of Medical Sciences and Research, a tertiary care private medical college hospital, in South India. The study period was from June 2013 to March 2015 among parents of pediatric day-care surgery patients. The Institutional Ethical Board approval was obtained (No: 13 / 036).

Inclusion criteria were children aged 1–15 years undergoing day-care surgery with the American Society of Anesthesiologists I and II and who can reach the hospital within 2 h in case of emergency. Exclusion criteria were children under 1 year and those who needed emergency surgery. Children under 1 year are generally admitted. The operations performed in day care are procedures as herniotomy, circumcision, and orchidopexy.

These children had a pre-operative assessment few days before the planned surgery. Parents were explained about day-care procedure, expected problems, anesthesia, and cost of surgery by the doctor and clinical nurse assistant. On the day of surgery, they were seen in the day-care area; surgery was performed under general anesthesia with or without caudal analgesia. They were monitored for 4 h and more if necessary. If the child had no problems, he was sent home after being seen by the treating surgeon on oral paracetamol for next 3 days. If necessary, they were admitted for observation. A follow-up visit was scheduled after 1 week.

Study tool

The core questionnaire for the assessment of patient satisfaction for general day care (COPS-D),[13] was chosen as it is a validated questionnaire designed for day care including day-care surgery. It assesses eight dimensions/domains: as preadmission visit (4 items), admission at the day-care center (3 items), operation room (3 items), nursing care (2 items), medical care (2 items), information (4 items), autonomy (3 items), and discharge and after care (3 items). The response for each item is assessed by 1–5 Likert scale; 1 being unsatisfied and 5 as very satisfied. Average of the item score constituted the domain score. Together all these categories aim to achieve a total picture of the quality of care. The reported internal consistency of the eight dimensions was good (α =0.82–0.90).

In addition, questions about variables related to surgery such as waiting time for surgery, postoperative complications such as vomiting, postoperative pain, readmission, and outcome of surgery were also included in the study. Postoperative pain was assessed on a numeric rating scale of 0–10. There was one item about the overall satisfaction of the quality of care which was marked on a scale of 1–10. One open-ended question was added for parent to comment regarding the services they have received on the day of surgery to counter the drawback of quantitative surveys. The responses were classified as compliments, complaints, and suggestions. Socio-demographic data were also collected.

The questionnaire was translated into the regional language and it was verified with back translation. The questionnaire was given to the parents when they came for their child's first postoperative visit, which was usually a week after surgery by the outpatient department staff. Informed consent was obtained from the respondent. Questionnaire response was kept anonymous. Incomplete questionnaires were excluded from the study. Privacy of the participants was ensured by excluding identification details from the study questionnaire. All questions were directed to the parents of the patients.

Sample size

We considered 75% as the anticipated satisfaction level of day-care surgery patients. At a confidence level of 95% and with 12% of relative precision, with the

[Downloaded free from http://www.jiaps.com on Tuesday, October 3, 2017, IP: 192.168.30.109]

nonresponse rate of 30%, an overall sample size of 121 was derived. A total of 121 consecutive parents of day-care surgery patients were included in this study. Responses were entered in Epi Info™ 7.1.2.0 (Centre for Disease Control and Prevention, Atlanta, USA) and results were analyzed using R software (R version 3.0.1. The R foundation for Statistical Computing. Vienna, Austria). Descriptive statistics such as means and standard deviation, percentage, Chi-square test, and ANOVA test were used in the analysis. A P value < 0.05 was considered statistically significant.

Results

Respondents

All 121 respondents returned the questionnaire. Twelve questionnaires were excluded from the study for many missing values making the sample size to 109. The characteristics of the study population are presented in Table 1. Male children predominated in our study (85.3%). Children under 4 years were 62.38%. Graduates were 53.21% and illiterates were <3% in our study group. Income was classified according to four quartiles. Circumcision (n = 55), hydrocele (n = 19), hernia (n = 12), tongue tie release (n = 11), orchidopexy (n = 5), node biopsy (n = 5), mass excision (n = 7), and meatoplasty (n = 1) were the surgical procedures performed as day care during the study. Six patients underwent two procedures.

Satisfaction scores

Analysis of rating of satisfaction of eight domains of the day care in Likert scale of COPS-D [Figure 1] showed that parents were satisfied in most of the domains. However, by comparing satisfaction of various domains with different age groups by ANOVA test [Table 2], there was relatively less satisfaction in domains of information and discharge in the older age group (11–15 years) and this was statistically significant. Sex of the child, education status of the parent, and income did not make any difference in the satisfaction score of various domains.

Overall satisfaction score and other variables related to surgery

Overall satisfaction score of patients was fair (score 4–7) in 10 (9.17%) and good (score 8–10) in 96 (88%) patients. Three had not recorded this score, but none had written unsatisfactory. One-fourth of children who underwent day care had more than mild pain. There were moderate pain in 17 patients (15.59%) and severe pain in 11 patients (10.09%). Overall satisfaction score of patients who had more than mild pain was less than those who had mild pain and it was statistically significant [Table 3].

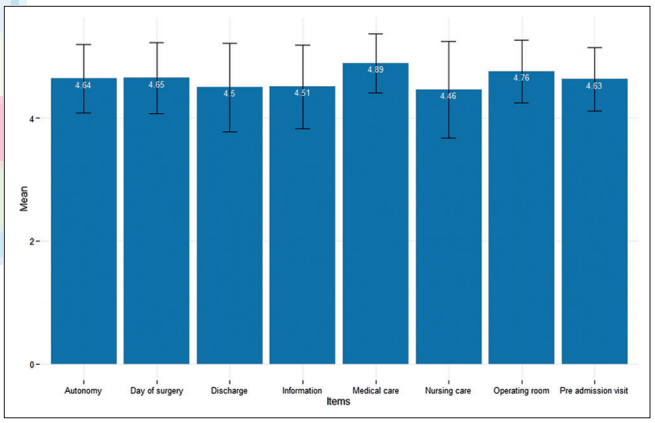

Figure 1: Comparison of rating of satisfaction in Likert scale (1–5) for the 8 dimensions/domains of core questionnaire for the assessment of patient satisfaction for general day care

Postoperative complications were present in 17 patients (15.60%) and it was temporary and mostly related to anesthesia. The problems encountered were nausea/vomiting (n = 5), urinary retention (n = 3), drowsiness (n = 2), headache (n = 2), sore throat (n = 1), bleeding (n = 2), and others (n = 2) as postoperative fever and wound infection. There was a delay in the operation theater (OT) in 13 patients (11.92%) of our study group. Both postoperative complications and delay in OT have not made any statistically significant difference in overall satisfaction score. Children who needed readmission were 2 (1.83%) out of 109. The outcome of surgery was good in all patients except one whose status was

*Statistically significant. SD: Standard deviation

not recorded and hence, its relationship to satisfaction could not be established.

Suggestions for improvement

Open-ended question was answered by 50 parents (45.87%). Compliments were given by 33 (30.27%), 6 (5.50%) gave a suggestion, and complaints were received from ten parents (9.17%). The complaints were about the delay at the pharmacy or dietary services. They also suggested improvement in waiting area, services provided by the staff nurses in the recovery area.

Discussion

Most of the study patients were male, the reason being the day-care procedures such as circumcision itself are more common in male children. Many of the study patients were under 4 years for the same reason and

[Downloaded free from http://www.jiaps.com on Tuesday, October 3, 2017, IP: 192.168.30.109]

this is similar in pediatric day-care services in other hospitals.[2] Level of satisfaction was almost equal among the various income groups, but this may not be representative as this is a private hospital. There were no significant differences in satisfaction score among parents of varying educational level in the current study. However, in other studies, it has been noted that higher the education, lesser was the satisfaction. It has been argued that the parents with higher education come the awareness and their expectation from the health providers goes up.[14]

Parental satisfaction score of various domains of care in day-care surgery patients in the current study had ranged from 4.46 to 4.89 out of 5 (i.e., 89.2%–97.8%). However, areas such as information about day care and discharge need some improvement, especially when catering for children above 10 years. There was no similar study (using domains) to compare among pediatric age group. A study conducted in a private sector hospital in North India among inpatients reported satisfaction in various domains ranging from 64.8% to 98.2%.[15]

The secondary outcome of this study showed that although the overall outcomes of the day-care surgery in children were good, there were some areas of care which need to be improved. They were delay in performing surgery which needs better planning, postoperative pain relief, and postoperative complications. Mandhan *et al*., have reported postoperative pain in 40% of their day-care surgery children while in our study 26% had more than mild pain. However, the nature of pain was not graded in their study.[16] Myles *et al*. noted that patients who had postoperative pain were less satisfied like the current study and hence, this factor has to be taken into consideration to improve the quality of day-care surgery.[17]

The occurrence of postoperative complications in the current study was 15.60%. Mandhan *et al*., reported complication of 44% (n = 368) out of which surgical complications were only 4%. In addition to complications we have noted, the study reports about feeding disturbance in first 24 h.[16] It had not affected the overall satisfaction scores. It is probably because parents were primed for it in their preoperative visit and the effects were temporary. Delay in OT to start the procedure (11.92%) had not affected satisfaction in the current study; although, it had been a significant factor affecting patient's satisfaction in other day-care surgery studies.[2]

Only 2 (1.83%) out of 17 who had postoperative complications, needed readmission. Readmission rate of 1%–2% is suggested as acceptable in day-care surgery. Day-care surgery performed in government sector in India showed readmission rate of 5.7%.[18] Other studies showed readmission rate varying from 0.2% to 6.2%.[16] In the current study, the overall outcome could be explained by proper selection of cases. However, parents need to be informed about waiting time in OT, postoperative pain, and immediate postoperative complications as they seem to be an integral part of day-care surgery.

Overall satisfaction score (in the scale of 1–10) was 88% in the current study population. Other pediatric day-care surgery centers from developed countries showed 93%–97% satisfaction level.[16,19] The patient satisfaction level reported among inpatients in Indian studies range from 23.4% in the government sector to as high as 84% in a private tertiary care.[14,20]

Open-ended question had helped us to identify what patients appreciate and the specific area which needed improvements such as recovery area, dietary services, and pharmacy services. This information was passed on to hospital quality control department for making necessary changes.

Limitation of the study

Gratitude bias is possible in the study as it was conducted by the same department. However, we had tried to reduce this effect by giving a self-response questionnaire and questionnaire response was kept anonymous.

Conclusion

The patients look at a facility every time the service is delivered and form distinct opinions about its effectiveness. Health-care organizations that aspire to excellence must constantly assess the quality of their service experience through their patients' eyes. The patient feedback may be routinely practiced to improve the health-care system. Variables related to surgery as pain may be included in a questionnaire assessing satisfaction in day-care surgery as it affects overall satisfaction score.

Abstract

Background: Mitigation measures to control the novel coronavirus disease 2019 (COVID-19) depends on the public adherence to preventive measures which is influenced by their knowledge and attitude. **Aim**: To find the knowledge, attitudes and practices (KAP) of the rural population toward COVID-19 and to establish its socio-demographic influencing factors. **Material and methods**: KAP study regarding Covid-19 was done among the rural population during August 2020 using a semi-structured questionnaire. **Results:** Among 500 participants, the mean knowledge, attitude and practice score was 21.55± 2.9 (Range 0- 30), 30.0± 2.88 (Range 12- 36) 9.4± 1.25 (Range 0-13) respectively. Higher knowledge was associated with higher education and employed individuals. Favourable attitude was among those aged <35 years and having higher education. Optimistic practices were exhibited by employed individuals and when children <12 years are present in their home. **Conclusions:** Study participants preceded good knowledge, positive attitude towards COVID-19 but practice is not sufficient enough to win the battle against the dreadful disease due to considerable knowledge- practice gap.

COVID-19; Knowledge; Attitude; Practice; Rural Population

Introduction

COVID-19 virus which emerged in Wuhan has spread over 200 countries and has become a pandemic claiming several lives. World Health Organization (WHO) announced a public health emergency of international concern to prevent its rapid spread.(1)In India, a confirmed case of COVID-19 was reported on 30thJanuary 2020, who was a student travelled from Wuhan, China.(2) More than eight million cases have been reported so far in India.[3] Tamilnadu, a state in India has the third largest number of cases approximately 7,30,000 cases till date.(3) While the government has issued advisory through various channels and media on the prevention and precautionary measures, people's observance is essential for controlling the spread of

COVID-19, which is affected by their knowledge, attitudes and practices (KAP) towards COVID-19. From compliance with lockdowns to following personal safety measures, the onus is on each individual to break the chain and flatten the curve.(4) While the urban community has the advantage and access of health care facilities and other ways of becoming aware of these measures such as social media and print media, the rural population may be limited in terms of access and awareness of these updates.(5) In addition, the recent trends indicate that the COVID crisis is moving towards the rural areas.(5) Considering the above facts it is more important and imminent to reach out to the community in a rural area to assess their knowledge, attitude and practice towards COVID 19 and recommend tailor made awareness programs to these population so that the disease control measures are effective and on-going prevention efforts can be strengthened. Therefore, we conducted a survey to investigate the knowledge, attitude and practice (KAP study) towards COVID-19 among the rural population as well as to find the socio-demographic determinants associated with it.

Aims & Objectives

1. To study the knowledge, attitude and practice (KAP) among the rural population towards COVID-19
2. To find the socio-demographic determinants influencing KAP among the study participants

Material & Methods

Study population and location: This cross-sectional study was conducted among those who attended the outpatient clinic at the PSG Rural Heath Training Centre (RHTC) attached to Department of Community Medicine in Coimbatore.

Questionnaire: A self-designed questionnaire was developed from WHO training material for emerging respiratory viruses including COVID-19(6) and Training Resources for COVID 19 Management in India. (7) Demographic details had questions on age, gender, occupation, education, socioeconomic class and presence of children less than 12 years. Knowledge section had 30 questions which dealt with clinical symptoms, transmission, high risk groups, prevention and control of COVID-19. Participants were asked to respond to knowledge items as either true or false, with an additional "don't know" option. The correct answer was assigned a score of one and false/I don't know answers were given a score of zero. The total score for knowledge ranged from zero to 30 with high score representing better knowledge. Those who scored more than 70 % of the score were considered as having adequate knowledge based on previous study.(8)

In the section on attitude, scores were calculated based on the respondents' answers to each of 12 attitudinal statements in likert scale as agree, neutral and disagree. Agree or Disagree was awarded 3 points based on positive or negative statement and the reverse one was given one point, neutral answer was given a score of 2. The total attitude score ranged from 12 to 36 with high scores indicating positive attitudes. In the section on practices, respondents were asked to respond "yes" or "no" to the 13 items. A score of one was given to answers that reflected good practice and a score of zero was given for wrong practice. Total practice score ranged from 0 to 13 higher averages represents a desirable practice.

Data Collection: IHEC clearance was obtained for the study. Convenient sampling method was used to enroll the participants attending the RHTC owing to the current pandemic situation and to conduct the physical interview with safety precautionary measures until a sample size of 500 was reached during the period of August 10 to August 30. Data was collected among permanent residents in the catchment area above 18 years after obtaining a detailed written informed consent.

Statistical analysis: Data was collected using epicollect app and was analyzed using SPSS (v20) software. Normality of the score was assessed using a test of normality - Kolmogorov-Smirnov and Shapiro-Wilk test. Comparison of KAP scores with demographic factors was done using independent samples t-test. Multivariate linear regression analysis was used to establish the relationship between independent variables and KAP outcome variable. P value < 0.05 was considered as statistically significant.

Results

Demographic information: Demographic profile of the enrolled 500 participants is shown in table 1. The mean age of the study participants was 37.49 ± 13.16. Among the participants who responded 52.6% were in the age group ≤ 35 years, 60.8% were females, 59% were employed with salary, 62.8% were educated above high school, 18.4 % belonged

to socio-economic class IV & V and 39.4% had children less than 12 years in their home.

Knowledge, Attitude and Practice Score related to COVID-19: The mean knowledge score was 21.55± 2.9 (Range 0- 30). 65.8 % of the participants scored more than 70 % and were considered as having adequate knowledge. 89% of them knew wearing mask help to reduce the transmission of the disease. 87% of the individuals said washing hands with water and soap can eliminate the disease causes. Nearly everyone (97.2%) knew that COVID-19 can be prevented by avoiding crowded places. The mean attitude score was 30.0 ± 2.88 (Range 12- 36). Majority of population (96.4 %) believed restriction of travel to contaminated area along with social distancing, wearing mask regularly and practising hand hygiene helps to prevent disease spread. 94.8% felt mental health of COVID-19 infected patients should be taken care. The mean practice score was 8.2 ± 1.25 (Range 0-13). Majority (99.6 %) of the participants use facial mask whenever they go out of home but 39.2 % have the habit of keeping the mask in the pocket and use it when required, 50.4% have the habit of pulling down the mask when talking to their friends / relatives .82 % avoid going out of home unnecessarily. Higher proportion (96.8%) of the participants practice washing hands with soap/ use sanitizer but only 36.6% wash hands with soap for at least 20 seconds.

Predictors for KAP regarding COVID_19: In multivariate regression analysis (as shown in Table 2) employed individuals (β=0.73: p=0.016), Higher education (β=1.35: p=0.002) have significant association with higher knowledge score. With regard to attitude those aged ≤ 35 years (β=0.69: p=0.016), Higher education (β=0.75: p=0.012) have good attitude score and is found to be statistically significant. Employed individuals (β=0.53: p=0.002) those who have children less than 12 years in their home (β=--0.31: p=0.010) have significant good practice.

Discussion

The battle against the novel COVID-19 is still in progress in India and evidence shows that public knowledge is important in tackling pandemics. Adequate knowledge was present among 65.8 % of the study participants. The knowledge acquired can be due to familiarity of the disease since this pandemic is in existence for more than six months. Significant predictors of participant knowledge were those who have education more than 10th standard and employed with salary. This supports the claim that educated and employed individuals have exposure to different information-gathering networks hence they are much aware which is consistent with other study. (9)

A positive and optimistic attitude among the study participants reflects the belief that COVID-19 was controllable and containable. Attitude was strongly associated with participants aged ≤ 35 years and those having higher education consistent with another study. (10) The younger generation use social media more often than the elderly individuals in the rural area which could have influenced their attitude.

Good practice indicates the translation of knowledge and attitudes into practices (behavioural change) which is a crucial determinant to control the disease. Despite government mitigation measures like restriction on public transport, gatherings, closures of theatres and malls etc. to enforce social distancing still practice measures are not satisfactory. Though 89 % of them are aware that wearing mask can reduce the transmission unfortunately nearly one-third of the participants has the habit of keeping the mask in their pocket and uses it when necessary and 50% have the habit of pulling down the mask while talking to their friends/relatives which hinder the purpose of using face mask. Similarly, though 87% of the individuals knew washing hands with water and soap can eliminate the disease only 36.6% wash hands with soap for at least 20 seconds. The predictors for optimistic practices in our study are employed individuals and presence of children less than 12 years in their home which was similar to another study. (9)

The current study has few limitations since community based sample surveys could reflect better KAP assessment but in the current situation it is not advisable. This study is one of the first among rural population assessing peoples' knowledge, attitudes, and practices toward COVID-19 and thus provides a useful baseline for future research. Though knowledge score is better in this study, good practice is inadequate which poses a major threat in the spread of the disease. There is a huge gap between knowledge and practice which emphasize an immediate need to address this gap for better disease control measures. Owing to relaxation of lockdown - colleges, schools, theatres and malls have started to function, so the potential barriers has to

be curbed and harness better practice in order to prevent the second wave of transmission.

Conclusion

There is a huge gap between knowledge and practice which emphasize an immediate need to address this gap for better disease control measures. Owing to relaxation of lockdown - colleges, schools, theatres and malls have started to function, so the potential barriers has to be curbed and harness better practice in order to prevent the second wave of transmission.

Recommendation

This study is one of the first among rural population assessing peoples' knowledge, attitudes, and practices toward COVID-19 and thus provides a useful baseline for future research. Encouragement of public to adopt precautionary behaviours for containment strategies as knowledge attitude and practice is foreground for public cooperation and backbone for implementing any health policy. Good practice indicates the translation of knowledge and attitudes into practices (behavioural change) which is a crucial determinant to control the disease.

Limitation of the study

Community based sample surveys could reflect better KAP assessment among rural population but in the current situation it is not advisable.

Relevance of the study

COVID-19 is an emerging infectious disease that poses a significant threat to public health. Preventive measures play an essential role in reducing infection rates and controlling the spread of the disease. This indicates the necessity of public adherence to preventive and control measures, which is affected by their knowledge, attitudes, and practices (KAP). Though knowledge score is better in this study, good practice is inadequate which poses a major threat in the spread of the disease.

Authors Contribution

All the authors have contributed at various stages of composition of the final manuscript.

Acknowledgement

We would like to express our gratitude to all the participants enrolled in the study for their co-operation.

Introduction

COVID-19 virus which emerged in Wuhan has spread over 200 countries and has become a pandemic claiming several lives. World Health Organization (WHO) announced a public health emergency of international concern to prevent its rapid spread.(1)In India, a confirmed case of COVID-19 was reported on 30thJanuary 2020, who was a student travelled from Wuhan, China.(2) More than eight million cases have been reported so far in India.[3] Tamilnadu, a state in India has the third largest number of cases approximately 7,30,000 cases till date.(3) While the government has issued advisory through various channels and media on the prevention and precautionary measures, people's observance is essential for controlling the spread of

COVID-19, which is affected by their knowledge, attitudes and practices (KAP) towards COVID-19. From compliance with lockdowns to following personal safety measures, the onus is on each individual to break the chain and flatten the curve.(4) While the urban community has the advantage and access of health care facilities and other ways of becoming aware of these measures such as social media and print media, the rural population may be limited in terms of access and awareness of these updates.(5) In addition, the recent trends indicate that the COVID crisis is moving towards the rural areas.(5) Considering the above facts it is more important and imminent to reach out to the community in a rural area to assess their knowledge, attitude and practice towards COVID 19 and recommend tailor made awareness programs to these population so that the disease control measures are effective and on-going prevention efforts can be strengthened. Therefore, we conducted a survey to investigate the knowledge, attitude and practice (KAP study) towards COVID-19 among the rural population as well as to find the socio-demographic determinants associated with it.

Aims & Objectives

1. To study the knowledge, attitude and practice (KAP) among the rural population towards COVID-19
2. To find the socio-demographic determinants influencing KAP among the study participants

Material & Methods

Study population and location: This cross-sectional study was conducted among those who attended the outpatient clinic at the PSG Rural Heath Training Centre (RHTC) attached to Department of Community Medicine in Coimbatore.

Questionnaire: A self-designed questionnaire was developed from WHO training material for emerging respiratory viruses including COVID-19(6) and Training Resources for COVID 19 Management in India. (7) Demographic details had questions on age, gender, occupation, education, socioeconomic class and presence of children less than 12 years. Knowledge section had 30 questions which dealt with clinical symptoms, transmission, high risk groups, prevention and control of COVID-19. Participants were asked to respond to knowledge items as either true or false, with an additional "don't know" option. The correct answer was assigned a score of one and false/I don't know answers were given a score of zero. The total score for knowledge ranged from zero to 30 with high score representing better knowledge. Those who scored more than 70 % of the score were considered as having adequate knowledge based on previous study.(8)

In the section on attitude, scores were calculated based on the respondents' answers to each of 12 attitudinal statements in likert scale as agree, neutral and disagree. Agree or Disagree was awarded 3 points based on positive or negative statement and the reverse one was given one point, neutral answer was given a score of 2. The total attitude score ranged from 12 to 36 with high scores indicating positive attitudes. In the section on practices, respondents were asked to respond "yes" or "no" to the 13 items. A score of one was given to answers that reflected good practice and a score of zero was given for wrong practice. Total practice score ranged from 0 to 13 higher averages represents a desirable practice.

Data Collection: IHEC clearance was obtained for the study. Convenient sampling method was used to enroll the participants attending the RHTC owing to the current pandemic situation and to conduct the physical interview with safety precautionary measures until a sample size of 500 was reached during the period of August 10 to August 30. Data was collected among permanent residents in the catchment area above 18 years after obtaining a detailed written informed consent.

Statistical analysis: Data was collected using epicollect app and was analyzed using SPSS (v20) software. Normality of the score was assessed using a test of normality - Kolmogorov-Smirnov and Shapiro-Wilk test. Comparison of KAP scores with demographic factors was done using independent samples t-test. Multivariate linear regression analysis was used to establish the relationship between independent variables and KAP outcome variable. P value < 0.05 was considered as statistically significant.

Results

Demographic information: Demographic profile of the enrolled 500 participants is shown in table 1. The mean age of the study participants was 37.49 ± 13.16. Among the participants who responded 52.6% were in the age group ≤ 35 years, 60.8% were females, 59% were employed with salary, 62.8% were educated above high school, 18.4 % belonged

to socio-economic class IV & V and 39.4% had children less than 12 years in their home.

Knowledge, Attitude and Practice Score related to COVID-19: The mean knowledge score was 21.55± 2.9 (Range 0- 30). 65.8 % of the participants scored more than 70 % and were considered as having adequate knowledge. 89% of them knew wearing mask help to reduce the transmission of the disease. 87% of the individuals said washing hands with water and soap can eliminate the disease causes. Nearly everyone (97.2%) knew that COVID-19 can be prevented by avoiding crowded places. The mean attitude score was 30.0 ± 2.88 (Range 12- 36). Majority of population (96.4 %) believed restriction of travel to contaminated area along with social distancing, wearing mask regularly and practising hand hygiene helps to prevent disease spread. 94.8% felt mental health of COVID-19 infected patients should be taken care. The mean practice score was 8.2 ± 1.25 (Range 0-13). Majority (99.6 %) of the participants use facial mask whenever they go out of home but 39.2 % have the habit of keeping the mask in the pocket and use it when required, 50.4% have the habit of pulling down the mask when talking to their friends / relatives .82 % avoid going out of home unnecessarily. Higher proportion (96.8%) of the participants practice washing hands with soap/ use sanitizer but only 36.6% wash hands with soap for at least 20 seconds.

Predictors for KAP regarding COVID_19: In multivariate regression analysis (as shown in Table 2) employed individuals (β=0.73: p=0.016), Higher education (β=1.35: p=0.002) have significant association with higher knowledge score. With regard to attitude those aged ≤ 35 years (β=0.69: p=0.016), Higher education (β=0.75: p=0.012) have good attitude score and is found to be statistically significant. Employed individuals (β=0.53: p=0.002) those who have children less than 12 years in their home (β=--0.31: p=0.010) have significant good practice.

Discussion

The battle against the novel COVID-19 is still in progress in India and evidence shows that public knowledge is important in tackling pandemics. Adequate knowledge was present among 65.8 % of the study participants. The knowledge acquired can be due to familiarity of the disease since this pandemic is in existence for more than six months. Significant predictors of participant knowledge were those who have education more than 10th standard and employed with salary. This supports the claim that educated and employed individuals have exposure to different information-gathering networks hence they are much aware which is consistent with other study. (9)

A positive and optimistic attitude among the study participants reflects the belief that COVID-19 was controllable and containable. Attitude was strongly associated with participants aged ≤ 35 years and those having higher education consistent with another study. (10) The younger generation use social media more often than the elderly individuals in the rural area which could have influenced their attitude.

Good practice indicates the translation of knowledge and attitudes into practices (behavioural change) which is a crucial determinant to control the disease. Despite government mitigation measures like restriction on public transport, gatherings, closures of theatres and malls etc. to enforce social distancing still practice measures are not satisfactory. Though 89 % of them are aware that wearing mask can reduce the transmission unfortunately nearly one-third of the participants has the habit of keeping the mask in their pocket and uses it when necessary and 50% have the habit of pulling down the mask while talking to their friends/relatives which hinder the purpose of using face mask. Similarly, though 87% of the individuals knew washing hands with water and soap can eliminate the disease only 36.6% wash hands with soap for at least 20 seconds. The predictors for optimistic practices in our study are employed individuals and presence of children less than 12 years in their home which was similar to another study. (9)

The current study has few limitations since community based sample surveys could reflect better KAP assessment but in the current situation it is not advisable. This study is one of the first among rural population assessing peoples' knowledge, attitudes, and practices toward COVID-19 and thus provides a useful baseline for future research. Though knowledge score is better in this study, good practice is inadequate which poses a major threat in the spread of the disease. There is a huge gap between knowledge and practice which emphasize an immediate need to address this gap for better disease control measures. Owing to relaxation of lockdown - colleges, schools, theatres and malls have started to function, so the potential barriers has to

be curbed and harness better practice in order to prevent the second wave of transmission.

Conclusion

There is a huge gap between knowledge and practice which emphasize an immediate need to address this gap for better disease control measures. Owing to relaxation of lockdown - colleges, schools, theatres and malls have started to function, so the potential barriers has to be curbed and harness better practice in order to prevent the second wave of transmission.

Recommendation

This study is one of the first among rural population assessing peoples' knowledge, attitudes, and practices toward COVID-19 and thus provides a useful baseline for future research. Encouragement of public to adopt precautionary behaviours for containment strategies as knowledge attitude and practice is foreground for public cooperation and backbone for implementing any health policy. Good practice indicates the translation of knowledge and attitudes into practices (behavioural change) which is a crucial determinant to control the disease.

Limitation of the study

Community based sample surveys could reflect better KAP assessment among rural population but in the current situation it is not advisable.

Relevance of the study

COVID-19 is an emerging infectious disease that poses a significant threat to public health. Preventive measures play an essential role in reducing infection rates and controlling the spread of the disease. This indicates the necessity of public adherence to preventive and control measures, which is affected by their knowledge, attitudes, and practices (KAP). Though knowledge score is better in this study, good practice is inadequate which poses a major threat in the spread of the disease.

Authors Contribution

All the authors have contributed at various stages of composition of the final manuscript.

Acknowledgement

We would like to express our gratitude to all the participants enrolled in the study for their co-operation.

ABSTRACT

Background: Recent studies have shown that workers on the transport industry are more predisposed to cardiovascular morbidity and other health morbidities due to their improper diet and sedentary lifestyle. This study was aimed at assessing the common morbidity profile among the truck drivers and associated demographic and clinical parameters considered relevant to the development of cardiovascular disease.
Methods: This was a cross sectional study conducted among 175 truck drivers aged 18-60 years at the Walayar check post, Coimbatore, southern India. After getting informed consent, a detailed physical examination was conducted. Socio demographic information was also elicited.
Results: It was observed that 50% of the truck drivers were overweight and obese. Hypertensives were 41.1% and diabetics were 12%. About 27.4% had raised systolic blood pressure (BP) and 29.1% had raised diastolic BP. Low back pain was observed in 34.3%, hip pain in 24.6%, knee pain in 9.7%, shoulder pain in 5.4%, diminished vision in 4.6%, giddiness in 2.3% and hearing defects in 1.1% of the truck drivers.56.6% were current smokers and 66.3% were taking alcohol consumption more than 4 times a month. Older age was found to be a significant independent predictor [odds ratio OR 1.04 (95% CI 1.03-1.05)] for the total number of cardio vascular disease morbidities.
Conclusions: We observed a higher morbidity among the truck drivers and observed that periodic health appraisals are needed.

Keywords: Truck driver, Morbidity, Hypertension

INTRODUCTION

Non communicable diseases are considered as one of the major health and development challenges of 21st century. The social and economic effect of increased morbidity and mortality associated with cardiovascular disease is a great challenge that has to be encountered in these decades.[1,2] Recent studies done in other countries have shown that workers in the transport industry are more predisposed to cardiovascular morbidity due to their improper diet and sedentary behavior and unhealthy life styles. The commonly seen morbidities reported among truck drivers were diabetes mellitus, obesity, hypertension and heart disease.[3-6] However, most of the research done in India among the truck drivers, have focused only on their sexual health. To the extent of our knowledge, very few studies were done in India to assess other co morbidities like cardiovascular morbidity profile. Many studies done in other parts of the country have reported that professional truck drivers and other road transport professionals have a higher risk of ischemic heart disease.[7-9]

Objectives

Considering the importance of truck drivers to our country's economy, more studies are needed to assess their morbidity profile in general and associated risk factors. Considering the inherent risks associated with the profession of truck driving and scarcity of studies aimed at evaluating the cardiovascular risk of morbidity profile in their profession, this study was aimed to assess the morbidity profile among truck drivers in general and to assess the independent predictors of the total number of cardiovascular risk factors identified among them. Thus, this study focused on truck drivers, whose working conditions favor the development of a set of cardiovascular risk factors and simultaneously impose difficulties in accessing health care and adhering to life style changes that enhance quality of life. The results would provide important information to be used at personal and community level to develop strategies and actions targeted at the prevention of cardio vascular disease and the promotion of general health of these workers.

METHODS

Study design, setting and participants

A cross sectional study was conducted on 25th August 2016 among 175 truck drivers aged 18-70 years at the Walayar check post, Coimbatore, Southern India. Ethical clearance was obtained from Institute Human ethics committee, PSG IMS&R. We also got permission from highway transport authorities. The study was conducted at Walayar check post which is located on a national highway of South India on 23rd August 2016 between 10am to 4pm. Drivers who came with valid driving license for submission of documents at the check post and those who gave informed consent were included. A detailed physical examination was conducted. Socio demographic questions were also included. Truck drivers with known congenital heart disease and genetic disorders were excluded. The truck drivers who exhibited risk factors were informed about their condition and advised to attend health care services.

Variables and measurement

Demographic details were collected first followed by measurement of systolic and diastolic blood pressures using mercury sphygmomanometer, two times over a period of 10 minutes and the mean value was calculated. Digital weighing machine was used to measure weight nearest to 0.1 kg. Height was measured with bare foot nearest to 0.1 cm using calibrated stadiometer. Random blood sugar was also measured. The following criteria and definitions were used: family history of CVD: when the individual mentions the occurrence of heart disease in a first degree relative, history of chronic diseases: truck drivers were asked whether they had been previously been diagnosed with any chronic diseases and what medicines they were taking, subjects were considered physically active if they are performing aerobic (walking, biking, dancing and racing) or anaerobic activities (body building) at least 150 minutes in a week and moderately active if they do 10 to 150 minutes in a week and insufficient if they do less than 10 minutes in a week, subjects were considered active smokers if they use tobacco daily in any quantity or at quit smoking in the previous 12 months. Subjects were considered non-smokers if they had not used tobacco for the past 12 months. For determining the body mass index (BMI) the truck drivers were weighed (in kg) without shoes on a 150kg mechanical anthropometric scale and height in meter. The BMI levels were classified according to the WHO guidelines; subjects were normal if their BMI was 18.5-24.5 kg/m^2, overweight if their BMI was 25.0-29.9 kg/m^2.[11] Grade 1 obese if the BMI was 30.0-34.9kg/m^2, grade 2 obese if the BMI was 35.0-39.9 kg/m^2 and grade 3 obese if the BMI was ≥40.0 kg/m^2. Hypertension was defined as systolic blood pressure greater than or equal to 140 mm Hg or diastolic blood pressure greater than or equal to 90 mmHg. Self-reported history of previously known disease was also included.

Sample size

With an expected prevalence of hypertension as 45% and 20% allowable error of prevalence, the minimum sample size required for the study was 122.[1] With a non-response rate of 20%, the total sample required for this study was 153. A total 175 truck drivers were studied.

Statistical methods

Data were analyzed using SPSS 19.Initially data were analyzed descriptively. The categorical variables were represented by absolute frequencies. The numerical variables were summarized with averages, minima, maxima and standard deviations. The existence of association between two categorical variables was verified using Chi square test. Student t test was used to compare the averages of the numerical variables between the groups of two independent samples. Mean (SD) were calculated for continuous variables and percentages for categorical variables. 95% confidence interval was calculated for prevalence assuming normal approximation. As the total number of morbidity is expected to follow Poisson regression, we have initially checked this assumption by analyzing whether mean of the total number of CVD risk factors is approximately equal to variance using Kolmogrov Smirnov Z test. After observing the goodness of fit, Poisson regression model was performed to determine the independent predictors of the total number of cardiovascular risk factors of the truck drivers. This includes diabetes mellitus, hypertension and overweight including obesity. The independent predictors considered were age, smoking, alcohol consumption, family history of CVD and duration of physical activity. A significant level of 5% used for all statistical tests.

