6th January,2022

SELF-DECLARATION

I, Dr T M SubbaRao, Principal, do hereby declare that PSG Institute of Medical Sciences and Research, Coimbatore has the prescribe number of teaching faculty, infrastructure etc., as per the statutes of the National Medical Commission, New Delhi and the TN Dr MGR Medical University, Chennai, for conducting Undergraduate and Postgraduate Courses.

The above said information is true to the best of my knowledge.

Dr T M SubbaRao
Principal

Dr. T.M. Subba Rao, MD.,
PRINCIPAL
PSG Institute of Medical Sciences
& Research / PSG Hospitals
Coimbatore - 641 004.

	Information of the medical college/institution Year of Inception: Government/private:	PSG Institute of Medical Sciences & Research 1985 PRIVATE
1.	Name	**PSG Institute of Medical Sciences & Research**
2.	Address with pin code	Post Box.No.1674 Peelamedu Coimbatore – 641 004 Tamil Nadu, India
3.	University address with pin code	The TN Dr.MGR Medical University, Anna Salai, Guindy, Chennai-600 032 Tamil Nadu, India
4.	Official website	www.psgimsr.ac.in
5.	Dean/ Principal/ Director	Dr T M SubbaRao
6.	Mobile Number	0422 4345802
7.	Email ID of Dean /Principal	psgmedschool@gmail.com
8.	Hospital	PSG HOSPITALS Post Box No.1674, Peelamedu, Coimbatore – 641 004. Phone 0422 – 4345802, 2598822 E.mail: psgmedschool@gmail.com Web: www.psghospitals.com
9.	Date and Year of Registration of the Hospital (DD/MM/YYYY)	November 15, 1989
10.	Number of Beds	1130
11.	Number of Beds for emergency	30 Beds
12.	Date of the First Letter of Permission(LoP) of MBBS (DD/MM/YYYY) & number of seats	• G.O.Me.No.1196, Health dated. 24thJuly 1985- Permission to start PSGIMS&R. • Lr. No.MCI 34(41)/96-Med./14804, dated.20.9.1996 - MCIRecognition of admission for MBBS 100 seats. • Lr.No.U.12012/864/2008-ME(P-II) dated.19.6.2009 - LOP issued by Central Govt., Ministry of Health & Family welfare for increase of seats in MBBS course from 100 to 150

		students. • Lr.No.MCI-34(41)(UG)/2014-Med/TN/117205 dt.01.07.2014 - MCI Recognition for increase of seats in MBBS course from 100 to 150 students. • MCI letter No:MCI 34(41)(UG)/ 2019-Med/157716,Dated22.10.19 – Continuation of recognition of MBBS degree with 150 admissions. • Lr. No. MCI 37(1)(UG)(I-26)/2019-Med/77. Dated. 24.09.2020 - LOP issued by BOG in supersession of MCI towards increase of seats in MBBS course from 150 to 250. • Lr. No. NMC/UGR/2020/000298/021304. Dated. 22.09.2021–Renewal of Permission (1st Renewal) for MBBS course for 2nd batch– against the increase intake of seats from 150 to 250 seats.
13.	Status of Recognition	The MBBS course with 150 seats is recognized as on 22.10.2019 and valid for 5 years. The Institute has obtained permission to increase MBBS admission from 150 to 250 seats in 2020. The institute offers Post Graduate programs in 24 disciplines covering Broad and Super Specialities. All of them are recognized.
14.	Number of MBBS and PG broad specialty and super specialty students admitted in this session*	MBBS: 250 MD/MS: 19 DM/MCh: 4
15.	Inpatients registered and admitted (01.01.2021-31.12.2021)**	2021 - 96781 2020 - 70908 2019 - 81963
16.	Outpatients registered (01.01.2021-31.12.2021)**	2021 - 1047920 2020- 986320 2019- 878085

17.	Number of Deaths reported to the Municipality/ village register	2021 - 1019 2020 - 825 2019– 657
18.	Address and pin code of the Corporation/village where the Death records are reported	Birth and death Registrar, 56th ward, Chandragandhinagar, Sowripalayam, Coimbatore -641028
19.	Website link/ email ID/ hyperlink of the corporation in case Death Records are reported	https://www.crstn.org/birth_death_tn/
20.	Number of Births reported	2021 - 2741 2020 - 2981 2019 – 3685
21.	Address and pin code of the Corporation/village where the Birth records are reported	Birth and death Registrar, 56th ward, Chandragandhinagar, Sowripalayam, Coimbatore -641028
22.	Website link/ email ID/ hyperlink of the corporation in case Birth Records are reported	https://www.crstn.org/birth_death_tn/
23.	Number of Rooms in Men's Hostel and students accommodated	475 Rooms, Occupied by 389 students.
24.	Total Number of Rooms in Women's Hostel and students accommodated	475 Rooms, Occupied by 415 students.
25.	Name of the Grievance Redressal Officer (PIO & CPIO):	PIO – Dr K Bhuvaneswari. Professor & Head Department of Pharmacology, PSGIMSR, Coimbatore.
26.	Address with Pin code	Post Box No.1674, Peelamedu, Coimbatore – 641 004. Phone 0422 – 4345802, 2598822 E.mail: psgmedschool@gmail.com Web: www.psghospitals.com
27.	Telephone Number Email Id	Phone 0422 – 4345802, 2598822 E.mail: psgmedschool@gmail.com
28.	Grievances reported	2021 - 2020 - 2019 -

29. Details of Post- Graduation Courses offered

Post- Graduate Course	Year of Commencement of the Course	Number of Students Currently pursuing the Course			Number of Students admitted in the current session
		2019	2020	Total	2021
MD- ANAESTHESIOLOGY	01.04.2011	4	4	8	ADMISSION PROCESS NOT YET STARTED
MD- BIOCHEMISTRY	31.03.2009	1	1	2	
MD-DERMATOLOGY	16.12.2002	5	5	10	
MD- MICROBIOLOGY	21.08.2001	3	3	6	
MD-PATHOLOGY	21.06.2001	4	4	8	
MD-TUBERCLOSIS & RESPIRATORY DISEASE	31.03.2011	2	2	4	
MS-OTO-RHINO-LARYNGOLOGY	23.03.2011	2	2	4	
MS - SURGERY	31.03.2009	4	4	8	
MD- GENERAL MEDICINE	21.06.2001	6	6	12	
MD- PAEDIATRICS	31.03.2009	6	6	12	
MD-PHARMACOLOGY	31.03.2009	2	1	3	
MD-PHYSIOLOGY	21.06.2001	0	0	0	
MD-PSYCHIATRY	31.03.2009	4	4	8	
MS-ORTHOPAEDICS	31.03.2009	2	2	4

30. Department wise list of Faculty Members

PSG Institute of Medical Sciences & Research

DEPARTMENT OF ANATOMY

SERVICE PARTICULARS

S.No	Name of the faculty, Qualification& TNMC registration number	Current Designation & Date of promotion	Nature of employment Regular/ permanent or contract/ outsourced	Mention the dates of completion of:	Details of Service in the Last 5 years (Mention name of institute, department and designation)		Number of lectures taken in 2021 until 15.12.2021. List the topics covered
1.	Dr. G. AMUDHA MBBS,MS-ANATOMY 54415	Professor & HOD 16.02.2015	Regular	RBC course: 02.08.2016 to 04.08.2016	2021 2020 2019 2018 2017	Professor	No. = 17 Topics covered: 1. General Anatomy I – Anatomical terminologies and Introduction to Systems of body 2. Mammary gland 3. Brachial plexus 4. Dissection of back 5. Shoulder Joint 6. Hand I 7. Blood supply of Lower Limb 8. Lungs 9. Blood supply of Heart & Cardiac plexus 10. Venous & lymphatic drainage of Thorax 11. Introduction to Histology of GIT, Esophagus & Stomach 12. Liver 13. Face 14. Cranial cavity with meninges and pituitary gland 15. Pharynx 16. Spinal cord with blood supply

Department of Anatomy

2.	Dr. M. JAMUNA MBBS, MS-ANATOMY 54783	Professor	Regular	RBC course:20th,21st and 22nd Sptember2016 Research Methodology – 2nd and 3rd November 2007	2021 2020 2019 2018 2017	Professor	No. = 18 Topics covered: 1. General anatomy, 2. Mammary gland, 3. Brachial plexus, 4. Shoulder joint, elbow, radioulnar, wrist joints, 5. Clinical anatomy charts of upper limb, 6. Front of thigh, 7. Hip joint, 8. Arches of foot, 9. Mediastinum and superior mediastinum, 10. Posterior abdominal wall and thoracolumbar fascia, 11. Histology of liver,gall bladder and pancreas, 12. Urinary bladder, 13. Deep cervical fascia, 14. Facial nerve, 15. Larynx, Sulci and gyri and functional areas of cerebrum, 16. White matter of cerebrum and basal ganglia

3.	Dr. A.K. MANICKA VASUKI MBBS, MD-ANATOMY 63015	Associate Professor 01.07.2019	Regular	RBC course:10th - 12th April 2017 Research Methodology / NPTEL course: Mar- June 2020	2021 2020 2019 2018 2017	Associate professor Associate professor Associate professor from 1st July Assistant professor Assistant professor	No. = 40 Topics covered: 1. Introduction of upper limb and pectoral region, 2. General Embryology I,II, III, IV, V, VI, VII, VIII, IX, 3. Hand II, 4. Front of thigh, 5. Sole of Foot, 6. Ankle Joint & Joints of foot, Pericardium, 7. Development of Heart I & II, 8. Introduction to Abdomen & Anterior Abdominal wall, 9. Scrotum & Testis, 10. Stomach with Coeliac trunk, 11. Development of GIT I & II, 12. Development of GUT I, II & III, 13. Parotid region, 14. Submandibular region, 15. Trigeminal nerve, 16. Development of face, palate and pharyngeal arches, 17. Fourth ventricle, 18. 3rd and lateral ventricles, 19. Development of brain and spinal cord.

4.	Dr. C. NANDHINI AISHWARYA MBBS, MD-ANATOMY 106910	Assistant Professor 12.03.2019	Regular	RBC course: Research Methodology / NPTEL course: NA	2021 2020 2019 2018 2017	Assistant Professor, PSGIMS&R Assistant Professor, PSGIMS&R Assistant Professor, PSGIMS&R Senior Resident, PSGIMS&R -	No. = 24 Topics covered: 1. Axilla - boundaries and contents, axillary artery 2. Back of arm and structures under cover of deltoid 3. Front of arm 4. Histology of bone 5. Histology of blood vessels 6. Hand II 7. Anterolateral Compartment of leg and Dorsum of Foot 8. Nerves of Lower Limb 9. Ribs & Introduction to vertebral column 10. Heart 11. Genetics I 12. Revision Anterior Abdominal wall, Scrotum & Testis 13. Genetics II 14. Genetics III 15. Genetics IV 16. Introduction to perineum, perineal pouches and ischiorectal fossa 17. Midline structure of neck and thyroid gland 18. Suboccipital region

							19. Eye ball and lacrimal apparatus 20. Medulla I & II 21. Cranial nerve 3, 4 and 6
5.	Dr. R. PRAVEENA MBBS, MD-ANATOMY 91993	Assistant Professor	Regular	RBC course: Research Methodology / NPTEL course: NA	2021 2020 2019 2018 2017	Assistant Professor, PSGIMS&R Assistant Professor, PSGIMS&R Senior Resident, JIPMER Senior Resident, JIPMER --------	No. = 18 Topics covered: 1. Adductor compartment of thigh 2. Back of thigh& Popliteal fossa 3. Osteology of Tibia, Fibula 4. Sternum & Thoracic vertebrae 5. Histology of Lungs & Trachea 6. Other chambers of heart 7. Pleura & Lungs 8. Rectus sheath & Inguinal canal 9. Anterior Abdominal wall, Scrotum & Testis 10. Histology of Small intestine, Large intestine & Appendix 11. Portal system with development 12. Prostate and Urethra 13. Triangles of Neck 14. Orbit - boundaries and contents 15. Ear with 8th cranial nerve 16. Blood supply of brain
6.	Dr. S. SUGANYA MBBS, MD-ANATOMY 84171	Assistant Professor 19.05.2020	Regular	RBC course: 12th-14th April 2021 Research Methodology / NPTEL course:	2021 2020	Assistant professor in PSGIMSR Assistant professor in PSGIMSR (from 19th May 2020)	No. = 22 Topics covered: 1. General Anatomy-Skin, Superficial fascia and Deep fascia 2. Bones & Joints

				March-June 2021	2019	Assistant professor in KFMSR	3. Muscular System 4. Circulatory system 5. Nervous system 6. Axillary & musculocutaneous nerves 7. Front of forearm 8. Hand I 9. Radial, ulnar & median nerves 10. Introduction to lower limb 11. Knee joint 12. Radiology & clinical charts of lower limb 13. External features of heart & right atrium 14. Peritoneum 15. Large intestine, Caecum, Appendix, Interior mesenteric artery 16. Uterus, tubes and ovary 17. Introduction to head and neck and scalp 18. Temporal and Infratemporal region 19. Nose 20. Pons 21. Thalamus, hypothalamus and limbic system 22. Clinical charts and Radiology of head and neck and neuroanatomy
					2018	Assistant professor in KFMSR	
					2017	-----	

7.	Dr. R. RAJA RAJESHWARI MBBS, MD-ANATOMY 106393	Assistant Professor 11.05.2021	Regular	RBC course: Research Methodology / NPTEL course: NA	2021 2020 2019 2018 2017	Assistant professor Senior resident till May Assistant professor after May Senior resident ----- -----	No. = 31 Topics covered: 1. General Histology I – Introduction to Histology, Cells & Tissues 2. General Histology II – Epithelium and Glands I 3. C1 - Histology of Connective tissue 4. Histology of cartilage 5. Histology of cartilage 6. Front of arm 7. Cubital fossa 8. Axillary & Musculo cutaneous nerves 9. Histology of muscle 10. Clinical anatomy, charts of upper limb 11. Histology of lymphatic system 12. Histology of Nervous tissue 13. Articulated foot 14. Histology of skin 15. Pleura 16. Mediastinum 17. Duodenum, small intestine with superior mesenteric artery 18. Pancreas & Extrahepatic biliary apparatus 19. Rectum and Anal canal 20. Pre and Para vertebral region

							21. Temporomandibular joint and muscles of mastication 22. Oral cavity, tongue and palate and tonsil 23. Mid brain 24. Optic nerve and pathway
8.	Mrs. K. RADHIKA M.Sc TNMC Registration Number: Not Applicable	Assistant Professor	Regular	RBC course: Research Methodology / NPTEL course: NA	2021 2020 2019 2018 2017	Assistant professor	No. = 17 <u>Topics covered:</u> Demo Lectures 1. Thoracic vertebra, ribs and sternum 2. Histology of Bone and skin 3. Introduction to skull, norma frontalis and mandible 4. Histology of Blood vessels, lymphatic system 5. Norma verticalis and occipitalis 6. Histology of nervous tissue 7. Norma lateralis, cervical vertebra 8. Norma basalis and cranial fossa 9. Frontal, parietal and occipitalis and hyoid bone 10. Tibia, fibula and articulated foot 11. Histology of female reproductive system 12. Femur, patella 13. Histology of male reproductive system 14. Pelvis and hipbone

							15. Histology of kidney, ureter, urinary bladder and cartilage 16. Sacrum 17. Histology of small intestine, large intestine and appendix
9.	Mrs. DEBORAH JOY HT M.Sc TNMC Registration Number: Not Applicable	Assistant Professor	Regular	RBC course: Research Methodology / NPTEL course: NA	2021 2020 2019 2018 2017	Assistant professor	No. = 13 <u>Topics covered:</u> 1. Axilla - boundaries and contents, axillary artery, 2. Back of arm and structures under cover of deltoid, 3. Cubital fossa, 4. Back of forearm and Dorsum of hand, 5. Elbow, wrist and radioulnar joints, 6. Radial, ulnar and median nerves, 7. Introduction to lower limb, 8. Adductor compartment of thigh, 9. Introduction to thorax and Intercostal spaces, 10. Posterior mediastinum, 11. Intercostals spaces & Mechanism of Respiration, 12. Lumbar vertebrae, Sacrum & Pelvis.

List the topics covered
1	Dr. K. Bhuvaneswari, MBBS, MD., PGDBE., TN MC Reg. No: 43193	Professor & HOD Date of promotion – 01/09/2004	Regular/ Permanent	RBC course:18th to 21st October 2016 Research Methodology – 28 to 30 November 2018- TNMGRUniversity NPTEL course: Mar – June 2021	2021	PSG IMSR, Pharmacology, Professor & HOD	No. = **13** Topics covered: **2019 Batch:** Absorption AETCOM Myocardial Infarction General Anesthetics Bronchial asthma & COPD AETCOM Antiarrhthymics **2018 Batch:** Antiarrhythmics Treatment of shock Treatment of MI **PG Lecture:**
					2020	PSG IMSR, Pharmacology, Professor& HOD	
					2019	PSG IMSR, Pharmacology, Professor& HOD	
					2018	PSG IMSR, Pharmacology, Professor & HOD	
					2017	PSG IMSR, Pharmacology, Professor & HOD	

							Cytokines in therapy Molecular drug delivery Drugs in pregnancy & lactation
2	Dr. S. Mohamed Musthafa, MBBS, MD., TN MC Reg. No: 37828	Associate Professor Date of Joining – 10/10/2019	Regular/ Permanent	RBC course: 12th to 14th April 2021 Research Methodology16th to 18thMarch 2021 TN MGR University NPTEL course: Mar – June 2021	2021	PSG IMSR, Pharmacology, Associate Professor	No. = **21** Topics covered: **2019 Batch:** Excretion Cholinergic drugs Skeletal Muscle relaxants Anti fungaldrugs Immunosupressants NSAIDS Antianginal drugs Anticoagulant drugs Antiepileptic drugs Alcohol Oestrogens& SERM Drugs affecting calcium balance Diuretic & antidiuretic Anti viraldrugs Anthelmintic drugs
					2020	PSG IMSR, Pharmacology, Associate Professor	
					2019	PSG IMSR, Pharmacology, Associate Professor	
					2018		
					2017		