RESULTS

Descriptive data

Table 1 shows some characteristics among the 175 truck drivers studied. The population consist young adults with mean age of 39.38 years with a range of 22 years- 67 years. 50% of the subjects were aged 40 years and above, 137 (78.3%) were ever married, 112 (64%) had education only up to 10th standard, 56% were current smokers, 66.3% consume alcohol more than 4 times a month and 42% had family history of CVD.

Table 1: Baseline demographic characteristics (n=175).

Variable	%	Minimum	Maximum	Mean	Median
Age (years)		22	67	39.38	39.00
Physical activity (in minutes per week)		0	460	93.25	0.00
Weight (kg)		46	100	73.23	73.00
Height (cm)		144	185.50	169.55	170.00
Body mass index (kg/m^2)		16.90	36.13	25.47	24.96
Systolic blood pressure (mmHg)		70	190	127.80	130.00
Diastolic blood pressure (mmHg)		55	120	80.29	80.00
Family history of CVD	41.7				
Smoking	56.0				
Alcohol consumption	66.3				

Table 2: Morbidity profile observed.

	Number (n=175)	%
Hypertension	72	41.1
Diabetes	21	12
Overweight/ obesity	86	49.1
Low back pain	60	34.3
Hip pain	43	24.6
Knee pain	17	9.7
Shoulder pain	10	5.4
Diminished vision	8	4.6
Giddiness	4	2.3
Hearing defects	2	1.1

Table 3: Distribution of hypertension according to body mass index.

Hypertension	BMI≤ 25 kg/m^2 (n=89)		BMI 25-29.99 kg/m^2 (n=72)		BMI≥ 30 kg/m^2 (n=14)	
	N	%	N	%	N	%
Systolic only	18	20.2	25	34.7	5	35.7
Diastolic only	19	21.3	24	33.3	8	57.1
Systolic + diastolic	27	30.3	35	48.6	8	57.1
General hypertension	28	31.5	36	50.0	8	57.1

Table 4: Distribution of Study subjects based on systolic and diastolic blood pressure.

Classification	Cut point	Number	%
Optimal	SBP<120	28	16
Normal	SBP 120-129	40	22.9
High normal	SBP 130-139	59	33.7
Hypertension	SBP ≥140	48	27.4
Optimal	DBP<80	49	28
Normal	DBP 80-84	73	41.7
High normal	DBP 85-89	2	1.1
Hypertension	DBP ≥90	51	29.1

Outcome data

The analysis of the parameters obtained during the clinical evaluation shows that (Table 2), 41.1% were having hypertension, 34.3% were having low back pain, 24.6% were having hip pain and 12 5% were diabetes. It was observed that 41.1% were overweight (Table 3) and 8.05 were obese. It was also observed that 1 subject was underweight. It was also observed that the mean BMI (Table 1) of 25.47 kg/m^2 was found to be in the overweight range (25 kg/m^2-29.99 kg/m^2). We are observing an increasing trend in the blood pressure according to the increase in BMI (Table 4).

Table 5: Factors associated with the total number of morbidity using Poisson regression model.

Variable	Odds ratio	95% CI	P value
Higher age	1.03	1.02 -1.05	p<0.001
Positive family history	1.04	0.83 -1.30	0.69
Smoking	1.04	0.83 -1.34	1.32
Alcohol consumption	0.82	0.65	1.04
Physical activity	1.00	0.99 -1.00	1.00

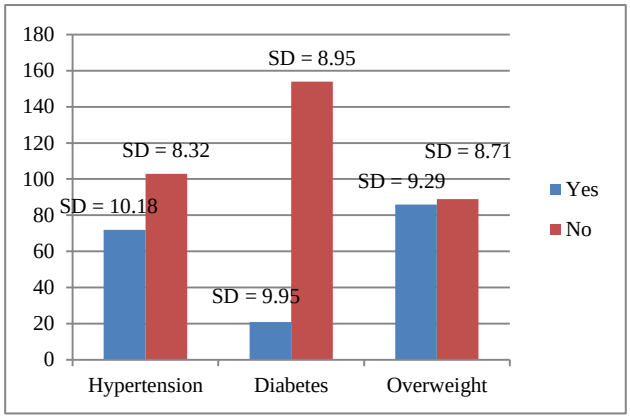

Figure 1: Mean (SD) of age (years) among cardio vascular disease morbidity.

In our study, 59 truck drivers (33.7%) were considered high normal and 48 truck drivers (27.4%) were hypertensive considering systolic blood pressure. Based on diastolic blood pressure, 2 drivers (1.1%) were considered as high normal and 51 drivers (29.1%) were hypertensive (Table 5). The prevalence of overweight and diabetes were higher in this study population compared to the recent study at Hyderabad in the year 2014. The prevalence of hypertension was similar to the reported prevalence of Hyderabad.[10]

Main results

It was observed that the mean is approximately equal to variance. From the results from Kolmogov Smirnov test, it is concluded that the total number of morbidity follows Poisson distribution (z=0.665, p=0.768) and hence decided to Poisson regression analysis. On using Poisson regression model, Age was found as a significant independent predictor [OR 1.03 (95% CI 1.02-1.05)] for the total number of cardio vascular disease morbidity. It was also observed that mean age of truck drivers with risk factors were between 42.45 years to 46.95 years which is the most productive years putting them at risk of CVD morbidity.

Other analyses

On further analysis it was observed that, a significant difference in the mean (SD) age of truck drivers between those who have hypertension 42.48 (10.18) compared with those who do not have hypertension 37.21 (8.32) (p<0.001). A similar difference in the age was observed for diabetes 46.95 (9.95) versus non diabetes 38.35 (8.95) (p<0.001) and for overweight and obesity 42.45 (9.29) versus others 36.41(8.71) (p<0.001).

DISCUSSION

The aim of the present study was to characterize a population of truck drivers with regard to demographic and clinical variables and the presence of cardiovascular risk factors. Our study highlights the need to retrospectively evaluate and systematize the presence of various risk factors in the population of long distance truck drivers. The main finding of our study is that truck drivers have a high prevalence of multiple factors that put them at high risk of cardiovascular events. This is an alarming prospect given the morbidity and mortality rates in the south Indian population and the risks these events pose to truck drivers and others who use roads.

Our study results showed that there is a high prevalence of behavioral risk factors such as overweight, obesity, hypertension, diabetes among the truck drivers and these risk factors were higher at older ages. A number of studies done on other parts other country have demonstrated that high prevalence of obesity among workers in the transport industry. According to Moreno et al., this category of workers in Brazil has a higher incidence of obesity, physical inactivity, inadequate diet, smoking habits, high levels of cholesterol and glycemia, hypertension, and obstructive sleep apnea in comparison to the general population in Brazil.[11,12] A study carried out in the United States involving more than 600 thousand workers found the highest prevalence of obesity to be among male employees who work as highway truck drivers.[13] A representative sample of the Australian in productive age compared ten different functional categories with regards to the risk of obesity and found that male employees of the transportation industry had a higher risk of overweight and obesity.[14] In our study, it was observed that nearly one third of the truck drivers were having low back pain (LBP). It has been pointed out by several studies that the factors leading occupational

LBP among truck drivers include exposure to vibration, repeatedly lifting heavy objects, strained postures, and sitting for work for many hours.[15] In a recent study conducted at Japan it was observed that 52.9% of the truck drivers were having LBP. Most drivers pointed out that vibration and road shock account for the LBP. Troup et al. noted that muscle fatigue due to mechanical stress such as road shock transmitted to the body and a restricted sitting posture contribute to truck drivers' LBP. From the viewpoint of prophylaxis, an improvement in the working condition is needed to reduce the incidence of drivers' LBP to some extent.

In this study we observed higher prevalence of hypertension among truck drivers. According to World Health Organization, systolic blood pressure greater than 115 mm Hg accounts 62% of cases of cardiovascular disease and 49% of cases of ischemic heart disease.[16] Moreover, arterial hypertension is one of the major risk factors of cerebro vascular accident. Many studies have also demonstrated an increase in the prevalence of systemic hypertension among professional drivers.[17,18]

In our study older age was found to be an independent predictor of the total cardiovascular morbidity profile life span. With aging, there is an increased acquisition of several CVD risk factors in an individual's life span. Several studies have shown that when age and other risk factors are used jointly to examine an individual's risk of CVD, it has been found that the contribution of age in the multivariate models may be a reflection of the intensity and duration of exposure to the traditional CVD risk factors.[19-23] Avoidance of these traditional risk factors at younger ages can reduce CVD risk associated with age per se.

People employed in the transport sector form a considerable workforce of our nation.[24-28] Intersectorial consideration between transport department and health department is needed to protect and provide health to transport employees. Thorough periodical medical examinations are to be conducted to these truck drivers and necessary steps are to be taken. In addition strict guidelines about diet are to be formulated to the truck drivers. In addition it is observed that the truck drivers must be educated at their younger age preferably early thirties to prevent overweight and obesity and thereby to reduce hypertension. Regular health education programs are to be conducted regarding various non-communicable diseases and attendance to such programs should be made compulsory. Strict guidelines about diet are to be formulated and implemented in all the eateries catering to the employees. Various recreational facilities, counseling centers with psychologists are to be established in all depots to help the employees cope with their stress.

Limitations

Our study has some limitations. First, this study does not allow the determination of causal associations since we used cross sectional study design. Another limitation of our study is that, we have not quantified the smoking and alcohol intake. Fasting blood sugar values were not studied. Because we were looking for a cluster of cardio vascular risk factors, another limitation of this study was the lack of measurements on lipid profiles or inflammatory markers.

CONCLUSION

In conclusion, we observed a higher morbidity among the truck drivers' ages. The data in the present study allow us to draw conclusion that truck drivers are highly vulnerable to developing CVD because of the high prevalence of variety of risk factors. Furthermore we must consider that the truck drivers we studied were adult men and that cardiovascular risk factors could decrease their maximum age and it affects their economy, the lives of the truck drivers and individuals who use the roads.

Recommendations and generalizability

More national studies are needed to look into what percentages of road traffic accidents involving human error and what percentages involve medical conditions involving cardiovascular conditions. Accordingly guidelines for the minimum standards required for fitness to drive those drivers with CVD. However, the driving restrictions may have disadvantage in the form of psychosocial effects on recipients and their family members. Instead, regular health education programs and appropriate healthcare action based on comprehensive public policies that focus on the truck drivers work environment and monitoring of these factors must be established at the national level. Accordingly various recreational facilities and counseling centers are to be established in highways for the truck drivers. Finally, intersectorial coordination between transport department and health department is needed to protect and promote health of transport employees.

ACKNOWLEDGEMENTS

The authors are deeply thankful to Dhanush M, and Prem Anand ES, medical interns helped us in conducting the study and in collecting clinical data. The authors are extremely thankful to Dr.SL Ravi Shankar, Professor and Head of the Department of Community Medicine, PSG Institute of Medical sciences and Research for his valuable guidance at various stages of the study. The authors are thankful to Mr. Abdul Navas, Regional Transport officer, Palghat for permitting us to do this study. We are thankful to Mr.vinod, Head of marketing and Mr. Sirajudeen for helping us to organize and conduct this study.

Funding: No funding sources
Conflict of interest: None declared
Ethical approval: The study was approved by the Institutional Ethics Committee of PSG Institute of Medical Sciences and Research

Objectives: To develop and assess Pediatric Appropriateness Evaluation Protocol for India (PAEP-India) for inter-rater reliability and appropriateness of hospitalization.

Design: Cross-sectional study.

Setting: The available PAEP tools were reviewed and adapted for Indian context by ten experienced pediatricians following semi-Delphi process. Two PAEP-India tools; newborn (≤28 days) and children (>28 days-18 years) were developed. These PAEP-India tools were applied to cases to assess appropriateness of admission and inter-rater reliability between assessors.

Participants: Two sets of case records were used: (*i*) 274 cases from five medical colleges in Delhi-NCR [≤28 days (*n*=51); >28 days to 18 years (*n*=223)]; (*ii*) 622 infants who were hospitalized in 146 health facilities and were part of a cohort (*n*= 30688) from two southern Indian states.

Interventions: Each case-record was evaluated by two pediatricians in a blinded manner using the appropriate PAEP-India tools, and 'admission criteria' were categorized as appropriate, inappropriate or indeterminate.

Main outcome measures: The proportion of appropriate hospitalizations and inter-rater reliability between assessors (using kappa statistic) were estimated for the cases.

Results: 97.8% hospitalized cases from medical colleges were labelled as appropriate by both reviewers with inter-rater agreement of 98.9% (k=0.66). In the southerm Indian set of infants, both reviewers labelled 80.5% admissions as appropriate with inter-rater agreement of 96.1% (*k*= 0.89).

Conclusions: PAEP-India (newborn and child) tools are simple, objective and applicable in diverse settings and highly reliable. These tools can potentially be used for deciding admission appropriateness and hospital stay and may be evaluated later for usefulness for cost reimbursements for insurance proposes.

Keywords: *Bed use, Cost, Hospital stay, In-patient, Utilization*.

Efficient and rationale allocation of health resources in India and other developing countries is essential. The recent National Health Policy of India and Ayushman Bharat Yojana aim at healthcare universalization and improving both out-patient and in-patient accessibility [1,2]. Hospitalizations consume a major proportion of healthcare resources in India and 50.9% of the resources are utilized for secondary (34.8%) and tertiary (16.1%) level services [3]. There is severe shortage of in-patient beds in India (0.7 beds/1000 population vs. world average of 3.96) with long waiting period for hospitalization particularly at government hospitals [4]. Standardizing admission and discharge processes has improved utilization, patient-flow and waiting time in several countries, and appropriateness evaluation protocols (AEP) are in wide use [5-7]. At present no Pediatric

Accompanying Editorial: Pages 1037-38

Appropriateness Evaluation Protocol (PAEP) tool is available for use in India.

We describe the development and pilot-testing of the PAEP-India tool to determine the inter-rater reliability for appropriateness of two sets of hospital admissions: (*i*) 274 in-patients from five medical colleges from Delhi and surrounding states and (*ii*) 622 hospitalized infants from a southern Indian cohort.

METHODS

Development of PAEP Tool

The tool development process used semi-Delphi technique [8]. The PAEP tool adaptation for India (PAEP-India) process followed the steps: (*i*) an expert group of ten experienced pediatricians from ten medical colleges, each with >10 years of clinical experience was constituted considering the differences in symptomology, diseases and threshold for hospitalization, the experts felt need for developing separate tools for newborns (≤28 days) and children (>28 days-18 years); (*ii*) review of the available literature was done and seven PAEPs (from 6 high- and 3 middle-income countries) were sourced [9-19]; (*iii*) two rounds of review and pilot testing of the tools was done by the experts; (*iv*) a face-to-face meeting was held for finalization of tools.

Each tool has two sections; 'admission criteria' to assess the appropriateness at admission and 'day of care' criteria for the appropriateness of hospitalization duration. For the PAEP- India (child) tool, the group made some amendments in both the admission criteria and day of care criteria for children (***Box* 1**).

The PAEP-India (newborn) tool was drafted with reference to the available management protocols for newborns [21-23]. The group did not suggest any change in the draft and finalized it. Finally, 'admission criteria' section comprised of 44 items in both the tools, and the 'day of care' for newborn and child tools comprised of 27 and 29 items, respectively (***Web Annexure* I** and **II**).

The group of ten pediatricians who participated in the development of the PAEP-India tools were invited as raters. Five pairs of raters were made and each pair was assigned the same set of case sheets in a blinded manner; raters in a pair were not from the same institution and did not know the other member of their pair. All the raters underwent orientation to have common understanding of using the PAEP reviewers' manual.

We had two sets of case-records drawn from different settings for inter-rater reliability assessment: 274 pediatric cases records drawn from five medical colleges located in Delhi and surrounding states (admitted during July-September 2015), and 622 cases-records from Kollam and Coimbatore, who were part of a cohort of 30688 infants recruited and followed-up in another study [24]. The case-records were anonymized and assigned unique study numbers.

The Ethics Committees of participating Institutes reviewed and approved the study. Waiver of informed consent was granted for data collection from the case records from five medical colleges. Informed consent was obtained for recruiting the infant cohort from Kollam and Coimbatore.

Statistical analysis: Inter-rater agreement was evaluated by the Cohen's kappa (*k*) statistic [25]. Landis and Koch guidelines were adopted as benchmark scales of κ coefficients (moderate: 0.41-0.60, substantial: 0.61-0.80, and almost perfect: 0.81-1.0) [26]. Statistical analyses was performed using STATA version 15.0 (StataCorp LLC, Texas, USA). Overall agreement was the proportion of judgements in which two raters agreed on categorizing as appropriate, inappropriate and indeterminate. We assessed the inter-rater reliability only for the 'admission criteria'; the 'day of care criteria' section could not be evaluated as complete clinical, nursing and laboratory assessment records were not available for most of the days in most of the case sheets in both datasets.

Box 1 ADMISSION CRITERIA AND DAY OF CARE CRITERIA FOR DEVELOPMENT OF PAEP-INDIA*(CHILD) TOOL

- "severity of illness" section, "any fever for >48 hours when a diagnosis has not been reached" was revised to ">72 hours".
- Considering accidents, "burns/inhalational injury" and "exposure to poison and snake/ scorpion bite" were added.
- Under the "severe electrolyte/acid base/ hematological abnormality" section, "hypocalcaemia", "raised creatinine", "thrombocytopenia", "increased respiratory rate" were added, modified "total leukocyte count cut-off to <5000/ mm^3" and added "raised diastolic blood pressure" to hypertension.
- Under the "intensity of services" section, revised "nebulisation use at least every 4 hours".
- Day of care criteria: added "lack of suitable care taker availability (for abandoned child)/protected place" under "patient condition" section; and clarified "unstable vitals in last 48 hours" under the "within 48 hours of the day reviewed" section.

TABLE I CLINICAL DIAGNOSES IN THE TWO DATA SETS USED FOR INTER-RATER AGREEMENT FOR APPROPRIATENESS OF ADMISSION USING PAEP-INDIA TOOLS

Characteristic	*Delhi and Surroundings (n=274)*	*Kollam and Coimbatore (n=622)*
Children >28 d -18 y		
Infections	122	524
Acute respiratory infections	23	427
Acute gastroenteritis	26	33
CNS infections	20	
Urinary tract infections	3	19
Acute febrile illness[@]	28	25
Other infections[#]	22	20
Congenital diseases[€]	4	26
Other systemic diseases	43	68
Seizure/CNS disorders	15	25
Other medical disorders*	28	43
Surgical conditions	54	4
Gastrointestinal	19	4[^]
Urological	12	0
Other surgical conditions	23	0
Neonates (<28 d)		_
Medical problems	42	_
Neonatal sepsis	24	_
Other medical disorders[$]	18	_
Surgical conditions	9	_

*[@]Acute febrile illness including malaria, dengue, enteric fever, urinary tract infection, and other for evaluation; [#]Multiple system infection involves infection of more than one organ, may be with features of sepsis; [€]Congenital diseases including cardiac and central nervous system (CNS) malformations and other parts; *Other medical conditions including malignancy, coagulopathy, severe acute malnutrition, drug reaction, poisoning, constipation, nephrotic syndrome and hematemesis; [^]All 4 children had intussusception; [$]Other medical conditions in neonates included preterm care, respiratory distress syndrome, hyperbilirubinemia, hypo/hyper-glycemia, and birth asphyxia.*

RESULTS

The age strata of 274 case-records from Delhi and surrounding states were: ≤28 days (*n*=51), >28 days-12 months (*n*=48), 13-59 months (*n*=67), and >5-18 years (*n*=108). There were 54 surgical cases (20.8%). Out of 622 cases from southern India cohort, 471 (75.7%) were from Kollam and 151 (24.3%) were from Coimbatore. The median age at entry and exit were 48 days (range 32-175 days) and 153 days (range: 67-562 days), respectively. There were equal proportion of boys (50.3%) and girls (49.7%) in the cohort (***Table* I**). Out of 622 cases hospitalized to 146 hospitals, 50% (*n*=311) were admitted to tertiary (level 3), 49% (*n*=304) to secondary (level 2) and 1% (*n*=7) were admitted to primary care (level 1) care facilities respectively.

TABLE II INTER-RATER AGREEMENT FOR APPROPRIATENESS OF HOSPITALIZATION USING PAEP-INDIA TOOLS

Reviewer 1	*Reviewer 2*		
	Appropriate	*Inappropriate*	*Indeterminate*
Medical colleges in Delhi and surrounding areas (n=274)			
Appropriate	268	0	1
Inappropriate	2	1	0
Indeterminate	0	0	2
Hospitals in Kollam and Coimbatore (infants) (n=622)			
Appropriate	480	13	0
Inappropriate	9	68	2
Indeterminate	0	0	50

Kappa (*k*) coefficient was 0.66 (95% CI 0.30, 1.0) for the overall dataset for hospitalized cases in medical college. Both raters categorized 97.8% admissions as appropriate. The observed inter-rater agreements were >98% for aggregated and the disaggregated data according to age and gender. The agreement for PAEP appropriate cases and inappropriate cases were >98% with values of 0.66 and 0.49, respectively (***Table* II**).

The *k* for overall dataset was 0.89 (95% CI 0.84, 0.93) for the Kollam and Coimbatore infants. Overall both raters categorized 80.5% admissions as appropriate. The appropriate admissions in public and private hospitals were 84.5% and 78.5%, respectively. The observed agreement was >90% in most categories except for the level 1 hospitals (85.7%) which had just seven admissions.

DISCUSSION

This is the first effort to develop a tool for assessing the appropriateness of pediatric admission and hospitalization duration in India. The PAEP-India tools performed well for admission appropriateness assessment, both for newborns and children and across different levels of hospitals.

In the absence of a gold standard and true valid measure of appropriateness, the consensual validity is reflected through inter-rater agreement. Studies on admission appropriateness using the PAEP tools in different countries have reported variable levels of both observed agreement and kappa statistic (0.29-0.89) [9-12,14,16,19]. With PAEP-India tools, observed agreements were uniformly high with both the datasets.

WHAT IS ALREADY KNOWN?

- Country- and context-specific Pediatric Appropriateness Evaluation Protocol (PAEP) tools are in use for rational use of in-patient facilities.

WHAT THIS STUDY ADDS?

- India-specific PAEP tools for the assessment of appropriateness of pediatric and newborn hospitalizations were developed and tested for reliability with two sets of hospitalized children.

Despite a high observed agreement, lower kappa values may be observed, when the marginal values are imbalanced. On the contrary, higher kappa value may be observed for asymmetrical imbalanced marginal totals. Kappa is affected by prevalence and may not be reliable for rare observations. Thus very low kappa values may not necessarily reflect low overall agreement. Decision on performance of a tool should also consider the observed *versus* expected agreement, consistency across contexts, and suitability of the criteria for specific settings besides kappa statistics [27,28].

The reported proportion of appropriate pediatric admissions reported in literature range between 68%-89.5% and 59.3%-98% in high- and middle-income countries, respectively [9-12,14-16,19]. The proportion of appropriate admissions in the present study was high, particularly in medical colleges, in view of the higher demand and pressure for admission. A previous study reported that one-third of the adult patients overstay in hospitals [29]; which was triangulated by the perceptions of 83% of resident doctors and 43% of nurses in another study [30].

Awareness of the raters about the source of cases in first dataset might have influenced the high expected and observed agreements (>90%). For the second dataset (southern Indian infant cohort), the raters were neither aware about the hospitals nor involved in the study implementation or patient care. We could not assess the appropriateness of the duration of hospitalization due to lack of necessary information at the time of discharge. In the first dataset, the experts involved in development of PAEP-India tools also applied the tools in cases drawn from some medical colleges where they worked. These factors might have increased observed agreement and categorization of cases as appropriate. The findings for the level one health facilities from southern India may not be generalized as the number of hospitalizations were too small.

In conclusion, the PAEP-India tools performed consistently in two different settings demonstrating consensual validity. The advantages of the PAEP-India tools is their simplicity, objectivity and applicability in different hospitals. Further application and evaluation of these tools is required in diverse settings across India including health facilities of all levels for triangulating the evidence of its utility. Meanwhile the PAEP-India tools have potential application in insurance systems, quality assessment processes, and resource-allocation.

Abstract

Papillon Lefevre syndrome (PLS) manifests with palmoplantar keratoderma, combined with a rapidly progressive periodontitis associated with mutations in Cathepsin C (*CTSC*) gene. This article reports a 15-year old male proband with typical PLS traits having a novel compound heterozygote with p.Q49X mutation in exon 1 and p.Y259C missense mutation in exon 6 of *CTSC* gene respectively. The exon 1 mutation, p.Q49X, (found in proband's mother) was located in exclusion domain and exon 6 mutation, p.Y259C (found in proband's father), was present in peptidase C1A, papain C-terminal domain. Interestingly, missense mutation p.Y259C identified in this study was found to be not reported so far. Upon computational analysis, this missense mutation was found to be lethal. Moreover, our protein modelling approach using mutant protein revealed the presence of monomeric structure on contrary to the tetrameric structure of the wild type protein. In addition, in vitro functional characterization of mutant p.Y259C expressed in HEK293 cells showed a significant reduction in CTSC activity (0.015 ± 0.009 mU/ml) when compared with wild type protein (0.21 ± 0.008 mU/ml). Thus, in this study, we have demonstrated that the pathogenic missense mutant p.Y259C might cause PLS by impaired CTSC function.

Keywords Papillon Lefevre syndrome · Cathepsin C · Compound heterozygote · Missense mutation · Palmoplantar keratoderma.

Abbreviations

PLS	Papillon lefevre syndrome
CTSC	Cathepsin C

Introduction

Papillon–Lefèvre syndrome (PLS) is an autosomal recessive disorder characterized by palmoplantar keratoderma in association with aggressively progressing periodontitis. Keratosis can occur in the knees and elbows [1, 2]. Mutations in *CTSC* gene predisposes to PLS [3] with an increased risk of medical manifestations in consanguineous marriages. Haim munk syndrome and PLS share common features but with supplementing components like arachnodactyly, acroosteolysis and onychogryphosis is found only in the former.

CTSC gene finds its locus on chromosome 11q14-q21 [4, 5] and encodes a lysosomal cysteine protease involved in activation of many serine proteinases within immune cells. It is involved in cell-mediated cytotoxicity, phagocytic destruction of bacteria, local activation or deactivation of cytokines. Many reports on *CTSC* mutation leading to loss of function

of CTSC protein and development of PLS has been reported [6, 7].

In our study, the proband suspected to be a PLS case was screened for *CTSC* gene mutation and found to have a compound heterozygous mutation, p.Q49X in exon 1 and p.Y259C in exon 6 of *CTSC* respectively. p.Y259C is a novel missense mutation not reported so far in association with PLS. It is a pathogenic mutation with a monomeric structure and had reduced enzyme activity.

Materials and methods

Patient and family unit

A 15-year old boy who attended the Dermatology outpatient clinic of PSG Hospitals, Coimbatore, India was clinically examined for dermatological, dental and radiological findings. The patient and his parents consented for genetic analysis and therefore, blood samples were drawn from them. Third degree parental consanguinity was documented. The phenotypic characteristics were then compared with the genotype results.

Mutation analysis of *CTSC*

Genomic DNA was isolated using EZ-10 Spin Column Blood Genomic DNA MiniPreps Kit (Bio Basic Canada Inc). The seven exons of *CTSC* gene were amplified using the primer sets reported [6]. The PCR reaction mixture of 20 µl containing 50 ng DNA as the template, 50 nM each of the forward and the reverse primer, 1 mM each of dNTPs, in a 1X PCR buffer (with1.5 mM $MgCl_2$) with 1U of Taq Polymerase (Ampliquon, Germany) was incubated in a thermal cycler (Eppendorf, USA). The cycling parameters included 95 °C for 2 min, 35 cycles of 95 °C for 30 s, 60 °C annealing for 40 s and extension of 72 °C for 1 min. The amplified exons were sequenced by Sanger's sequencing and analysed.

Computational analysis

The CTSC protein was analysed using InterProscan and PROSITE database tools to identify significant domains and functional active sites in the protein respectively. In order to predict the potential pathogenecity of *CTSC* mutations, two bioinformatics tools were used, PolyPhen-2 (Polymorphism Phenotyping v2) in a scale from 0.00 (for benign) to 1.00 (for deleterious) (http://genetics.bwh.harvard.edu/pph2) and Mutation Taster (http://www.mutationtaster.org/). Multiple protein sequence alignments were performed using COBALT (Constraint-based Multiple Alignment Tool). Moreover, the wild type and the mutant proteins were modelled using SWISS MODEL (https://swissmodel.expasy.org) tool to obtain the comparative 3D structure of both the proteins.

Site directed mutagenesis

The Q5 Site-Directed Mutagenesis Kit (NEB, USA) was used to construct the missense mutant, Y259C. The kit manufacturer's instructions were followed to obtain the mutant clones and were confirmed through sequencing.

Cell culture and transfection

HEK293T cell line was cultured in Dulbecco's Modified Eagle's Medium (DMEM) supplemented with 10% fetal bovine serum and 100 U/ml penicillin and 100 µg/ml streptomycin (Sigma Aldrich, USA) at 37 °C in a 5% CO_2 atmosphere. The cells were transiently transfected with the Lipofectamine 3000 reagent (Invitrogen, USA) and Opti-MEM Reduced Serum Medium in 24 well plates. After 48 h, the medium was replaced with complete DMEM with 100 µg Hygromycin to obtain the cells bearing the plasmid (pCMV3) with Hygromycin resistance.

Mutant and wild type CTSC protein expression and purification

The transfected cells were disrupted in 100 µl lysis buffer (10 mM Na_3PO_4, 0.1% Triton X-100) and centrifuged at 2500 g for 5 min at 4 °C. The supernatant (5 µg per lane) was separated on 10% SDS PAGE. Proteins were quantified using the Bradford assay. The His—CTSC protein fractions were selectively purified using Ni-NTA column (Qiagen, Germany). The protein mixture was incubated in the binding buffer (20 mM Tris/HCl, 200 mM NaCl; pH 7.5), washed (20 mM Tris/HCl, 200 mM NaCl, 5 mM imidazole; pH 7.5) and eluted (20 mM Tris/HCl, 200 mM NaCl, 200 mM imidazole; pH 7.5) to obtain pure protein fractions. The protein fractions were allowed to undergo activation by with 20 µg/ml papain at 37 °C, pH 6.5 for 6 h to generate active peptides of CTSC. To inhibit the activity of the mature enzyme, 1 mM iodoacetamide (Sigma Aldrich, USA) was used.

Recombinant CTSC enzyme activity assay

Enzymatic activity was assayed by mixing 20 µl of the purified protein with 30 µl reaction buffer (100 mM Na_3PO_4, 2 mM NaCl, 2 mM DTT), 30 µl dilution buffer (10 mM Na_3PO_4, 0.1% Triton -X-100), and 100 µl of chromogenic CTSC substrate (1.5 mM gly-phe-para-nitroanilide). Absorbencies were measured at 405 nm, samples were incubated at 37 °C for 1 h, and read again. Cathepsin C activity of samples, expressed as para-nitroanilide released (nmol/mg of protein * hour), was determined interpolating

Author's personal copy

the difference between first and second reads in a standard curve (0.0351–2.24 nmoles) of pure 4 para-nitroaniline (4 pNA) (Sigma-Aldrich, USA) [8].

Statistical analyses

Data were expressed as mean ± standard error of the mean (SEM) from three independent experiments. The data were evaluated for statistical significance with unpaired *t* test. $p < 0.05$ was considered statistically significant. All the statistical analyses were carried out using GraphPad Prism software version 5.0 Windows (GraphPad Software, USA).

Results

Clinical manifestations of the patient with PLS

A 15 year old boy, born out of third degree consanguineous marriage, presented to the dermatology OPD with complaints of thickened skin involving the palms and soles since infancy. He had erythematous lesions involving elbows, knees and few areas of trunk. The patient gave history of failure of eruption of lower incisors following the fall of primary teeth. The patient had developed multiple furuncles in the past. On examination, the patient had diffuse palmoplantar keratoderma with multiple erythematous papules and plaques seen involving the dorsum of hands, feet, elbows, knees and few areas of the trunk. On examining the teeth, the lower central incisors were absent (Fig. 1a). The nails showed multiple transverse ridging. Biospy done from the cutaneous lesions showed evidence of psoriasiform hyperplasia of epidermis with dermis being unremarkable. Routine blood investigations and X ray of the hands were normal.

CTSC mutation analysis

The seven exons of the *CTSC* gene from the proband and parents were sequenced using Sanger sequencing method. Further, *CTSC* gene analysis (NCBI reference sequences for mRNA: NM_001814.6, Concensus CDS: CCDS44693.1 and Protein: NP_001805.4) of the proband showed a compound heterozygous mutation, Q49X in exon1 and Y259C in exon 6 (Fig. 1b, c). The parents were heterozygous carriers of the mutations and were unimpacted. The nonsense mutation *c.145C > T* (p.Q49X) in exon 1 was inherited from mother while missense mutation *c.776A > G* (p.Y259C) in exon 6 was from father (ESM_1).

Evolutionary conservation of *CTSC* and in silico analysis

The mutations, p.Q49X and p.Y259C belonged to the exclusion domain (25-142 aminoacids) and Peptidase C1A, papain C-terminal domain (231-458 aminoacids)

respectively as identified from InterProscan analyses. The PROSITE database search revealed that cathepsin C protein has a thiol (cysteine) protease enzyme whose active sites are composed of Cys258, His405 and Asn427. PolyPhen2 predictions of the functional effect of the missense mutation proved that mutation was predicted to be damaging with a score of 1.00. Another tool, Mutation Taster also predicted this mutation to be disease causing. Moreover, the aminoacid Y (tyrosine) at 259th position was found to be highly conserved among different species like house mouse, rat, zebra fish, dog, cattle, chimpanzee, monkey, chicken and frog (Fig. 2a).

Author's personal copy

The protein sequence derived from the wild type and mutant protein (Y259C) were subjected to sequence based structure prediction using SWISS MODEL protein modelling software. The wild type protein was predicted by the SWISS MODEL as a tetramer having A, B, C and D chains (Fig. 2b). On the other hand, the mutant protein carrying the novel mutation p.Y259C was predicted to be only a monomer having the A chain (Fig. 2c).

In vitro expression of mutant p.Y259C CTSC protein

The pCMV3-CTSC vector was subjected to site directed mutagenesis to create a p.Y259C mutation. After mutagenesis, the clones were confirmed by Sanger's sequencing (Fig. 2d). To obtain the rCTSC protein, the following vectors were transfected into HEK 293T cell lines; pCMV3-CTSC, pCMV3-CTSC Y259C and pCMV3 negative control vector. After transfection, the cells bearing hygromycin resistant phenotypes were selectively harvested. DNA was isolated from the harvested cells and *CTSC* gene *was* amplified (Fig. 3a). The cells were lysed to obtain the protein fractions which were purified. The purified protein (inactive) was of size 55 kDa which is a propeptide. It was activated by papain treatment which yielded bands of sizes 25 kDa and 6 kDa (Fig. 3b).

Mutant p.Y259C CTSC shows reduced activity

The mutant p.Y259C CTSC protein showed a statistically significant reduction in its activity (0.015 ± 0.009 mU/ml) when compared to wild type CTSC protein (0.21 ± 0.008 mU/ml). Upon treatment with 1 mM iodoacetamide, a cysteine protease inhibitor, the activity of both mutant and wild type protein was reduced by 10 folds (Fig. 3c).

Discussion

PLS is caused by mutation in cathepsin C (*CTSC*) gene which encodes a lysosomal enzyme expressed predominantly in palms, soles, elbow, knee and gingiva. This explains the disordered keratinization leading to cutaneous lesions in these areas. Cathepsin C also plays an important role in the function of polymorphonuclear cells and macrophages, thus explaining the reason for recurrent pyoderma and gingivitis in PLS [9].

Among the PLS cases, missense mutations predominates nonsense and frameshift mutations in *CTSC* gene. The first compound heterozygous individual with PLS was reported in 2000 [10]. In the current study, a nonsense mutation p.Q49X (*c.145C > T*) and a missense mutation p.Y259C (*c.776A > G*) was present in a compound heterozygous state in the proband. This nonsense mutation truncated the protein to a 49 amino acid polypeptide as a nonfunctional enzyme resulting in PLS phenotype. p.Q49X has been reported in an Indian family coupled with PLS [11] and Haim Munk syndrome [12].

A missense mutation *c.776A > G* (p.Y259C) observed in the affected patient was located in Peptidase C1A, papain C-terminal domain which is important for the intracellular protein degradation activity of the enzyme as this domain corresponds to the 233 amino acids mature enzyme unit [13] of cathepsin C. Moreover, this mutation Y259C lies next to the active site Cys258, thus, raising a suspicion of any possible Cys-Cys disulfide bond formation between Cys258 and Cys259 in the mutant protein and abolishing the active site availability. The 3D structure prediction results show that the p.Y259C mutant protein lacked the tetrameric structure unlike the wild type protein and

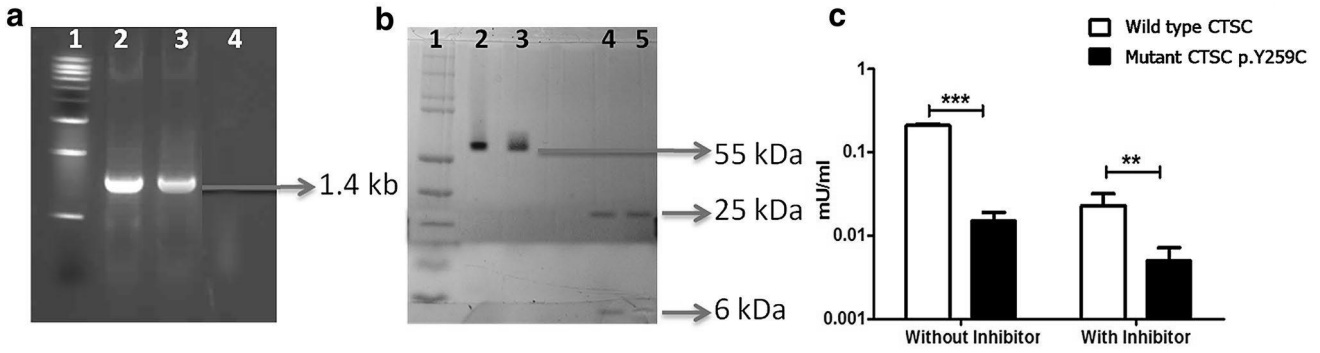

Fig. 3 Cloning, expression and enzyme activity of wild type and p.Y259C mutant CTSC protein. **a** *CTSC* amplified from cells transfected with wild type (lane 2), mutant plasmid (lane 3) and negative control vector (lane 4). **b** The image shows propeptide form of His-CTSC (lane 2) and His-CTSC Y259C (lane 3) purified from the cell lysate of wild type and mutant plasmid transfected HEK 293T cell lines. The active form of His-CTSC (lane 4) and His-CTSC Y259C (lane 5) after papain treatment is also shown. 5 µg of the protein was loaded onto 10% SDS PAGE and followed by Coomassie blue staining. Lane 1: Prestained protein ladder (Biorad, USA). **c** Mutant CTSC (p.Y259C) protein showed a statistically significant 14 fold reduction in the enzyme activity when compared to wild type CTSC protein. 1 mM iodoacetamide inhibited the CTSC enzyme activity proportionally in mutant CTSC (p.Y259C) and wild type CTSC by tenfolds

Author's personal copy

had a monomeric structure (A chain). It is reported that tetramerization is crucial for the enzymatic activity [14]. Therefore, the structure modelled by SWISS MODEL substantiates the fact that this missense mutation has resulted in the development of PLS phenotype by abolishing the formation of tetrameric structure. Similarly, structural effects leading to functional abnormalities were also reported as a result of P35delL and R272P mutations in CTSC gene [15]. The inactive form of CTSC protein was of 55 kDa which after maturation yielded bands of molecular weights of 25 kDa and 6 kDa observed in earlier studies [16].

This missense mutation identified in our study, p.Y259C, was found as a novel pathogenic mutation associated with PLS syndrome In addition, there was a statistically significant 14 fold reduction in CTSC enzyme activity in the mutant protein when compared to the wild type protein. The presence of cysteine protease inhibitor, iodoacetamide further reduced the enzyme activity in both the wild type and the mutant proteins by 10 folds as observed in other studies [17]. Similarly, 85% reduction in the enzyme activity was observed in Mexican patients with PLS in a study [18]. Recently, many reports on requirement of early identification of PLS and proper dental management was emphasized [19–22]. Therefore, our study has helped to broaden the list of reported mutations associated with PLS.

PREVALENCE OF DEPRESSION AND ITS ASSOCIATED FACTORS IN ADULTS WITH DIABETES MELLITUS: A CROSS-SECTIONAL STUDY IN A TERTIARY CARE CENTRE

Shweta Paulraj[1] , Senthil Rajasekaran[2] and Anil C Mathew[3]

[1,2] Department of Endocrinology, [3]Department of Community Medicine, PSG Institute of Medical Sciences and Research, Coimbatore, India

ABSTRACT

The prevalence of Diabetes Mellitus has been rising steadily owing to several factors such as sedentary lifestyle, obesity and an aging population. The prevalence of diabetes is predicted to double globally from 171 million in 2000 to 366 million in 2030 with a maximum increase in India with up to 79.4 million individuals in India. Depression occurs frequently with diabetes but there are not many studies in India to estimate its prevalence and associated factors. This study was done with the aim of estimating the prevalence of depression among diabetes patients using the validated Patient Health Questionnaire-9 and also its associated factors. A cross sectional study was done on 100 consecutive patients with Diabetes Mellitus (both type 1&2) attending the Outpatient Endocrinology clinic from September 2015 to November 2015. The Patient Health Questionnaire diagnostic algorithm was used to identify major depression. The covariates studied were age, gender, duration of diabetes, presence of hypertension and glycaemic control. Chi-square test was done to find the association of demographic and clinical characteristics of depression. Multiple logistic regressional analysis was done to identify the statistically significant variables. The prevalence of major depression was found to be 35%. People with hypertension were found to have a significantly higher prevalence of depression (adjusted odds ratio=3.02, 95% CI: 1.17 to 7.7, P=0.022). Also, employed people were at a lower risk for depression when compared to the unemployed /retired population (adjusted odds ratio=0.319, 95% CI: 0.11-0.85, P=0.023).Interestingly age, duration of diabetes and glycaemic control were not significantly associated with depression. Over one-third of the patients with diabetes mellitus had depressive symptoms. The prevalence varied by demographic and clinical characteristics.

KEYWORDS

Diabetes, Depression, Patient Health Questionnaire- 9, Hypertension.

1. INTRODUCTION

The prevalence of Diabetes Mellitus has been rising steadily owing to several factors such as sedentary lifestyle, obesity and an aging population. The prevalence of diabetes is predicted to double globally from 171 million in 2000 to 366 million in 2030 with a maximum increase in India with up to 79.4 million individuals in India.[1]

Depression occurs frequently with diabetes and has been found to be associated bidirectionally with diabetes mellitus.[2,3] However, it was observed that the reported prevalence in the studies varied tremendously in terms of definition, study design, source of subjects, time frame and measurement methods.[4-6] Moreover, with the predicted rise of diabetes in India, and risk factors

for depression such as low socioeconomic status, financial constraints being rampant here it is quintessential to establish regional studies as a guideline to aid in a holistic patient approach. [7]

Apart from this, most of these studies used self-administered questionnaires which cannot directly establish a diagnosis of depression. [4,5,6,8] Standard interviews, such as the Structured Clinical Interview for DSM Disorders (SCID)[9] and the Composite International Diagnostic Interview (CIDI) [10] can yield a clinical diagnosis according to the Statistical Manual of Psychiatric Disorders, 4th edition (DSM-IV) [11] ; however, lengthy assessments and high costs preclude the extensive use of such structured diagnostic interviews in large population-based surveys.

The Patient Health Questionnaire (PHQ) can establish provisional diagnoses of major and minor depression as well as evaluate the severity of depressive symptoms. [12] ; The PHQ-9 diagnosis of major depression yielded acceptable sensitivity and specificity. The present study aims to estimate the prevalence of depression among diabetes patients using the validated Patient Health Questionnaire-9 and its associated factors.

The variables taken into consideration for association with depression in this region include age, gender, duration of diabetes, glycaemic index and presence of hypertension . This stems from previous studies which show significant correlations between the above variables and depression[6,13,14]

2. MATERIALS AND METHODS:

This study is a cross-sectional study on 100 consecutive patients presenting at a tertiary care centre, aged >18yrs diagnosed with Type 2 diabetes mellitus by a certified Endocrinologist. The study was carried out after obtaining institutional ethics committee clearance. Written informed consent was obtained from the study participants and the PHQ-9 questionnaires were distributed. Those subjects that couldn't read were assisted in filling the questionnaires by an interpreter (Figure 1). During multivariate analysis we have combined the scores 0-9 (none, minimal and mild depression categories) as "no major depression" and scores of 10-27 (moderate, moderately severe and severe categories) as " major depression".[15,16]

Patients with complications from diabetes (retinopathy, neuropathy, nephropathy), previous history of mental illness, previous illnesses known to increase a risk for depression (CAD,CVA), and patients already on antidepressants for other symptoms were excluded from the study.

The demographic variables considered were age, gender, duration of diabetes, glycaemic index and presence of hypertension. Age was measured in completed years. Duration of diabetes and glycaemic control were taken from the patients' case records. Hypertension was defined in the study as systolic BP level of ≥140mmHg and diastolic BP of ≥90mmHg, or current treatment for hypertension with prescription medication. [17,18]

Data were analysed using SPSS(19). Chi-square test was done to find the association of demographic and clinical characteristics of depression. Further, multiple logistic regressional analysis was done to identify the statistically significant variables. *P* value of <0.05 was considered as statistically significant

PATIENT HEALTH QUESTIONNAIRE (PHQ-9)

NAME:_____ DATE:_____

Over the last *2 weeks*, how often have you been bothered by any of the following problems?
(use "✓" to indicate your answer)

	Not at all	Several days	More than half the days	Nearly every day
1. Little interest or pleasure in doing things	0	1	2	3
2. Feeling down, depressed, or hopeless	0	1	2	3
3. Trouble falling or staying asleep, or sleeping too much	0	1	2	3
4. Feeling tired or having little energy	0	1	2	3
5. Poor appetite or overeating	0	1	2	3
6. Feeling bad about yourself—or that you are a failure or have let yourself or your family down	0	1	2	3
7. Trouble concentrating on things, such as reading the newspaper or watching television	0	1	2	3
8. Moving or speaking so slowly that other people could have noticed. Or the opposite — being so figety or restless that you have been moving around a lot more than usual	0	1	2	3
9. Thoughts that you would be better off dead, or of hurting yourself	0	1	2	3
	add columns		+	+

3. RESULTS:

Among the 100 patients studied, 35 were found to have major depression (Figure 2). In the univariate analysis, those who were having hypertension and those who were unemployed were significantly associated with depression (P<0.05). In the multiple regression analysis(Table I), people with hypertension were found to have a significantly higher prevalence of depression (adjusted odds ratio=3.02,95% Confidence Interval :1.17 to 7.7,P=0.022) (Figure 3).Also, employed people were at a lower risk for depression when compared to the unemployed /retired population(adjusted odds ratio=0.319,95% Confidence Interval :0.11-0.85,P=0.023) (Figure 4) that bar graph has nothing written on x axis. Interestingly age, duration of diabetes and glycaemic control were not significantly associated with depression.

4. DISCUSSION:

In the present study the prevalence of depression among patients with diabetes mellitus was found to be 35% which was slightly smaller than the prevalence in a study conducted by Joseph N et al., in an adjoining area that reported a prevalence of 45.3%.[13] It was also found to be more than twice as common as depression in the general population of our region.[7,19]

This leads us to ask the more imposing question, “Why is depression more prevalent in people with diabetes mellitus?”. The study by Talbot F et al., suggested that the extent to which diabetes intrudes in life, rather than diabetic complications per se or personal control, is a key factor in

relation to depressive symptomatology in individuals with diabetes. [20]In an animal model, Wang and colleagues demonstrated that experimentally induced type 1 diabetes impairs hippocampal neurogenesis, which may contribute to diabetes-related depression.[21] Another study demonstrated decreased plasma brain-derived neurotrophic factor (BDNF) in patients with type 2 diabetes compared to controls, which has been hypothesized to play a role in learning and memory and has also been implicated in the pathogenesis of depression.[22]

Among the risk factors, depression was found to be significantly associated with hypertension. This is in line with the findings of Saeed AK et al., where the prevalence of depression in hypertensive people with diabetes mellitus was 57% whereas in people with diabetes alone it was 40%. (P is less than 0.05). [23] There are also other studies which showed that depression is common in patients with uncontrolled hypertension irrespective of presence of diabetes and may interfere with blood pressure control. [24, 25] Studies have shown that plasma noradrenaline, as an indirect marker of sympathetic tone, was elevated in patients with essential hypertension.[26] There is also reported evidence showing abnormal autonomic nervous system function in depression, specifically regarding increased sympathetic activity and poor vagal control. Several studies have examined cerebrospinal fluid (CSF), plasma or urinary levels of norepinephrine (NE) and its major central nervous system metabolite, 3-methoxy-4-hydroxyphenylglycol (MHPG). Plasma NE and/or MHPG levels have been reported to be elevated in depressive patients.[27,28] Thus, the existing relationship between hypertension and depression by itself could have contributed to the statistically significant presence of depression among hypertensive people with diabetes mellitus.

Also, we found that depression among diabetes was significantly associated with employment status with a higher prevalence in the unemployed population. This is in line with other studies which showed a higher prevalence of depression in the unemployed population. [13,29,30] The unemployed individuals lack sociological functions such as time structure, status and identity, social contacts, participation in collective purposes and regular activity which could predispose them to depression.[30]

A methodological innovation of our study was the application of the PHQ-9[12] which was developed for clinical use, scoring each of the DSM IV criteria on grades from 0-3 based on the frequency of the symptoms[31] Scores of 20-27,15-19,10-14,5-9 and 1-4 represent severe, moderately severe, moderate, mild and minimal depression respectively. [11]

Our results indicate that a substantial number of people with diabetes are at an increased risk of having major depression, and those who care for patients with diabetes should routinely screen them for major depression using the PHQ-9 or other such instruments. Among the umpteen methods to screen for depression, the PHQ-9 is a promising tool with its ease of administration, convenient scoring system, brief and simple questions. Most importantly, the use of PHQ-9 can serve in comparisons of depressive symptomatology on an international basis given its worldwide validation. [32,33]

This study has some limitations. The study was conducted in a tertiary care hospital, so a possible selection bias cannot be excluded. This could be because the patients coming to the tertiary care hospital belong to the relatively higher socioeconomic status of the community. A large sample community based study could throw more light on this relationship. Since this study is a cross-sectional study, temporal relationship between depression and diabetes cannot be determined.

5. CONCLUSIONS

Over one-third (35%) of the patients with diabetes mellitus had depressive symptoms. It is widely associated with unemployment and co-existent hypertension in this population.

This emphasizes that the mind/body dualism is a false dichotomy and there is an increasing need to integrate mental health services in these patients. We recommend routine screening of diabetic patients with PHQ-9 to identify those at risk as it is a quick and easy tool to identify depression and refer patients appropriately for further counselling and support.

In addition, the issue of depression in association with socioeconomic factors such as unemployment is to be addressed by the health policy to aim for an overall betterment of the welfare of the people in this region.

ACKNOWLEDGEMENTS

My sincere thanks to my Guides, Dr. Senthil Rajasekaran and Dr. Anil Mathew stood by my side and helped me carry out this research perfectly at each and every step. I would also like to thank the Department of Endocrinology and Community Medicine, and all the supporting staff for their help. Finally I wish to thank the study participants for sparing their valuable time and for providing the information which enabled us to complete our research.

ABSTRACT

Aim: The aim of the study was to examine the association of consumption of tea with the risk of type 2 diabetes mellitus. **Methods:** A case control study was conducted at PSG Hospitals between 1st June 2017 and 1st July 2017. All those who had newly diagnosed type 2 diabetes mellitus and attended Department of Endocrinology for follow-up visit were the cases and the relatives accompanying them without the history of diabetes mellitus were the controls. Tea consumption and other dietary factors were elicited. The mediating factors studied were age, sex, Body Mass Index (BMI), educational levels, smoking status, alcohol consumption, family history of diabetes mellitus, potassium intake, magnesium intake and use of statins. **Results:** After adjusting the potential confounders, tea consumption was inversely associated with risk of type 2 diabetes mellitus with odds ratio of 0.652 (95% CI = 0.43 – 0.98). The association was also observed with participants who consumed tea 3 or 4 cups per day compared to those who did not drink tea on a daily basis (odds ratio = 0.368, 95% CI = 0.14 – 0.96). However, the association was not observed among those who take 5 or more cups of tea per day (odds ratio = 0.328, 95% CI = 0.06 – 1.60).**Conclusion:** Our findings suggest that consumption of 3 to 4 cups of tea per day has a decreased risk of type 2 diabetes mellitus. The results from our study also suggest that adjusting for mediating factors did not alter the results and hence other unknown factors may explain inverse relation between tea consumption and type 2 diabetes mellitus. Further studies are warranted.

Keywords: Tea consumption, type 2 diabetes mellitus, chocolate consumption, potassium intake

Introduction

The prevalence of type 2 diabetes mellitus has increased dramatically in the past decades [1, 2].

Professor of Biostatistics, Department of Community Medicine, PSG Institute of Medical Sciences and Research, Coimbatore, India
E Mail: anilpsgmet@gmail.com

The majority of cases of diabetes mellitus could be prevented by changes in life style. However, the association of tea consumption with the risk of type 2 diabetes mellitus is not entirely clear. Few studies found an inverse association between tea intake and type 2 diabetes mellitus, while few other studies did not observe an association between tea consumption and risk of type 2 diabetes mellitus [3-6].The underlying mechanism regarding the relation between tea consumption and type 2 diabetes mellitus is also

unclear. Several components of tea have been suggested as possible causal factors [7].Magnesium plays a role in regulating insulin action and is inversely associated with insulin sensitivity and type 2 diabetes mellitus. Potassium intake has also been associated with reduced risk of diabetes mellitus [8].So far; there is no conclusive evidence about whether these factors explain the association of tea intake and type 2 diabetes mellitus. Besides these, earlier studies have not accounted for the effect of long term medication such as statin use which may confound the results. Therefore the present study is aimed to investigate the association of tea consumption with the risk of type 2 diabetes mellitus adjusting for multiple covariates.

Materials and Methods

Study population and design

A case-control study was conducted at PSG Hospitals. All those who have newly diagnosed in the past 1 year as type 2 diabetes mellitus and attending the Department of Endocrinology for follow up between 1stJune 2017 – 1st July 2017 were considered as cases. Controls were those who accompany them and do not have history of diabetes mellitus. We then retrospectively evaluated their food practices and other demographic information.

General assessments

The general assessment survey was conducted at the outpatient Department of Endocrinology, PSG Hospitals, Coimbatore. The general questionnaire contained questions on demographic characteristics. Body weight (in kg) and height (in meter) were also measured. However in few cases, we were not able to measure height. Food intake was assessed using a validated Food Frequency Questionnaire in this population and from this magnesium intake and potassium intake were estimated. The questionnaire also asked about smoking status, practice of alcohol intake, whether previously diagnosed as diabetes mellitus, other medical histories and medications taken. The information on baseline consumption of coffee, tea and other beverages were also collected. We also collected the data about consumption of chocolates, since chocolates are also a source of caffeine.

Statistical analysis

To examine the association between tea consumption and incidence of type 2 diabetes mellitus, we used four logistic regression models. In the first model, odds ratio and 95% confidence intervals for type 2 diabetes mellitus were calculated against a reference group of low consumers adjusted for age (continuous) and gender (male/female). A second logistic regression model corrected the other known diabetes mellitus risk factors which include smoking status (present/absent), BMI, education attainment (classes up to 12th standard/college and above), family history of diabetes mellitus (present/absent); alcohol intake (gm. per week). Body mass index was calculated by the formula, body weight (kg) divided by the square of the body height in meter. A third model corrected for coffee (considering the fact that those who drank a lot of tea tend to drink less coffee and vice versa) and chocolate consumption. Mediating factors were included in the final model. The mediating factors considered were daily intake of magnesium and potassium, which were elicited from their food consumption practices and the effects of long term medications particularly the use of statins[9].

Results

The study included 150 cases and 150 controls. Baseline characteristics of the study participants among cases and controls were presented in Table 1. Most of the demographic factors were comparable between cases and controls. However cases were having slightly older age compared to controls. Family history of diabetes mellitus and level of education was higher among cases compared to controls. In the multivariate regression model, odds ratio shows that the participants who drank more tea had a significantly decreased risk of diabetes mellitus compared with those who do not drink tea on a daily basis (odds ratio = 0.652, 95% CI = 0.43 – 0.98). On further analysis, it was observed that the participants who consumed 3 or 4 cups of tea per day had a decreased risk of type 2 diabetes mellitus compared to those who do not drink tea on a daily basis (odds ratio = 0.368, 95% CI = 0.14 – 0.96) (Table 3) with no significance in analysis of trend (Figure 1). The reduced risk was not observed among those who take 5 cups or more tea per day (odds ratio = 0.328, 95% CI = 0.06 – 1.60)

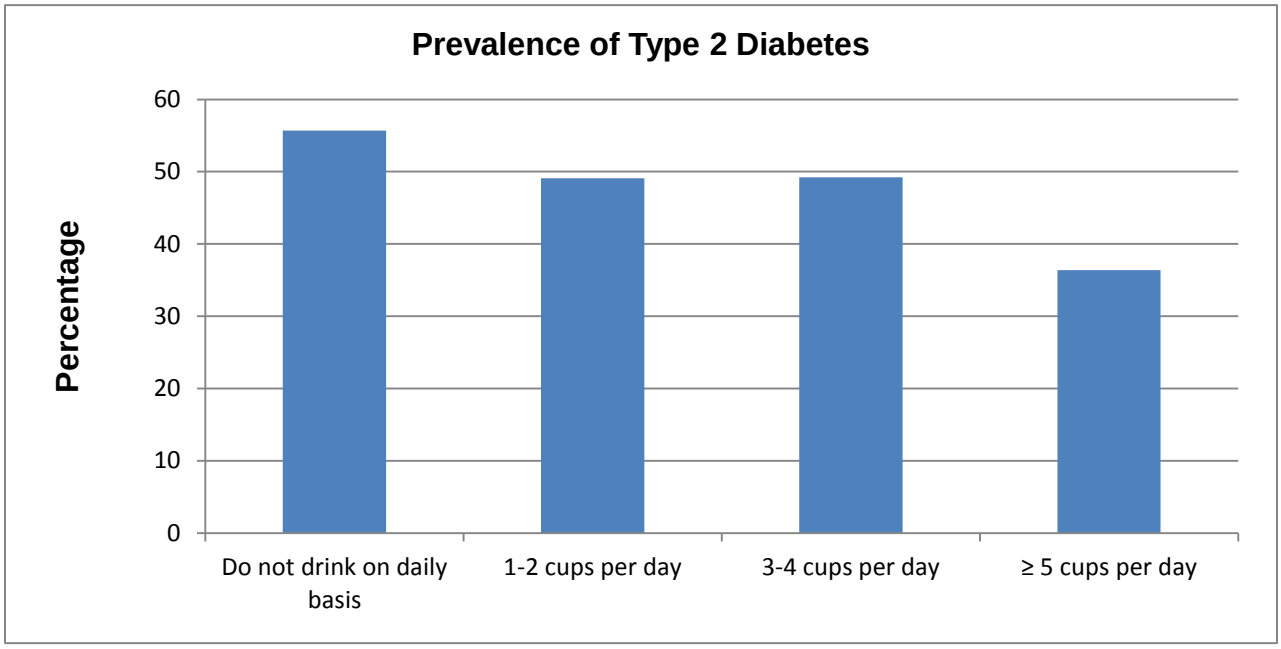

Fig1: Prevalence of type 2 diabetes mellitus according to the consumption of tea cups per day

Discussion

Several studies have investigated the association between tea consumption and type 2 diabetes mellitus[10-14]. Some of these studies did not find any association, while other studies observed an inverse association between tea consumption and type 2 diabetes mellitus. Another study found an association only for green tea and not for black tea. However, our study strongly support the findings of the recent meta-analysis[11] which concluded that consumption of 4 cups of tea per day may lower the risk of type 2 diabetes mellitus, but a reduced risk was not observed for 1 to 2 cups per day. In addition, we also observed that the reduced risk was not observed for those who take more than five cups of tea per day. This is perhaps due to the reduced sample size in this group.In univariate analysis, we observed an inverse association between potassium intake and the risk of type 2 diabetes mellitus. In our study, intake of magnesium and potassium were included in the final model to assess whether these factors mediated the observed association between tea intake and type 2 diabetes mellitus, but none affected the association. Hence, results from our study suggest that other factors may be more important to explain inverse relation between tea consumption and type 2 diabetes mellitus. Tea contains flavonols and flavones are antioxidants. Antioxidants may reduce the amount of reactive oxygen species, which activate stress-sensitive pathways. These pathways can lead to insulin resistance, impaired insulin secretion and beta cell dysfunction. Our study has several limitations, first we relied on self-reported tea consumption and therefore misclassification may have occurred. Second, we relied on self-reported information on non-diabetic status among controls. Third, we could not assess the influence of physical activities due to some practical reasons. The strengths of this study are a large number of covariates studied and extensive information on diet of the participants.

In conclusion, the results from our study suggest that consumption of 3 to 4 cups of tea per day has a decreased risk of type 2 diabetes mellitus. Further large scale prospective studies can provide more information in this field.

Acknowledgement

The authors are extremely thankful to Dr. S. Ramalingam, Dean, PSG Institute of Medical Sciences and Research for permitting us to do the study. We are thankful to Dr. S.L. Ravishankar, Professor and Head of the Department of Community Medicine for his continuous support to conduct the study. We are also grateful to Ms. B Divya, Senior Dietitian, Department of Dietary for her valuable support in estimating the magnesium and potassium

intake using the dietary history of the participants. We do not have any conflict of interest and not received any research grants for this study.

Abstract

Background and Aim:

The incidence of heart failure (HF) is rising to epidemic proportions in developing countries like India. A lack of adequate Indian studies underscores the importance of pursuing research into HF in an Indian population. G protein-coupled receptor kinase 5 (*GRK5)* Gln41>Leu (rs2230345) polymorphism was reported as a genetic modifier associated with survival in HF patients. A prospective study was conducted to investigate the association of *GRK5* Gln41>Leu polymorphism with response to β-blocker therapy in Indian HF patients.

Methods:

HF patients (*n*=584) were recruited for the study. The patients were genotyped by tetra-primer based allele specific polymerase chain reaction and confirmed with Sanger sequencing. The HF patients were evaluated for *GRK5* gene expression and followed up for ~3 years. Drug dosages, cardiac output and hospitalization-free survival were evaluated as study outcomes. HF subgroups (i.e. systolic or diastolic dysfunction, biventricular dysfunction and pulmonary artery hypertension) were also analyzed in association with hospital-free survival.

Results:

HF patients showed genotype frequencies of AT (15%) and TT (1%). AT/TT genotype carriers showed downregulated *GRK5* gene expression and significant reduction in carvedilol drug dosage (p=0.0001). Moreover, AT/TT genotype carriers on β-blockers showed improved ejection fraction from 27% to 36% (p=0.0007) and increased hospitalization-free survival in comparison to other HF patients. HF patients with AA genotype showed an increased rate of hospital admission in comparison with patients with the AT/TT genotype. HF subgroups with the AT/TT genotype showed an increased hospitalization-free survival versus subgroups with the AA genotype.

Conclusions:

GRK5 Gln41>Leu polymorphism in response to β-blocker therapy improved cardiac function in HF patients.

Relevance for Patients:

This study presents a comprehensive clinicofunctional pharmacogenetic characterization of *GRK5* Gln41>Leu polymorphism in a cohort of Indian HF patients. *GRK5* Gln41>Leu polymorphism can confer improved cardiac function and reduce hospitalization, thus improving the quality of life in HF patients.

Keywords: β-blocker, genotype, GRK5, heart failure, India, polymorphism

1. Introduction

Heart failure (HF) is a major, multifactorial global health disease affecting approx. 6.5 million adults/year in the United States [1] and 491,600 – 1.8 million individuals/year in India [2]. The common etiologies of HF are coronary artery disease, hypertension, valvular heart disease, arrhythmia, dilated cardiomyopathy, infection, and inflammation [3]. Other risk factors include hypertension, ischemic heart disease, obesity, Type II diabetes mellitus, and rheumatic heart disease [2]. Growing evidence show that mortality rates as a result of HF are higher in Indian patients than in western countries with death records of 0.1-0.16 million individuals/year in India [4].

The use of beta (β)-adrenergic receptor (β-AR) antagonists continues to be the standard treatment for HF [5] and has effectively reduced mortality and morbidity rates over the past decade. β-AR, a G protein-coupled receptor expressed by cardiomyocytes has been documented as important for effective cardiac function [6]. Many studies have shown that elevated activation of β-AR results in abnormal β-AR signaling which leads to the pathogenesis of HF [7,8]. Therefore, much of the therapeutic drugs like β-blockers that target the β-AR, antagonize catecholamine-stimulated β-AR signaling [6] and have resulted in increased survival of HF patients.

As a regulator of β-AR signaling, G protein-coupled receptor kinases (GRKs) act by phosphorylating the activated β-AR, leading to receptor desensitization and diminished β-AR signaling [9]. Overexpression of GRK5 and GRK2 contribute to dysregulation of β-AR by excess desensitization and

is also considered a hallmark of HF pathology [10]. Therefore, genetic polymorphisms in β-AR regulator genes may influence HF outcome. One such functional polymorphism being *GRK5* Gln41>Leu (rs2230345, c.122A>T, p.Q41L) in the *GRK5* gene. This nonsynonymous single nucleotide polymorphism (SNP) in the noncatalytic regulatory domain is prevalent in African Americans and confers a gain-of-desensitization function akin to the effects of β-blockade in cells. This polymorphism, however, did not alter the risk of HF but facilitated β-blocker response and reduced death [11,12].

We conducted a prospective study in a cohort of Indian HF patients to investigate the association of *GRK5*Gln41>Leu polymorphism in relation to β-blocker therapeutic response. The hypothesis behind this study was that as GRKs impose β-AR blockade by desensitization, the presence of genetic GRK variants might alter the outcome in HF patients. Therefore, the main aim of this study was to identify *GRK5* variants and to study their response to β-blocker treatment which might allow curtailing β-AR blocker usage in these selected patients to avoid potential harmful effects.

2. Materials and Methods

2.1. Study population

The study was conducted in multispecialty, tertiary care hospital. This prospective study recruited HF patients (n=584) with systolic or diastolic dysfunction, dilated cardiomyopathy or biventricular dysfunction (BVD) that attended the in- and outpatient cardiology clinic in our hospital. The study was initiated after obtaining the institutional ethics committee approval and getting informed consent from the patients. The HF patients considered for this study were diagnosed following the Framingham criteria [13]. The Framingham criteria for HF diagnosis should include either two major criteria or one major and two minor criteria. The major criteria included acute pulmonary edema, cardiomegaly, hepatojugular reflex, neck vein distention, paroxysmal nocturnal dyspnea or orthopnea, pulmonary rales, and third heart sound (S3 gallop rhythm). The minor criteria included ankle edema, dyspnea on exertion, hepatomegaly, nocturnal cough, pleural effusion, and tachycardia (heart rate >120 beats/min). Healthy controls (n=60) without any comorbidity were recruited for gene expression studies.

Stage-appropriate medications given to HF patients included diuretics, angiotensin-converting enzyme (ACE) inhibitors or β-blockers or angiotensin receptor blockers (ARBs) alone or in combination. If needed, mineralocorticoid receptor antagonists and hydralazine were also included. β-blockers were determined by the treating physicians (60% carvedilol, 17% metoprolol, 12.5% nebivolol, and 10.5% bisoprolol) and defined as continuous therapy for at least 6 months. β-blocker dosages were monitored during the follow-up period. Initial dosage refers to the dosage administered at the start of the β-blocker therapy after the diagnosis of HF. The final dosage refers to the dosage followed at the last follow-up time. The number of hospitalizations was monitored for each patient and the follow-up data were collected for 3-7 years. The mean follow-up duration was 3.7 years and 3.5 years for the β-blocker group and non-β-blocker group.

2.2. Clinical and echocardiography assessment

A complete resting two-dimensional and M-mode echocardiography color flow and spectral Doppler as well as annular tissue Doppler imaging data were obtained from the subjects using a Philips IE33™ ultrasound system (Philips Medical Systems, Eindhoven, The Netherlands). Standard two-dimensional parasternal short-axis and apical 2- and 4-chamber views were recorded. Left ventricular (LV) ejection fraction (EF) was calculated using the Teichholz formula. Mitral Doppler signals were recorded in apical 4-chamber view and early diastolic mitral inflow peak velocity (E), late diastolic mitral inflow

peak velocity (A), and E/A ratio were calculated. Thus, confirmation of HF in patients was determined on clinical and echocardiography assessment. Echocardiographic parameters were measured according to current recommendations [14].

2.3. Genotyping

Blood samples from the patients were collected by venipuncture in EDTA coated vials and immediately aliquoted and frozen at −80°C. Genomic DNA was isolated using EZ-10 spin column blood genomic DNA purification kit (Bio Basic Inc., Markham, Ontario, Canada). *GRK5* (c.122A>T, p.Q41L) polymorphism was screened and confirmed through in-house developed tetra-primer based allele specific polymerase chain reaction (PCR) and confirmed with restriction fragment length polymorphism (RFLP) method and Sanger sequencing. PCR reaction mixture containing 100 ng of DNA, Taq polymerase mix (Ampliqon, Odense, Denmark), primers for tetra primer PCR (35nM GRK5F primer: 5'- GAAGGCTGTGGTCTAGTCTAGGGGAACAG - 3'and GRK5R primer: 5'- TTGATTAGCAAAAAGGTCAGCCTGGAGC - 3', 45nM SNPTF primer: 5' - TGGCTAATGTGAGGGAAC - 3'and SNPTR primer: 5' -TGTGTGAAGACCTCCGA - 3') or primers for RFLP method (50 nM BSRF primer: 5'- CTACAGCCCGTCCCTCTGT - 3'and BSRR primer: 5' - GCAAAAAGGTCAGCCTGGAGC - 3') were subjected to thermal cycling (Eppendorf, Hamburg, Germany). For RFLP, PCR product was digested using 1.5 units of *Bsr*I (New England Biolabs® Inc., Ipswich, Massachusetts, USA) as per manufacture instructions. The genotype was identified for tetra-primer PCR (AA: 580 bp and 225 bp, AT:580 bp, 380 bp and 225 bp, and TT:580 bp and 380 bp) and RFLP method (AA:202 bp and 179 bp, AT:381 bp, 202 bp and 179 bp, and undigested TT:381 bp) with these banding patterns after resolving on the gel.