							2018 Batch: Treatment of CHF I& II Treatment of urinary tract infections Antimalarial drugs **PG Lecture:** Therapeutic drug monitoring Paediatric Pharmacology
3	Dr. Ramanujam Narayanan, MBBS, MD (Pharmacology), TN MCI Reg. No. 82834; PhD, PG Diploma in Bioethics (PGDBE),	Associate Professor, Department of Pharmacology, Date of promotion – 01/07/2018	Regular/ Permanent	RBC course: 20th-22nd September 2016 Research Methodology / NPTEL course: Mar – June 2021	2021	PSG IMSR, Pharmacology, Associate Professor	No. = **28** Topics covered: **2019 Batch:** Pharmacodynamics I & II New drug development Adrenergic drugs Antiadrenergic drugs I Corticosteroids DMARD & Antigout Anticancer drugs I & II Betalactams II Quinolones Hematinics Drug abuse and deaddiction Anterior pituitary
					2020	PSG IMSR, Pharmacology, Associate Professor	
					2019	PSG IMSR, Pharmacology, Associate Professor	
					2018	PSG IMSR, Pharmacology, Assistant & Associate Professor	
					2017	PSG IMSR, Pharmacology, Assistant Professor	

							Androgens & anti androgens + drugs for erectile dysfunction Diabetes mellitus I & II Antiparkinson drugs Anti-ulcer drugs Anti malarial drugs Treatment of UTI and gram Negative infections Iron poisoning case discussion **2018 Batch:** Anti hypertensives Systemic Corticosteroids Antiviral drugs Anticancer drugs **PG Lecture:** Chronopharmacology Gene knockout models in drug development
4	Dr. S. Shanmuga Priya, MBBS, MD., TN MCI Reg. No 76725	Associate Professor, Department of Pharmacology, Date of	Regular/ Permanent	RBC course: 10th to 12thApril 2017 Research Methodology:	2021 2020	PSG IMSR, Pharmacology, Associate Professor PSG IMSR, Pharmacology, Associate Professor	No. =**21** Topics covered: **2019 Batch:** Distribution

		promotion – 01/07/2019		March 30-April 1 2021 TN MGR University NPTEL course: March – June 2020	2019	PSG IMSR, Pharmacology, Assistant & Associate Professor	Pharmacovigilance Antiadrenergic drugs I Histamine & antihistamines Aminoglycoside Broad spectrum & Miscellaneous Calcium Channel blockers Hypolipidemic drugs Opioids Antitubercular drugs Antipsychotic drugs Antihypertensives Drugs for Constipation and Diarrhea Cyanide poisoning case discussion **2018 Batch:** Diuretics & Antidiuretics Antitubercular drugs Bronchial asthma Introduction & Sources of drugs **PG Lecture:** PharmacovigilanceMelatoni
					2018	PSG IMSR, Pharmacology, Assistant Professor	
					2017	PSG IMSR, Pharmacology, Assistant Professor	

							n Therapeutics gases
5	Dr. A. Umamaheswari, MBBS, MD., TN MC Reg. No: 92266	Assistant Professor Date of joining 17.10.2016	Regular/ Permanent	RBC course: 10th to 12th April 2017 Research Methodology / NPTEL course: Aug – Dec 2020	2021	PSG IMSR, Pharmacology, Assistant Professor	No. = **23** Topics covered: **2019 Batch:** Metabolism AntiCholinergic drugs Antimicrobial intro Prostaglandins Seratonin and treatment of migraine Betalactams I Sulfonamide & macrolide Anti platelet drugs Drugs affecting RAS Hypnosedatives Posterior pituitary, Drugs acting on uterus Progestin & anti progestin & oral contraceptives Thyroid and anti-thyroid drugs Antidepressant Treatment of cardiac failure I &
					2020	PSG IMSR, Pharmacology, Assistant Professor

9	Dr Lalitha N MD, MRCOG TNMC Reg 65300	Assoc. Professor 01.01.2020	Regular	RBC course: 12th to 14th Apr, 2021 Research Methodology / NPTEL course: Mar-June, 2021	2021 2020 2019 2018 2017	PSG IMSR, Obstetrics &Gynaecology, Assoc. Professor PSG IMSR, Obstetrics &Gynaecology, Asst. Professor	No. = 4 Topics covered: 1. Physiology of pregnancy 2. Laparaoscopy and hysterectomy 3. Fertilisation& Implantation 4. Define, classify and discuss abnormal uterine bleeding, its aetiology, clinical features
10	Dr Maheswari S MD TNMC Reg 78424	Assoc. Professor 01.01.2020	Regular	RBC course:27th to 29th Aug, 2018 Research Methodology /	2021 2020 2019	PSG IMSR, Obstetrics &Gynaecology, Assoc. Professor PSG IMSR, Obstetrics	No. = 5 Topics covered: 1. Physiology of labour 2. Heart disease in pregnancy

				NPTEL course:	2018 2017	&Gynaecology, Asst. Professor	3. Hypertensive disorders in pregnancy 4. Postdated pregnancy 5. Normal puerperium
11	Dr Pooranidevi A MD TNMC Reg 77886	Asst. Professor 01.06.2016	Regular	RBC course: Research Methodology / NPTEL course:	2021 2020 2019 2018 2017	PSG IMSR, Obstetrics &Gynaecology, Asst. Professor	No. = 6 Topics covered: 1. Face & Brow presentation 2. Abruptio Placenta 3. History taking – Antenatal case 4. Placenta 5. Describe and discuss the physiology of lactation 6. Introduction to contraception, counseling for FP, Natural FP and barrier methods
12	Dr Krishnapriya MS,DGO,DNB TNMC Reg 78907	Asst. Professor 01.09.2016	Regular	RBC course: 12th to 14th Apr, 2021 Research Methodology / NPTEL course:	2021 2020 2019 2018 2017	PSG IMSR, Obstetrics &Gynaecology, Asst.Professor	No. = 5 Topics covered: 1. Physiology of labour 2. Primary amenorrhoea 3. Hormonal contraceptives, IUCD, sterilisation 4. Describe and discuss the etiology, pathology, clinical features, differential diagnosis, investigations, management and long term implications of genital tubeculosis 5. Describe and discuss the etiopathogenesis; clinical features; differential diagnosis; investigations; management, complications of PCOS

13	Dr Sumangali. T MS TNMC Reg 75422	Asst. Professor 01.01.2018	Regular	RBC course: Research Methodology / NPTEL course: 9th& 10th Sep, 2016	2021 2020 2019 2018	PSG IMSR, Obstetrics &Gynaecology, Asst.Professor	No. = 4 Topics covered: 1. Applied anatomy – female genital tract 2. Endometriosis 3. Vesicular mole and other GTD 4. IUCD, Hormonal contraceptives
					2017	PSG IMSR, Obstetrics &Gynaecology, Sr. Resident	
14	Dr Anupriya. K MD TNMC Reg 80894	Asst. Professor 01.09.2018	Regular	RBC course: Research Methodology / NPTEL course:	2021 2020 2019 2018	PSG IMSR, Obstetrics &Gynaecology, Asst.Professor	No. = 7 Topics covered: 1. History taking – Gynaec case 2. GTN 3. Secondary amenorrhoea 4. Applied anatomy – female genital tract 5. Normal mullerian development and sex differentiation 6. Describe and discuss the etiology, pathology, clinical features, differential diagnosis, investigations, management and long term implications of sexually transmitted infections 7. Describe and discuss the etiology, pathology, clinical features, differential diagnosis, investigations, management of long term implications of HIV
					2017	PSG IMSR, Obstetrics &Gynaecology, Senior Resident	
15	Dr Savitha. V MD TNMC Reg 78908	Asst. Professor 01.01.2020	Regular	RBC course: Research Methodology /	2021 2020	PSG IMSR, Obstetrics &Gynaecology, Asst.Professor	No. = 7 Topics covered: 1. Postdated pregnancy
					2019	PSG IMSR, Obstetrics	

				NPTEL course:	2018 2017	&Gynaecology, Senior Resident	2. Sterilisation (Male and female) 3. Conduct of labour 4. Menopause and HRT 5. Abnormal mullerian development 6. Primary and secondary amenorrhoea 7. Premalignant lesions of cervix
16	Dr Aswini. P DGO,DNB TNMC Reg 81194	Assistant Professor 01.11.2021	Regular	RBC course: Research Methodology / NPTEL course:	2021 Dec 2020 – 21 Nov 2019 2018 2017	PSG IMSR, Obstetrics & Obstetrics &Gynaecology, Asst. Professor PSG IMSR, Obstetrics & Obstetrics &Gynaecology, Senior Resident Karpagam Faculty of Medical Sciences & Research, Obstetrics &Gynaecology, Senior Resident -	No. = 6 Topics covered: 1. Introduction to contraception, counseling for FP, natural FP & barrier methods 2. Normal puerperium & Physiology of lactation 3. STD 4. Diabetes in pregnancy 5. Abruptio placenta 6. Describe the clinical characteristics of physiological vaginal discharge
17	Dr Vishranthi MD TNMC Regn.No:71870	Senior Resident 08.10.2019	Regular	RBC course: Research Methodology / NPTEL course:	2021 2020 2019 2018 2017 2017	PSG IMSR, Obstetrics & Gynaecology, Senior Resident - - -	No. = 4 Topics covered: 1. Induction of labour 2. Discuss the aetiology, clinical features, differential diagnosis of acute abdomen in early pregnancy (with a focus on ectopic pregnancy) and enumerate the principles of medical and surgical management 3. Enumerate and discuss the physiology of normal