2.4. Quantitative PCR (qPCR)

RNA was isolated from the HF patients and unaffected controls using the Aurum™ total RNA mini kit (Bio-Rad, Hercules, California, USA). The RNA was qualitatively verified on denaturing formaldehyde 1.2% agarose gel electrophoresis. Using 1 μg of RNA, respective cDNAs was synthesized using iScript™first strand cDNA synthesis kit (Bio-Rad, Hercules, California, USA). qPCR was carried out to compare *GRK5* gene expression in HF cases and healthy controls using relative quantification with β-actin as reference gene. PCR mixture of 20μL contained 2X SYBR green (Sso Advanced universal SYBR® Green supermix, Bio-Rad, Hercules, California, USA), 50 nM of forward and the reverse primer of the respective gene, cDNA template corresponding to 1 μg RNA and nuclease free water. The primers used were GRK5 FP (5' - ACCTGAGGGGAGAACCATTC - 3'), GRK5 RP (5' -TGGACTCCCCTTTCCTCTTT - 3'), ACTIN FP (5' - TCCCTGGAGAAGAGCTACG - 3'), and ACTIN RP (5' - GTAGTTTCGTGGATGCCACA - 3'). Reaction included an initial denaturation of 95°C for 3 min followed by 45 cycles of 95°C for 30 s, 60°C for 30 s, 72°C for 45 s, and a melt curve analysis (65 – 95°C) was performed at the end of 45 cycles. Normalized fold expression was calculated using $2^{-\Delta\Delta Ct}$ method.

2.5. Variables

In this study, the independent variables were age, sex, and socio-demographic data. Covariates were (EF%), comorbidities, use of β-blockers, and use of other medications. The covariates adjusted for hospital-free survival analysis were age, sex, EF%, and comorbidities.

2.6. Statistical analysis

Student *t*-tests (paired and unpaired) and Chi-square tests were used to assess significant differences in variables between the groups, drug dosages, genotype classes, gene expression, and EF%. Continuous variables are expressed as mean ± standard deviation (SD). Fischer's exact test was carried out to compare cardiac output between groups. Hardy-Weinburg equilibrium was assessed to compare predictions with that of the obtained results. Kaplan–Meier curves were also constructed to plot the percentage of survival of patients. Comparisons of overall survival were performed using a log-rank (Mantel-Cox) test. All the statistical analyses were carried out using GraphPad Prism software version 5.0 Windows (GraphPad Software, San Diego, California, USA).

3. Results

3.1. Clinical and demographic characteristics of the HF patient cohort

The HF patient cohort (n=584) was considered for the study after clinical and echocardiographic assessment. Table 1 shows the clinical and demographic characteristics of the HF patient cohort. The HF patients were categorized into β-blocker group and non-β-blocker group. There was no statistically significant difference in variables such as age, sex, body mass index, and hemodynamics between the two groups. BVD (24%; p=0.002) and LV diastolic dysfunction (32.8%; p=0.002) were observed as statistically significant HF characteristics in the β-blocker group. Dilated cardiomyopathy (54%; p=0.0002) was observed as statistically significant HF etiology in the β-blocker group versus the non-β-blocker group whereas rheumatic heart disease (8%; p=0.0001) and coronary artery disease (44%; p=0.0001) were significantly higher in the non-β-blocker group. Type II diabetes mellitus (60%; p=0.0001) and its associated disorders were significantly frequent in the non-β-blocker group whereas systemic hypertension (42%; p=0.002) and dyslipidemia (25%; p=0.002) were higher in the β-blocker group. Approximately 52% of the patients were on β-blocker therapy. Among the medications administered, 38% of the HF patients received ACE inhibitors, 20% ARBs, 70% diuretics, 35% digitalis glycosides, 22% statins, and 19% anticoagulants.

Table 1

Clinical and demographic characteristics of the HF patient cohort

Variables	HF patient cohort (*n*=584)	
	β-blocker group (*n*=304)	Non-β-blocker group (*n*=280)
Mean Age±SD (years) (range)	60±10 (24 – 89)	59±11 (25 – 90)
Males (%)	73	73
Mean body mass index (kg/m^2) (range)	22 (19.5 – 24.5)	23.5 (21.1 – 26.5)
Mean follow up time (years) (range)	3.7 (3 – 7)	3.5 (3 – 7)
Hemodynamics		
Heart rate (beats/min)	78	80
Mean systolic blood pressure (mmHg)	128 (81 – 171)	123 (80 – 170)

3.2. GRK5 Gln41>Leu polymorphism in HF patient cohort

GRK5 Gln41>Leu polymorphism was screened by in-house developed tetra-primer based allele specific PCR and reconfirmed with RFLP and the Sanger sequencing method (Figure 1). Genotype distribution was in agreement with the Hardy-Weinberg equilibrium (p=0.595). The genotype (84% for AA, 15% for AT, and 1% for TT) and allele frequencies (0.916 for A allele and 0.084 for T allele) of *GRK5* Gln41>Leu polymorphism in the HF patient cohort is presented in Table 2. On comparing the genotype frequencies, AT genotype was more prevalent in the β-blocker group (19%) compared to the non-β-blocker group (10%) (p=0.011). The unaffected healthy controls were also screened for this polymorphism. The genotype and the allele frequencies of the healthy controls (Supplementary Table 1) did not differ significantly from the HF cases (p=0.94 for genotype frequency, p=0.82 for allele frequency) ensuring a lack of association of this polymorphism with development of HF.

Figure 1

Genotyping of GRK5 Gln41>Leu polymorphism. Tetra-primer based allele specific polymerase chain reaction (A) results on showing banding pattern for Gln/Leu heterozygous AT genotype (lane 2: 580 bp, 380 bp and 225 bp), Leu/Leu homozygous TT genotype (lane 3: 580 bp and 380 bp), Gln/Gln homozygous AA genotype (lanes 4, 5: 580 bp and 225 bp). RFLP (B) results showing banding pattern for Gln/Leu heterozygous AT genotype (lanes 2, 3: 381 bp, 202 bp and 179 bp), Leu/Leu homozygous TT genotype (lane 4: 381 bp) and Gln/Gln homozygous AA genotype (lanes 5, 6, 7: 202 bp and 179 bp). Lanes 1a, 1 b: 100 bp DNA ladder (Biobasic, Canada). Sanger sequencing results of Gln/Gln homozygous AA genotype C), Gln/Leu heterozygous AT genotype (D) and Leu/Leu homozygous TT genotype (E).

Table 2

GRK5 genotype and allele frequencies in the HF patient cohort

Genotype	HF patients (n=584), n (%)	HF patients (β-blockers) (n=304), n (%)	HF patients (non-β-blockers) (n=280), n (%)	p-value
AA	493 (84)	244(80)	249(89)	0.011
AT	85 (15)	57 (19)	28 (10)	
TT	6 (1)	3 (1)	3 (1)	
Allele				0.07
A	535 (91.6)	273 (90)	263 (94)	
T	49 (8.4)	31 (10)	17 (6)	

Results were expressed as n (%) for genotype and allele distribution. $\chi 2$ test was significant for genotype frequency and not significant for allele frequency between β-blocker group and the non-β-blocker group.

As the frequency of homozygous TT genotype was low, we intended to divide the HF patients into two group, those having AA genotype alone (AA genotype group) and those with AT and TT genotype (AT/TT genotype group), to study the influence of *GRK5* Gln41Leu (rs17098707) polymorphism on response to β-blocker therapy in the HF patients.

3.3. Downregulated GRK5 expression among the GRK5 Leu41 variants (AT/TT genotype)

The *GRK5* gene expression was evaluated among different groups of HF patients. The gene expression among The AT/TT genotype carriers showed a downregulated *GRK5* expression than AA genotype carriers among β-blockers and non-β-blockers. For gene expression analysis (Figure 2), healthy controls (n=60) were included for comparison. The β-blocker AT/TT group (n=60) showed a 0.5135±0.1593-fold decrease in gene expression and the β-blocker AA group (n=60) showed a slightly but significant upregulated pattern of 1.752±0.0.2775 gene expression (p<0.0001). On comparing the non-β-blockers, there was a significant difference in the gene expression (p<0.0001) between the AT/TT group (n=31, 0.5507±0.1322) and the AA group (n=60, 1.681±0.2688).

Figure 2

GRK5 expression among different groups of HF patients. β-blocker AT/TT group versus β-blocker AA group (p<0.0001), non-β-blocker AT/TT group versus non-β-blocker AA group (p<0.0001) along with healthy controls (HC) were analyzed for _GRK5_ normalized gene expression. Student's _t_-test was used to compare the groups.

3.4. Improvement in the EF of the GRK5 Leu41 variants (AT/TT genotype)

The EF% is the measure of LV systolic function and cardiac output. Among the β-blocker group (29±4.8%) and non-β-blocker group (41.5±2.3%), the mean EF% remained significantly varied (p=0.0286). The EF% of the patients before and after pharmacological treatment was recorded and improvement in their cardiac output was compared among the groups (Figure 3). The increment in the EF% after treatment was considered as an improvement in cardiac output. About 56% of HF patients on β-blockers and 41% on non-β-blockers showed improvement in their EF% (p=0.0004; Figure 3A). As expected, 71% of the *GRK5* Leu41 variants (AT/TT genotype) showed remarkably higher cardiac output (p=0.0001; Figure 3A) versus those with *GRK5*Gln41 (AA genotype, 45%). Since the non-β-blockers had HF preserved EF, only the β-blocker group having HF reduced EF was considered for further analysis. When the HF patients with different genotypes in the β-blocker group were compared it was evident that those with the AT/TT genotype (83%) improved significantly (p=0.0001; Figure 3B) compared to those with the AA genotype (49%).

Figure 3

Percentage improvement in cardiac output among the cohort of HF patients. The percentage of HF patients improved among β-blocker and non-β-blocker groups (p=0.0004) and different genotype groups of *GRK5* (p=0.0001) (A). The percentage of HF patients improved among β-blocker group with different genotypes (p=0.0001) (B). Fischer's exact test was carried out for analysis.

The improvement in cardiac output was compared among the HF patients in β-blocker group with different genotypes (Figure 4). EF% has improved from 25.2±1.041% to 28.2±0.7638% among the AA group (p=0.0091) and 27.4±1.021% to 36±1% in the AT/TT group (p=0.0007).

Figure 4

Improvement in ejection fraction in HF patient cohort. The improvement in EF% in HF patients with different genotypes of β-blocker group was measured. AT/TT group (p=0.0091) improved significantly in comparison with the AA group (p=0.0091). Paired t-test was carried out for computing p-values.

3.5. GRK5 Leu41 variants (AT/TT genotype) show decrement in β-blocker drug dosage

Among the β-blocker group (n=304), 60% of the HF patients were treated with carvedilol, 17% with metoprolol, 12.5% and 10% with nebivolol and Bisoprolol, respectively. The initial and the final drug dosages over the follow-up period were noted and analyzed. Initial dosages administered at the start of the β-blocker therapy and final dosages followed at the last follow-up were noted. There was a statistically significant reduction in carvedilol drug dosage in the overall β-blocker group when the initial (11.2±7.7 mg) and final drug dosages (10.2±7.1 mg) were compared (p=0.0114; Figure 5A). Furthermore, the drug dosages remained unchanged in the AA genotype group (p=0.8211; Figure 5B) when the initial (11.06±7.3 mg) and final (11.1±7.4 mg) drug dosages were compared. Interestingly, there was a statistically significant reduction in the drug dosage in the AT/TT genotype group (p=0.0001; Figure 5B) when the initial (11.6±9.2 mg) and the final (6.4±4 mg) drug doses were compared. Thus, the *GRK5* Leu41 variants in the homozygous and heterozygous forms were associated with a lower dose of β-blockers.

Figure 5

GRK5 Gln41>Leu polymorphism influences β-blocker (carvedilol) drug dosage. Carvedilol drug doses were reduced in the overall β-blocker group (p=0.0114) (A). The drug doses remained unchanged in the AA genotype group (p=0.8211), whereas in the AT/TT genotype group there was a significant reduction in the drug dosage (p=0.0001) (B). Paired t-test was used to compare the drug doses between groups.

3.5. Reduced event of hospitalization among the GRK5 Leu41 variants (AT/TT genotype)

The HF patients were followed-up for ~3 years (40 months) after the initiation of pharmacological treatment. The influence of β-blocker therapy and *GRK5* genotype on hospitalization-free survival of HF patients was studied through Kaplan–Meier survival curves (time-to-event analysis). When the overall HF patients administered with β-blockers and non-β-blockers were compared for hospital-free survival, the patients on β-blockers showed higher survival than the non-β-blockers (hazard ratio [HR]: 1.167, 95% confidence interval [CI]: 0.325 – 2.008, log-rank $p<0.0001$; Figure 6A). The same was found when the overall HF patients with AA and AT/TT genotypes were compared; the presence of AT/TT genotype reduced the risk for hospitalization (HR: 0.8387, 95% CI: 0.07042 – 1.607, log-rank $p<0.0001$; Figure 6B). On further analysis of the HF subgroups, β-blocker AT/TT group versus β-blocker AA group, it was found that the presence of AA genotype increased the risk for hospitalization (HR: 1.143, 95% CI: 0.4337 – 1.852, log-rank $p<0.0001$; Figure 6C) even under the influence of β-blocker therapy. When non-β-blocker AT/TT group versus non-β-blocker AA group was analyzed, AA genotype increased the risk for hospitalization (HR: 1.364, 95% CI: 0.7020 – 2.025, log-rank $p=0.0003$; Figure 6C). In the β-blocker AT/TT group versus non-β-blocker AT/TT group analysis, the use of non-β-blockers increased the risk for hospitalization (HR: 1.067, 95% CI: 0.463 – 1.670, log-rank $p=0.0231$; Figure 6C). As expected, when β-blocker AA group versus non-β-blocker AA group was analyzed, the presence of AA genotype and use of non-β-blocker therapy increased the risk of hospitalization (HR: 1.273, 95% CI: 0.441 – 2.104, log-rank $p<0.0001$; Figure 6C).

Figure 6

Influence of β-blocker therapy and *GRK5* genotype on hospital-free survival of HF patients. HF patients were stratified by β-blockers usage (β-blockers ($n=304$); non-β-blockers ($n=280$); $p<0.0001$) (A). HF patients were stratified by *GRK5* Leu41 carrier status (AT/TT genotype) (GRK5 AA group ($n=493$); *GRK5* AT/TT genotype ($n=91$); $p<0.0001$) (B). β-blocker treated subjects and non-β-blocker subjects stratified by *GRK5* Leu41 carrier status (AT/TT genotype) (β-blocker AA group ($n=244$); β-blocker AT/TT group($n=60$); non-β-blocker AA group($n=249$); non-β-blocker AT/TT group ($n=31$) (C). Log-rank test (Mantel-Cox) test was utilized for comparisons of survival curves.

The overall HF patients were subdivided based on HF characteristics such as systolic dysfunction ($n=218$), diastolic dysfunction ($n=150$), BVD ($n=114$), and pulmonary artery hypertension (PAH) ($n=102$). The groups were compared for hospitalization-free survival. The patients with PAH showed higher survival and patients with systolic dysfunction showed the lower survival than the other groups (log-rank $p=0.02$; Figure 7A). When the subgroups with systolic dysfunction and diastolic dysfunction were compared with *GRK5* polymorphism genotypes (AA and AT/TT), it was evident that the HF patients with AA genotype under both the subgroups indicated the lower hospitalization-free survival than the HF patients with AT/TT genotype under both subgroups (log-rank $p=0.0002$; Figure 7B). When the subgroups with BVD and PAH were compared with *GRK5* polymorphism genotypes (AA and AT/TT), it was evident that the HF patients with AA genotype under both the subgroups indicated lower hospitalization-free survival than those with the AT/TT genotype under both subgroups (log-rank $p=0.0051$; Figure 7C).

Figure 7

Influence of *GRK5* genotype on hospital-free survival of HF patient subgroups. HF patients were stratified by HF characteristics systolic dysfunction (*n*=218); diastolic dysfunction (*n*=150); BVD (*n*=114); PAH (*n*=102); *p*=0.02) (A). HF patients with systolic and diastolic dysfunction were stratified by *GRK5* Leu41 carrier status (AT/TT genotype) (systolic dysfunction AA group (*n*=193); diastolic dysfunction AA group (*n*=128); systolic dysfunction AT/TT group (*n*=25); diastolic dysfunction AT/TT group (*n*=22); *p*=0.0002) (B). HF patients with BVD and PAH were stratified by *GRK5* Leu41 carrier status (AT/TT genotype) (BVD AA group (*n*=90); PAH AA group (*n*=82); BVD AT/TT group (*n*=24); PAH AT/TT group (*n*=20); *p*=0.0051) (C). Log-rank test (Mantel-Cox) test was utilized for comparisons of survival curves.

To compare the frequency of hospital admissions between the genotype groups within a month, the rate of hospital admission/month was compared (Figure 8). From the results, it was evident that the HF patients in the AA group (0.0769±0.003; *n*=493) were significantly more frequently ($p<0.0001$) admitted in hospital than the AT/TT group (0.0409±0.004; *n*=91; Figure 8A). Among the β-blocker group, HF patients with the AA genotype (0.0790±0.005; *n*=244) were significantly more frequently admitted in the hospital than the AT/TT variants (0.0374±0.005; *n*=60; *p*=0.0002). Among the non-β-blocker group, HF patients with the AA genotype (0.0749±0.005; *n*=249) had more hospital admissions compared to the AT/TT variants (0.0477±0.008; *n*=31) although not statistically significant (*p*=0.0674; Figure 8B).

Figure 8

Comparison of frequency of hospital admission between the genotype groups. The AA group of HF patients (*n*=493) had more hospital admissions than the AT/TT HF group (*n*=91; $p<0.0001$) (A). Among the β-locker group, HF patients with the AA genotype had more frequent hospital admission than the AT/TT variants (*p*=0.0002) (B). A similar trend was observed among the non-β-blocker group but the results were no statistically insignificant (ns). β-blocker AA group (*n*=244); β-blocker AT/TT group (*n*=60); non-β-blocker AA group(*n*=249); and non-β-blocker AT/TT group (*n*=31). Student's *t*-test was used to compare the gr.

4. Discussion

Genetic polymorphisms impact HF outcomes. One such polymorphism is *GRK5*Gln41>Leu (A>T), which was proven to have a role in promoting β-AR desensitization [11]. Our results show that HF patients with *GRK5* Leu41 variant in its homozygous and heterozygous forms show decreased events in hospitalization and specifically respond to β-blockers and require reduced β-blocker drug dosage in comparison to *GRK5* Gln41 carriers. Moreover, *GRK5* Leu41 variants in combination with β-blocker therapy showed improved cardiac output.

The *GRK5* genotype frequencies in this study (AT/TT15% and TT1%) were comparatively lower than that reported in African Americans (AT/TT39% and TT6%) [15]. The T allele frequency in our study (0.084) was lower than African Americans (0.23) [15] but, higher than that found in the Chinese population (0.009) [16] and Caucasians (0.017) [17]. As GRK5 is highly expressed in myocardium [18], and given its established role in cardiac failure pathology [10], this prompted our group to examine and evaluate *GRK5* expression in a cohort of Indian HF patients. GRK5 is reportedly overexpressed in HF conditions and could attenuate cardiac burden in response to adrenergic surge [19,20]. In view of this, a slight upregulation observed in *GRK5* expression in a subpopulation of HF patients could be expected. However, gene expression was downregulated in the AT/TT subset of HF patients in our study. A possible reason could be that the role of overexpressed GRK5 in β-AR desensitization is compensated by the allelic variation, bringing about an augmented desensitization, thus attempting to regulate *GRK5* expression for better cardiac performance. Interestingly though inhibiting GRK5 expression restores the cardiac muscle damage incurred during HF [21]. These observations support the fact that *GRK5* Leu41 variant confers protection from congestive HF [22].

Human and rodent data have proven that *GRK5*Leu41 protected against death or cardiac transplantation [11]. Coinciding with these data, our study reaffirms that the *GRK5*Leu41 allele improved quality of life, promoted hospitalization-free survival of South Indian HF patients. Independently, both the administration of β-blocker therapy and the presence of Leu41 allele yielded a positive outcome on hospitalization-free survival. The Leu41 allele carriers among the different HF subgroups showed increased hospitalization-free survival in comparison to Gln41 carriers. The previous reports support the fact that Indians are highly sensitive to β-blockers [23] and also speculated that polymorphic variations in β-AR gene in Indians [24] might be the reason for higher sensitivity [25]. Our data indicate that the prevalence of *GRK5* gene polymorphisms in Indian HF patients and its role in cardiac failure might be the reason for responders to β-blocker treatment. In response to β-blocker treatment, *GRK5*Leu41 allele carriers (AT/TT genotype) showed better hospital-free survival than *GRK5* Gln41 allele carriers (AA genotype) and β-blocker naïve *GRK5*Leu41 and Gln41 allele carriers. This observation was also reported in a study where HF patients with the Gln41Leu genotype had reduced hospitalization rates (18.6%) [26]. These results also justify the continued use of β-blockers as standard therapy for cardiac failure and their benefits over other pharmacological interventions [27-29]. Interestingly, it was found that although Leu41 carriers among African Americans survived better than Gln41 carriers, they exhibited a reduced response to β-blockers [11,17] such as atenolol [30]. Another study among African race demonstrated that Leu41 impacted negatively on survival of HF patients, but the effect seemed to be stabilized upon β-blocker usage. In other words, Gln41 carriers survived better in the presence and absence of β-blockers [15].

The Leu41 allele seemed to act as a genetic β-blockade [11], promoting reduced dependency on β-blockers for improvement in HF patients. Although β-blocker has been validated as a lifesaving drug in HF, in view of its adverse effects such as HF deterioration, hypotension, and impaired left atrial function [31,32], minimizing its usage is recommended. In our study, the presence of Leu41 allele has helped in curtailing the dosage of carvedilol during the course of treatment and reduced the frequency of hospital admission compared to the Gln41 allele. Carvedilol, a nonselective β-blocker with better efficacy than other β-blockers [10,33] was used in 60% of the HF patients in this study. The usage of β-blockers has substantially improved the LV systolic function by increasing the EF in 56% of HF patients in this study. Literature also supports the usage of β-blockers in recovering from LV systolic dysfunction [34]. The improvement in EF was pronounced in *GRK5* Leu41 variants compared to Gln41 carriers and this observation coincided with another study reporting *GRK5* polymorphism having a

positive effect on systolic HF after β-blocker therapy [16]. Taken together, these data present convincing evidence that the Leu41 allele and β-blocker therapy synergistically work to stabilize cardiac function in Indian HF subjects.

Ethical Approval

Human samples to carry out the study were obtained following informed consent of patients according to the Declaration of Helsinki and its later amendments or comparable ethical standards. Research involving humans was authorized by the Institutional Ethics committee from PSG Institute of Medical Sciences and Research, Coimbatore, Tamil Nadu, India.

Acknowledgments

The authors gratefully acknowledge Dr. Thiagarajan Sairam, Seetha Arunachalam, Ranjani S, Brindha A and Madhu Elango for their technical contribution towards this study.

[2]Professor of Biostatistics, PSG Institute of Medical Sciences and Research, Coimbatore, India

Abstract

Purpose: The study aims to assess the emergence of deafness, blindness, cerebral palsy, and mental retardation among very low birth weight (VLBW) infants, aged 21-24 months.

Methods: A study was conducted with a total of 123 premature Saudi infants, who were recruited from King Khalid University Hospital. The association among demographic factors and neurodevelopmental morbidities were identified with the help of regression analysis.

Results: A significant relationship between deafness and cerebral palsy was found. However, there was no significant relationship between retinopathy of prematurity and intraventricular hemorrhage. Furthermore, maternal education plays a positive role in the neurodevelopment of preterm newborns.

Conclusion: This study has concluded that there has been significant relationship between cerebral palsy and deafness in preterm infants with very low birth weight. On the contrary, there was no significant relationship found between intraventricular hemorrhage and retinopathy of prematurity.

Keywords: Blindness, Cerebral Palsy, Deafness, Neonatal Care, Neonatal Morbidity

Introduction

The primary cause of neonatal morbidity and mortality is the preterm birth of an infant [1]. Developments in perinatal care have enhanced the chances of survival of preterm low birth weight infants of gestational age of less than 25 weeks. Although, the survival rate has increased, the chances of neonatal morbidity and neurodevelopment impairment have also augmented and increased. On the other hand, the lower the gestational age and the birth weight of the preterm infant; the higher the infants' likelihood of suffering from major neonatal morbidity [2].

The disabilities occur due to the improper development of the infant or poor functioning of nervous system. The limitations that are manifested during infancy or early stage of childhood include cognition, vision, behavior, and hearing. There are the modalities that these disabilities are traced in the early stage of neurodevelopment. However, the cognitive disabilities among infants and children includes mental retardation as well as it further leads to the learning disabilities. Moreover, distress and chronic stress usually leads to psychological changes, which further result in causing physical distress, psychiatric disorder, and psychological distress [3].

Early years of childhood are important for language development and communication because during this time the brain is at its highest capacity to go about structural changes in regard to external stimulation and is termed as neural plasticity [4]. According to American Academy of Pediatricians (AAP), there are 2% to 3% of infants with developmental disabilities. In most of the cases, no definite cause is ever found. Intellectual disabilities can be further classified as mild, moderate, severe, and profound; and this is done on the basis of various intellectual disabilities. Mental disability is usually result of genetic disorders; for instance, Down syndrome. In case of infants, the genetic disorders are usually detected at an

early stage. It is due to certain physical or facial characteristics that alert the parents or the clinician.

Experts, who are always associated with disabled children, believed that in such cases early intervention pays off immensely [5]. Not much work has been done in order to investigate the outcome of early intervention for children, who are deaf and blind. However, various studies illustrated that, the early identification and intervention for hearing loss, proved out to be beneficial for infants as it enhances their language skills [6]. Continued ill-health of the mother can lead to further morbidities or disabilities and can negatively impact baby's health. Whereas, these complications and consequences are not much focused upon in various countries in low-income countries. Families situated in Middle Eastern regions complaint about isolation and lack of community resources to help them in improving their child's abilities. One of the main reasons behind the lack of awareness or medical care is that there are no health professionals or researchers available in such regions. In most cases, these disabilities also come forward due to the mother's depressive state [7].The aim of the present study is to assess the relationship between Retinopathy of Prematurity and Intraventricular hemorrhage as well as the relationship between deafness and cerebral palsy.

Methods

A total of 123 premature Saudi infants, with birth weight less than or equal to 1500 grams & gestation less than equal to 32 weeks were recruited. These infants that were chosen for the study were from the King Khalid University Hospital in which these premature infants were delivered. The study was approved from the ethics committee. The analysis was done on the basis of neurological and developmental assessment, along with medical and social history. It was done in order to determine functional and neurodevelopmental outcomes among infants. The neurologic examinations were performed by certified physicians, who had been well trained in this department. The neurological assessment included the evaluation of strength reflex, angles as well as posture. The demographics include age, gender, and gestation age and body weight. The factors examined included were maternal education, birth weight, early-onset sepsis, late-onset sepsis, grades 3 to 4 IVH/PVL, Bronchopulmonary Dysplasia (BPD), Retinopathy of Prematurity (ROP), Hypoxic Ischemic Encephalopathy (HIE), Persistent pulmonary hypertension (PPHN), Patent ductus arteriosus (PDA).

During the first four weeks of life, Intraventricular hemorrhage (IVH) is usually detected by head ultrasound during first four weeks of life. Moreover, it is graded in accordance with Papile's classification. Periventricular echogenicity, which is noticed on the head ultrasound and is performed at any time during the NICU stay, is known as Preventricular Leucomalacia (PVL). Retinopathy of Prematurity (ROP) is detected during routine retinal examination. Furthermore, Patent Ductus Arteriosus (PDA) is established through an echocardiography with signs of left-to-right shunting. Bronchopulmonary Dysplasia (BPD) refers to the requirement of oxygen at 36 weeks, corrected age.

Table 1: Gestational Age of the study participants

Gestational age	Number	Percent
26	3	2.4

The data were analyzed to evaluate the impact of morbidities on various neurodevelopmental disabilities like blindness, deafness, cerebral palsy (CP) and mental retardation (MR). Severe mental retardation syndrome includes optic atrophy, microcephaly, that further results in impaired vision, defect in hearing, seizures, restricted movements of large joints and spasticity. The study examined the influence of maternal education and early intervention on BINS at 21 to 24 months infants. Maternal education is considered as one of the strongest determinants that ensures infant survival in developing countries. The statistical analysis was done to assess maternal education and its association with disabilities. BINS was classified into two different groups. First group was low and the other group was taken as moderate (Mod) and high. However, 'Low' illustrated that no further follow-up is required; whereas, 'high' suggested that further developmental testing is necessary. Descriptive statistics were calculated using mean and standard deviation. Spearman rank correlation analysis was done to find the correlation between Retinopathy of Prematurity and Intraventricular hemorrhage. Chi square test was done to find the association deafness and cerebral palsy. $P<0.05$ was considered as statistically significant (Table 2).

Table 2: Association between Deafness and CP

	CP (No)	CP(Yes)	Total
Deafness (No)	120(98.4%)	2(1.6%)	122
Deafness(Yes)	0 (0.0%)	1 (100%)	1
Total	120	3	123

Results

The total number of neonates who were examined in the study were 123. Out of the total, newborn females totaled 53 (43.1%). The mean (SD) of the gestation age in weeks was 29.65 (1.82). Amongst the total number of neonates, the lowest gestational age of preterm infants was 26 weeks and the highest gestational age was 38 weeks. Apart from this, the premature neonates that had a gestational age of 28 weeks were 25 (20.3%) infants. Similarly, the preterm neonates that had a gestational age of 30 weeks were 36 (20.3%) infants and were the highest number of infants in that particular classification group (Table 1). Among the 123 mothers, 85 (69.1%) were educated. The

correlation between ROP and IVH was examined and found that spearman, s rho r=0.145 p=0.109 which is not statistically significant.). The association between Deafness and Cerebral Palsy was found to be statistically significant

(Chi-square=40.38, P<0.001)

Discussion

The results revealed that there is significant relationship between Deafness and Cerebral Palsy. However, there was no significant relationship between Retinopathy of Prematurity (ROP) and Intraventricular hemorrhage (IVH). The results are consistent with the study conducted by Neubauer et al. (2008), in which it was discovered that the proportion of disabilities has increased with decreasing gestational age of the newborn. Infants having high grade intraventricular hemorrhage, neonatal seizures, necrotizing enterocolitis and bowel perforation were at a significant risk for developing and enduring major impairment [8].

In a study conducted by Wilson-Costello et al. (2007), modern therapies that were incorporated with regard to low birth weight infants were compared to traditional therapies that were provided to low birth weight infants in the previous two decades. The comparison features were the rate of survival and death with and without impairment and the therapies that were provided. The population comprised of 496 low birth weight infants born (2000-2002), 1749 neonates that were born (1982-1989) and 233 newborns born (1990-1999). The findings revealed that between 1990 and 1999, survival rate has increased from 49% to 68%, but so did neonatal morbidity. Therefore, it leads to survival without impairment as well as survival with impairment [9].

The therapy modification between 2000-2002 included a reduction of postnatal steroid use. Apart from this, antenatal steroid use was increased. It was observed that there were no changes in the rate of lung disease. In addition, there was found to be a decrease in morbidities; such as, severe intraventricular hemorrhage (IVH) and early-onset sepsis (EOS) and late-onset sepsis (LOS). With therapeutic care, the rate of neurodevelopmental impairment has reduced from 35% to 23%. More specifically, the rate of cerebral palsy reduced from 13% to 5%. It was concluded that there was significant reduction in the neurodevelopment impairment in neonates with very low birth weight between 2000-2002 as compared to a decade early. The improved outcomes and the increase in the survival rate of newborns with low birth weight were due to modern therapies that were being provided. These included both perinatal and neonatal factors. However, despite the use of postnatal steroids, the lung condition of the infants showed no improvement [10]. Many studies revealed that maternal education has a positive impact on neurodevelopmental outcome among very low birth infants. The results conducted by Voss et al. (2012) revealed that the maternal educational background was directly associated with the intellectual growth of pre-term infants. Low maternal educational background was connected to reduced composite intelligent quotient of pre-term kids, who were between the ages of 10-13 years old during the study [11-14].

Conclusion

The preterm birth of an infant can be the cause of neonatal morbidity and mortality. Preterm neonates with a very low birth weight have an increased risk of suffering from neurological, sensory, development, and functional morbidity. The neurodevelopment of all very low birth weight newborns must be monitored and the relevant therapies must be incorporated to ensure and optimize their survival. Some morbidities are directly associated with long-term outcomes of the development of preterm infants. This study has concluded that there is a significant relationship between Deafness and Cerebral Palsy in infants. On the contrary, there was no significant relationship found between Intraventricular hemorrhage (IVH) and Retinopathy of Prematurity (ROP). Additionally, maternal education played a significant role in the development of preterm newborns. However, more studies must be conducted in relation to preterm babies and neonatal morbidity and mortality to get further insights into the causes of morbidities, suffered by preterm babies with very low birth weight.

Physical properties of menstrual hygiene waste as feedstock for onsite disposal technologies

Sarani Sasidaran, Prateek Kachoria, Antony Raj, Sudha Ramalingam, Brian R. Stoner, Katelyn L. Sellgren and Sonia Grego

ABSTRACT

Onsite incinerators offer a promising solution to the challenges of menstrual waste disposal, particularly in institutional settings. However, thermochemical processes are well known to depend on the nature of the feedstocks and their moisture content (MC). An analysis is presented of the physical properties of menstrual waste as potential feedstock for onsite incinerators. Waste was generated in three institutional settings – from women of wide age range and from people with different socioeconomic backgrounds such as workers and students. Over 10 separate collections, 613 discarded menstrual pads were obtained with over 93% of the waste representing commercially disposable pads and less than 7% of the waste appearing to be homemade cloth pads. A surprising finding of this study was that a significant fraction of the commercially disposed pads (23–37%) had a large wet weight (over 20 g) which was associated with MC exceeding 50 wt%. This high MC was attributed to the practice of washing the pads prior to disposal, and it was much higher than what is standard for thermal processing. These data suggest that testing protocols for menstrual waste incinerator technology performance should include an evaluation of the effects of higher MC, unfolded pads, and occasional cloth pads.

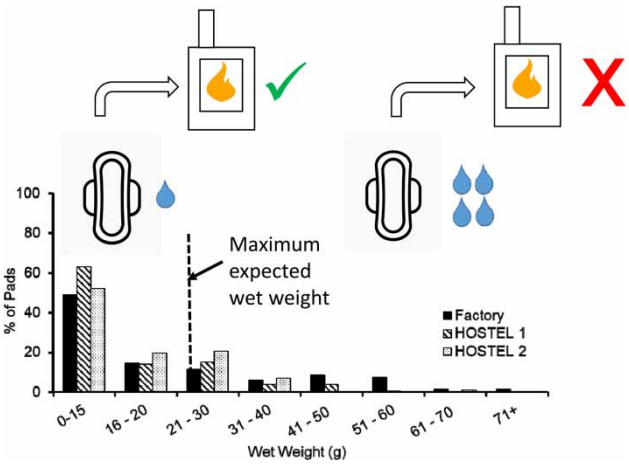
HIGHLIGHTS



- Menstrual waste consists mainly of commercially disposable pads (93% or more) and of homemade cloth pads (6–7%).
- This study found that nearly a third of commercial pad waste had a wet weight of over 20 g, which was associated with moisture content (MC) exceeding 50 wt%.
- High MC waste is attributed to the practice of washing pads prior to disposal.
- Moist waste may result in pollutant emission and incomplete processing by onsite incinerators.

GRAPHICAL ABSTRACT

INTRODUCTION

Menstrual hygiene is an essential aspect of sanitation for women and girls, which is often neglected in sanitation program implementation in low- and middle-income countries, yet is critical for women's health and dignity as well as environmental safety (Sommer *et al.* 2013; Tilley *et al.* 2013).

A body of research has shown that the lack of access to proper menstrual hygiene management has a negative impact on women's health (Balamurugan & Bendigeri 2012; Das *et al.* 2015) and women's participation in education and the workforce (Bodat *et al.* 2013; Sommer *et al.* 2016).

Challenges related to menstrual health and hygiene (MHH) in low- and middle-income countries are related to both access to safe sanitary products and safe disposal options at the household and community levels (Elledge *et al.* 2018).

The most used menstrual products are absorbents such as sanitary pads, tissue paper (disposable, one-time use) and cloth, typically homemade (Elledge *et al.* 2018). Cloth pads are the traditional and cheaper option, while disposable sanitary pads are increasingly available, especially in urban environments, and considered as aspirational products (van Eijk *et al.* 2016). Statistical associations have been reported between the use of disposable sanitary pads and younger age, higher social class, and urban residence (Elledge *et al.* 2018); however, affordability represents a major constraint (Crofts & Fisher 2012).

Disposal of used sanitary pads is a critical element of the MHH value chain. Cloth pads are cheaper and environmentally less polluting, but cleaning is challenging since it requires access to water, privacy and drying in the sun for its disinfecting effect, as opposed to a hidden drying area utilized for a sense of shame (van Eijk *et al.* 2016). Disposable pads offer convenience of use and are considered as aspirational products for women and girls; however, they present a solid waste challenge. A woman will have an average of 459 periods over her lifetime and dispose of 125–150 kg of sanitary waste (Bharadwaj & Patkar 2004).

The lack of disposal solutions leads to negative health outcomes, e.g. infrequent pad changes during school (Singh & Bhardwaj 2017) as well as environmental issues. Where solid waste management is not available, disposal practices for sanitary pads include throwing them in the open where they can contaminate water bodies, burning (in an open pit), burying them (whether waste is compostable or not), or flushing in the toilet, where they cause clogging and impair the biological degradation of human waste in sanitation systems (Path 2017).

In addition to the lack of sanitation infrastructure, menstruation is associated with stigma and taboos such as the perception of impure or shameful processes leading to restrictions of women's activities during menstruation

Downloaded from http://iwaponline.com/washdev/article-pdf/11/3/474/889950/washdev0110474.pdf
by guest

and secrecy around menstrual fluid management (Sommer *et al.* 2013; Garg & Anand 2015). Importantly, cultural beliefs and taboos, in addition to convenience and information, contribute to the selection of disposal method (e.g. bury or burn) and to practices such as washing pads before disposal (Ali & Rizvi 2010; Sommer *et al.* 2013).

Onsite incineration is an option for managing the disposal of menstrual waste to achieve both pathogen and volume reduction, thus alleviating the environmental problems associated with improper disposal. Small-scale incinerators placed within a toilet facility may provide an effective and discrete way of disposing menstrual absorbents, align with decentralized waste treatment practices, and are well suited for institutional settings such as schools and worksites (Elledge *et al.* 2018).

Concerns in regard to the adoption of incineration are related to negative health and environmental impacts associated with the release of pollutants and toxic emissions as well as incomplete waste processing (Sommer *et al.* 2013); in the past decade, poor design and insufficient operation and maintenance have resulted in negative experiences for people (Tilley *et al.* 2013).

The Government of India has promoted the adoption of incineration for menstrual waste as part of its Swatch Bharat (Clean India) mission (2018). In India, menstrual waste volume is significantly high, with an estimated 121 million women disposing of 113,000 tons of menstrual hygiene waste (12.3 billion pads) annually (Path 2017). A number of programs implemented to increase access to sanitary pads have been successful in achieving widespread adoption recently, with an estimated 98% urban women using them (Dixit *et al.* 2016) and 64% of women in low-income areas gaining access to such pads (Garikipati & Boudot 2017). It is estimated that over 50 suppliers on the Indian market sell sanitary pad incinerators in institutional settings, with the majority being electric incinerators processing batch sizes as small as 10 pads (Bill & Melinda Gates Foundation 2021). The Government of India has classified sanitary pads as solid waste (SWM 2016), with associated emission thresholds for incineration, and since 2016 has stipulated the manufacturers of sanitary napkins to, among other things, provide wrappers for used sanitary napkins. However, lack of oversight and enforcement of regulations remains a concern for menstrual waste incineration (Elledge *et al.* 2018).

To our knowledge, there are no published reports on the performance of menstrual waste incinerators on the Indian market nor is there any information that includes the details of operation with actual menstrual waste.

Thermochemical processes such as incineration are well known to depend on the nature of the feedstock and its moisture content (MC). A very low MC is advantageous to incineration, and, to give some examples, the maximum MC allowed for thermal processes including incineration has been reported to be <15% (Burguete *et al.* 2016; Eke *et al.* 2019), while municipal solid waste thermal processes operate at no more than 20–25% moisture (Dong *et al.* 2016). In general, a higher MC can result in higher pollution and incomplete treatment (Youcai *et al.* 2004).

In order to enable the evaluation of menstrual pad incinerators based on realistic feedstock characteristics, this paper characterizes the physical properties of menstrual waste in the context of feedstocks for incineration. We collected and characterized menstrual waste from women's bathrooms from three institutional sites in India, and this paper reports our findings on the nature of the waste and its physical parameters: wet weight and MC.

MATERIAL AND METHODS

Site characteristics and study population

Menstrual waste was collected from three sites in the city of Coimbatore, India, between September 2019 and March 2020. All sites were communal women's toilet facilities: a private textile factory and two student residence halls in an educational institute, Hostel 1 and Hostel 2. The collection of pads was carried out by the caretakers (custodian or janitor) of each facility. The caretakers received an orientation about the purpose of the project prior to the beginning of the study and wore personal protective equipment (masks and gloves).

Site 1: The private textile factory site is a shared toilet for live-in and day workers. According to the warden, the number of users ranges between 20 and 50 women

Downloaded from http://iwaponline.com/washdev/article-pdf/11/3/474/889950/washdev0110474.pdf
by guest

between 18 and 50 years of age. The facility has five toilet stalls, with a dedicated lidded bin for menstrual waste disposal. After an accumulation period of 2–3 weeks, the five bins were collected by the caretaker by placing the waste in one larger disposal bag and delivered to the investigators for analysis. Five separate collections were used for this study, yielding a total of 304 pads.

Site 2: Hostel 1 is a multistorey building housing approximately 900 female students, estimated to be between 23 and 30 years of age. Each floor contains a toilet facility with 25 individual toilet stalls. Each stall has a dedicated lidded bin for menstrual waste (Figure 1(a)). Caretakers empty the waste bins daily. Standard disposal operations involve the caretaker collecting the contents of all individual bins from one floor into one large disposal bag. In order to preserve the contents of each bin and prevent clumping of the pads, black garbage liner bags were provided to the caretakers the day before collection and placed in each bin. Black liners containing at least one pad were delivered to the investigators (Figure 1(b)). Four separate collections were carried out at this site for one or more floors for a total of 47 bags.

Site 3: Hostel 2 is a multistorey building housing approximately 350 female students, estimated to be between 23 and 30 years of age. Each floor contains a toilet facility with 10 individual toilet stalls. One waste bin is shared between two toilet stalls. The janitors empty the individual waste bins daily into one large disposal bag per floor, similar to hostel 1. Black garbage liners for the bins were provided to the caretakers the day before collection. After 1 day, liners containing at least one pad were delivered to the investigators. One collection was carried out at this site for a total of 24 bags.

Menstrual waste physical analysis

Analysis began the same day menstrual waste was received from the caretakers. Metal tongs were used to sort the waste into individual pads. For each pad, its type was recorded as either commercially disposable cellulose or homemade cloth (Figure 1(c)). Commercial pads were further analyzed for disposal shape and assigned one of the following categories: unfolded, rolled up/crumbled, or stuck together. Pads that were stuck together due to exposed adhesive liners were recorded as such and not analyzed further. Additional information collected from commercial pads included the presence of wings and additional coatings, as determined by a different color of the substrate material. Cloth pads were homemade and nonuniform in size; therefore, we recorded the length, width, and layers of cloth of the pad.

In a fume hood, an analytical balance was used to record the wet weight for all individual pads received. A subset of approximately 15–18 pads from each collection was further evaluated for MC analysis. Pads were assigned to three weight categories based on wet weight: low (5–20 g), medium (21–40 g), and heavy (>41 g). The pads for MC measurements were randomly selected in quantities proportional to their number in each of the three weight categories.

MC was calculated using the conventional formula $\%\ \mathrm{MC} = (W_{\mathrm{wet}} - W_{\mathrm{dry}}/W_{\mathrm{wet}})*100$, where W_{wet} is the wet

Figure 1 | (a) Photograph of a bathroom stall with individual waste bins. (b) Waste bin bag liner as received. (c) Disposed of homemade cloth pad. (d) Individually labeled commercial pads in a dry oven for moisture measurement.

Downloaded from http://iwaponline.com/washdev/article-pdf/11/3/474/889950/washdev0110474.pdf
by guest

weight and W_{dry} is the dry weight. Pads were placed inside a vented hot air oven whose temperature did not exceed 100 °C (typically 55 – 70 °C) (Figure 1(d)). The drying temperature is lower than the standard value of 105 °C because of the limited temperature control capability of the oven. By drying at 55–70 °C, we ensured that no temperature swings exceeded 105 °C, which would cause mass loss to volatilization, and thus, we obtained an accurate dry weight value at the cost of longer drying times. The weight of the pads was recorded over multiple days until it did not change more than 4% from prior measurement, thereby providing the dry weight value. After the completion of analytical characterization, all specimens were discarded as biohazardous waste.

Ethics

PSG IMSR's Institute Human Ethics Committee (IHEC) reviewed and approved the study as exempted (2018/Appr/Exe/017). Duke University IRB determined the study to be non-human subject research.

RESULTS AND DISCUSSION

A total of 613 discarded menstrual pads were collected over multiple collections from three institutional sites, a factory and two residence halls from an institution of higher education (Hostels 1 and 2). Two types of menstrual waste were observed: commercially disposable cellulose pads and homemade cloth pads. The overwhelming majority (≥93%) of the pads collected from the three sites were commercially disposable pads, and of these, a large majority had wings or some type of cellulose coating as detected by different colored pad material. Homemade cloth pads were found in waste in two of the three sites, namely, the factory and Hostel 1. Results over multiple collections at the same sites were consistent over time. Table 1 summarizes the

Table 1 | Descriptive statistics of waste collection and its weight and moisture properties

results of the physical analysis of the disposable commercial pads for all collections.

Properties of commercial pads

There was a difference in the manner of disposal across sites, with the pads at the factory site being largely disposed of as unfolded, while at the hostels, we observed a mix of unfolded and rolled up, often wrapped by a piece of newspaper. We note that India being a country with a washing culture, bathrooms do not feature toilet paper, which is commonly used as a wrapper prior to disposal in other geographies. Unfolded pads are likely to stick to each other and form clumps that may be problematic for incineration, cause them to stick to surfaces, or be improperly positioned inside the incinerator.

The number of clustered pads was higher at the factory site than at the hostels due, in part, to both the manner of collection and the adoption of liner bags for the menstrual waste bins at the hostels.

The wet weight of the pads had a similar median value consistent across sites (median wet weight between 13.9 and 15.8 g); however, the range was very broad, from 5.7 to 89 g. The dry weight of the pads had median values 7.6–8.9 g and ranged between 4.7 and 14.1 g, consistent with typical ranges for different commercial pad sizes.

Commercial pads are designed to absorb typically 5 ml and, in some models, up to 10 ml of liquid (Fraser *et al.* 2001). Given that blood density is slightly more than water (1.06 g/ml), we estimate that blood adds 5–10 g to the dry weight of pads. Using the largest dry weight measured, for pad, of 14 g, we estimate 14 g (pad) +5 g (blood) ~ 20 g as the maximum weight of used pads (dashed line in Figure 2), being aware that in some cases we may observe 14 + 10 = 24 g.

Figure 2 shows the wet weight distribution of the pads, indicating that approximately half of the collected waste was below 15 g, with the majority below the expected maximum weight of 20 g. However, a long distribution tail of wet weights higher than 20 g was recorded for all three sites, particularly at the factory site, where as many as 37% of the pads were heavier than 20 g. Weights are plotted against measured MC in Figure 3. The data show that, consistently across the three sites, heavier wet pads feature very high MCs reaching 80–90%. The dotted line at 50% MC

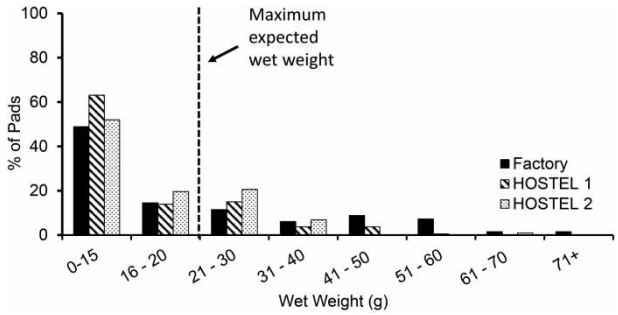

Figure 2 | Wet weight distribution of commercial pads shown as a percentage of the total number of pads from each site.

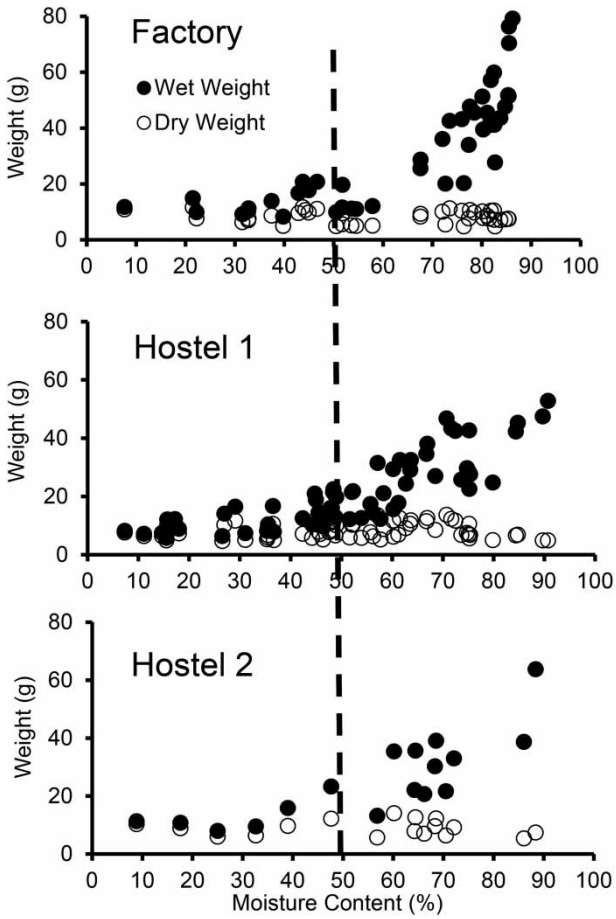

Figure 3 | MC results: wet and dry weights are reported by site. The dashed line represents 50% moisture, the expected upper limit for moisture for used menstrual pads.

corresponds to an 8 g dry pad receiving 8 ml of blood. This is expected to be an upper limit for MC for two reasons: (1) the typical volume of blood for pad rarely exceeds 5 ml and (2) in this study, drying of the pad can occur during

Downloaded from http://iwaponline.com/washdev/article-pdf/11/3/474/889950/washdev0110474.pdf
by guest

the time between disposal and collection (time lag = 1 day for hostels, 1–2 weeks for the factory site). Yet, the measured moisture values are too high to be consistent with moisture from menstrual blood alone. While we did not conduct chemical analysis on the liquid, we note that since India has a washing culture, a tap with water per personal wash is available in each of the toilets included in this study. Thus, we infer that wet heavy pads derive from the practice of washing them prior to disposal (Ali & Rizvi 2010; Sommer *et al.* 2013). This practice is associated with the concept that menstrual blood is impure and the belief that others should not see it, and also possibly with a lack of awareness on proper disposal practices (Garg & Anand 2015).

While MC was not measured for all pads (wet weight was measured), all pads in Figure 3 whose wet weight exceeded 20 g had a MC exceeding 50% (dotted line). Thereby, a significant portion of disposed pads (23, 28 and 37%) with wet weight above 20 g were estimated to have a MC ranging from 50 to 90%. Such high moisture levels could be problematic for thermal processing because they significantly exceed the optimal 15–25% feedstock moisture (Dong *et al.* 2016; Eke *et al.* 2019).

Properties of cloth pads

Out of the 613 pads collected in this study, 33 were homemade cloth pads. We note that since the cloth pads are reusable, the low fraction of disposed cloth pads does not represent an indication of how prevalent their use is. It is, however, an indication that the menstrual pad incinerator should be evaluated for its ability to process feedstock that contains a percentage of cloth material that has been reused multiple times.

Figure 4(a) illustrates the distribution of wet weight of cloth pads. Higher weights were observed particularly at the factory site, where cloth as long as 88 cm and as wide as 38 cm was folded in layers to serve as a pad (for reference, the length and width of a typical commercial pad product is 25 cm length × 7.2 cm width). The MC of the homemade cloth was, however, narrower than that observed for the commercial pads and ranged between 16 and 40%. Also, the MC was not associated with wet weight, with some of the heavy pads consisting of a larger quantity of material. A possible explanation for the difference in MC between cloth and commercial pads is the fact that commercial cellulose pads are designed to absorb liquid and, therefore, when washed, retain a large amount of liquid, while cloth pads can dry more easily after disposal.

Comparison with prior studies

Prior studies of menstrual waste are based on surveys, and only a few of them address specific questions on disposal practices that are relevant to our physical assessment results.

A key finding of this study is that a significant fraction of the commercial pads (23–37%) was associated with a high MC consistent with washing prior to disposal.

Prior literature that investigated reproductive tract health included questions about the pad material type and the frequency of personal washing. Within the studies that included details on menstrual hygiene material, the topic of pad washing emerged in the context of cloth pads and their reuse (Omidvar & Begum 2010; Das *et al.* 2015), while separate studies addressed the topic of pad disposal, with no mention made on washing (Wagh *et al.* 2018). Combining

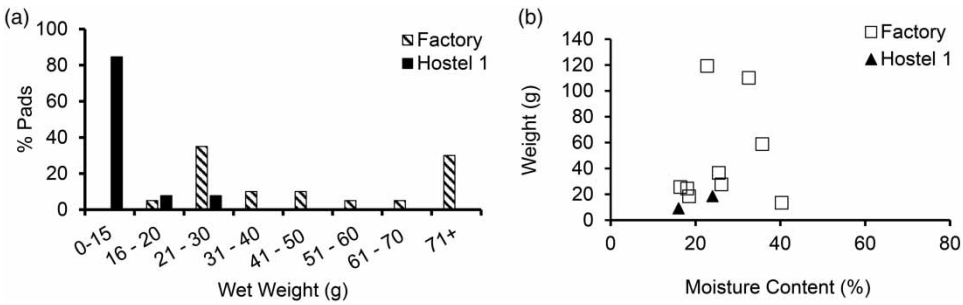

Figure 4 | Analysis of homemade pad properties. (a) Distribution of wet weight (factory: 20 pads; Hostel 1: 13 pads). No cloth pads were collected from Hostel 2. (b) MC was measured for a range of wet weights.

questions on both washing and disposing, a study in Pakistan reported that as many as 60% of the respondents washed and discarded cloth pads; however, there was no explicit question about the washing of disposable pads (Ali & Rizvi 2010). We identified one publication (Kumar & Srivastava 2011) that, while reporting on social restrictions and taboos around menstruation, found that the majority of girls from residential areas in a city in India used disposable pads and that 25% of them washed such sanitary napkins after using them and then disposed them. This observation of washing sanitary napkins prior to disposal is consistent with the high MC in waste that we measured.

Another finding of our work is that a large portion of the pads are disposed of unfolded and, therefore, not wrapped in any paper or plastic. This result is not reflected in prior literature, because the question whether pads are wrapped prior to disposal was not directly asked. In Nayak *et al.* (2017), 98% of the respondents described the material selected to wrap pads (either paper or plastic), and only 1% of the surveyed women did not respond to the question. In Dipali *et al.* (2009), the questionnaire asked about the material the pad was disposed in, not whether it was wrapped; thus, no information on unfolded pads was captured. This difference between our findings and prior reports on this matter highlights the complementarity of physical assessments and surveys in the study of behavior and practices.

CONCLUSIONS

We investigated the physical properties of menstrual waste as feedstock for incinerators that represent an attractive solution to the challenges of menstrual waste disposal, particularly in institutional settings.

Menstrual waste was generated by women of different ages (18–50 years) and different education/income (workers vs. college students), yet consistent outcomes were observed across the two groups. The use of commercial cellulose pads was prevalent at all sites (>93%), in agreement with recent reports (Dixit *et al.* 2016; Garikipati & Boudot 2017). In two out of three sites, 6–7% of the waste consisted of homemade cloth pads, suggesting that a menstrual pad incinerator technology will encounter multiple types of feedstock. The commercial pads were disposed both unfolded or folded, indicating that the incinerator configuration should be robust with respect pad insertion and positioning inside the unit; folded pads were not wrapped in manufacturer-provided wrappers, despite country regulations and standard use instructions.

A major finding of this study was that a significant fraction of the commercial disposed pads (23–37%) had a large wet weight (over 20 g), which was associated with MCs exceeding 50%. This MC is much higher than ideal for thermal processing (<25%) and can be quite problematic for typical incinerators, leading to incomplete combustion and increased hazardous air emissions. We infer that the MC is due to the practice of washing pads before disposal, a practice that has been reported in washing cultures. While this study on menstrual waste in India is limited to three sites, hundreds of pads were collected in repeated collections over periods of months, and the results were consistent across collections. These findings suggest that further research is needed to fill the knowledge gap on practices in menstrual disposal and that testing protocols of disposal technologies should include an evaluation of the effects of high MC, unfolded pads, and occasional cloth pads on waste processing performance.

ACKNOWLEDGEMENTS

This work was supported by the Bill & Melinda Gates Foundation through grant no. INV-001513 to Duke University and through the STeP project (contract service agreement ID 43951). We thank the caretakers of the three facilities for supporting the waste collection and gratefully acknowledge the analytical support of this study by Ms Viswa Barani and Mr Praveen Rosario.

ABSTRACT

Background: The prevalence and magnitude of childhood obesity is increasing in pediatric age group. Incidence of metabolic syndrome is high among obese children and adolescents leading to increased risk of cardiovascular morbidity in long term. For this reason, recognition of metabolic syndrome in obese children is of great importance.
Methods: This study was a cross-sectional study carried out among children aged 10-18 years from both urban and rural schools in Coimbatore. Children were screened, sample for metabolic studies collected after consent and analyzed.
Results: Total 1582 children in the age group of 10-18 years were screened. 300 children were recruited. Among the studied group, 19.3% were overweight, 30.7% were obese. Metabolic syndrome was present in 55.1% of obese and overweight children. Hyperinsulinemia was present in 30% of obese children.
Conclusions: This study done in adolescent school children showed a strong association between obesity and early onset of metabolic syndrome. Early intervention with lifestyle modifications is strongly recommended to prevent long term cardiovascular morbidity.

Keywords: Adolescent children, Metabolic syndrome, Obesity

INTRODUCTION

The prevalence and magnitude of childhood obesity is alarmingly increasing in pediatric population. Incidence of metabolic syndrome is high among obese children and adolescents, and it proportionately increases with worsening obesity. There is significantly increased risk of coronary morbidity and mortality in early adulthood among obese adolescents.[1] For this reason, the recognition of the metabolic syndrome in obese children is of great importance from a clinical and public health perspective. There are only few studies regarding the prevalence of the metabolic syndrome in children and adolescents in India.[2-4] This cross-sectional study was done to evaluate the pattern and prevalence of metabolic syndrome among adolescents aged between 10-18 years in Coimbatore, India. Metabolic syndrome was defined by using WHO and modified National Cholesterol Education Program Adult Treatment Panel III [NCEP ATP III] criteria.

In 1988, Reaven and colleagues coined the term Metabolic Syndrome (MetS) that refers to a combination of hypertension, abdominal obesity, insulin resistance, and hyperlipidemia and it was closely associated with obesity and increased risk for atherosclerotic cardiovascular disease.[5,6] What was first considered as adult condition has now been recognized in children.[7] With increasing prevalence of childhood obesity, it is very likely that pediatric metabolic syndrome will also be more prevalent recently, with implications for future increase in cardiovascular morbidity and mortality.

The International Association for the Study of Obesity (IASO) and International Obesity Task Force (IOTF) estimate that 200 million school children are either overweight or obese.[8]

A recent study among 38,296 children aged 8-18 y from five cities of India reported the prevalence of overweight and obesity (based on IOTF reference) as 14.4% and 2.8% respectively.[9] This may have major implications towards increasing prevalence of non-communicable diseases like diabetes, hypertension and cardiovascular disease in early adulthood.[10] Worldwide estimates of the prevalence of MetS range from 1.2% to 22.6% for youth and 9.0% to 35.0% for adults, depending on the definition of MetS used, the region, the study design, the years of the study, and the age group and study population.[11-15] Only very few data are available in India in this context.

METHODS

This study was a cross-sectional study and was carried out among children aged 10-18 years from schools in Coimbatore, including urban and rural areas. Children were screened for overweight and obesity based on BMI and waist circumference.

Weight was measured while the subjects were minimally clothed without shoes in upright position using digital scales and recorded to the nearest 0.1 kg. Height was measured in a standing position, without shoes, using a stadiometer and inch tape to the nearest 0.1 cm. BMI was calculated as weight in kilograms divided by height in meters squared. Waist circumference was measured in centimeters to the nearest 0.1 cm using a non-stretchable measuring tape, without any pressure to body surface at the narrowest level between the lower border of ribcage and iliac crest. Those adolescents classified under overweight and obesity are further evaluated for the presence of metabolic syndrome. Age and sex matched normal children were taken as control. They were selected by simple random sampling.

Informed consent was obtained from parent/guardians and assent from the children. A qualified physician measured blood pressure two times with the subject in a seated position during physical examinations after one initial measurement for determining peak inflation level using a standard mercury sphygmomanometer. The mean of two measurements was considered to be the participant's blood pressure. The systolic blood pressure was defined as the appearance of the first sound (Korotkoff phase 1) and diastolic blood pressure was defined as the disappearance of the sound (Korotkoff phase 5) during deflation of the cuff at a 2 - 3 mm/s decrement rate of the mercury column.

Fasting blood samples for the serum glucose and lipid profile was drawn after the subjects had fasted overnight. Samples were collected for rural children from rural health centre and urban children at PSG Hospital respectively. Fasting plasma glucose was measured on the day of blood collection by the glucose oxidase peroxide method, and lipid profile was measured by enzymatic assay on a Hitchi 704 system auto-analyzer. Lipid profiles [(triglyceride (TG), total cholesterol (C), high-density lipoprotein-cholesterol (HDL-C), low-density lipoprotein-cholesterol (LDL-C), and very-low-density lipoprotein-cholesterol (VLDL-C)] were determined in the fasting blood samples.

Fasting insulin was measured. Pubertal stage was determined in each patient using Tanner's criteria and hyperinsulinism (H1) was defined according to the norms for fasting insulin according to pubertal stage: prepubertal ≥ 15 mIU/L, mid-puberty (breast, genital stages 2-4)≥30 mIU/L post-pubertal≥20 mIU/L. Insulin resistance (IR) was analyzed using the homeostasis model assessment of insulin resistance (HOMA-IR). HOMA-IR was calculated by the following formula: fasting insulin* fasting glucose/22.5. An HOMA-IR value greater than 3.16 was used to determine IR in pubertal students.

Definition of metabolic syndrome

For the diagnosis of MetS, the presence of at least three of the following criteria (in accordance with the WHO and National Cholesterol Education Program Adult Treatment Panel III [NCEP ATP III] recommendations) was considered. These criteria included:

- Obesity: BMI≥95th percentile for age and gender (6-18 years, WHO growth charts)
- Abnormal glucose homeostasis: the presence of one of the following:
  - Hyperinsulinemia and insulin resistance (using fasting blood insulin appropriate for pubertal stage or sum of insulin levels in the first 120 min of oral glucose tolerance test)
  - Elevated fasting glucose (EPG): FG≥110 mg/dL
  - Impaired glucose tolerance (IGT), glucose at 120 min: 140-200 mg/dL
- Hypertension: systolic/diastolic blood pressure ≥95th percentile for age and sex.
- Dyslipidemia: presence of one of the following: (AAP Clinical Report on Lipid Screening in children).
  - High TG (≥95th percentile for age and sex)
  - Low HDL-C levels (<5th percentile for age and sex).
  - High total or LDL-C (≥95th percentile for age and sex).

Inclusion criteria

Children and adolescents aged between 10-18 years of age studying in urban and rural schools in Coimbatore, India. Study was done over a period of one year.

Sample size

Previous studies have estimated the prevalence of metabolic syndrome to be 4%. With this prevalence, the power of 80% and excluding the underweight children (prevalence of 30%), the screening sample size calculated as 1582. Considering the prevalence of 8% for overweight and obese children, sample size for second stage was calculated to be 150 with equal number of normal children. The samples were distributed evenly through urban and rural areas.

The data were entered in individual proforma. The collected data were then converted to excel format.

Data analysis

All statistical analyses were performed using the Statistical Package for Social Sciences (SPSS Inc., Chicago, IL) version 19. Data expressed as percentage. Chi square test was used to find out association between categorical variables.

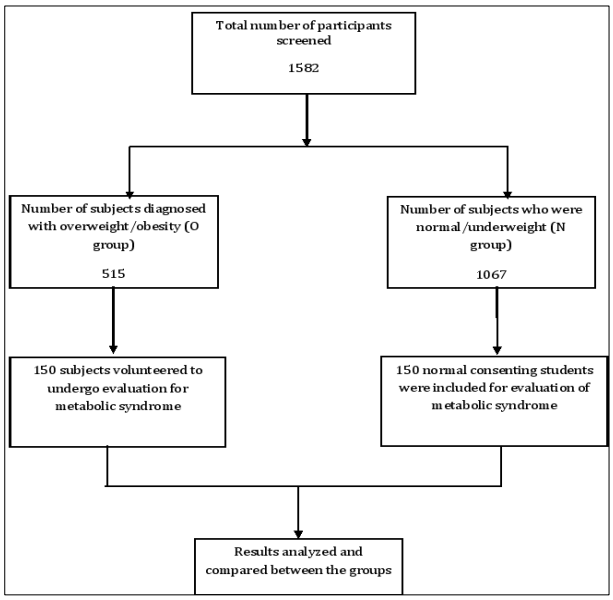

Figure 1: Flow diagram of subject recruitment.

RESULTS

Total number of school children recruited for this study in the age group of 10-18 years were 300, among whom 149 (49.7%) were boys and 151 (50.3%) were girls; in our study, there was almost equal distribution of boys and girls. Among the studied group 58 (19.3%), 92 (30.7%), 124 (41.3%), 26 (8.7%) children were overweight, obese and normal weight and underweight children respectively. Abnormal FBS (>110mg/dL) was seen in 5% of obese children and 2.1% in normal weight group, which was statistically significant. Abnormal total cholesterol level was found in 6% of obese and overweight group and 3.3% in normal group. (p value = 0.27) Triglyceride level was abnormal in 40.6% of O group children and 12.6% in N group children which was statistically significant (p=0.0001%). HDL was abnormal in 24.6% of O group children and 9.3% in N group children also had statistically significant difference (p=0.0001%). Hyperinsulinemia was present in 30% of O group children and 9.3% of N group children. HOMA - IR elevated in 60.6% of O group children and 22% in N group children. Both are statistically significant. Elevated BP was observed in 4.6% of N group children and 7.3% of O group children. Stage 1 hypertension seen in 3.3% of N group children and 14% of O group children which was statistically significant (p=0.002%). Among studied group MS was present in 55.1% in obese, overweight children. MS was more evidenced in the age group of 10-12 years (38.3%) as compared to the other age groups.

Table 1: Baseline characteristics of the study population.

Parameters		Number	Percentage
Age in years	10-12	122	40.7
	13-15	121	40.3
	16-17	57	19
Sex	Males	149	49.7
	Females	151	50.3
Overweight		58	19.3
Obese		92	30.7
Normal		124	41.3
Underweight		26	8.7

Table 2: Lipid profile, HOMA-IR, insulin levels, blood pressure between normal and overweight/obese children.

Variables		Overweight and obese(%)	Normal and underweight(%)	Chi square and p-value
TC		6	3.3	1.19,0.27

Table 1 indicating baseline characteristics of the study population including 1. Age group, majority of the children studied were between 10-15 years of age (81%). 2. Equally distributed between both sexes. 3. 30.7% children were obese and 19.3% were overweight.

Table 2 depicting the variables of lipid profile, insulin levels and blood pressure between normal and overweight, obese group.

Table 3 depicts that 50% of children with obesity in the study population had criteria to fulfill metabolic syndrome. 5.1% of children in the overweight group and 3.3% in the normal weight group had metabolic syndrome.

Table 3: Metabolic syndrome in the study population.

Category	Number	Percentage
Normal and under weight	5	3.3
Overweight	3	5.1
Obese	46	50

Table 4 shows the distribution of metabolic syndrome, age wise amongst overweight and obese children. 38.3%between 10-12 years, 28.5% between 13-15 years and 21.4 percent 16 and 17 years fulfilled criteria for metabolic syndrome. This indicates that screening and interventions should be planned early.

Table 4: Distribution of metabolic syndrome age-wise among overweight and obese children.

Age	Number	Percentage
10-12	28	38.3
13-15	18	28.5
16-17	3	21.4

DISCUSSION

Metabolic syndrome is a group of risk factors which has been increasingly prevalent concurrent with obesity.[16] Consistently high prevalence of MS has been recorded in obese and overweight adolescents across the globe varying from 24% to 38.8% of obese children (Turkey). These figures have varied in accordance with the criteria used. Using a combination of WHO and ATP-III criteria in the present study, we found that 50% of obese and 5.1% of overweight adolescent had MS respectively. Such figures in children is a potential harbinger of adult onset cardiovascular morbidity and mortality thereon. In this study, we found that there was equal preponderance of male and female adolescents for MS.

The children between 10-12 years had higher percentage of MS as compared to older adolescents.[17] This fact highlights early screening and dietary and lifestyle modifications for younger adolescents.

Authors observed that there was no statistically significant difference in total cholesterol and LDL levels between the 2 groups. However, the circulatory triglyceride levels were statistically more in the overweight and obese children with MS. High TG has been reported in studies.[2,17,18] The significance of hypertriglyceridemia in adolescents as a harbinger of adult onset of cardiovascular disease is gradually being appreciated. (Another factor noted in this study was that a small subsect of normal weight adolescents had triglyceride values above the age specific cutoff with other parameters remaining normal.) Levels of HDL were statistically significantly lower in the overweight and obese groups as quoted by other studies.[17,19,2] Hyperinsulinemia was present in 30% of obese and overweight adolescents qualifying for MS as observed by Mehmet Atabek.[20] Acanthosis nigricans as an external marker for hyperinsulinemia was seen in 3% of obese adolescents. High FBS (>110mg/dL) was found in 5% of obese and overweight children in the study. HOMA - IR was found to be elevated in 60.6% of the overweight and obese group which was statistically significant (p value 0.0001).11 adolescents (7.3%) in the overweight and obese group had elevated BP and 14% of children in the group and high BP qualifying for stage I hypertension.

Limitation of the study was that detailed dietary assessment could not be done as it was a school based study. Exact duration of physical activity was not included in the proforma.

CONCLUSION

This study done in children between 10-18 years has shown a strong association between obesity and incidence of metabolic syndrome. Early intervention with lifestyle modifications is strongly recommended to prevent long-term cardiovascular morbidity.