							labour, mechanism of labour in occipito-anterior presentation; monitoring od labour including partogram 4. Gynaec Ca screening modalities – VIA, VILI, Pap smear, LBC, Colposcopy, Tumour markers
18	Dr Kanmani. M MS TNMC Regn.No:112609	Senior Resident 02.09.2020	Regular	RBC course: Research Methodology / NPTEL course:	2021 2020 2019 2018 2017	PSG IMSR, Obstetrics & Gynaecology, Senior Resident - - -	No. = 5 Topics covered: 1. Normal mullerian development and sex differentiation 2. Placenta 3. Physiology of pregnancy 4. Normal puerperium & Physiology of lactation 5. Reproductive physiology
19	Dr Bavanisree. P MS TNMC Regn.No:111055	Senior Resident 21.09.2020	Regular	RBC course: Research Methodology / NPTEL course:	2021 2020 2019 2018 2017	PSG IMSR, Obstetrics & Gynaecology, Senior Resident MAPIMS, OBG, Senior Resident - -	No. = 5 Topics covered: 1. Physiology of pregnancy 2. Describe the physiology of ovulation, menstruation, fertilization, implantation and gametogenesis 3. Describe and discuss the basic embryology of fetus, factors influencing fetal growth and development, anatomy and physiology of placenta, and teratogenesis 4. Describe and discuss the development and anatomy of the female reproductive tract,

							relationship to other pelvic organs, applied anatomy as related to Obstetrics and Gynaecology. 5. Describe and discuss the changes in the genital tract, cardiovascular system, respiratory, haematology, renal and gastrointestinal system in pregnancy
20	Dr Aneri Parikh MS G-60009 G-27945	Senior Resident 11.03.21	Regular	RBC course: Research Methodology / NPTEL course:	2021 2020 2019 2018 2017	PSG IMSR, Obstetrics & Gynaecology, Senior Resident GMERS Medical College, GOTRI, OBG, Senior Resident - - -	No. = 5 Topics covered: 1. Diagnosis of pregnancy 2. Physiology of labour 3. Pubertal and adolescent problems 4. Enumerate, describe and discuss the objectives of antenatal care, assessment of period of gestation, screening for high-risk factors 5. Describe the etiopathology, impact on maternal and fetal health and principles of management of hyperemesis gravidarum
21	Dr Athilakshmi MS TNMC Regn.No:78067	Senior Resident 12.07.2021	Regular	RBC course: Research Methodology / NPTEL course:	2021 2020 2019 2018 2017	PSG IMSR, Obstetrics & Gynaecology, Senior Resident - - - -	No. = 2 Topics covered: 1. Primary amenoorhoea 2. Describe and discuss the physiology of menopause, symptoms, prevention, management and the role of hormone replacement therapy

22	Dr Vishnupriya MS TNMC Regn.No:106963	Senior Resident 15.11.2021	Regular	RBC course: Research Methodology / NPTEL course:	2021	PSG IMSR, Obstetrics & Gynaecology, Senior Resident	No. = 2 Topics covered: 1. Tuberculosis of genital tract 2. Enumerate and discuss the diameters of maternal pelvis and types
					2020	GMC, MANJERI, OBG, Sernior Resident

SERVICE PARTICULARS

S. No	Name of the faculty, Qualification& TNMC registration number	Current Designation & Date of promotion	Nature of employment Regular/ permanent or contract/ outsourced	Mention the dates of completion of:	Details of Service in the Last 5 years (Mention name of institute, department and designation)		Number of lectures taken in 2021 until 15.12.2021. List the topics covered
1	Dr.C.Ganesan Professor & Head TNMC Reg No 49255	Professor & Head 1.1.2009	Regular& Permanent	RBC course: 20 -22 Sep 2016 Research Methodology / NPTEL course: Not Applicable	2021 2020 2019 2018 2017	PSG IMSR, Department of Anaesthesiology, Professor&Head .	No. = 10 Topics covered: 1.Valvular heart diseases & Anesthesia 2.Cardiopulmonary bypass 3.Anesthesia & burns 4.Anemia complicating pregnancy 5.Thoracic anesthesia 6.One lung ventilation 7.IHD & Anesthesia 8.Myocardial protection 9.TOF & Anesthesia 10.PDA & Anesthesia

2	Dr.G.Dhanabagyam Professor TNMC Reg No 48894	Professor 1.7.2011	Regular & Permanent	RBC course: 10 – 12 Apr 2017 Research Methodology / NPTEL course: Not Applicable	2021 2020 2019 2018 2017	PSG IMSR, Department of Anaesthesiology, Professor	No. = 7 Topics covered: 1.Mitral stenosis 2.Case Presentation – Burns 3.PIH 4.Atrial septal defect 5.Monitoring in anaesthesia 6.Basic Life support 7.Preoperative Assessment
3	Dr.Prasanthkumar.M.S Professor TNMC Reg No 70825	Professor 15.3.2021	Regular & Permanent	RBC course: 20 -22 Sep 2016 Research Methodology / NPTEL course:	2021 2020 2019 2018 2017	PSG IMSR, Department of Anaesthesiology, Professor PSG IMSR, Department of Anaesthesiology, Associate Professor	No. = 7 Topics covered: 1.Congenital Heart Disease 2.Obstructive Jaundice 3.Case Presentation – Gestational Diabetes Mellitus 4.Tetralogy of Fallot

							5.Anaesthesia Machine checklist 6.Anaesthesia for liver transplant 7.Thromboelastogram
4	Dr.Arunkumar.R Associate Professor TNMC Reg No 66112	Associate Professor 1.10.2019	Regular & Permanent	RBC course: 12.04.2021 to 14.04.2021 Research Methodology / NPTEL course:	2021 2020 2019	PSG IMSR, Department of Anaesthesiology, Associate Professor	No. = 7 Topics covered: 1.Chronic Obstructive airway disease 2.Basic Life Support 3.Cirrhosis of Liver 4.How to perform well in university examination 5.Ischaemic Heart Disease 6.Obstructive jaundice 7.Advanced Cardiovascular Life Support
					2018 2017	PSG IMSR, Department of Anaesthesiology, Assistant Professor	
5	Dr.Silvy Anna Varughese Assistant professor TNMC Reg No 154526	Assistant professor	Regular & Permanent	RBC course: Research Methodology / NPTEL	2021 2020 2019 2018	PSG IMSR, Department of Anaesthesiology, Assistant Professor	No. = 7 Topics covered: 1.Introduction, preoperative evaluation, premedication in anesthesia

				course: December 2020	2017		2.Pulmonary Function test 3.Pacemaker & Anesthesiologist 4.Anaesthetic considerations in Liver Transplantation 5.Neonatal Resuscitation 6.Tracheal tubes 7.Intercostal Drainage
6	Dr.Dhivya Assistant professor TNMC Reg No 90013	Assistant professor 01.02.2019	Regular & Permanent	RBC course: 12.04.2021 to 14.04.2021 Research Methodology / NPTEL course:	2021	PSG IMSR, Department of Anaesthesiology, Assistant Professor	No. = 9 Topics covered: 1. Epidural Anaesthesia 2. Capnography 3. Diagnosis and treatment of arrhythmias 4. Obesity and Anaesthetic implications 5. Pathophysiology and assessment of blood loss 6. Massive blood transfusion 7. Muscle relaxants 8. Vapourizer
					2020	PSG IMSR, Department of Anaesthesiology, Assistant Professor	
					2019		
					2018	PSG IMSR, Department of Anaesthesiology, Senior Resident	
					2017		

							9. Spinal & Epidural needles
7	Dr.Aswin.A.B Assistant professor TNMC Reg No 112384	Assistant professor 1.10.2019	Regular & Permanent	RBC course: Research Methodology / NPTEL course: Aug –Dec 2020	2021 2020 2019 2018 2017	PSG IMSR, Department of Anaesthesiology, Assistant Professor PSG IMSR, Department of Anaesthesiology, Senior Resident	No. = 8 Topics covered: 1. LASER and Anaesthesia 2. One lung Ventilation and Double lumen tubes 3. Vasopressors nad Inotropes 4.Anaesthetic considerations in Renal Transplantation 5. Obstetric emergencies 6. Neuro Muscular Monitoring 7. Cerebral physiology and CSF circulation 8.Advanced Cardiac Life Support
8	Dr.JayaprakashArunachalam Assistant professor TNMC Reg No 105748	Assistant professor 1.10.2019	Regular &Permanent	RBC course: Research Methodology / NPTEL	2021 2020 2019	PSG IMSR, Department of Anaesthesiology, Assistant Professor	No. = 8 Topics covered: 1. Carbondioxide transport and Regulation of respiration 2. Hyperbaric Physiology and

				course:	2018 2017	PSG IMSR, Department of Anaesthesiology, Senior Resident	Anaesthesia 3. Regional anaesthesia and Anticoagulant 4. Renal function tests and its implications in anaesthesia 5. Blood Conservation strategies 6. Journal club 7. Circle System 8.Spinal Anaesthesia
9	Dr.Arun.P Assistant professor TNMC Reg No 106384	Assistant professor 01.09.2020	Regular & Permanent	RBC course: Research Methodology / NPTEL course:	2021 2020	PSG IMSR, Department of Anaesthesiology, Assistant Professor	No. = 8 Topics covered: 1. Regulation of Acid base balance and Interpretation of ABG 2. Nebulisation in anaesthetic practice 3. Conduct of GA and failed Intubation Drill in pregnancy 4. Neonatal emergencies and Neonatal Resuscitation 5. Neonatal emergencies 6. Factors regulating Cerebral blood flow and influence of anaesthesia on
					2019	PSG IMSR, Department of Anaesthesiology, Senior Resident	
					2018 2017	Kasturba Medical College, Junior Resident / PG	

							cerebral blood flow 7. Various approaches of tracheostomy 8.Basic Life Support
10	Dr.Renjith Viswanath Assistant professor TNMC Reg No 153206	Assistant professor	Regular & Permanent	RBC course: Research Methodology / NPTEL course:	2021	PSG IMSR, Department of Anaesthesiology, Assistant Professor	No. = 6 Topics covered: 1. CVP Monitoring 2. Pain Pathway of Labour& Methods of labour analgesia 3. Caudal Anaesthesia and JR circuit 4. Safety features in anaesthesia machine 5. Double lumen tubes &Bronchial blocker 6.Oxygen Therapy
					2020	All India Institute of Medical Sciences, New Delhi, Senior Resident	
					2019		
					2018	Amala Institute of Medical Sciences, Junior Resident/PG	
					2017		
11	Dr.Santhosh Raja Assistant professor TNMC Reg No 97713	Assistant professor 01.04.2021	Regular & Permanent	RBC course: Research Methodology / NPTEL course:	2021	PSG IMSR, Department of Anaesthesiology, Assistant Professor	No. = 4 Topics covered: 1. Pain Pathway of Labour& Methods of labour analgesia 2. Various approaches of tracheostomy
					2020	PSG IMSR, Department of Anaesthesiology, Senior Resident	