Abstract

Background:

Globally, type-2 diabetes mellitus is increasing in epidemic proportions. A major cause of concern in India is the increasing incidence of cases, especially troubling is the observed increase in younger age groups with no risk factors. New evidence suggests that many environmental factors, such as air pollution, persistent organic pollutants (POPs), and environmental estrogens are implicated as risk factors for type-2 diabetes mellitus. Animal and human epidemiological studies have shown ubiquitous lipophilic substances, including POPs, are frequently associated with type-2 diabetes mellitus. Such studies have not been undertaken in Indian youth.

Methods:

This is a cross-sectional study that explored the association between POPs and type-2 diabetes mellitus in Indian urban and rural population. About 7 ml of venous blood was collected from all consenting patients and serum was separated immediately and was transported to the lab for further analysis. Serum levels of POPs, including organochlorine (OC) compounds and organophosphorus pesticides, were estimated using sample gas chromatography-mass spectrometry (GC-MS). The fasting blood sugar values and the serum levels of POPS were tested using Pearson correlation coefficient. The magnitude of increase in blood sugar corresponding to increase in POPs was analyzed using linear regression analysis. The odds ratios (ORs) were expressed at 95% confidence intervals (CIs).

Results:

Three OC pesticides and one organophosphate pesticide were strongly associated with increasing blood sugar levels after adjusting for age, sex, and body mass index – lindane (OR 4.95, 95% CI 1.03–23.73), DDT o, p' (OR 3.50, 95% CI 1.04–11.73), dimethoate (OR 19.31, 95% CI 4.22–88.37), and dichlorvas (OR 6.33, 95% CI 1.28–31.18).

Keywords: DDT, dimethoate, health effects, persistent organic pollutants, pesticides, type- 2 diabetes mellitus.

Introduction

Incidence of diabetes is rapidly increasing worldwide.[1] The dominant risk factors include obesity, sedentary lifestyle, poor diet, old age, ethnicity, family history of diabetes, and dyslipidemia. Prevalence of diabetes for all age groups worldwide was estimated to be 2.8% in 2000 and expected to rise to 4.4% by 2030. The total number of people with diabetes is projected to rise from 171 million in 2000 to 366 million in 2030.[1] Type-2 diabetes is an epidemic in Asia, characterized by a rapid increase in onset at relatively young ages and low body mass index (BMI),[2] and environmental estrogens implicated in the rise of the same.[3] Persistent organic pollutants are a class of compounds characterized by their ability to persist in the environment, due to their low water, high lipid solubility and bio-magnification in the food chain.[4] POPs include polychlorinated dibenzo-p-dioxins, polychlorinated dibenzofurans, polychlorinated biphenyls (PCB), hexachlorobenzene, p, p'-dichlorodiphenyldichloroethylene (DDE), and several organochlorine (OC) mixtures. These have been studied by international organizations for their impact on environment and humans alike and have been implicated in several adverse effects on human health especially with impaired glucose metabolism and prevalence of diabetes mellitus.[4,5] India, a highly populated middle-income country, is subjected to environmental contamination of POPs from several activities and sources like production units, illegal imports as well as stockpiles of obsolete pesticide.[6] Except for DDT seven other pesticide POPs listed in the Stockholm Convention are banned for manufacture but are in wide use because large stockpiles are still available. In a nationwide food survey in 2001, 75% of the samples had detectable levels of DDT with about 10–15% of the samples having levels of DDT that exceeded the levels prescribed by the Food and Agricultural organization and World Health Organization. Aldrin and dieldrin were also frequently detected pesticides in foodstuffs.[7,8] Racial and ethnic differences in responses to POPs are well known.[9] POPs may be associated with T2DM with a higher magnitude in Asians, contributing to the epidemic. Hence, prevention and control of diabetes is a top public health priority in Asian populations.[10]

Many studies based on self-reported diabetes and mortality rate analysis indicate an association between pollutants and diabetes/prediabetes.[11,12] Many POPs act as endocrine disrupting agents in animals and humans.[13] Concentrations of most of these pollutants have been diminishing in the

environment, food chain, and human body over recent decades in Europe and the United States. However, there are subgroups within these populations that still show an elevated body burden because of dietary habits and current or past exposures.[11] Diabetes has been associated with dioxin-like chemicals, nondioxin like PCBs, DDE, and/or other OCs in several cross-sectional investigations.[4,11,14,15] Altered glucose transport, lipid metabolism, and modifications in the insulin signaling pathways are potential mechanisms that might be involved in the association between POPs and diabetes.[11] The Jørgensen group showed that POPs may affect insulin secretion rather than insulin resistance.[16]

POPs metabolism, particularly low-level exposures, warrants investigations using a cohort study design.[17] There have been few studies that have used fasting blood glucose levels (≥126 mg/dL or 7.0 mmol/L), HbA1c, or random glucose level (≥200 mg/dL or 11.1 mmol/L) to diagnose diabetes.[4,14] The Morgan lab at University of Iowa College of Medicine, Iowa observed that workers with incident diabetes had significantly elevated levels of DDE+DDT in their serum compared to workers without diabetes.[18] Vasiliu *et al*.[12] found that PCBs were associated with incident diabetes in women but not in men and remained associated when cases encountered during the first 15 years of follow-up were excluded, suggesting that reverse causality was an unlikely explanation for the relationship. Investigations on Operation Ranch Hand Veterans, who were exposed to 2,3,7,8- tetra chlorodibenzo-p-dioxin (TCDD) through application of Agent Orange in Vietnam, were found to have incident diabetes associated with TCDD exposure.[19] Also, diabetes was associated with DDE exposure but not with mono-ortho PCB-118, total PCBs, or years of sport fish consumption.[5] In another case-control study it was confirmed that p, p'- DDE exposure could be a potential risk factor for T2DM.[11] A cross-sectional survey conducted in a heavily polluted area of eastern Slovakia demonstrated increasing serum concentrations of individual POPs considerably increased prevalence of prediabetes and diabetes in a dose-dependent manner.[20] Based on the current literature, there is a strong implied linkage between POPs exposure in humans and type-2 diabetes. There have been many studies analyzing the presence of POPs in Indian population, but none connecting the link and establishing association between POPs and diabetes.[21] Hence in this study, we investigated the association of blood sugar with the serum concentrations of POPs in south Indian population.

Methods

This is a cross-sectional study conducted at the rural and urban outreach centers affiliated to the PSG Institute of Medical Sciences and Research, Coimbatore, India. The study was conducted with approval from Institutional Human Ethics Committee at PSGIMS&R. A written informed consent was obtained from all eligible participants. All participants who consented were recruited in the study. Details about the study were informed by health workers from the center by house to house visit in addition to distribution of pamphlets which included details of the study and requirement of 8 h fasting for the collection of samples. Both male and female of age above 18 were included based on convenience sampling. Diabetics were confirmed as evidenced by fasting blood sugar above 126 mg/dL or HbA1c above 6.4% or use of hypoglycemic medications. Participants with type-1 diabetes and terminally ill conditions were excluded from the analysis. Basic demographic details, socioeconomic status, family history of diabetes, hypertension, general health, and medical history were elicited using a questionnaire. Anthropometric measurements were recorded and blood pressure was recorded in the sitting posture in the right arm. Age, gender, body weight, and height were recorded for each patient. Body mass index was calculated as weight in kilograms divided by height in meter squared. Blood was drawn after at least 8 h overnight fasting. Fasting blood sugar (FBS) was determined by hexokinase method which is a standard laboratory procedure. Serum POPs were determined by method described by Koc and Karakus.[22] Briefly, OC pesticide residues were determined using florisil packed-columns

and GC-MS. Linear response between FBS and POPs were measured by the Pearson correlation method. The association between increasing sugar level and POPs was calculated by linear regression after adjusting for age, sex and BMI. All statistical analyses were conducted using R version 3.5.1 (R Development Core Team, http://www.r-project.org).

Results

The total numbers of participants in our study was 191, out of which FBS was not available for five participants. The demographic characteristics for the remaining 186 participants are given in Table 1. Box plots for age and BMI stratified as per gender are given in Figure 1a and 1b. Of the 44 compounds, 11 of them contributed to 93% of total POPs load [Figure 2]. The serum levels of the following four compounds – lindane, dichlorvas, DDT o p', and dimethoate were significantly correlated with increasing blood sugar levels [Table 2]. Among the remaining compounds 31 were not comparable and seven were below limit of detection. Correlation statistics among selected compounds is illustrated in Figure 3, nonsignificant correlation indicated by cross mark, positive correlation by blue solid circles, and negative correlation by red solid circles. Size the circle indicates the magnitude of correlation. Figure 4a–d illustrates the trend analysis by Pearson method showing increasing linear relationship as sugar level increases. Since POPs are obesogenic, we checked its correlation between different strata of BMI [Table 3] and with age [Table 4]. The participants were categorized as normal, overweight, and obese based on the height and weight. The odds ratio (OR) and 95% confidence intervals (CIs) of POPs showed significant risks for compounds like lindane (OR 4.95, 95% CI 1.03–23.73), DDT o, p' (OR 3.50, 95% CI 1.04–11.73), dimethoate (OR 19.31, 95% CI 4.22–88.37), dichlorvas (OR 6.33, 95% CI 1.28–31.18). Similar compounds are found to be significantly associated with blood sugar after adjusting for age, sex, and BMI [Table 5].

Discussion

Our study demonstrated that environmental exposure to various OC and organophosphate pesticides are associated with prevalent type-2 diabetes in Indian population. Our findings are supported with published literature, which implicate OC pesticides in risk of diabetes among general population.[14,15] Benzene Hexachloride (BHC) beta isomer was shown to be a strongly correlated with age in our study. One possible mechanistic pathway for BHC isomers is via pancreatic and extra-pancreatic actions, i.e. caspase 3 activation due to reactive oxygen species generation causing membrane destabilization and mitochondrial dysfunction of the beta cell.[15,20,23,24] Other OCs like DDD and DDT were also moderately associated with sugar levels, their ORs a little above 1.00. Epidemiological evidence also substantiates the positive risk DDT and its metabolites can have on diabetes.[20,24] DDT and its metabolites are inducers of cytochrome P450 (CYP 2BA and CYP 4A1), enzymes involved in lipid and steroid metabolism.[25,26] Moreover, these compounds can inhibit aromatase, an enzyme that metabolizes steroids like cortisol.[27] As a result of aromatase inhibition, steroidal compounds tend to accumulate leading to anti-estrogenic effects, although at a receptor level, they are pro-estrogenic in action.[28] These effects coupled with cross talk with catecholamines in the adrenal gland lead to endocrine disruption. These compounds are also known to inhibit expression of Dio-2, low-density lipoprotein (LDL), Protein kinase B (AKT), extracellular-signal-regulated kinase (ERK), Patatin-like phospholipase domain-containing protein (PNPLA), and Glut-4 genes in target tissues.[29] Although we could not find epidemiological evidence for dimethoate even after PubMed search with the following terms “Dimethoate” [MESH] AND “Diabetes” [MESH], we were able to find animal studies

implicating omethoate (a break-down product of dimethoate) with insulin resistance.[30] The epidemiological evidences are summarized in Table 6. Major limitation of the study is the cross-sectional nature, which might not have captured the cause-effect relationship.[31,32]

Table 6

Epidemiological and animal studies substantiating our study

Compounds	Odds ratio (CI)	Exposure contrast	Reference
p, p'- DDT	2.52 (1.26-5.02)	20.8-26.6 vs. ≤20.7 (ng/g lipid adj.)	Everett and Matheson[24]
	1.96 (1.29-2.98)	≥20.7 vs. ≤20.7 (ng/g lipid adj.)	Everett and Matheson[24]

	1.08 (0.59-1.97)	QU3 vs. QU1 (ng/g lipid adj.)	Ukropec *et al.*[20]
	0.8 (0.3-2.2)	Q4 vs. Q1 pg/g	Lee *et al.*[4]
	8.2 (1.3-53.4)	T3 vs. T1 ng/g lipid adj.	Son *et al.*[31]
Lindane	2.02 (0.88-4.65)	Not available	Zhang *et al.*[30]
Dichlorvas	1.21 (0.98-1.49)	Not available	Montgomery *et al.*[32]
Dimethoate	Study suggested Omethoate could potentially cause insulin resistance.		Zhang *et al.*[30]

Conclusion

This exploratory study found that serum levels of several OCs and organophosphate pesticides were associated with type-2 diabetes in a south Indian population. This is the first study in the Indian population to report the association of POPs and type-2 diabetes mellitus. Our finding complement other studies on Asian groups providing evidence for adverse effects of POPs, which explains the current epidemic of type-2 diabetes in Asia.

Declaration of patient consent

The authors certify that they have obtained all appropriate patient consent forms. In the form, the patient(s) has/have given his/her/their consent for his/her/their images and other clinical information to be reported in the journal. The patients understand that their names and initials will not be published and due efforts will be made to conceal their identity, but anonymity cannot be guaranteed.

Financial support and sponsorship

The study was funded by “Collaborative grant between ICMR-University of Minnesota, USA.”

Conflicts of interest

There are no conflicts of interest.

Acknowledgement

The authors are thankful to Dr K. Kalaiselvi, PhD and Dr M. Palanivel, PhD, Greenlink Laboratories, Coimbatore, for sample analysis. The study was funded by “Collaborative grant between ICMR-University of Minnesota, USA.”

Abstract

Due to the increasing adoption of nutrient discharge regulations, many research groups are stepping into new territory with phosphorus (P) measurements. Accurate reporting of P concentrations in effluent from novel wastewater treatment technologies is critical for protecting both environmental and human health. Analysis of P in wastewater is prone to pitfalls because of the (1) variety of chemical forms of P in wastewater (orthophosphate, condensed P, and organic P), (2) availability of different chemical assays for measuring different P forms, and (3) different conventions in the units for reporting P. Here, we present a case study highlighting how these pitfalls affect analysis and interpretation of P measurements. We show that, when used appropriately, commercially-available kits are indeed accurate tools for evaluating reactive P and total P concentrations. For both standard solutions and real wastewater, we systematically remove steps from the total P protocol to show how protocol deviations affect the results. While standard solutions are important for validating analytical methods, commercially-available wastewater standard solutions only contain P as orthophosphate (reactive P).

We therefore demonstrate options for making a mixed-P standard solution containing acid-hydrolyzable and/or organic P compounds that can be used to validate both reactive P and total P assays.

Keywords: Wastewater, nutrient pollution, standard solutions, onsite treatment, phosphorus, phosphate, non-sewered sanitation

Introduction

An intense area of research is non-sewered sanitation solutions for rural areas and low- and middle-income countries[1-14] to address the urgent need for safely-managed sanitation to improve human health and the environment.[15,16] In addition to removing pathogens and organic compounds, a key requirement of wastewater treatment is removal of nutrients including nitrogen and phosphorus (N and P) due to their potential toxic effects on aquatic environments.[17,18] The concern with P is that phosphates are limiting nutrients in freshwater aquatic environments; an overabundance can lead to decreased dissolved oxygen, accelerated eutrophication, and harmful algal blooms.[19] These algal blooms can also pose a human health risk through the production of cyanotoxins.[20] Additionally, P is a limited, valuable natural resource that should be recovered and reused.[21,22]

Nutrient discharges from inadequate onsite wastewater treatment systems are a growing concern globally and likely underreported.[16,23] Affordable and sustainable methods for effective N and P removal in decentralized treatment systems remain technologically challenging.[24,25] Recently, an international standard ISO 30500 was specifically developed to provide performance requirements for non-sewered sanitation systems[26] and sets a minimum threshold reduction of 80% for total P. As P regulations are increasingly enforced, wastewater P content will need to be regularly measured and reported as new technologies are pilot-tested.[2,14,27,28] Standardized P reporting is required to compare performance across different technologies and wastewater streams to accelerate technology adoption, yet a critical gap exists due to lack of a common set of metrics.[29] This knowledge gap in reporting metrics for P and its different chemical species is also highlighted in a recent systematic review of nutrient removal and recovery technologies by Kogler et al.[30] In reviewing 292 articles across 46 sources, Kogler et al.[30] found that removal efficiency and achievable effluent concentrations for P removal and recovery technologies are generally underreported, with only 16% of the articles reviewed giving adequate quantitative information for meaningful interpretation of technology performance.

As we embarked on the journey of adding total P to our routine testing regimen, we identified several specific points of confusion. We determined that measurement and reporting of P requires particular attention because of the (1) variety of chemical forms of P in wastewater, (2) availability of several different chemical assays for measuring different forms of P, and (3) different conventions in the units used for reporting P. Due to the interrelated nature of these topics, there is potential for inconsistencies in reporting results for P. Here, we present a case study highlighting the importance of accurate and clear reporting of P units and strict adherence to chemical assay protocols for measuring P in wastewater samples. The objective of this paper is to share our experiences in identifying and overcoming these P-related pitfalls so that others may avoid these issues in their future work. The aims of this paper include (1) determining the root cause(s) of discrepancies in P results and (2) developing new standard solution mixtures to ensure accurate analytical method implementation and data reporting.

We begin with a brief review of the forms of P in wastewater and typical units used for reporting P. We then describe our recent experiences where we identified discrepancies in P concentrations we measured using a commercially-available test kit and those measured by a third-party lab for the same

samples. Due to the transparent and productive relationship with the third party lab, we were able to identify two distinct sources of confusion as the likely reason for these discrepancies: (1) the factor of 3.066 difference in results reported as mg L^{-1} "PO_4-P" versus mg L^{-1} "PO_4^{3-}"; and (2) the omission of the digestion heating step in the total P protocol. By systematically omitting steps from the total P chemical assay procedure, we show that skipping the digestion heating step results in a significant undercounting of total P, both for standard solutions and for real wastewater samples.

To avoid these issues in future studies, regularly testing known P standard solutions to validate analytical methods and reporting methods is needed. However, we observed that the common commercially-available wastewater standard solutions only contain P as orthophosphate (reactive P). This is perhaps due to the fact that soluble orthophosphate is the majority P form in effluents from traditional wastewater treatment systems and therefore also the P form of primary concern for anthropogenic nutrient pollution.[31] However, our analysis reveals that the assumption that orthophosphate = total P does not necessarily hold for wastewater influent of novel onsite wastewater treatment technologies. We therefore believe that including acid-hydrolyzable P and/or organic P components in known standard solutions is especially important to ensure accurate reporting of novel wastewater treatment technology performance. To this end, we have prepared and validated our own standard mixtures of orthophosphate, acid-hydrolyzable P, and organic P using readily available and inexpensive chemical reagents.

Methods

Unless otherwise indicated, all glass wares used in this study were cleaned by soaking in 1:1 HCl:water (v:v), rinsing thoroughly in distilled or ultrapure water, then filling with fresh distilled or ultrapure water and storing until needed. Mean and standard deviation values for replicate measurements were calculated using Excel. Data were plotted using OriginPro 2018.

Standard solutions

A mixed-parameter quality control standard solution for wastewater was purchased (Hach, product LCA720) that features 10.0 mg L^{-1} PO_4-P in addition to ammonia, nitrate, COD, and TOC. A wastewater influent inorganics quality control standard solution was also purchased (Hach, product #2833149) that contains 10 mg L^{-1} PO_4^{3-} in addition to ammonia, nitrate, COD, sulfate, and TOC. (See Supplemental Material for details.)

The other standard solutions used to validate assay performance were prepared in-house. Phosphate stock standard solutions (PO_4^{3-} = 10 and 25 mg L^{-1}, labelled P 10 and P 25, respectively) were prepared by dissolving potassium dihydrogen phosphate (KH_2PO_4) in distilled water. Mixed standard solutions were prepared using KH_2PO_4, sodium trimetaphosphate ($Na_3P_3O_9$), and adenosine 5'-triphosphate, disodium salt (ATP), all purchased from Sigma-Aldrich (see Supplemental Material for additional reagent information).

Real wastewater samples

Effluent from a toilet was collected to serve as wastewater samples for evaluation. A women's shared toilet facility at a privately-owned textile mill in Coimbatore, India (described in a previous study) was the sample collection site.[13] The facility is used by 20 to 50 employees and features five toilet stalls equipped with Indian squat plates, each connected to cistern flush. The effluent of one of the toilets can be easily tapped into from the pipe and was diverted from its septic tank to a 200 L collection tank. After collecting all toilet effluent (containing flush water, urine, and feces) from 8 am to 5 pm local

time, the wastewater was left to settle overnight. The supernatant was collected the morning after and then the contents of the tank were homogenized by with a macerator pump (Jabsco Model: 18950, 45 lpm). Both supernatant and macerated wastewater samples were analyzed with the commercially-available test kit on the same day.

Commercially-available test kits (ascorbic acid method)

Total P (method 8190) and reactive P (method 8048) test kits were purchased from Hach and used with a Hach DR 900 colorimeter. Unless otherwise indicated, the test kits were used exactly as per the manufacturer's instructions (see Supplemental Material for more detail). Both test kits use the ascorbic acid method, are USEPA accepted for reporting wastewater analyses, and the procedures follow USEPA and Standard Method 4500-P.[32] Distilled (in India) or ultrapure 18.2 MΩ cm (in the US) water was used for dilution as necessary to bring the samples within the assay detection range. The total P test kit includes two powder pillows (potassium persulfate, PhosVer 3), a bottle of sodium hydroxide 1.54 N, and glass reaction vials containing a pre-measured sulfuric acid solution. A Hach DRB 200 digester heating block was used for the digestion step in the total P protocol. The reactive P test kit includes one powder pillow (PhosVer3) and either glass reaction vials containing a pre-measured volume of deionized water or a reusable glass sample cell (see Supplemental Material).

Third-party laboratory measurement (stannous chloride method)

Samples sent to a NABL certified laboratory (T.STANES Coimbatore) were analyzed using the Indian Standard IS:3025 part 31[33] stannous chloride method for the measurement of total P, a method essentially similar to Standard Method 4500-P.[32] According to the IS:3025 part 31 stannous chloride method, samples are decolorized by shaking with activated carbon for 5 minutes, then filtered. A phenolphthalein indicator is added to the filtered sample, and if a pink color develops, the pink color is discharged through the addition of up to 5 drops of a strong acid solution. Finally, ammonium molybdate and stannous chloride reagents are added and allowed to react for 10 minutes. The sample is then quantified spectrophotometrically at 690 nm. Fresh standard solutions were prepared by the third-party lab to calibrate their instrument upon receipt of each set of samples. Distilled water was used for sample dilution when necessary to bring the sample within the assay detection range. Analytical results from the third-party lab were reported to us in units of "Phosphorus (mg/L)."

Results and Discussion

Forms of P relevant for wastewater analysis

In aqueous solutions relevant for wastewater treatment technologies, P exists in three main forms, commonly referred to as orthophosphate, condensed phosphate, and organic phosphate (Table 1).[32] Phosphate anions can be detected colorimetrically, and chemical assays are commercially available for measuring only orthophosphate (sometimes called "reactive P"), "acid-hydrolyzable P" (orthophosphate + condensed phosphate), or "total P" (orthophosphate + condensed phosphate + organic phosphate). The specific chemical reactions responsible for the colorimetric responses have been described in detail elsewhere[32] and should be included with each commercially-available assay. Briefly, orthophosphate anions form a colored complex with a transition metal under the chemical assay conditions.

Table 1.

Common assays, with naming and unit conventions, for forms of P in wastewater analysis.[32]

Commercially-available chemical assays	"Orthophosphate" or "reactive P"	"Acid-hydrolyzable P"	"Total P" or "total phosphate"
Forms of P detected	Orthophosphate	Orthophosphate + condensed phosphate	Orthophosphate + condensed phosphate + organic phosphate
Digestion required?	No	Yes	Yes
Strong oxidant required?	No	No	Yes
Typical reported units (mg L^{-1})	PO_4^{3-} or PO_4-P	PO_4^{3-} or PO_4-P	PO_4-P or P

The color response for all the different assays is due to detection of orthophosphate. Other forms of P (condensed phosphate and organic phosphate) must first be converted to orthophosphate before they can be detected. Condensed phosphates require a preliminary acid hydrolysis step at elevated temperatures before the colorimetric response can be observed. Some organic phosphates also require addition of a strong oxidant to the acid hydrolysis step. Orthophosphate and acid-hydrolyzable P are typically reported using units of either mg L^{-1} "PO_4^{3-}" (orthophosphate) or "PO_4-P" (orthophosphate as P). Total P is typically reported as mg L^{-1} "P."

Potential Pitfall #1: Distinguishing and converting between the different units used for P reporting

Note that the "typical" reporting units in Table 1 are just a guideline. In our experience, these do not appear to be hard rules, and all three units are used for reporting all types of phosphorus data. *The units alone will not tell you which forms of phosphorus have been measured.* It is therefore important to understand what the different units mean and how they are interrelated. Some standards, such as the ISO 30500, are written as percent reduction requirements; in this case, the units in which P quantities are reported is not particularly important as long as it is internally consistent within any given study. However, P units must still be accurately and clearly reported in order to compare values across different studies and to nominal values for other discharge standards. Briefly, units of "PO_4-P" and "P" are equivalent and therefore interchangeable. "PO_4^{3-}" units are calculated differently and a mathematical conversion must be performed to compare to the other units.

Converting between values reported in the three different units requires accounting for the mass of atoms which are counted in each unit. Units of PO_4-P and P only count the 1 P atom (30.97 amu). Therefore, values reported in mg L^{-1} PO_4-P will be identical to values reported in mg L^{-1} P and no conversion is required. In contrast, units reported in PO_4^{3-} count all atoms in the phosphate anion—1 P atom (30.97 amu) and 4 O atoms (each 16.00 amu). Values reported in mg L^{-1} PO_4^{3-} can be converted to P or PO_4-P by dividing by 3.066, which is the stoichiometric ratio of the mass of the phosphate anion (1P + 4O = 30.97 + 4(16.00) = 94.97 amu) to that of a single P atom (30.97 amu). Similarly, values reported in units of P or PO_4-P can be converted to units of PO_4^{3-} by multiplying by 3.066:

$$1.000\ \text{mg L}^{-1}\text{P} = 1.000\ \text{mg L}^{-1}\ \text{PO}_4\text{–}P = 3.066\ \text{mg L}^{-1}\ \text{PO}_4^{3-} \quad \text{Eq. (1)}$$

As an example, consider the two wastewater (WW) quality control standard solutions, both purchased from Hach for use in this study. The first WW standard solution (1) is listed by the supplier as containing "10.0 mg L^{-1} PO_4-P," while the other (2) is listed as containing "10 mg L^{-1} PO_4^{3-}." It is an easy mistake at first glance to think that the phosphate concentrations of these solutions are equivalent. However, when we convert WW standard solution (1) to PO_4^{3-} units, we see that it actually contains 3 times as much phosphate: (10.0 × 3.066) = 30.7 mg L^{-1} PO_4^{3-}. To directly compare these wastewater standard solutions, we will hereafter label them as (1) WW 30 and (2) WW 10 to reflect the expected phosphate concentration in PO_4^{3-} units.

We use a commercial test kit for total P (Hach 8190) for our in-house field testing, because this field-friendly method utilizes only two small, easily-transportable pieces of equipment (the DRB 200 digester and the DR 900 colorimeter) and pre-portioned reagents in pre-measured vials and sealed "powder pillow" packets. The results for total P are displayed by the DR 900 colorimeter in units of "mg L^{-1} PO_4^{3-}." We used the WW 30 standard solution described above to validate the total P test kit, as recommended by the manufacturer. Results were obtained for samples collected in glass bottles cleaned with or without a HCl acid wash. (The acid wash is used to eliminate possible contamination from the detergent used to clean bottles, which may contain phosphate.) Figure 1 shows that all results obtained were within 15% of the expected value (n = 4; mean = 29.6 ± 4.2 mg L^{-1} PO_4^{3-}), however the variability in the acid-washed results was lower, within 5% of the expected value (n = 3; mean = 30.6 ± 1.5 mg L^{-1} PO_4^{3-}). We therefore used acid-washed containers for all subsequent measurements, including with samples sent for analysis to the third-party lab.

Open in a separate window

Figure 1.

(A) Total P test results (measured by Hach kit) for the commercially-available standard solution WW 30 and in-house prepared phosphate solutions (P 25 and P 10). Each standard solution was tested multiple times; the results of individual tests are shown as open symbols, with the mean for each column shown as a short dashed line and the expected values shown as solid horizontal reference lines. The variability in test results is highest for WW 30 measured without acid washing of glassware (diamonds, n = 4, 29.6 ± 4.2 mg L^{-1} PO_4^{3-}). The variability is similar for all three standard solutions when glassware is acid washed prior to contact with the samples (circles; WW 30, n = 3, 30.6 ± 1.5; P 25, n = 6, 25.3 ± 1.0; P 10, n = 6, 10.8 ± 1.1). Position along the x-axis is not meaningful—data points within each column are offset from one another for clarity. (B) Total P measured for identical samples tested in-house with the Hach test kit and by the third-party lab. Values for units of PO_4^{3-} are shown on the left y-axis and values for units of PO_4-P are shown on the right y-axis. Expected values are shown as solid horizontal reference lines. Values reported by the third-party lab (in PO_4-P units) are similar to those measured in-house (in PO_4^{3-} units) once the correct unit conversion is applied.

In addition to the WW 30 standard solution, we evaluated phosphate solutions prepared in-house of known concentrations (PO_4^{3-} = 10, 25 mg L^{-1}, labelled P 10 and P 25, respectively) obtained by dissolving KH_2PO_4 in distilled water. Again, these solutions gave results close to the expected values (P 10, n = 6, mean = 10.8 ± 1.1 mg L^{-1} PO_4^{3-}; P 25, n = 6, mean = 25.3 ± 1.0 mg L^{-1} PO_4^{3-}). These results confirm that solutions of KH_2PO_4 can effectively serve as standards for P in orthophosphate form, and that acid-washing of sample glassware reduces test-to-test variability in the results.

Initial reports showed different units for P analysis performed by a third-party lab, leading to a discrepancy which required further validation. Our third-party collaborator, a certified laboratory located in the same city, uses the stannous chloride method for total P measurement. This third-party lab requires a large volume (>150 mL) of sample to run their assay, thus we diluted by 5× the WW 30 standard solution prior to delivering it. We also sent for analysis a sample of the P 25 solution.

The third-party lab reported values of 10.25 mg L^{-1} for the WW 30 sample and 7.84 mg L^{-1} for the P 25 solution, both reported with units of "Phosphorus (mg/L)." Initially, we were surprised to find that the third-party lab results appeared much lower than the values we expected (30.7 and 25.1 mg L^{-1}, respectively) for the WW 30 and P 25 samples. After clarifying discussions with the third-party lab, we determined that their results were reported in "PO_4-P" units. Thus, the expected values would be 10.0 and 8.15 mg L^{-1} for units of PO_4-P, respectively, for these two samples. In Figure 1B, the results are shown for both units of PO_4^{3-} (on the left axis) and PO_4-P (on the right axis). It is clearly seen that by resolving the ambiguity of the reported units, the total P values were measured by the third-party lab within a few percent from the expected values.

Potential Pitfall #2: Omission of steps from the total P test protocols

Despite reconciling the difference in reported units between our in-house total P test results and those from the third-party lab, we noticed that there was still a discrepancy between results from the two labs when real wastewater samples were analyzed. Total P results from the third-party lab were always lower than those measured in-house, although not always lower by a consistent nominal amount or percentage. Importantly, we learned through fruitful discussions with the third-party lab that while a digestion (heating) pre-treatment step is listed in the IS:3025 protocol, digestion was not actually performed. This indicates that while the third-party lab results were accurate in determining total P content from the standard solutions (where only orthophosphate was present), their procedure will under-report the total P content for samples where condensed and organic phosphates are present (e.g., real wastewater samples from field testing evaluation of onsite treatment technologies).

The full protocol for Hach total P measurement includes a digestion step performed by heating the sample in acid at 105 °C for 30 minutes with a persulfate ($S_2O_8^{2-}$) reagent added to the solution. Heating in acid converts any acid-hydrolyzable P to orthophosphate. The addition of the strong oxidant $S_2O_8^{2-}$ ensures that organic phosphates are fully converted to orthophosphate. Figure 2 shows in-house results for two raw wastewater samples where steps from the total P protocol were systematically and intentionally omitted. Samples A and B were collected on different days from the same shared toilet effluent, and the liquid supernatant as well as a macerated sample containing higher fecal load were analyzed. The primary soluble form of P in wastewater is orthophosphate, therefore orthophosphate is expected to dominate in the supernatant fraction, while the macerated fraction is expected to contain a higher concentration of organic and condensed P forms.

Figure 2.

Comparison of total P results obtained during systematic omission of testing steps for two raw wastewater samples A and B collected from the Coimbatore field testing site. The photograph shows the typical appearance of the supernatant and macerated sample fractions. For each sample, both the macerated fraction (closed circles) and the supernatant fraction (open circles) were measured. The macerated fraction contains more fecal matter and thus a higher total P concentration. Omitting the heating step ("-heat") from the testing protocol has the largest effect on the measured total P concentration, while omitting the persulfate reagent ("-$S_2O_8^{2-}$") has a smaller effect that is most visible for the macerated fraction. Samples were diluted with distilled water by 10× to 25× to bring them within the range of the total P Hach test kit.

Figure 2 shows that omitting the heating step has the largest effect on the total P results, both for the macerated and supernatant sample fractions. Omitting the $S_2O_8^{2-}$ reagent has a measureable, but smaller, effect. When the protocol is followed fully, the total P measured for Sample A was 45.8 mg L^{-1} PO_4^{3-} for the macerated fraction and 42.2 mg L^{-1} PO_4^{3-} for the supernatant fraction. These values drop to 35.4 and 35.6 mg L^{-1} PO_4^{3-}, respectively, when the heating step is omitted. This results in an under-reporting of total P by 23% for the macerated fraction and 16% for the supernatant. For Sample B, omitting the heating step results in under-reporting of total P by 35% for the macerated fraction and 21% for the supernatant. Omitting only the $S_2O_8^{2-}$ reagent under-reported the total P in the supernatant samples by ~5%, which is similar to the test-to-test variability for standard solutions as shown in Figure 1. In contrast, omitting only the $S_2O_8^{2-}$ reagent from the macerated fraction under-reports the total P by 8% for Sample A and 18% for Sample B.

In summary, total P content in raw wastewater samples can be substantially under-reported if any step in the digestion protocol is omitted. The largest differences in total P values were found with heating and/or persulfate omission for the macerated sample fractions. This shows that the risk of P under-reporting increases as the fecal content (and thus the amount of condensed and/or organic P) increases. This is important when testing new treatment technologies, particularly those which involve novel solid/liquid separation processes, solids-settling techniques, or other methods of solids treatment where solid fecal matter is broken down and mixed with liquid effluent.

Impact of the pitfalls

While the major contribution of water soluble P in human excreta is inorganic orthophosphate, orthophosphate may not always be the sole contributor to total P in effluent from onsite wastewater treatment technologies. Raw influent of onsite wastewater treatment technologies is highly variable and impacted by many factors such as number of toilet uses, flush volume, and diet.[34,35] We suspect that concentrations of condensed and/or organic P may be significant in influent and in effluent from some technologies with novel solid/liquid separation or solids processing methods.

Our group has previously evaluated one such novel system. We reported in a previous publication total P values of system effluent of 8.3 and 21.5 "mg P L^{-1}"[5] that we now suspect were measured omitting the heating step; thereby, those values represent only the orthophosphate as opposed to the total P. In a different publication,[13] we reported values of "P," without specifying the form (which was orthophosphate) nor clarifying the reporting units (mg L^{-1} P). In another recent paper,[14] we did specify

in the methods section that both reactive P and total P were reported in units of "mg L^{-1} PO_4^{3-}." However, table columns and figure axes in that work were labelled only as "mg L^{-1}" for both reactive P and total P. For added clarity in the future, we will explicitly include the full unit "mg L^{-1} PO_4^{3-}" or "mg L^{-1} P" in all tables and figure axes, as demonstrated in the present work.