							3. Foreign body in the bronchus 4. Regional anaesthesia and Anticoagulant
12	Dr.Archana.S.K Assistant professor TNMC Reg No 90616	Assistant professor 1.11.2021	Regular & Permanent	RBC course: Research Methodology / NPTEL course:	2021	PSG IMSR, Department of Anaesthesiology, Assistant Professor	No. = 7 Topics covered: 1. Local Anaesthesia 2. Coronary circulation & factors regulating cardiac output 3. Anatomy of Lumbar plexus and lower limb blocks 4. Foreign body in the bronchus 5. Anatomical, Physiological & Pharmacological consideration in Pregnancy 6. Head Injury – Diagnosis & Management 7. ICP Monitoring
					2020 2019	PSG IMSR, Department of Anaesthesiology, Senior Resident

					2018	PSGIMSR, DENTAL OPD, ASSISTANT PROFESSOR	
					2017	PSGIMSR, DENTAL OPD, ASSISTANT PROFESSOR	
3	DR.B.DINESH BABU MDS TNMC Reg No. 14509	ASSISTANT PROFESSOR 01/09/2018	REGULAR/PERMANENT	MET course: 4/10/2017 to 6/10/2017	2021	PSGIMSR, DENTAL OPD, ASSISTANT PROFESSOR	No. = 6 Topics covered: Clinical posting:
					2020	PSGIMSR, DENTAL OPD, ASSISTANT PROFESSOR	

				12/04/2021 to 14/04/2021 Research Methodology / NPTEL course: -	2019	PSGIMSR, DENTAL OPD, ASSISTANT PROFESSOR	1) Discuss the various causes for partial/complete loss of teeth and associated structures. 2) Discuss the local and systemic sequelae of the above. 3) Identify complete complement of teeth and identify missing teeth. 4) Enumerate common ways of restoring the edentulous state. 5) Counsel patients on the importance of restoring missing teeth/tissues with respect to the benefits on oral and systemic health. Theory class 1) Edentulous disease
					2018	PSGIMSR, DENTAL OPD, ASSISTANT PROFESSOR	
					2017	PSGIMSR, DENTAL OPD, SENIOR RESIDENT	
4	DR.C.VINODHA MDS TNMC Reg No. 14316	ASSISTANT PROFESSOR 01/07/2019	REGULAR/PERMANENT	MET course: 29/10/2021 & 30/10/2021 Research Methodology / NPTEL course: -	2021	PSGIMSR, DENTAL OPD, ASSISTANT PROFESSOR	No. = 6 Topics covered: Clinical posting: 1) Enumerate the parts of the tooth.
					2020	PSGIMSR, DENTAL OPD, ASSISTANT PROFESSOR	
					2019	PSGIMSR, DENTAL OPD, ASSISTANT PROFESSOR	

					2018	PSGIMSR, DENTAL OPD, SENIOR RESIDENT	2) Discuss the role of causative microorganisms in the aetio-pathogenesis of dental caries. 3) Identify dental caries. 4) Discuss the role of dental caries as a focus of sepsis. 5) Counsel patients with respect to oral hygiene, diet and the direct bearing on systemic health. Theory class: 1) Dental caries.
					2017	PSGIMSR, DENTAL OPD, SENIOR RESIDENT

Abstract

Introduction: In Indian medical schools, most of the undergraduate teaching is mainly theoretical and mostly teacher centric, though now it is slowly changing to learner centric. In Microbiology, the second year medical students are taught "organism based" instead of "infection based". Interactive Case-based learning (CBL) helps in better understanding of the basic concepts and helps in clinical correlation.

Objective of the Study: To evaluate the effectiveness of an interactive case based learning methodology in teaching microbiology to undergraduate medical students.

Methodology: The crossover interventional study was undertaken at government medical college, Palakkad. The second year MBBS students were briefed regarding the study and were divided into two groups (test and control group). The case-based learning modules were prepared after discussion with the department- faculty and clinician and then validated by renowned faculties from different medical colleges and implemented. Pre and post tests were conducted and the results analyzed using unpaired T test. Feedback from students and faculty too were obtained and analyzed.

Results: The study showed that there was significant difference in the post test scores of students who were part of Case based learning methodology. The feedback analysis using the Likert scale also gave a positive feedback for the CBL sessions.

Conclusion: The interactive case based learning helped the students to understand the basic microbiological concepts better. It also motivated the students and helped them in clinical correlation.

Keywords: Case based learning, Learning modules, Microbiology.

Introduction

Present day Educational training programs in microbiology are mainly theoretical and concentrate more on micro-organisms rather than on common infections in the medical schools in India. In this process, students become disinterested, as they don't realize its clinical importance. Current attitudes of medical students towards basic science courses points to a need to change the training methodology. The method of teaching clinical microbiology based on clinical concepts will facilitate higher ordered learning, critical thinking and self-directed learning.[1] The goal of case-based learning is to prepare the students for clinical practice through the use of authentic clinical cases.[1] It prepares the students to become better clinicians.

Goal: To help the MBBS students understand and apply the Microbiological concepts in the diagnosis of common infectious diseases

Objectives

1. To design learning modules for the case based learning sessions
2. To apply the designed CBL modules as a routine to teach clinical microbiology to MBBS students
3. To evaluate the effectiveness of case based learning methodology

Methodology

Institutional human ethical clearance was obtained. Informed consent was taken from the students for the interventional study. The learning modules were prepared based on KEMPs instructional design model.[2,3] The clinical cases were decided after discussion with five department faculty and a clinician and 20 learning modules were prepared for the selected clinical cases. The learning modules comprised of the clinical case scenario, few important learning objectives, few critical thinking questions and reading material on the same.[1] The learning modules were validated for construct and content validity with the help of external subject experts (belonging to the same specialty but from different colleges in India) and FAIMER faculty based on Waltz and Bausell's criteria.[4]

After validation, the case- based modular learning (CBL) was implemented. The second MBBS students (82 students) were randomly divided into study group and control group. The students were divided into small groups of 8-10 students. Each CBL sessions were held for two hours each. Informed consent was obtained from the students. All the students had the regular lecture class, which was followed by interactive case-based learning for the study group. Pre and post test questions were prepared and they were validated by subject experts and then they were administered to both the groups. A pre-test before the CBL session followed by the post test was administered. The results of the pre

Abstract

Introduction Jugular foramen is one of the most fascinating foramina of the human skull. It is a complex, irregular bony canal located between the occipital bone and petrous part of the temporal bone. Many important structures, like 9th, 10th, 11th cranial nerves, meningeal branch of occipital and ascending pharyngeal arteries, internal jugular vein, and inferior petrosal sinus, are passing through it. The jugular fossa has a septum and a dome. The septum divides the foramen into two compartments: anteromedial compartment (pars nervosa) and posterolateral compartment (pars vascularis). The dome contains superior bulb of internal jugular vein. The architecture of the foramen varies in size, shape, and laterality besides differences related to sex and race. The morphometric measurements of jugular foramen are very important for neurosurgeries and head and neck surgeries.

Objectives The aim of the present study is to study the morphology of jugular foramen along with its dimensions, compartments, presence of partial or complete septa and dome.

Materials and Methods A total number of 60 jugular foramina were examined from 30 adult dry human skulls of unknown age and sex from the Department of Anatomy, PSG Institute of Medical Sciences and Research, Coimbatore. Measurements were taken using Digital Vernier calipers. Results were analyzed statistically.

Results The length, width, and surface area of jugular foramen of right side were measured and compared with the left side. Length and width of the jugular foramen was significantly higher on the right side. The presence of partial septum was found in 27 skulls (90%) on the right side and 29 skulls (99.7%) on the left side, respectively. Dome was present in 100% of the jugular foramina on the right side and 90% of the jugular foramina on the left side. Separate opening for inferior petrosal sinus was found in eight skulls (27%) on the right side and four skulls (13%) on the left side.

Conclusion This study provides a clear understanding of anatomy of jugular foramen and supports the reported morphometric variations. The morphometric variations of jugular foramen in the parameters of the skull are probably due to ethnic and racial factors. Knowledge of these variations is important for neurosurgeons and radiologists who deal with space occupying lesions of the structures surrounding jugular foramen. This study may be helpful for ENT surgeons while performing middle ear surgeries.