From our experiences described here, particularly those during collaboration with a third-party laboratory, we now fully appreciate how critical it is for groups working on wastewater treatment technologies to report the correct P form in clear, specific units. Our concern that inconsistencies in P reporting are widespread is further supported by a recent systematic review of the literature on nutrient removal and recovery technologies by Kogler et al.[30] In sorting reports for P removal efficiencies and effluent concentrations, three separate categories were required for reports of "TP = total phosphorus" and "PO_4 = phosphate," and "P = general phosphorus species if species was not identified clearly."[30] This review shows that there is a prevalent need to standardize quantitative performance metrics of nutrient removal and reuse technologies.

The ambiguity in reporting units introduces lingering questions of whether variable P concentrations in wastewaters across different studies is due to variability in the wastewater itself or variability in reporting and analysis methods. For example, Cid et al.[2] reported 0.64 mmol L^{-1} "PO_4^{3-} + HPO_4^{2-}" in average macerated toilet wastewater from one of their self-contained bathroom + wastewater treatment and recycling prototypes. The specific analytical method used in that work is not reported, but assuming based on the units that this represents a measurement of orthophosphate (reactive P), this would be approximately 60.8 mg L^{-1} PO_4^{3-}. This value is similar to what we report here for total P concentrations in macerated toilet wastewater, but also aligns well with our previous report of reactive P in toilet effluent.[14] Another recent study by Reynaert et al.[27] reported 36.2 mg L^{-1} average soluble phosphate "PO_4" concentration in toilet wastewater influent from a urine-diverting toilet with solids separated from the flush water. While the use of the "PO_4" unit is ambiguous, the analytical test used (Spectroquant) appears to give results in units of PO_4-P. This would indicate that the average influent concentration in this study was 36.2 mg L^{-1} PO_4-P or 111 mg L^{-1} PO_4^{3-}, and the nominal average concentration in the treated clean water tank is 25.4 mg L^{-1} PO_4-P or 77.9 mg L^{-1} PO_4^{3-},[27] which would be unable to meet water reuse or discharge standards with nominal effluent P concentration limits (eg, <1 mg L^{-1} P in India).[36]

Pitfall prevention: Preparation of mixed-P standard solutions for analytical test validation

For pitfall #1, we determined that validating test protocols and reporting units for reactive P, both in-house and with the third-party lab, can be accomplished by testing commercially-available standard solutions of orthophosphate. But what about validating methods when samples contain condensed and/or organic forms of P? Researchers should clarify the analytical methods used by explicitly stating whether samples were digested prior to analysis. For example, Chapter 4500-P in the 22nd edition of Standard Methods for the Examination of Water and Wastewater contains ten subsections detailing sample filtration pretreatments, three digestion methods, and three colorimetric methods.[32] Therefore, simply referencing "standard method 4500-P" is insufficient for determining the fraction or form of P that has been analyzed. For samples containing condensed and/or organic P, definitive confirmation that digestion has been performed requires an analytical validation step testing a standard solution of known composition. However, the wastewater standard solutions readily available for purchase only contain orthophosphate. Testing these standard solutions will not clarify whether sample digestion is performed as required to convert all P forms to orthophosphate.

We therefore set out to prepare our own in-house, mixed standard solution for validating total P testing protocols. In addition to KH_2PO_4 to provide orthophosphate, we identified two non-hazardous compounds which are readily-available and relatively inexpensive to represent condensed and organic P forms: trisodium trimetaphosphate ($Na_3P_3O_9$) and adenosine 5'-triphosphate, disodium salt (ATP). Figure 3 shows the structures of these compounds and relevant properties, such as number of PO_4^{3-} equivalents (i.e., number of PO_4^{3-} anions detected in total P test per molecule of the compound). While KH_2PO_4 will be detected in a reactive P test, $Na_3P_3O_9$ and ATP will only be detected in a total P test, as digestion is required to hydrolyze P-O and O-C bonds to release free orthophosphate into the solution.

Open in a separate window

Figure 3.

Chemical compounds used in this study to make in-house mixed-P standard solutions. KH_2PO_4 dissociates readily to give phosphate anions that are detected in reactive P tests. $Na_3P_3O_9$ and ATP each contribute 3 phosphate equivalents, but these molecules must undergo acid digestion to release phosphate anions. $Na_3P_3O_9$ and ATP are thus detected in total P tests but are not detected in reactive P tests.

Solutions were first prepared containing only KH_2PO_4, $Na_3P_3O_9$, or ATP and analyzed using total P and reactive P Hach kits (see Supplemental Material for a complete table of all solution recipes). Figure 4 shows these results by comparing samples that contain no reactive P (top; ATP only and $Na_3P_2O_9$ only) to samples with only reactive P (bottom; P 25, P 10, WW 10). For samples with no reactive P ($Na_3P_3O_9$ and ATP), the total P results match the expected values only when the heating step was included in the protocol. When heating was omitted from the protocol, both samples showed <1.5 mg L^{-1} PO_4^{3-} for the total P measurement. As expected, the reactive P test for both $Na_3P_3O_9$ and ATP measured almost zero ($Na_3P_3O_9$ = 0.34 mg L^{-1} PO_4^{3-}; ATP = 0.08 mg L^{-1} PO_4^{3-}). Standard solutions purchased (WW 10) and prepared in-house (P 25, P 10) which only contained reactive P showed no difference in the values for the total P test when steps were omitted from the protocol. As expected, the results of the reactive P test and total P test are identical for samples containing only reactive P.

Figure 4.

Demonstration of the different results obtained from total P and reactive P tests for identical samples, including tests where steps were systematically omitted from the total P protocol. Expected values are shown as horizontal reference lines (dashed lines = ATP). As expected, samples containing condensed and organic P (top, triangles) show no response to the reactive P test (shaded column). Samples containing ATP (closed symbols) and $Na_3P_3O_9$ (open symbols) are accurately measured only when the total P test has been performed according to the protocol. Eliminating the heating step ("-heat" and "-heat, -$S_2O_8^{2-}$") results in a complete failure of the total P test. Eliminating only the persulfate pouch ("-$S_2O_8^{-2}$") shows only a small effect on the total P result for ATP. In contrast, samples that only contain reactive P (bottom, circles; WW 10, shaded symbols; P 25, open symbols; P 10, closed symbols) show nearly identical results for total P and reactive P (shaded column), and omitting steps from the total P protocol imparts no effect.

We also prepared two standard solutions with mixed-P forms that could be used to validate results from reactive P or total P tests using the same solution. Figure 5 shows total P and reactive P results for a 2-part standard solution (containing KH_2PO_4 and $Na_2P_3O_9$) and a 3-part standard solution (containing KH_2PO_4, $Na_3P_3O_9$, and ATP). Both the 2-part and 3-part standard solutions give measured total P concentrations close to their expected values. When the heating step is omitted, the total P results are nearly identical to the reactive P results.

Figure 5.

Comparison of total P and reactive P (shaded column) results for two mixed standard solutions prepared in-house. The 2-part mixed standard solution (open symbols) is a mixture of KH_2PO_4 and $Na_3P_3O_9$. The 3-part mixed standard solution (closed symbols) contains KH_2PO_4, $Na_3P_3O_9$, and ATP. Expected values are shown as horizontal lines (solid lines for 2-part standard solution; dashed lines for 3-part standard solution). Measured results for both mixed standard solutions were close to the expected values. When the heating step is omitted from the total P protocol, the measured value is the same as that for the reactive P test.

The results in Figure 5 show that a 2-part standard solution of KH_2PO_4 and $Na_3P_3O_9$ is sufficient to conclude whether the digestion heating step proceeds as necessary. These chemicals are affordable and do not require any special handling or storage considerations, so a solution of these two compounds could serve as a simple, yet robust mixed-P standard solution. The ATP salt has some disadvantages compared to $Na_3P_3O_9$; it is more expensive, requires storage under refrigeration, and can have a variable water content bottle-to-bottle, making the calculation of the expected concentration slightly more complicated (see Supplemental Material).

However, there are two advantages for why some researchers may choose to include ATP in their in-house standard-solution formulation. First, as persulfate is expected to affect hydrolysis of organic P (ATP) but is not necessary for hydrolysis of condensed P ($Na_3P_3O_9$), we hypothesized that including

ATP in the mixture could validate that the persulfate reagent is included in the total P protocol. When the $S_2O_8^{2-}$ is omitted from the solution of only $Na_3P_3O_9$ or from the WW 10 standard solution (see Figure 4), the total P result does not decrease. In fact, there is a slight increase in the measured total P values (55.6 to 56.6 mg L^{-1} PO_4^{3-} for $Na_3P_3O_9$ from 9.8 to 10.0 mg L^{-1} PO_4^{3-} for WW 10), although this change is well within the test-to-test variability demonstrated in Figure 1. On the other hand, when $S_2O_8^{2-}$ is omitted from the solution of only ATP, the total P value measured decreases from 46.4 to 43.8 mg L^{-1}. Similarly, for the 3-part mixture, omitting $S_2O_8^{2-}$ gives a small decrease in total P from 50.4 to 49.4 mg L^{-1}, however, this is on the border of the test-to-test variability of 1.0 to 1.5 mg L^{-1} shown in Figure 1. If validating inclusion of persulfate is desired, increasing the ratio of ATP in the 3-part mixed standard solution may be prudent. Alternatively, a 2-part standard solution containing only KH_2PO_4 and ATP would also be suitable. The second advantage of including ATP is that it also contains N atoms (5 N equivalents per ATP molecule) and can therefore be used to validate total nitrogen digestion protocols as well. Using the Hach low range total N kit (method 10071), we measured total N concentrations of 8.9 mg L^{-1} N in the ATP only solution and 2.0 mg L^{-1} N in the 3-part standard solution, both of which are in close agreement with the expected values of 11.4 and 2.3 mg L^{-1} N, respectively.

Finally, we evaluated the stability of the in-house mixed-P standard solutions over time, with and without refrigeration of the solutions. If either the $Na_3P_3O_9$ or ATP is susceptible to degradation over time (e.g., slow hydrolysis), then the reactive P concentration of the standard solutions should increase as the samples age. Figure 6 shows reactive P values measured for $Na_3P_3O_9$, ATP, 2-part, and 3-part mixtures after ageing for several days in sealed glass bottles. Only the 3-part mixture was stored under refrigeration; the other solutions were left in the laboratory ambient (21 °C). Small increases in the reactive P concentration were observed for all three solutions stored at room temperature (0.91, 1.98, and 1.40 mg L^{-1} PO_4^{3-} for ATP, $Na_3P_3O_9$, and the 2-part mixture, respectively) for 6 to 11 days. The 3-part mixture stored for 13 days at 4 °C increased by only 0.2 mg L^{-1} PO_4^{3-}. All of these values are within the test-to-test variability of 1.0 to 1.5 mg L^{-1} PO_4^{3-}, except for the $Na_3P_3O_9$ solution, which is only slightly higher.

Figure 6.

Comparison of reactive P results for freshly prepared samples (open symbols) and the same samples after ageing for several days (closed symbols) under laboratory conditions. Samples containing ATP and/or $Na_3P_3O_9$ show very small increases in reactive P when stored at 20 °C for 6 to 11 days. The 3-part standard solution showed no increase in reactive P after 13 days when stored at 4 °C.

In summary, solutions prepared in-house with $Na_3P_3O_9$ and/or ATP are sufficiently stable for several days without refrigeration to serve as standards for validation of total P protocols. These compounds show minimal degradation once dissolved in water and stored at room temperature. The mixed standard solutions can be used in-house or sent to third-party laboratories to confirm that the total P sample digestion protocol is followed correctly.

Conclusions

Accurate and clear reporting of P in effluent from novel wastewater treatment technologies is critical for preventing eutrophication of receiving water bodies and in protecting human health. New research into methods to mitigate nutrient discharge in effluent from non-sewered sanitation systems and the adoption of nutrient discharge standards has many research groups stepping into new territory with phosphorus measurements. We have shown that commercially-available kits are accurate tools for evaluating reactive P and total P concentrations in standard solutions, and results were consistent across the two testing methods used in-house and at third-party lab once the correct unit conversion was applied. We also described options for making a standard solution containing condensed and/or organic P compounds that can be used to validate the digestion step in total P assays. We hope that the mixed-P standard solution recipes will be useful for other research groups, as commercially-available wastewater standard solutions only contain orthophosphate.

The work described here leads us to give recommendations for best practices going forward:

1) Regularly include P standard solutions of known concentration in P analyses. We advise that both an orthophosphate and organic phosphate standard solution (or a mixture) be used to validate which P assay is being used, determine the presence of a digestion step, and confirm the reported units.

2) Clearly state the fraction of phosphorus measured—reactive P, acid-hydrolyzable P, or total P—when reporting phosphorus results. Neither the units for reporting P nor a reference to "standard method 4500-P" are sufficient to convey this important information.

3) Discontinue use of the unit "PO_4-P" in reporting results, and instead only use either PO_4^{3-} or P. We think this may be the root of much confusion in the field, as (1) "PO_4-P" and "P" units are interchangeable and therefore redundant, (2) "PO_4-P" and "PO_4^{3-}" are *not* interchangeable, yet look quite similar, and (3) "PO_4-P" is not a chemically meaningful notation (see Supplemental Material for further discussion).

We hope that these recommendations will be useful and widely adopted by groups (including ours) who are adding or continuing with total P analysis as part of their routine testing.

Abstract

Preoperative prediction of morbidity in colorectal cancer (CRC) surgery helps to optimize the surgical outcome. In this study, we aim to develop a dedicated equation for predicting operative morbidity using colorectal possum scoring system and also to validate the predictive accuracy of CR-POSSUM scoring system in prognosticating actual complications. We did a retrospective analysis of 322 patients undergoing colorectal cancer surgery from a single centre in South India from 2004 to 2016. Mortality and morbidity risk factors as defined by CR POSSUM were collected from 322 patients who underwent CRC surgery and were used to derive equations to predict morbidity, and the results were compared with the observed morbidity. Logistic regression analysis was used to derive the equation. The model fit and model discrimination were analysed using the Hosmer-Lemeshow statistical test for goodness of fit, the Nagelkerke R^2 and area under the receiver operating characteristic (ROC) curve respectively. Out of 322 patients, 103 (32%) patients developed complications and 10 (3%) died due to complications. The regression equation we derived has an overall correct classification of about 70% ($P < 0.01$) with positive and negative predictive value of 60% and 73% respectively. The Hosmer-Lemeshow goodness of fit was 3.147 ($P = 0.829$), and the Nagelkerke R^2 was 17% and area under ROC as model discrimination was 71.6%. Hence, CR-POSSUM scoring which was originally used for predicting mortality risk can also be extrapolated to predict morbidity.

Keywords Colorectal POSSUM · POSSUM · Colorectal surgery · SSI · Morbidity and mortality · Prediction model

Introduction

Colorectal malignancy is the third most common malignancy among men and the second most common among women around the world [1]. Fortunately, in India, the incidence is not too high. However, the incidence has been found to be rising, with the AAR (adjusted annual incidence rate) for colon cancer in men and women being 4.4 and 3.9 per 100,000, respectively [2]. Being in a country, where people living with poor access to quality healthcare, extreme presentation like advanced stage and perforation are common in tertiary care centres [3, 4]. In such scenarios, the mortality and morbidity for the patients undergoing surgery are relatively high [5]. Complications following major surgeries will proportionately increase the hospital cost and duration of hospital stay [6]. Apart from such hardships, complications also had an adverse impact on long-term survival [7]. So in a country like India, where the spending on health by the government is low and health insurance is under-penetrated, morbidity following a major surgical procedure will further drain the already constrained resources [8]. The complication rates are not uniform and cannot be generalised, as there are certain factors, such as age, patients' co-morbidity and operative severity, influencing the outcome of surgery [9]. So, putting together these factors and assessing the postoperative outcome preoperatively will help in optimizing the available resources. In such cases, the predictive scoring has to be more accurate, and its predictive ability should

Key message: CR-Possum can be used to predict morbidity in patient undergoing colorectal cancer surgery.

be proven in multiple centres. In our study, we devised a morbidity scoring system with already established parameters in CR-Possum which influence the outcome of colorectal surgery in terms of mortality and assessed the model calibration and discrimination with statistical analysis tools.

Patient and Methods

Data of 506 patients undergoing colorectal surgery for colorectal malignancy from January 2004 to December 2017 was collected from the medical records department of a single tertiary care centre. The in-patient files were analysed and the required variables as per CR-POSSUM scoring [physiologic severity score (PSS) (age, cardiac failure if any, systolic blood pressure, pulse, urea, haemoglobin) and operative severity score (OSS) (operative severity, peritoneal soiling, operative urgency, cancer staging in Dukes)] were collected and entered in an excel data sheet. Patient files, with single missing variable, were excluded from the study. Therefore, only 322 patients with complete details were included. The dichotomous outcome of each patient, either dead/alive, with/without complication, was entered. Presence or absence of complications, such as haemorrhage, wound infection, wound dehiscence, anastomotic leak, deep vein thrombosis, pulmonary embolus, cerebrovascular accident, myocardial infarction, cardiac failure, impaired renal function and respiratory failure were also entered. Complications were also graded based on Clavien-Dindo scale of surgical morbidity, and all grades were considered. Duration of hospital stay in terms of number of days for each patient was also recorded. The study was approved by institutional ethics committee.

Statistical Analysis

The data was analysed using SPSS version 24. Mean and standard deviation were calculated for continuous variables. Chi-square test was done to check association between categorical variables. The equation to predict morbidity was derived using multiple logistic regression analysis, and the model discrimination was measured by calculating the area under ROC (receiver operating characteristic) curve. The Nagelkerke R^2 and the Hosmer-Lemeshow statistics were used for model calibration (goodness of fit). Positive and negative predictive values were also calculated. $P < 0.05$ was considered as statistically significant.

Results

Out of a total of 506 patients undergoing colorectal surgery for malignancy, 322 (63.2%) satisfied the criteria to be included in the study. Among the 322 patients, 103 (31.9%) developed complications and 10 (3%) patients died of complications. The average duration of hospital stay for all patients who underwent surgery was 15.5 days. The mean duration of in-hospital stay for patients with and without complications was 18 and 14.5 days respectively ($P = 0.01$) which was statistically significant. The proportion of patients with and without complications and in-hospital stay days are shown in Fig. 1. The summary of procedures and their associated complications were shown in Table 1. The complications rates were more in tumours located in sigmoid and rectum compared to other sites ($P < 0.05$). The complications were graded as per Clavin-Dindo classification. Wound-related complication tops the list (37%) followed by respiratory complications (18%). These are shown in Table 2. The patient's demographic characteristics and the in-hospital morbidity rates for the factors taken into consideration for CR-POSSUM scoring are shown in Table 3. Majority of the patients are in the age group less than 60 years (51%) and there is a male preponderance (61%). Table 4 summarizes the CR-POSSUM scoring system which we used for the analysis. The equation we derived using above data was $In\ (R/(1-R)) = -4.83 + 0.09(PSS) + 0.35(OSS)$($P < 0.001$). The positive and negative predictive value of the equation was 60.87% and 73.09% respectively. The overall percentage of correct classification was 70%. The goodness of fit was looked at to check whether the predicted probability was assigned accordingly to individual patient's outcome. The Hosmer-Lemeshow test statistics was 3.147 ($P = 0.829$) which was reasonably a good fit for higher the P value, more fit the model is. The Nagelkerke R^2 which was another test to check goodness of fit was fairly good (17%). Model discrimination calculated by area under ROC curve was 71.6% (Fig. 2), which was reasonably a fair discrimination. The observed and expected ratio was almost close to 1 among the different range of predictions.

Discussion

POSSUM AND P-POSSUM were original scoring systems which enumerated the mortality and morbidity in a patient undergoing major surgeries [10, 11]. These have been validated in numerous studies outside the UK, and their value in surgical audit has been proven beyond doubt [12–14]. A study conducted by the American College of Surgeons (ACS-NSQIP) in 2005 to 2006 showed that ten procedure groups among various general surgical operations accounted for 62% of complications, and colectomy was topping in the list [15]. It accounts for 24% of adverse events. CR-POSSUM, developed by Tekkis et al., a modification in the original scoring system, was designed for enumeration of mortality in patients undergoing colorectal procedures [16]. Since the mortality following colorectal surgery was brought down with

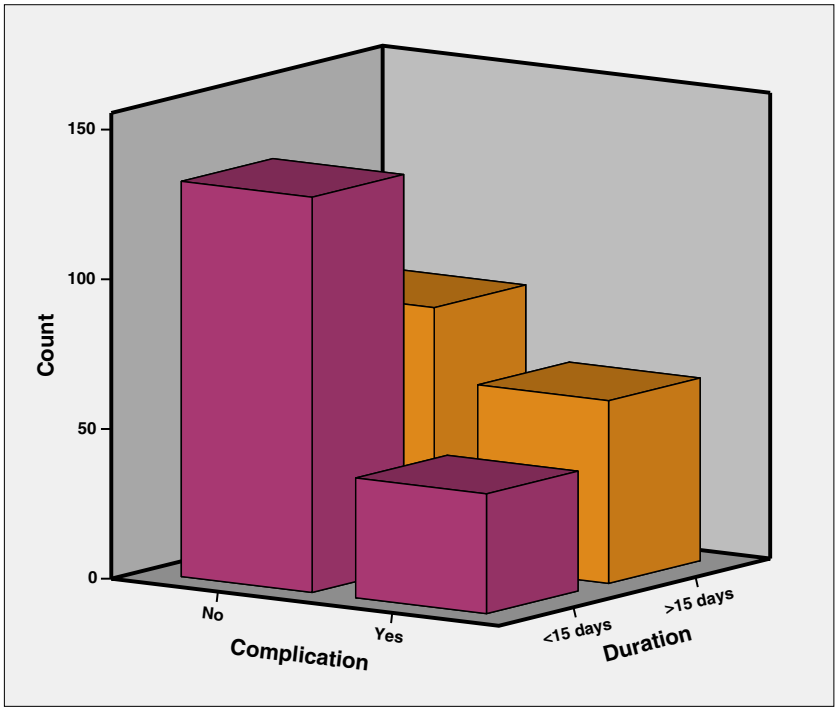

Fig. 1 Duration of hospital stay in patients with and without complications

improvement in postoperative critical care but the morbidity following such procedures especially in patients undergoing emergency surgery for perforation and obstruction was considerably high [17]. Complication rates in surgery for colorectal malignancy elective and emergency were 26 and 38% respectively. In our study, the overall complication rate was 31.9%. The original CR-POSSUM was devised by identifying odds of risk factor causing mortality. However, it was a well-known fact that mortality was the end point of severe morbidity [18, 19]. Therefore, we used the same scoring system to analyse the outcome in terms of complications in our study. The equation, though, using the same odds as for mortality did not overpredict morbidity in our study. But in the physiological severity scoring, except for preoperative cardiac status and urea level, other variables have no significant correlation

Table 1 Tumour location and procedures with in-hospital complication rates

Location of the tumour	Patients	Morbidity (%)	X^2 (P value)
Rectum	99	33(32)	14.40 ($P = 0.04$)
Sigmoid colon	77	31(30.1)	
Ascending colon	43	9(8.7)	
Transverse colon	39	9(8.7)	
Caecum	24	6(5.8)	
Descending colon	17	3(2.9)	
Rectosigmoid junction	11	7(6.8)	
Others	12	4(3.8)	
Type of procedure	Patients	Morbidity (%)	
Right hemicolectomy	99	25(24.2)	11.34 ($P = 0.18$)
Anterior resection	74	18(17.4)	
APR	46	19(18.4)	
Left hemicolectomy	34	9(8.7)	
Sigmoidectomy	31	14(13.5)	
Diversion colostomy	24	9(8.7)	
Total colectomy	5	3(2.9)	
Subtotal colectomy	2	1(0.9)	
Others	9	3(2.9)	

Table 2 Severity of complications graded as per Clavien-Dindo classification

Grade of complication	Type of complication	No. of patients (%) ($n = 103$)
I	Wound infection requiring drainage	16(15.5)
	Post op ventilation for > 1 day	6(5.8)
II	Wound infection needs resuturing	22(21.3)
	Respiratory infection	17(16.5)
	PTE/DVT	4(3.8)
III	Re-exploration due anastamotic leak	15(14.5)
	Burst abdomen/resuturing	3(2.9)

	Seizure	2(1.9)
	Sepsis and hypotension	1(0.9)
V	Severe sepsis	7(6.7)
	ARDS	2(1.9)
	Multivisceral metastasis	1(0.9)

Table 3 Patient demographic and in-hospital complication rates

Variables in consideration	No. of patients $n = 322$	No. of complication (n = 103)
Age		
< 60	165 (51.2%)	50 (48.5%)
61–70	104 (32.3%)	36 (35.0%)
71–80	38 (11.8%)	11 (10.7%)
> 80	15 (4.7%)	5 (4.9%)
Sex		
Male	197 (61.2%)	65 (63.1%)
Female	125 (38.8%)	37 (35.9%)
PSS		
6 to 10	273 (84.8%)	81 (78.6%)
11 to 15	49 (15.2%)	22 (21.4%)
Operative severity scoring		
Intermediate	27 (8.4%)	8 (7.8%)
Major	228 (70.8%)	61 (59.2%)
Complex major	67 (20.8%)	34 (33.0%)
Peritoneal soiling		
None	275 (85.4%)	80 (77.7%)
Local pus	6 (1.9%)	3 (2.9%)
Faceal contamination	41 (12.7%)	20 (19.4%)
Operative urgency		
Elective	280 (87%)	81 (78.6%)
Urgent	34 (10.6%)	18 (17.5%)
Emergency	8 (2.5%)	4 (3.9%)
Cancer staging		
Dukes A, B	162 (50.3%)	43 (41.7%)
Dukes C	120 (37.3%)	42 (40.8%)
Dukes D	40 (12.4%)	18 (17.5%)

with outcome. Since wound infection and its sequelae occupy a considerable share (37%) of complications in our study, the role of physiological factors influencing the result may be less significant compared to operative severity score where later affects the outcome in terms of surgical site soft tissue infection [20]. Next common complications were respiratory (16.5%) and anastamotic leak (14.5%). Regarding mortality, CR-POSSUM observed and expected mortality ratio was 1

Table 4 Colorectal POSSUM scoring system

Score	1	2	3	4	8
Physiologic score					
Age (yr)	≤ 60		61–70	71–80	≥ 81
Cardiac failure	None or mild	Moderate	Severe		
Pulse (beats/min)	40–100	101–120	> 120 or < 40		
Systolic BP (mmHg)	100–170	> 170 or 90–99	< 90		
Urea (mmol/l)	≤ 10	10.1–15	> 15		
Haemoglobin (g/dl)	13–16	10–12.9 or 16.1–18	< 10 or > 18		
Operative severity score					
Operative severity	Minor		Intermediate	Major	Complex major
Peritoneal soiling	None or serous	Local pus	Free pus/feces		
Operative urgency	Elective		Urgent		Emergency
Cancer staging (dukes)	None or dukes A, B	Dukes C	Dukes D		

and area under ROC curve was 80% showing good model discrimination. But with low mortality rate [$n = 10$ (9.7%)] in our study, the validity of it may not be reliable.

Among the various risk factors, age and cancer staging are considered non-modifiable risk factors. The rest are modifiable risk factors and give the extent of scope to which the complications can be prevented by addressing such factors. But once patients present to tertiary centres in emergency or semi-emergency conditions, most of the risk factors will be present. Tackling such elements will be time-consuming and lead to a further chance of increasing complication [21]. Surgical site-related complications top in our study (37%) and elsewhere, as well [22]. They have an adverse impact in terms of long-term survival [23]. Since operative factors play a significant role in outcome in terms of wound infection as per our study, measures that reduce the chance of acquiring surgical site infections with high level of evidence are appropriate and timely administration of antibiotic, discontinuation of prophylactic antibiotic within 24 h of surgery, optimization of blood glucose levels and avoiding spillage of bowel contents [21]. Similar to SSIs, respiratory complication and anastomotic leak leading to deep-seated infection also affect the long-term survival [24]. PSS and OSS both play a significant role in predicting the latter two complications here. Hence tackling both physiological and operative variable assumes an important role prevention of these two problems.

CR-POSSUM, which was originally developed to predict mortality, can also be used to predict morbidity. But, there are some limitations to our study. Both CR-POSSUM and POSSUM models for mortality and POSSUM model for predicting morbidity left many variables like preoperative nutrition level, operative duration, BMI and length of preoperative stay, all of which influence the eventual outcome. These were not considered while developing the equation [21]. But these scoring systems were developed 10 and 25 years ago respectively, and many new influencing variables were found in subsequent research.

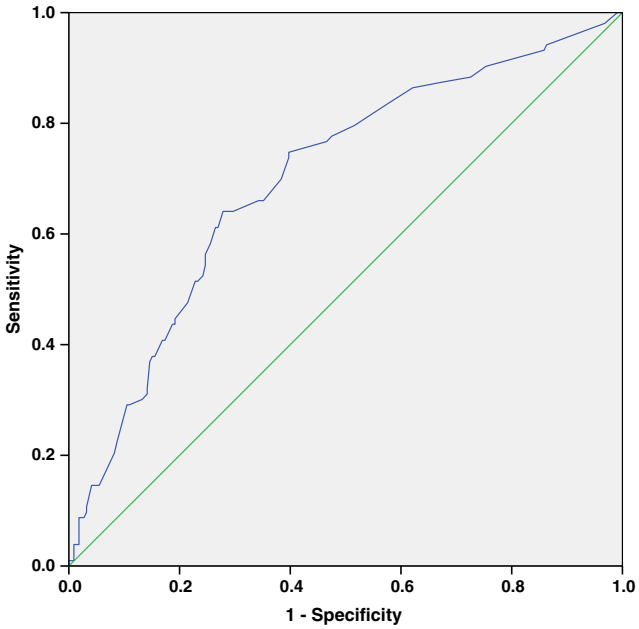

Fig. 2 Receiver operator characteristic curve (ROC) for the derived equation (Area under the curve is 71.6%)

Our results may be biased since there is a high proportion of SSI-related complication. We, therefore, validated the equation after excluding this group of patients. We excluded surgical site infection (SSI) in further analysis, to check whether physiological factors had a role in predicting non-SSI-related complications. We found that there was, indeed, a significant association ($P = 0.005$) between PSS and other non-SSI complications. The results were similar with few minor variations in predictive values. So, if a new model is developed considering the various new variables, then the predictive accuracy of such an equation can be close to reality.

To conclude, these predictive models once validated, across various centres in India, can be used as a measure of quality control in different institutions. Secondly, they can also be used to allocate resources and adequately trained professionals to deal with those patients whose expected morbidity and mortality are high.

Acknowledgements We thank our institute, its medical records and IT department for providing immense support in collecting data of the patients. We also offer special thanks to Prof. Dr. Karthikeyan of respiratory medicine department for his valuable input in design of the study. We thank Prof. Malmarugan Devanathan for his guidance in statistical analysis and make us to understand the statistical results.

ABSTRACT

Background: Inadequate breastfeeding results in hypernatremia in otherwise healthy neonates. **Objective:** This study finds out the predisposing factors and clinical outcome of hypernatremia in breastfed late preterm and term neonates. **Materials and Methods:** A descriptive study was conducted in a tertiary hospital with retrospective data from July 2013 to June 2016. Babies with serum sodium ≥ 150 mEq/L were identified. Breastfed babies with little or no formula feeds, gestational age ≥ 34 weeks, and birth weight ≥ 2000 g were included. Babies with congenital anomalies, sepsis, prior parenteral fluid therapy and renal or endocrine diseases causing fluid and electrolyte disturbances were excluded. Total weight loss > 10% or daily weight loss > 5% from the birth weight were considered as excess weight loss. **Results:** A total of 201 babies were studied. Hypernatremia was significantly more common in babies of primiparous mothers ($p < 0.01$). There was no difference in incidence between vaginal born and cesarean-born babies. Positive correlation was seen between age at presentation, percentage of weight loss ($p = 0.001$) and serum sodium ($p = 0.01$). Significantly more cases were seen in summer season ($p < 0.01$). Excess weight loss, jaundice, fever, and dehydration were the common symptoms. Complications observed were acute kidney injury, seizures, intracranial bleed, apnea, and bradycardia. Babies with complications mostly presented after 7 days of age, had > 25% weight loss and had serum sodium ≥ 170 mEq/L. There was no death. Three babies had neurodevelopmental problems on follow-up. **Conclusion:** Breastfed babies of primiparous mothers and born in summer are predisposed to hypernatremia. Babies presenting at a later age had severe weight loss, severe hypernatremia, and complications.

Key words: *Breastfeeding, Hypernatremia, Primiparity, Summer season, Weight loss*

Exclusive breastfeeding for the first 6 months of life is recommended by the World Health Organization to optimize the growth and development of the infants [1]. Breast milk in addition to nutrients provides various immunological factors that help to reduce the diarrheal and respiratory illness in children [2]. Breastfeeding is an instinct behavior and many mother-baby dyads accomplish it successfully [3]. However, some babies may not receive enough milk from their mothers due to various reasons. If breastfeeding is inadequate, then malnutrition and hypernatremic dehydration can occur in the baby [4]. Moritz *et al*. have termed this condition as "breastfeeding associated hypernatremia" (BFAH) [5].

An increase in the incidence of BFAH in otherwise healthy neonates has been observed in the past few years [5-8]. The clinical features and complications seen in these babies have been reported in various studies [9]. It has been found that daily weighing of the babies helps in the early recognition of this illness [10,11]. Thus, the discrepancy in clinical features and complications reported in various studies were probably related to weight monitoring practices and timing of presentation of the cases [10,11]. This study was planned to find out the predisposing factors and outcome of hypernatremia in breastfed late preterm and term neonates in a hospital with regular weight monitoring practice.

MATERIALS AND METHODS

This descriptive study was done using retrospective data from July 2013 to June 2016. The study was conducted in an urban tertiary care medical college hospital with an average delivery rate of 2500 per year. Exclusive breastfeeding was promoted for all babies in the hospital. The mother-baby dyads were discharged at around 72 h after normal delivery and 120 h after cesarean delivery. As per hospital protocol, all babies were weighed daily. Excess weight loss was defined as total weight loss more than 10% from birth weight or weight loss per day more than 5% of birth weight [12]. Serum sodium level was checked for babies with excess weight loss. Hypernatremia was defined as serum sodium more than or equal to 150 mEq/L. Babies with hypernatremia were treated with liberal oral feeds, intravenous (IV) fluids, and other supportive therapies. Serum sodium <150 mEq/L was considered an end point of treatment.

The Institutional Ethics Committee approved the study. Babies admitted during the study period with hypernatremia were identified from the hospital database. Their case records were scrutinized and babies who fulfilled the following criteria were included in the study: (1) Breastfed babies with little or no formula supplementation, (2) gestational age more than or equal to 34 weeks, and (3) birth weight more than or equal to 2000 g. The babies who had major congenital anomalies, blood culture positive sepsis, received IV fluids within 48 h before diagnosis of hypernatremia and renal or endocrine disorders which may affect the fluid and electrolyte balance were excluded from the study. The following data were collected: Gestational age as completed weeks, age at diagnosis as completed days, birth weight, weight at diagnosis, maternal age, obstetric details, details about baby feeding, clinical features, treatment, complications, condition at discharge, and neurodevelopment at follow-up.

The total weight loss and weight loss per day were calculated as a percentage of the birth weight. Axillary temperature more than 38°C was considered as fever. The rate of decline in serum sodium was calculated using the sodium before and after treatment and the time taken to achieve it. Acute kidney injury (AKI) was diagnosed if serum creatinine increased by >0.3 mg/dl in 24 h or if it was >1.5 mg/dl with normal maternal renal functions [13]. Jaundice treated with phototherapy was considered as significant. At the time of discharge, babies were said to have improved if their serum sodium level was <150 mEq/L and was taking feeds well. At follow-up, their neurodevelopment was said to be normal if gross motor, fine motor, language, and social milestones were appropriate for age and had no other neurological problem.