Anatomy of Lumbar Plexus and Implications to Regional Anaesthesiologist

G. Amudha[1], Sandeep Diwan[2]
[1]Department of Anatomy, PSG Institute of Medical Sciences and Research, Coimbatore, Tamil Nadu, India.
[2]Department of Anaesthesia, Sancheti Hospital Pune, Maharashtra, India.

Abstract

Lumbar plexus is one of the two nerve plexuses which supply the lower limb. It is formed in the posterior abdominal wall within the psoas major muscle. The branches of the plexus exit via the medial and lateral borders as well as its ventral surface. It is a complex plexus which gives a branch to complete the formation of lumbo sacral plexus. The branches mainly supply the groin, anterior and medial compartments of thigh. They also supply the hip and knee joints. The cutaneous innervation by the branches of lumbar plexus is limited to the anterior, lateral and medial parts of the thigh, medial side of the leg and foot and also the lower part of anterior abdominal wall and perineum. Regional anaesthesia is a highly skilled and precise technique used widely in the patients to reduce the drug usage and decrease the intra and post operative complications. Lumbar plexus block can be used in surgeries related to hip joint and anterior part of thigh and groin. To execute the procedure successfully, sound knowledge in anatomy of lumbar plexus is required.

Keywords: Lumbar plexus, Branches, Regional anaesthesia.

Introduction:

Lumbar plexus is one of the nerve plexuses which supply the lower limb. It is a plexus which is formed inside the substance of the psoas major muscle and its branches emerge out of the muscle through its medial and lateral borders and also through its anterior surface. It is predominantly formed by the ventral rami of spinal nerves L 1, 2, 3 and 4. There is a small contribution from the T12 spinal nerve too. [1] The branches of lumbar plexus contribute to the innervation of lower limb predominantly the hip joint, knee joint, anterior and medial compartments of thigh. They also give cutaneous innervation to the anterior, lateral and medial surfaces of thigh, medial surface of the leg and foot. A small area parallel to inguinal ligament in the anterolateral part of lower abdomen and groin also is supplied by its branches. It gives motor innervation to the lower part of muscles of anterior abdominal wall and cremaster. Communication between the sensory branches of lumbar plexus will result in sensory overlap. [2]

Formation:

The roots of spinal nerves from L1 to L5 emerge in front of the transverse processes of lumbar vertebra. These roots enter into the part of psoas major muscle which is in between the muscle fibres taking origin from the bodies of lumbar vertebra and intervertebral discs and muscle fibres arising from the transverse processes of lumbar vertebra. [4]

When traced from body of L1 to lower lumbar vertebra, the plexus shares the same coronary plane at L1 but when it comes down, it is more anterior in position. The first four lumbar ventral rami with a contribution from subcostal nerve form the lumbar plexus. The plexus is complex and prone to have variations. The incidence of variations in lumbar plexus is around 20%.

The L1 ventral rami with a branch from ventral rami of subcostal nerve form a common trunk which divides and give rise to iliohypogastric and ilioinguinal nerves. L1 ventral ramus gives a branch which joins with a branch from L2 ventral rami to form genitofemoral nerve.

The ventral rami of L2 L3 and L4 spinal nerves divide into ventral and dorsal divisions. The ventral divisions of L2, L3

Abstract

Introduction: Knowledge of the normal and variant anatomy and anomalies of coronary circulation are vital component in the management of coronary artery disease. Any coronary artery disorder may reduce the blood supply to the heart and may lead to Myocardial infarction and death.

The aim of the study was to identify right coronary artery branching pattern and its variations. This may indirectly affect the patient's prognosis. This study describes the presence of normal arterial pattern and variations of right coronary artery in fifty heart specimens.

Materials and Method: This study was carried out on fifty formalin fixed adult human cadaveric heart specimens of both sexes. Visceral pericardium and subepicardial fats were removed. The right coronary artery and its branches were carefully dissected and followed till their termination.

Results: The right coronary artery was found to be arising from pulmonary trunk in three heart specimens in our study. Third coronary artery was found in one specimen. Sinu atrial nodal artery was arising from right coronary from right coronary artery in 94% and from left coronary artery in 6% Right dominance was observed in 35(70%) specimens. Fistula between right coronary artery and pulmonary artery was found in one specimen.

Conclusion: Branching pattern of right coronary artery is important for interpretation of coronary angiography and surgical revascularization of myocardium.

Keywords: Coronary artery, Sinu – atrial nodal artery, Fistula, pulmonary artery

Introduction

Coronary arteries represent the only supply to the myocardium. The two main coronary arteries, right and left coronary arteries arise from ascending aorta. Right coronary artery arises from right anterior aortic sinus and left coronary artery arises from left posterior aortic sinus. Patency of left coronary artery is vital for sufficient perfusion of the heart. The left coronary artery is responsible for irrigation, not only of most of the left ventricle, but also considerable portion of right ventricle.[1]

Right coronary artery runs between pulmonary trunk and right auricle and then runs downwards and is divided into two segments. First segment runs along the right border of the heart up to inferior border of heart. It gives right conus artery and supplies infundibulam of the right ventricle. If the right conus artery arises separately from the aortic sinus, then it is called as Third coronary artery. The second segment runs up to the apex as right marginal artery and supplies right ventricle. Sometimes it may runs in the posterior interventricular groove and may give rise to Posterior interventricular branch. Hence according to the origin of posterior interventricular artery, the coronary artery dominance has been considered. Right coronary artery ends in the crux by anastomosing with circumflex artery. It supplies the right atrium, right ventricle, atrioventricular septum and part of left ventricle.

Sinu atrial nodal artery may arise as atrial rami from initial segment of right coronary artery in 65% of the cases and from circumflex artery in 35% of the cases. Atrioventricular nodal artery arises as first septal ramus of posterior interventricular artery in 90% of the cases and 10% from the left coronary artery.[2]

Numerous studies on the variations of the arteries have been reported, but still it is better to study them further with respect to their clinical significance.

Coronary anomalies are a poorly understood topic in modern cardiology. Clinicians should be aware of such anomalies because some of them may produce sudden death.

The incidence of congenital coronary artery anomalies is 5–6%. By definition, the term anomalous or abnormal is used to define any variant form observed in less than 1% of the general population.[3]

The aim of the study is to identify the normal pattern of the coronary arteries and its variations. Though the modern techniques of revascularisation and coronary bypass surgeries are available, the knowledge about the anatomy of coronary arterial pattern and its variations are important for the cardiologists and cardio – thoracic surgeons.

Materials and Method

Fifty formalin fixed heart specimens of both sexes with intact coronary arterial pattern were studied in Anatomy department, PSG IMS & R, Coimbatore. The right coronary artery and its branches were carefully dissected out till their termination and were analysed for normal and abnormal patterns of coronary arteries.

Anatomical Study of Left Coronary Artery and its Variations–Cadaveric Study

ANAIMALAI KANDAVADIVELU MANICKAVASUKI[1], MEENAKSHISUNDARAM JAMUNA[2], THANASINGH DEBORAH JOY HEBZIBAH[3], MURUGESAN NIRMALADEVI[4], BEULAH PRIYALATHA SWAMICKEN[5], KUTTAN RADHIKA[6], K KALYANA SUNDARAM[7]

ABSTRACT

Introduction: Variations of the anatomy of the Coronary arteries are quiet common and have been reported previously in the literature. Right and Left coronary arteries which supply blood to the heart originates from the ascending aorta. Any coronary artery disorder may have serious implications by reducing the blood supply to heart leading to myocardial infarction and death.

Aim: To identify left coronary artery branching pattern and its variations.

Materials and Methods: Fifty formalin fixed wet specimens of heart of both sexes with intact coronary arterial pattern were collected and studied. The left coronary artery and its branches were carefully dissected out and were analysed for variable pattern in each specimen.

Results: Left coronary artery (LCA) was found to be hypoplastic in six (12%) specimens. In one specimen (2%), hypoplastic LCA was crossed by a vein and had communication with the vein. Trifurcation of LCA was seen in 17 (34%) specimens, Circumflex artery was short in one (2%) specimen. Kugel's artery was observed in three (6%) specimens. Median artery was found in seven specimens (14%). The left coronary artery and circumflex artery were absent in one (2%) specimen. In case where left coronary artery was absent, left anterior descending artery and circumflex artery were taking origin directly from left anterior aortic sinus. Left anterior descending artery showed variation in the form of short course (2 cm), discontinuous and embedded within myocardial tissue in 2% of cases each. However the circumflex artery also showed short course in one (2%) case.

Conclusion: The variations of the left coronary artery observed in the study are important for interpretation of coronary angiography, surgical revascularization of myocardium and embryological interpretations.

Keywords: Angiography, Circumflex artery, Kugel's artery, Left Anterior descending artery

INTRODUCTION

Left coronary artery (LCA) originates from left posterior aortic sinus. Patency of left coronary artery is vital for sufficient perfusion of the heart. The left coronary artery supplies most of the left ventricle and considerable portion of right ventricle [1].

LCA bifurcates into left anterior descending and circumflex artery and passes between pulmonary trunk and left auricle. The left anterior descending artery (LAD) runs in the left anterior interventricular groove and ends at the apex or may run up to crux of the heart [2]. Circumflex artery (CX) then runs in the posterior atrioventricular groove and ends at the crux of heart by anastomosing with right coronary artery (RCA) or may end before the crux. Sometimes posterior interventricular artery may arise from circumflex artery and may run in the posterior interventricular groove as left coronary dominance [2].

Numerous studies on the variations of the arteries have been reported [3,4]. Coronary artery (CA) variations is a topic of interest in modern cardiology. Cardiologists, cardiothoracic surgeons and radiologists should be aware of such anomalies because some of them may produce sudden death. Such rare coronary anomalies are poorly understood thus a detailed variation in them will add onto the existing clinical knowledge. The incidence of congenital coronary artery anomalies is 5–6%. By definition, the term anomalous or abnormal is used to define any variant form observed in less than 1% of the general population [3]. The incidence of all coronary anomalies is 0.23% in autopsy series and ranges between 0.3 to 5.6% in angiographic series [4]. The recent introduction of selective coronary angiography provides information about the normal coronary arterial pattern and also its variations [3].

The frequency of various anomalies of left coronary artery and the arterial dominance of the heart were observed in current study.

Numerous studies [3,4] on the variations of the arteries have been reported, but still it is better to study them further with respect to their clinical significance. The aim of the study was to identify the normal arterial branching pattern of left coronary artery and its variations in fifty heart specimens.

MATERIALS AND METHODS

The Cross sectional observational study was conducted from September 2016 to November 2016. The study was carried out after obtaining ethical clearance from Institutional ethical committee. Fifty formalin fixed heart specimens of both sexes with intact coronary arterial pattern were studied. Specimens with damaged arterial pattern were excluded. The left coronary artery and their branches were carefully dissected out till their termination and were analysed for variable patterns.

Length of the arteries were measured with the help of thread and Vernier caliper from the point of origin of the arteries to the point of termination. The course of artery was delineated and thread was passed around the vessel. Then thread with mark was measured using the Vernier caliper. Percentage incidence of various patterns was recorded and tabulated.

ABSTRACT

Introduction: Seven cervical vertebrae constitute the skeletal framework of the neck. Along with the other identification points, the cardinal feature of a cervical vertebra whether typical or atypical is the presence of Foramen transversarium on the transverse process. This foramen transmits the Vertebral artery, Vertebral vein and Sympathetic nerves. These foramina are known to have variations in size, shape and numbers and may be absent, incomplete or duplicate, which may lead to various symptoms. Their etiology is related with the variations in the course of the Vertebral artery due to developmental reasons.

Materials and methods: Three hundred dry human cervical vertebrae were collected and studied in the department of Anatomy, PSG Institute of Medical Sciences and Research, Coimbatore. We included all the Cervical vertebrae including Atlas, Axis and all other cervical vertebrae. We observed the presence, size, shape and variations of Foramen transversarium of cervical vertebrae during our study.

Observations and results: Out of three hundred Cervical vertebrae, One hundred and twenty five cervical vertebrae (42%) had variations of Foramen transversarium like Complete / incomplete Accessory foramen, triple foramen on one side, absence of foramen on one side and unequal size of foramen on both the sides. The different types of shapes of foramen transversarium were also analysed and tabulated. The areas of foramen transversarium were measured after measuring all the diameters.

Conclusion: Variations in the Foramen transversarium may indicate, the variation in the course of the Vertebral artery. The present study was important clinical implications for Head and neck and vascular surgeries. These variations should be kept in our mind during surgeries on cervical spine.

KEY WORDS: Foramen transversarium, shape, cervical vertebrae, accessory, absent and variations.

Anatomical Study of Lobes and Fissures of Lungs and its Clinical Significance-A Cadaveric Study

A K MANICKA VASUKI[1], K KAILASH KRISHNAN[2], M JAMUNA[3], DEBORAH JOY HEPZIBAH[4], K KALYANA SUNDARAM[5]

ABSTRACT

Introduction: The human lungs are divided by fissures into lobes which permit movements of lobes to one another. The fissures act as barriers to avoid the spread of the diseases. Knowledge of variations in the lobes and fissures of the lungs is important for the Radiologists to interpret the radiological images and for the cardiothoracic surgeons to plan for segmental resection or lobectomy.

Aim: To study the patterns of fissures and lobes of the lungs and their variations and to find their clinical implications and to compare with the previous studies.

Materials and Methods: Forty pairs of lungs were used for the study. They were obtained from formalin fixed cadavers. The patterns of lobes, fissures and hilar anatomy of lungs and its variations were noted and specimens were photographed.

Results: In the present study, incomplete horizontal fissure was found to be in 23(57.5%) right lung specimens and incomplete oblique fissure was observed in 20(50%) left lung specimens. Absence of horizontal fissure was about 10(25%) and oblique fissure was about six (15%) in right lung specimens. Absence of oblique fissure was about four (10%) in left lung specimens. According to Craig and Walker classification, Grade 1 and Grade 3 fissures were found to be more in both the lung specimens. Accessory fissure was observed in 5 (12.5%) specimens in the right lung and 10 (25%) specimens in the left lung. Single lobe was observed in both the lungs, 7.5% in the right lung and 5% in the left lung.

Conclusion: Variations of fissures and lobes and of hilar anatomy is of great significance. Knowledge of these variations is important for Radiologists and Cardiothoracic surgeons for interpreting the data and to plan for the surgeries.

Keywords: Accessory fissure, Hilar anatomy, Lobectomy

INTRODUCTION

The lungs are a pair of essential organs of respiration located within the thoracic cavity, on either side of heart and other mediastinal contents. Each lung is half – conical in shape, divided into lobes by fissures. Anatomically, left lung is divided into upper and lower lobes by oblique fissure whereas right lung is divided into upper, middle, lower lobes by oblique and horizontal fissures. In each lung, the oblique fissure begins from mediastinal surface above and behind the hilum and cuts the posterior border of the lung about 2.5 cm lateral to the junction of the T3 &T4 spine. Then, it runs along the costal surface, cuts the inferior border of the lung and will reappear on the mediastinal surface and ends at the lower end of the hilum. The horizontal fissure begins at the oblique fissure, courses along the costal surface, cuts the anterior border and appears to end at the hilum [1].

Finding of an accessory fissure in lung specimens is not uncommon but appreciating them on radiographs and Computed Tomography (CT) scans is difficult and hence, they are not appreciated as distinct entities or are completely misinterpreted. They usually occur at the boundaries between bronchopulmonary segments [2]. The commonly found accessory fissures are superior accessory fissure, inferior accessory fissure and left minor accessory fissure. The superior accessory fissure separates superior segment from the rest of the segments of lower lobe of lung, the inferior accessory fissure separates small infracardiac lobe from other segments of lower lobe of lung on the diaphragmatic surface and the left minor fissure separates the lingula from the other segments of upper lobe of left lung [2].

The fissures may vary in the degree of completeness and tend to divide the lobe into smaller divisions. Complete fissures have continuity of lobes at their bottom. The adjacent lobes are connected by a small portion of pulmonary tissues because of clefts it fails to reach the hilum in the incomplete fissures. The fissure may be absent altogether. The fissures are important for uniform expansion of lobes. They allow movements of lobes in relation to each other. This is more involved in the lower lobes at the time of breathing [3].

The appearance of accessory lung fissure may be seen as in relation to its completeness or its depth and that varies with X-ray and CT scan [4].

Knowledge of classical accessory lobes and fissures is necessary for radiological interpretation. This gives proper guidance to Cardio thoracic surgeons in performing segmental lung resection and lobectomies to have an uncomplicated perioperative outcome.

To assess the patterns of lobes and fissures of lung and to find out any variations in the fissures and lobes and hilar structures of the lungs in human cadavers and to find their clinical significance and to compare with them with the previous studies.

MATERIALS AND METHODS

Forty pairs of lung specimens (32 lung specimens from male cadavers and 8 lung specimens from female cadavers) free from pathological lesions, removed at the time of teaching for first year of MBBS from the 10% formalin fixed human cadavers from the Department of Anatomy, PSG Institute of Medical Sciences and Research, Coimbatore were included in the study. The study was conducted in the month of November 2016 to April 2017 after Ethical clearance (Proposal Number.16/291). The lung specimens were observed and were photographed for:

1. The patterns of lobes and fissures;
2. Variations in fissures, complete or incomplete;
3. Accessory fissure if any;
4. Hilar structures and its variations.

The anatomical classification proposed by Walker WS et al., was followed to determine the presence of completeness of fissures [5].

Abstract

Background and Aims: Profunda femoris artery is the largest branch of femoral artery. It is the principal supply to the muscles of the thigh as well as head and neck of femur. Its branches form anastomosis around the head of the femur. Profunda femoris artery is also used for arteriography. It is frequently used in vascular reconstructive procedures in the proximal thigh. It forms main route of collateral circulation in occlusion of femoral artery. The study of variation of Profunda femoris artery is of great value for radiologists and surgeons during diagnostic and surgical intervention.

Aim of the study is to observe the origin of Profunda femoris artery, to measure the distance between midinguinal point and site of origin of Profunda femoris artery and to study the anatomy of Profunda femoris artery and its branches and to find out any variations in its course and its branches.