SPSS software version 24 was used for analysis. Numerical data were presented as mean±standard deviation or median±interquartile range as appropriate. Categorical data were presented as percentages and analyzed using Chi-square test. Ordinal data were analyzed with Mann–Whitney U-test or Student's t-test. Correlation was done with Spearman rank correlation coefficient where appropriate. $p<0.05$ was considered as significant.

RESULTS

There were 213 babies with hypernatremia satisfying the inclusion criteria during the study period. 12 babies were excluded due to various reasons. The remaining 201 babies were considered for analysis (Fig. 1). During the study period, there were 7613 live births, with 4570 vaginal births, and 3043 cesarean births. There were 4463 primiparous and 3150 multiparous mothers. Hypernatremia was seen in 2.4% of vaginally born babies and 3.1% of cesarean-born babies. This difference was not statistically significant. 3.1% babies of primiparous mothers and 1.6% babies of multiparous mothers had hypernatremia, and this different was statistically significant (Chi-square 16.7, $P<0.01$). All babies were born of singleton pregnancy. Most of the (80%) mothers had no problem in breastfeeding their babies (Table 1).

Serum sodium had a negative correlation with mother's age ($r=-0.23$, $p=0.01$) and baby's gestational age ($r=-0.2$, $p=0.004$). No correlation was seen between serum sodium level and birth weight. A positive correlation was seen between age at presentation and total weight loss ($r=0.65$, $P=0.001$). Serum sodium at admission had a positive correlation with age at presentation ($r=0.704$, $p=0.01$) and percentage of total weight loss ($r=0.652$, $p=0.001$). More than 50% of the cases were seen during the summer season in this study. This seasonal variation in the incidence of cases was statistically significant (Chi-square-26.9, $p<0.01$) (Table 1).

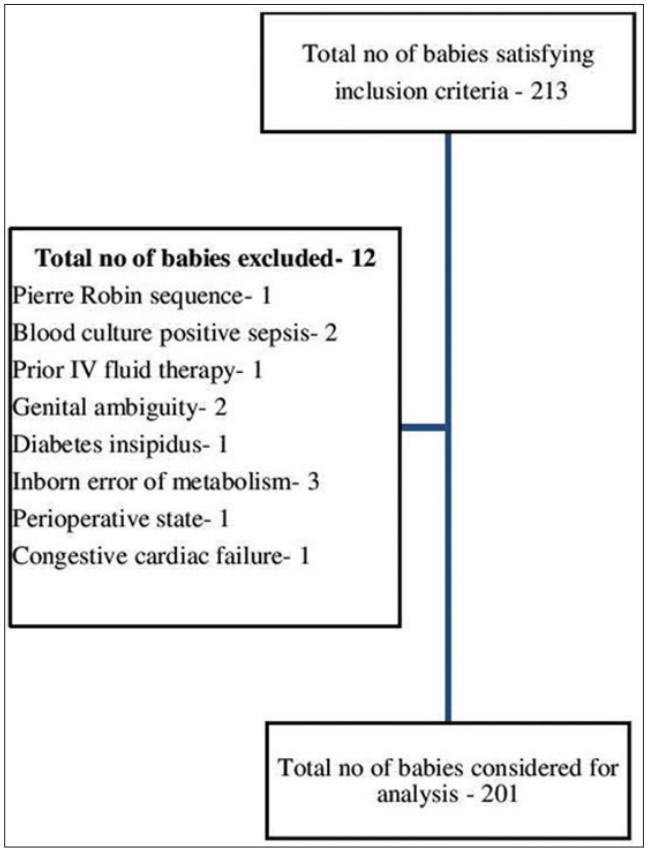

Figure 1: Flow of cases in the study

Significant jaundice was seen in 57.2% babies, but none required exchange transfusion. Phototherapy (median duration 24 h) before the onset of hypernatremia was given to 26 babies. Other common clinical findings observed were fever (33.8%) and dehydration (17.4%). No symptom other than excessive weight loss was seen in 21.4% of babies. Severe hypernatremia with serum sodium ≥170 mEq/L was seen in only five babies, and all other babies (98%) had moderate hypernatremia (serum sodium 150–169 mEq/L). About 89% of babies improved after treatment and got discharged. There was no death in the study population (Table 2). The babies who improved had a median birth weight of 3000 g (2800–3300), median admission weight of 2700 g (2460–2930), and median discharge weight of 2800 g (2540–3070).

Five babies (2.5%) had complications during the course of hypernatremia. One male baby with serum sodium of 151 mEq/L had apnea after vomiting of feeds and developed aspiration pneumonia. He improved with mechanical ventilation and antibiotics. All other four babies presented after 7 days of life

Table 1: Baseline characteristics of hypernatremic babies

Characteristics	Observation
Median maternal age (years) (n=183)*	26.9 (23-29)
Number of babies born to primiparous mothers	138/188 (73.4%)
Number of babies born to cesarean mothers	108 (53.7%)
Number of mothers reported problem in breastfeeding	42 (20.1%)
Male to female ratio	1.34:1
Median gestational age (weeks) (n=189)*	38 (37-39)
Median age at diagnosis (days)*	3 (2–18)
Number of babies presented on 2–3 days age	161 (80.1%)
Median birth weight (g)*	3080 (2810-3410)
Median weight at diagnosis (g)*	2710 (2470-3020)
Median daily weight loss (%)*	3.9 (3.3-4.7)
Median total weight loss from birth (%)*	11.3 (10-12.8)
Number of babies with 10–15% weight loss	139 (69.2%)
Season and number of babies admitted	
a. March to June (Summer)	103 (51.2%)
b. July to October	40 (19.9%)
c. November to February (Winter)	58 (28.9%)
Number of babies on exclusive breastfeeding	177 (88.1%)

*Median (IQR). IQR: Interquartile range

Table 2: Clinical features and outcome of hypernatremic babies

Characteristics	Observations
Median serum sodium at diagnosis (mEq/L)*	153 (151–155)
Serum sodium range and number of babies	
a. 150–159 mEq/L	184 (91.5%)
b. 160–169 mEq/L	12 (6%)
c. ≥170 mEq/L	5 (2.5%)
Mean time to normalize serum sodium	
a. 150–159 mEq/L (n=161)	17.8 h
b. 160–169 mEq/L (n=12)	26.6 h
c. 170–179 mEq/L (n=3)	48.8 h
d. ≥180 mEq/L (n=2)	71.3 h
Outcome	
a. Improved	178 (88.6%)
b. Left against medical advice	23 (11.4%)
Neurodevelopment problem at follow-up	3/154 (1.9%)

*Median (IQR). IQR: Interquartile range

with weight loss more than 25% of birth weight and severe hypernatremia (serum sodium ≥170 mEq/L). Complications observed were AKI (4), seizures (2), apnea (2), intracranial hemorrhage (1), and bradycardia (1). Peritoneal dialysis was done for one baby with AKI. No baby had peripheral or cerebral vessel thrombosis. Neurosonogram done for one baby with seizures showed increased white matter echogenicity. Another baby with seizures had normal neurosonogram. The treatment and outcome details of babies with severe hypernatremia are given in Table 3.

Follow-up details were available in 154 cases (76.6%) for a median duration of 1.5 months (0.5–11 months). Three babies had abnormal neurodevelopment. One female baby with serum sodium 150 mEq/L had a prolonged period of jaundice requiring phototherapy for 9 days. At follow-up, she had a global developmental delay with a seizure disorder. One male baby with serum sodium 150 mEq/L was found to have hyperactivity and aggressive behavior at 3 years. Neuroimaging was not available for these two babies. Another female baby had severe hypernatremia with AKI, seizures and normal neurosonogram in the neonatal period; and on follow-up at 1 year was found to have left hemiparesis and magnetic resonance imaging of the brain showed chronic infarct in right front parietal region and white matter changes in subcortical and deep cerebral white matter.

DISCUSSION

In this study, we have found BFAH to be more common among babies of primiparous mothers. Although breastfeeding is an instinct behavior, mothers have to learn the technique and need social support to successfully breastfeed their babies [3]. Systematic review on BFAH has found cesarean delivery, primiparity and absent previous breastfeeding experience as risk factors for BFAH [9]. However, there was no difference between cesarean babies and vaginally born babies in this study. Similarly, two studies had found no significant difference in mode of delivery among hypernatremic babies compared to control group [5,14].

It is stated that the parents of hypernatremic babies have poor recognition of their baby's illness [7,15]. About 80% of our baby's mothers have not felt any problem with their baby's feeding behavior. Excess weight loss gave a clue to identify these cases early. Thus, majority of our cases were identified at an early age, had less severe weight loss and less severe hypernatremia. Many studies report that babies presenting at a later age have higher weight loss and more severe hypernatremia [16,17]. Hence, daily weighing of babies along with appropriate lactation support during the first 4–5 days of life has been suggested for early detection of BFAH [10,11,18]. The seasonal variation in the incidence of hypernatremia was reported in some studies [12,19-21]. This was attributed to excess insensible water loss due to the hot climate in summer and overuse of room heaters in winter [9,21]. In this study, we have found significantly more number of cases during the summer season. This seasonal variation may be related to hot environmental temperature during summer seen in Tamil Nadu state of India where the study was done.

At admission, jaundice, fever, and dehydration were common symptoms in our study population. Lavagno *et al*. through systematic review have found jaundice, poor feeding, and dehydration each seen in about 45% of all reported cases [9]. Yang *et al*. have showed that percentage of weight loss within first 3 days of life has a positive correlation with jaundice at 72 h after birth in healthy term breastfed babies [22]. The hypernatremia and the resultant hyperosmolar state may damage the blood–brain barrier and facilitates bilirubin entry into nervous tissues at

Table 3: Clinical features and outcome of babies with severe hypernatremia

Gestational age (weeks)	Birth weight (g)	Total weight loss (%)	Day of diagnosis	Maximum Sr. sodium (mEq/L)	Complications	Treatment	Time to correct Sr. sodium (h)	Outcome at follow up
40	2700	25.9	12	182	Seizures, AKI, apnea, bradycardia	½ DNS+oral feeds; peritoneal dialysis; anticonvulsant	57	Normal
40	3630	14.3	4	173	Nil	½ DNS	43	Normal
37	2510	37.5	18	174	AKI, cerebral hemorrhage	NS bolus, ½ DNS	69.75	Normal
36	3060	27.5	8	173	AKI	½ DNS+oral feeds	33.5	Normal
Term	2700	24.1	17	186	AKI, seizures	NS bolus, DNS, ½ DNS; anticonvulsants	85.5	Left hemiparesis

AKI: Acute kidney injury

lower serum bilirubin level [5,23]. This has to be considered in one baby with neurodevelopmental impairment in our study who had hypernatremia and prolonged jaundice. About 20% of our babies had no symptoms at admission except for excess weight loss. Similarly Uras *et al*. and Korgali *et al*. have found that 14% and 2.4% of their hypernatremic babies were asymptomatic at admission, respectively [24,25].

Four out of five babies with severe hypernatremia had neurological and/or renal complications. Similarly, Ahmed *et al*. have found that babies with AKI presented at a later age, had higher weight loss and higher serum sodium [26]. However, less number of babies in this study had complications compared other studies [5,8,9,20,25-27]. This may be due to earlier age at presentation and a lesser degree of hypernatremia seen in the large proportion of babies in our study. There was no death in our study population and on follow-up only three babies had a neurodevelopmental problem. Mortality rate of 1-5% has been reported by various authors [8,26-28]. Koklu *et al*. have reported neurodevelopmental impairment in 47.8% cases [27]. Similarly, a high rate of neurodevelopmental impairment is also reported by Bolat *et al*. and Ergenekon *et al*. [29,30]. This emphasizes the need for formal neurodevelopmental follow-up of hypernatremic babies.

In this study, we have reported the correlation of serum sodium level with various other clinical parameters in babies with BFAH. Our study has the following limitations due to retrospective nature of the study: Some data were incomplete and long-term formal neurodevelopmental assessment was not done. Our study was hospital based, and many babies had a less severe degree of hypernatremia with fewer complications. A larger scale prospective study with neurodevelopmental follow-up is needed to have a clear understanding of the risk factors, complications and long-term effects of BFAH.

CONCLUSION

Breastfed late preterm and term babies born to primiparous mothers and born in summer season have predisposition to develop hypernatremia. These babies commonly presented with excess weight loss, jaundice, fever, and dehydration. Babies presenting beyond 7 days of age and with more than 25% weight loss are likely to have severe hypernatremia. Neurological complications and AKI were common complications observed with severe hypernatremia. These babies are at risk of neurodevelopmental impairment. Prospective study with long-term follow-up is needed.

Abstract

Context: Highest intensity of soil-transmitted helminthiasis (STH) is seen among school age children. **Aims**: The aim of this study is to find out the prevalence and factors associated with soil-transmitted helminthic infection among school age children (5–14 years) in a rural area of Coimbatore district. **Settings and Design:** The study was conducted in the field practice area of the Rural Health Training Centre (RHTC) Vedapatti, Coimbatore. RHTC caters to a total population of 23,841 distributed in 14 villages. After getting ethical clearance, five of the 14 villages of Vedapatti were selected by the cluster sampling method. Totally, 819 participated in the survey conducted between November 2015 and July 2016 in the field practice area. **Subjects and Methods:** Structured questionnaire was used to collect the information. Consent from parents and assent from child were obtained. Totally, 610 gave one adequate stool sample. Early morning samples were collected and transported to the laboratory within four hours. Formal ether concentration method was performed, and examination was done. **Statistical Analysis Used:** Data analysis was performed with the SPSS version 19 software. The prevalence is expressed in percentage with 95% confidence interval (CI). Univariate and multivariate analyses were performed. Strength of association was expressed in terms of odds ratio (OR) and adjusted OR with 95% CI. $P < 0.05$ was considered as statistically significant. **Results:** The prevalence of STH was 7.70% (95% CI: 5.58–9.82). *Ascaris lumbricoides* was highly prevalent 6.9% (4.89%–8.91%) followed by Hook worm 0.7% (0.04%–1.36%), and *Trichuris trichiura* 0.2% (0.15%–0.55%). Mulitivariate logistic regression analysis showed that pucca houses offered protection against STH. **Conclusions:** The prevalence of STH in a rural area of Coimbatore is 7.7% (95% CI: 5.58–9.82), and is continuing as a public health problem.

Full Text

Introduction

The soil-transmitted helminthes causing major illness among human beings include Ascaris lumbricoides, Trichuris trichiura, Necator americanus, and Ancylostoma duodenale.[1] STH are considered neglected tropical diseases.[2] STH affects more than one fourth of the world's population, and it is reported more in tropical and subtropical areas.[3] The greatest number of cases are occurring in sub-Saharan Africa, the Americas, China, and East Asia.[4] In India, the reported prevalence of STH infection can be striked out varied from 7.8% to 92.6%.[5],[6],[7],[8],[9] The reported prevalence varies according to the place and time of the study conducted.

The highest intensity of soil-transmitted helminthes occur in school age children.[10] Children do not fully understand the connections between illness and behavior.[11] It has been demonstrated that children often than adults tend to go barefoot, resulting in more contact with soil, and fail to use sanitary facilities even when they are present.[12] STH infections are considered an important cause of sickness absenteeism. They are accounting for loss of 12.3% and 11.4% of disability adjusted life years in girls and boys, respectively.[13] Over 270 million preschool-age children, and over 600 million school-age children live in areas where sanitation is poor and these parasites are intensively transmitted.[14] In India, more than 241 million children are at the risk of parasitic worm infections. Ministry of Health and Family Welfare, Government of India launched the National Deworming Day (NDD)[15] on Feb 10, 2015. NDD aims to de-worm all children between the ages of 1–19 years. The tablets were supplied to children through government, government-aided and private schools, and Anganwadi centers.

When regular deworming is accompanied by appropriate sanitation and hygiene activities designed to prevent re-infection, a long-term impact can be achieved. Epidemiological studies are needed to identify the risk factors which may represent critical control points. There is no recently published article on the prevalence of soil-transmitted helminthes in Coimbatore, where open-air defecation is a common practice. As per the 2011 census, 46% of the households in Coimbatore district lack toilets. Hence, this cross-sectional study was proposed and conducted with the objective of finding the prevalence and risk factors associated with soil-transmitted helminth infections in school age children (5–14 years) in a rural area of Coimbatore district.

Subjects and Methods

The study was conducted in the field practice area of the Rural Health Training Center (RHTC) Vedapatti, Coimbatore. RHTC caters to a total population of 23,841 distributed in 14 villages.

of Thondamuthur and Madukarai block of Coimbatore district. The total number of school-aged children (aged 5–14 years) is 3266.

Ethical clearance was obtained from Institutional Human Ethics Committee, in 2014. The sample size was calculated to be 819 assuming 34.5% as prevalence, relative precision of 15%, design effect of 2, and nonresponse rate of 20%.[16] Five out of 14 villages were selected by the cluster sampling method. House-to-house survey was conducted in the five villages during November 2015–July 2016. All school-age children (aged 5–14 years) who were permanent residents of Vedapatti field practice area of RHTC were included in the study. Children who were not available on three visits within a week time were excluded from the study.

At the home setting, after getting consent from the parent and assent from the child any one of the parents of the child was interviewed in the evening hours of the day. A structured questionnaire was used to collect the information on demographic, socioeconomic, and environmental information such as availability of type of drinking water and availability of functioning sanitary toilet. Few questions were asked regarding the knowledge and attitude of the parents on STH. Respondent was asked to give comment on the personal hygiene practices of child such as washing hands with soap before taking food and after defecation, eating fallen foods on the floor, wearing foot wear outside the house and intake of de-worming tablets in the past 3 months. Observations were also made regarding the personal hygiene of the children related to STH such as clipped nails. Knowledge and attitude score was generated from the correct responses for the knowledge and attitude questions. The correct responses were given a score of one, and maximum score one could get was nine. Score five and above was considered as adequate knowledge and attitude score.

At the end of survey, a screw-capped plastic container with the identification of the child was given to collect the stool sample of the child on the next morning. Instructions regarding stool collection were given. The stool samples were collected and transported to microbiology laboratory within 4 h of sample collection. Stool samples were examined by saline wet mount and iodine wet mount.[17] Iodine preparation was done for the better visualization of morphological details of ova. All samples were re-examined after concentrating with WHO recommended.[18] Formalin-ether sedimentation method.[19] To reduce the human error, duplicate slides (both direct and after concentration method) were prepared from each sample and the slides were read by two different microbiologists and the opinion of chief microbiologist was considered as final.

Analysis

Data entry was made in the Microsoft Excel software in codes and analysis was done with SPSS-19 (IBM, Armonk, New York ,United States) computer package. The presence of ova of A. lumbricoides, Trichuris trichiura, N. americanus, and A. duodenale was considered as the dependent variable. The prevalence is expressed in percentage with 95% confidence interval (CI). Univariate analysis and logistic regression were performed to find the associations between the independent variables and dependent variables. Strength of association was expressed in terms of odds ratio (OR) and adjusted OR with 95% CI and $P < 0.05$ was considered as statistically significant.

Results

The results of this study are based on 610 children, who gave one adequate stool sample. Totally, 819 children participated in the survey; hence, the nonresponse rate was calculated as 25.52.

The distribution of the study population and their risk factors is shown in [Table 1] and [Table 2]. The mean age of the study population was 8.92 ± 2.68. Among them, children below 10 years (58.5%), female participants (52.1%), belonged to families with members four and above (54.92%), children living in kutcha and semi-pucca houses(80%), and children belonged to low socioeconomic status (52.3%) Class IV and V according to the modified Prasad classification were found in majority. Illiteracy was found among 20.2% of mothers. Open air defecation was found among 33.4% of the children. Regarding the toilet usage, only 50.7% of the children were using the toilets in the home. Around 66% did not wash their hands with soap before taking food. Moreover, 44.6% did not wash their hands with soap after defecation. Around 63% children regularly used foot wear and around 70% of the children had trimmed nail during the visit. Nearly half of the parents of children had adequate knowledge on STH. Only 59% reported intake of de-worming tablets in the past 3 months.{Table 1}{Table 2}

The prevalence of STH among 610 children who had given one adequate stool sample and whose parents participated in survey was 7.70% (95% CI: 5.58–9.82). Among all STH, A. lumbricoides was highly prevalent 6.9% (95% CI: 4.89%–8.91%) followed by Hook worm 0.7% (0.04%–1.36%), and Trichuris trichura 0.2% (0.15%–0.55%).

There was no significant association found between STH and factors influencing STH by univariate analysis. However, when all independent variables were subjected to multivariate logistic regression analysis, only pucca houses offered protection OR: 0.34(95% CI: [0.10–0.91]) against STH.

Discussion

Relatively high nonresponse rate (25.52%) was noted in this study. It is also evident from a similar study by Shubha and Fatima[20] that surveys involving bio samples shows high nonresponse rate (30.9%) when compared to simple questionnaire-based surveys.

The prevalence of STH in the study population is 7.7% (95% CI 5.58–9.82%). The results of the current study were less than other studies conducted in the nearby areas.

The explanations for the low prevalence are more number of risk group (29.13%) were found among the nonresponders compared to younger children (22.72%, P = 0.02). The study results were based on single stool sample, modified formol-ether concentration (FEC) method with low sensitivity (63.1%)[21] which could have estimated the low prevalence. The other probable explanations are Mass Drug Administration (MDA) under NDD[15] might have changed the scenario.[5],[6],[7],[8],[9] However, there are no sufficient data from to compare prevalence before de-worming in this area to support this statement. Coimbatore first round of NDD was just completed and second round was on-going at the time of the survey (2016-Feb). Kattula et al.[8] also explains the reason for the low prevalence of STH (7.8%) in Vellore area is due to Albendazole supplied in MDA along with diethylcarbamazine since 2004 Deworming using albendazole rapidly declines the overall prevalence of STH, and this is evident from Mani et al.[22] study on efficacy of albendazole in Tamil Nadu. However, there are other studies reported with a higher prevalence in the nearby areas. Kaliappan et al.[23] explains the reason for the increased prevalence (39%) in Thiruvanamalai District in the year 2013 could be due to five stool samples collected among tribal population where open-air defecation and bare foot walking were common practice. Ragunathan et al.[16] explains the reason for higher prevalence (34.56%) reported in Pudhucherry, a coastal area using FEC method in year 2006 is due to poor hygienic practices of the participants.

This study showed the most common soil-transmitted helminth as A. lumbricoides with the prevalence of 6.9% (95% CI: 4.89%–8.91%) followed by Hook worm 0.7% (95% CI: 0.04%–1.36%) and T. trichura 0.2% (95% CI: 0.15%–0.55%). In general studies showed that A. lumbricoides and T. trichura were more common among urban children and hookworm infestation among rural children.[24]

Regarding the factors influencing STH pucca houses offered protection OR: 0.34(95% CI: [0.10–0.91]) against STH, by multivariate analysis. A cross-sectional study by Kattula et al [8].showed that children living in Hut/Kutcha houses are at higher risk for STH.

Kattula et al.[8] also showed that children of more than 10 years of age, living in households without toilet, open air defecation, unhygienic practices like keeping untrimmed nails are important risk factors for STH. Kattula et al.[8] showed that the consumption of deworming tablets offered protection. However, there was no significant association noted in this study. This is a cross-sectional study; hence, the cause-effect relationship cannot be determined and is the major limitation of this study. Moreover, the other limitations are as follows: the study results were based on single stool sample which could have estimated the low prevalence. The newer techniques with higher sensitivity would have given higher prevalence. Sample size was not adequate to comment on factors influencing STH.

Conclusion

The prevalence of STH in a rural area of Coimbatore is 7.7% (95% CI: 5.58–9.82), and is continuing as a public health problem. Open-air defecation is a biggest concern (33.4%), hence, more private, public toilets should be built in this area. The children should be trained to use toilet facilities either private or public. It is very important to raise the awareness about these infections; hence, parents of children with inadequate knowledge should be given health education. When regular deworming is accompanied by appropriate sanitation and hygiene activities designed to prevent reinfection, a long-term impact can be achieved.

The prevalence of STH in a rural area of Coimbatore is 7.7% (95% CI: 5.58–9.82), and is continuing as a public health problem. ABSTRACT

Background: Working women are constantly facing the problems of role conflict or dual role. Due to role conflict, there are reports of psychological distress, mental tension, anxiety, etc, which affect the psychological well being of working women. Due to outside work, they have psychological problems such as anxiety, stress, burn out, fatigue, etc. This way, the mental health status of working women is neglected and hence, the present study **aims** to assess the psychological wellbeing of women in an industrial setup. **Methods:** A cross sectional study was done among women workers of 18 years and above. A standardized questionnaire was used to collect data. The data was analyzed using SPSS version 24. A total of 136 participants completed the study. **Results:** Present study showed that majority of the workers (67%) had low level of psychological well-being. **Conclusion:** Women workers have low level of psychological well-being and further studies are needed to understand factors influencing it.

Key Words: Psychological well-being, Women workers, Garment industry.

INTRODUCTION

"The mind is everything. What you think you become." – Buddha

According to the World Health Organization (WHO), mental health includes "subjective well-being, perceived self-efficacy, autonomy, competence, inter-generational dependence, and self-actualization of one's intellectual and emotional potential, among others". WHO further states that the well-being of an individual is encompassed in the realization of their abilities, coping with normal stresses of life, productive work and contribution to their community. [1]

Psychological well-being is a very subjective term meaning contentment, satisfaction with all elements of life, self-actualization (a feeling of having achieved something with one's life), peace and happiness.[2]Psychological well-being is defined as the presence of psychological and social skills and abilities that contribute to optimal functioning in daily life. [1]

The concept of mental health is inextricably linked to that of psychological well-being. A comprehensive model developed by C. Ryff provides an integration of different viewpoints. It encompasses six inter-related psychological dimensions: positive evaluation of one's self (Self-Acceptance), a sense of continued growth and development (Personal Growth), the belief that life is purposeful and meaningful (Purpose in Life), the possession of quality relations with others (Positive Relations with Others), the capacity to manage effectively one's life (Environmental Mastery), and a sense of self-determination (Autonomy). Lack of psychological well-being has been found to be a risk factor for depression. [3]

Garment workers around the world, especially those involved in tailoring, are predominantly women. The Indian garment industry is dominated by women workers and 80% of them are young women between 21-25 years. [4]

The workplace is one of the key environments that affect our mental well-being and health. It is difficult to quantify the impact of work alone on personal identity, self-esteem and social recognition; most mental health professionals agree that the workplace environment can have a significant impact on an individual's mental well-being. [5]

Working women have many problems such as career related problems, social problems such as domestic violence, health problems such as psychological distress due to role conflict, mental stress, tension, anxiety, physical health problems such as Anemia, arthritis, etc.

As discussed above, due to outside work, they have psychological problems such as anxiety, stress, burn out, fatigue, etc. This could lead to neglect of mental health. Hence this study is proposed with the objectives of

assessing the psychological well-being of women workers in garment industries and to find out its association with socio demographic factors.

MATERIALS & METHODS

A cross sectional study was conducted in a selected garment industry in Tirupur district of Tamilnadu state. This factory is mainly involved in manufacture of garments for export. Majority of the workers are unmarried women.

Sample size: Based on 63.5% prevalence of moderate level of psychological well-being study done by K.S.Velmurugan, Dr.K.Maheswari, in Tiruchirappalli [6] sample size was calculated as 136.

Inclusion criteria: There were 200 women workers above 18 years in our study factory. Prestuctured and pre validated questionnaire was administered to 136 women workers who were selected by simple random sampling.

Study tool: Carl Ryff's 18 item psychological well-being questionnaire translated into local language was used capturing various dimensions: autonomy, environmental mastery, personal growth, positive relations and self-acceptance, purpose in life. These items were measured using Likert scales of 1 to 6, with 1 indicating strong disagree and 6 indicating strong agree. The maximum score for psychological well-being that could be obtained under each dimension is 18.The maximum score that could be obtained for overall psychological well-being is 128.

Data collection: Data collection was done using the above tool as self administered questionnaire. Data entry and analysis was done using Statistical Package for Social Sciences (SPSS) version 24. The data were analyzed by using mean, standard deviation and two-way analysis of variance (ANOVA) and p <0.05 was considered statistically significant.

Ethical Issues: Approval for the study was obtained from the Institutional Human Ethics Committee of PSG Institute of Medical Sciences and Research.

RESULTS

A total of 136 participants completed the survey. The study participants were in the age group of 18 to 25 years. The participants were representative of different sections of the factory with majority (45%) being tailors. The demographical details of the participants are shown in Table1.

Table 2 shows the mean scores of the participants under each dimension of psychological well-being. For all dimensions the mean score was 12 and below which indicates low psychological well-being. The findings indicated that workers scored high in personal growth (M= 12.02, sd= 4.05) and least in environmental mastery (M=10.10, sd=4.05).

Table 1: Demographic details of the participants

Demographic factors	Percentage
Age	
Below 20 years	58%
Above 20 years	42%
Education Qualification	
High school	48%
Hr.sec.school	40%
Diploma	4%
Graduate	8%
Work experience	
Below 1 year	57%
Above 1 year	43%
Type of family	
Nuclear family	73%
Joint family	27%
Residence	
Hostel	97%
Day scholar	3%

Table 2: Overall level of workers Psychological well-being

Indicators of Psychological well-being	Mean±SD
Autonomy	11.50±3.39
Positive relations	11.92±2.37
Self-acceptance	10.13±3.52
Environmental mastery	10.10±4.05
Purpose in life	11.66±2.24
Personal growth	12.02±4.05
Total score	67.36±13.20

Table 3: Association of various factors with psychological well-being

Socio economic Factors	Total score of Psychological well-being (Mean±SD)	p value
Age		
Below 20 years	67.69±12.74	0.728
Above 20 years	66.89±13.91	
Education Qualification		
High school	68.39±13.26	
Hr.sec.school	67.59±13.14	
Diploma	68.20±14.06	0.241
Graduate	59.63±11.84	
Work experience		
Below 1 year	67.02±12.26	0.733
Above 1 year	67.81±14.46	
Type of family		
Nuclear family	67.02±13.00	0.625
Joint family	68.27±13.84	

Table 3 shows the association of various demographic variables with psychological well-being. Age was categorized less than 20 and more than 20, also between various educational level and work experience of at least a

year and whether they belonged to nuclear or joint family. The findings indicated that there is no significant difference between demographic factors like age, education and years of education with psychological well-being.

DISCUSSION

The present study showed that overall psychological well-being of women garment workers was low (mean value 67.36). In garment industry women workers work for longer hours (10 hours). Also due to high production pressure, hourly targets are set for workers. Staying away from family and having long working hours could be reasons which need to be explored.

Our study findings revealed relatively higher score for personal growth compared to other dimensions. It indicates that women workers had more positive feelings towards their continued development and ready to experience new challenges in life. Similarly, a study done on 2015 showed that a high score in personal growth and positive relations subscales. [7]

The result of present study concurs with a similar study done in Perambalur which showed that women in higher age have low psychological well-being. In our study there is no significant difference between workers age & their psychological well-being. But a woman with higher age shows low psychological well-being. In the same study it was found that women with more work experience had higher psychological wellbeing. In our study though not significant the mean score was comparatively higher among women with more work experience. [6]

In our study we couldn't find out any reasons for poor psychological well-being. Instead, we say above mentioned reasons could be the reason for poor psychological well-being. The present study concurs with a similar study, done in Mysore where the mean score for psychological well-being was 193. [8]

Conclusion and way forward

From the study we conclude that psychological well-being is low among women workers. Management should develop policies for addressing mental health issues and creating access to counseling services.
Though quantitative analysis did not reveal statistical association between psychological well-being and demographic profile, further qualitative studies would help in better understanding the factors influencing psychological well-being.

Received January 25, 2017

In India, research prioritization in Maternal, Newborn, and Child Health and Nutrition (MNCHN) themes has traditionally involved only a handful of experts mostly from major cities. The Indian Council of Medical Research (ICMR)-INCLEN collaboration undertook a nationwide exercise engaging faculty from 256 institutions to identify top research priorities in the MNCHN themes for 2016-2025. The Child Health and Nutrition Research Initiative method of priority setting was adapted. The context of the exercise was defined by a National Steering Group (NSG) and guided by four Thematic Research Subcommittees. Research ideas were pooled from 498 experts located in different parts of India, iteratively consolidated into research options, scored by 893 experts against five pre-defined criteria (answerability, relevance, equity, investment and innovation) and weighed by a larger reference group. Ranked lists of priorities were generated for each of the four themes at national and three subnational (regional) levels [Empowered Action Group & North-Eastern States, Southern and Western States, & Northern States (including West Bengal)]. Research priorities differed between regions and from overall

Supplementary material available from *http://www.ijmr.org.in/article.asp?issn=0971-5916;year=2017;volume=145;issue=5;spage=611;epage=622;aulast=Arora*

national priorities. Delivery domain of research which included implementation research constituted about 70 per cent of the top ten research options under all four themes. The results were endorsed in the NSG meeting. There was unanimity that the research priorities should be considered by different governmental and non-governmental agencies for investment with prioritization on implementation research and issues cutting across themes.

Nation-wide Network[18]

Names of participants in the Nation-wide Network are provided in Supplementary Table I (available on *http://www.ijmr.org.in/articles/2017/145/5/images/IndianJMedRes_2017_145_5_611_215547_sm6.pdf*) and also on *www.inclentrust.org*

Prioritization of research options in health is essential to plan for achieving efficient and impactful investment of limited resources against a large number of competing research options[1]. There is an increasing need and effort to set research priorities in health in a systematic way using a sound and transparent methodology and through engagement of the various key stakeholder constituencies[2,3]. Research priority setting (RPS) in India has traditionally been guided by a small group of experts, mostly identified from major metropolitan areas of the country. Subsequent to India's impressive yet inadequate improvement towards achieving Millennium Development Goals (MDGs) 1, 4 and 5, an expert group had convened on May 23, 2011 at the Indian Council of Medical Research (ICMR) Headquarters in New Delhi to discuss RPS. The participants observed that evidentiary gaps in the country impeded informed action in Maternal, Newborn, and Child Health and Nutrition (MNCHN) themes, and that an inclusive and transparent method should be adopted to decide the national research agenda. The agenda so developed should also identify areas for innovation and strategies to improve deliverability, efficiency, scalability and sustainability of existing interventions, avoid common blind spots in MNCHN research (*e.g*., still birth & neonatal health) and engage the multiple stakeholder constituencies including end users of any funded health research activity. This led to the formalization of the ICMR-INCLEN collaboration for undertaking the national RPS exercise for MNCHN using the Child Health and Nutrition Research Initiative (CHNRI) methodology. Since 2006-2007, the CHNRI priority setting methodology has been increasingly acknowledged as a flexible yet systematic priority-setting method for ranking competing research options using an objective, quantified and inclusive approach[2-7]. The method is opined to be effective at the national level where the results derived from inputs from national stakeholders can have a direct and prominent impact on the research investment policy[8]. As a major conceptual advancement, this method ranks the broadly defined competing research options that not only generate new knowledge but also synthesize evidence for efficient implementation of what is already known[9]. The ranking of these research options employs 'crowdsourcing' through the engagement of a wide range of stakeholder constituencies with due cognizance of their core expertise. The various dimensions of the research priorities are carefully examined by the experts using a predefined context and set of strictly defined scoring criteria. The collective optimism of the stakeholders, which can be considered as the 'wisdom of the crowd', helps in identifying research priorities through a democratic method of scoring, weighting and ranking of competing research options[1,5].

National Research Priority Setting (RPS) exercise for Maternal, Newborn, and Child Health and Nutrition (MNCHN)