Materials and Methods: The study was conducted as a prospective study from April 2018 to October 2018. All the lower limbs with the intact Femoral artery and Profunda femoris artery and their branches were included. Femoral artery and its branches had got cut during dissection were not included in the study. Thirty two Profunda femoris arteries (20 on the right side and 12 on the left side) were studied in the department of Anatomy. The femoral triangle was exposed by making incisions along the inguinal ligament from pubic symphysis to anterior superior iliac spine. Midpoint was taken as Midinguinal point (MIP). MIP was marked with a coloured pen. The distance between MIP and the site of origin of

Abstract

Introduction: Knowledge of the normal and variant anatomy and anomalies of coronary circulation are vital component in the management of coronary artery disease. Any coronary artery disorder may reduce the blood supply to the heart and may lead to Myocardial infarction and death.

The aim of the study was to identify right coronary artery branching pattern and its variations. This may indirectly affect the patient's prognosis. This study describes the presence of normal arterial pattern and variations of right coronary artery in fifty heart specimens.

Materials and Method: This study was carried out on fifty formalin fixed adult human cadaveric heart specimens of both sexes. Visceral pericardium and subepicardial fats were removed. The right coronary artery and its branches were carefully dissected and followed till their termination.

Results: The right coronary artery was found to be arising from pulmonary trunk in three heart specimens in our study. Third coronary artery was found in one specimen. Sinu atrial nodal artery was arising from right coronary from right coronary artery in 94% and from left coronary artery in 6% Right dominance was observed in 35(70%) specimens. Fistula between right coronary artery and pulmonary artery was found in one specimen.

Conclusion: Branching pattern of right coronary artery is important for interpretation of coronary angiography and surgical revascularization of myocardium.

Keywords: Coronary artery, Sinu – atrial nodal artery, Fistula, pulmonary artery

Introduction

Coronary arteries represent the only supply to the myocardium. The two main coronary arteries, right and left coronary arteries arise from ascending aorta. Right coronary artery arises from right anterior aortic sinus and left coronary artery arises from left posterior aortic sinus. Patency of left coronary artery is vital for sufficient perfusion of the heart. The left coronary artery is responsible for irrigation, not only of most of the left ventricle, but also considerable portion of right ventricle.[1]

Right coronary artery runs between pulmonary trunk and right auricle and then runs downwards and is divided into two segments. First segment runs along the right border of the heart up to inferior border of heart. It gives right conus artery and supplies infundibulam of the right ventricle. If the right conus artery arises separately from the aortic sinus, then it is called as Third coronary artery. The second segment runs up to the apex as right marginal artery and supplies right ventricle. Sometimes it may runs in the posterior interventricular groove and may give rise to Posterior interventricular branch. Hence according to the origin of posterior interventricular artery, the coronary artery dominance has been considered. Right coronary artery ends in the crux by anastomosing with circumflex artery. It supplies the right atrium, right ventricle, atrioventricular septum and part of left ventricle.

Sinu atrial nodal artery may arise as atrial rami from initial segment of right coronary artery in 65% of the cases and from circumflex artery in 35% of the cases. Atrioventricular nodal artery arises as first septal ramus of posterior interventricular artery in 90% of the cases and 10% from the left coronary artery.[2]

Numerous studies on the variations of the arteries have been reported, but still it is better to study them further with respect to their clinical significance.

Coronary anomalies are a poorly understood topic in modern cardiology. Clinicians should be aware of such anomalies because some of them may produce sudden death.

The incidence of congenital coronary artery anomalies is 5–6%. By definition, the term anomalous or abnormal is used to define any variant form observed in less than 1% of the general population.[3]

The aim of the study is to identify the normal pattern of the coronary arteries and its variations. Though the modern techniques of revascularisation and coronary bypass surgeries are available, the knowledge about the anatomy of coronary arterial pattern and its variations are important for the cardiologists and cardio – thoracic surgeons.

Materials and Method

Fifty formalin fixed heart specimens of both sexes with intact coronary arterial pattern were studied in Anatomy department, PSG IMS & R, Coimbatore. The right coronary artery and its branches were carefully dissected out till their termination and were analysed for normal and abnormal patterns of coronary arteries.

Anatomical Study of Left Coronary Artery and its Variations–Cadaveric Study

ANAIMALAI KANDAVADIVELU MANICKAVASUKI[1], MEENAKSHISUNDARAM JAMUNA[2], THANASINGH DEBORAH JOY HEBZIBAH[3], MURUGESAN NIRMALADEVI[4], BEULAH PRIYALATHA SWAMICKEN[5], KUTTAN RADHIKA[6] K KALYANA SUNDARAM[7]

ABSTRACT

Introduction: Variations of the anatomy of the Coronary arteries are quiet common and have been reported previously in the literature. Right and Left coronary arteries which supply blood to the heart originates from the ascending aorta. Any coronary artery disorder may have serious implications by reducing the blood supply to heart leading to myocardial infarction and death.

Aim: To identify left coronary artery branching pattern and its variations.

Materials and Methods: Fifty formalin fixed wet specimens of heart of both sexes with intact coronary arterial pattern were collected and studied. The left coronary artery and its branches were carefully dissected out and were analysed for variable pattern in each specimen.

Results: Left coronary artery (LCA) was found to be hypoplastic in six (12%) specimens. In one specimen (2%), hypoplastic LCA was crossed by a vein and had communication with the vein. Trifurcation of LCA was seen in 17 (34%) specimens, Circumflex artery was short in one (2%) specimen. Kugel's artery was observed in three (6%) specimens. Median artery was found in seven specimens (14%). The left coronary artery and circumflex artery were absent in one (2%) specimen. In case where left coronary artery was absent, left anterior descending artery and circumflex artery were taking origin directly from left anterior aortic sinus. Left anterior descending artery showed variation in the form of short course (2 cm), discontinuous and embedded within myocardial tissue in 2% of cases each. However the circumflex artery also showed short course in one (2%) case.

Conclusion: The variations of the left coronary artery observed in the study are important for interpretation of coronary angiography, surgical revascularization of myocardium and embryological interpretations.

Keywords: Angiography, Circumflex artery, Kugel's artery, Left Anterior descending artery

INTRODUCTION

Left coronary artery (LCA) originates from left posterior aortic sinus. Patency of left coronary artery is vital for sufficient perfusion of the heart. The left coronary artery supplies most of the left ventricle and considerable portion of right ventricle [1].

LCA bifurcates into left anterior descending and circumflex artery and passes between pulmonary trunk and left auricle. The left anterior descending artery (LAD) runs in the left anterior interventricular groove and ends at the apex or may run up to crux of the heart [2]. Circumflex artery (CX) then runs in the posterior atrioventricular groove and ends at the crux of heart by anastomosing with right coronary artery (RCA) or may end before the crux. Sometimes posterior interventricular artery may arise from circumflex artery and may run in the posterior interventricular groove as left coronary dominance [2].

Numerous studies on the variations of the arteries have been reported [3,4]. Coronary artery (CA) variations is a topic of interest in modern cardiology. Cardiologists, cardiothoracic surgeons and radiologists should be aware of such anomalies because some of them may produce sudden death. Such rare coronary anomalies are poorly understood thus a detailed variation in them will add onto the existing clinical knowledge. The incidence of congenital coronary artery anomalies is 5–6%. By definition, the term anomalous or abnormal is used to define any variant form observed in less than 1% of the general population [3]. The incidence of all coronary anomalies is 0.23% in autopsy series and ranges between 0.3 to 5.6% in angiographic series [4]. The recent introduction of selective coronary angiography provides information about the normal coronary arterial pattern and also its variations [3].

The frequency of various anomalies of left coronary artery and the arterial dominance of the heart were observed in current study.

Numerous studies [3,4] on the variations of the arteries have been reported, but still it is better to study them further with respect to their clinical significance. The aim of the study was to identify the normal arterial branching pattern of left coronary artery and its variations in fifty heart specimens.

MATERIALS AND METHODS

The Cross sectional observational study was conducted from September 2016 to November 2016. The study was carried out after obtaining ethical clearance from Institutional ethical committee. Fifty formalin fixed heart specimens of both sexes with intact coronary arterial pattern were studied. Specimens with damaged arterial pattern were excluded. The left coronary artery and their branches were carefully dissected out till their termination and were analysed for variable patterns.

Length of the arteries were measured with the help of thread and Vernier caliper from the point of origin of the arteries to the point of termination. The course of artery was delineated and thread was passed around the vessel. Then thread with mark was measured using the Vernier caliper. Percentage incidence of various patterns was recorded and tabulated.

Anatomical Study of Lobes and Fissures of Lungs and its Clinical Significance-A Cadaveric Study

A K MANICKA VASUKI[1], K KAILASH KRISHNAN[2], M JAMUNA[3], DEBORAH JOY HEPZIBAH[4], K KALYANA SUNDARAM[5]

ABSTRACT

Introduction: The human lungs are divided by fissures into lobes which permit movements of lobes to one another. The fissures act as barriers to avoid the spread of the diseases. Knowledge of variations in the lobes and fissures of the lungs is important for the Radiologists to interpret the radiological images and for the cardiothoracic surgeons to plan for segmental resection or lobectomy.

Aim: To study the patterns of fissures and lobes of the lungs and their variations and to find their clinical implications and to compare with the previous studies.

Materials and Methods: Forty pairs of lungs were used for the study. They were obtained from formalin fixed cadavers. The patterns of lobes, fissures and hilar anatomy of lungs and its variations were noted and specimens were photographed.

Results: In the present study, incomplete horizontal fissure was found to be in 23(57.5%) right lung specimens and incomplete oblique fissure was observed in 20(50%) left lung specimens. Absence of horizontal fissure was about 10(25%) and oblique fissure was about six (15%) in right lung specimens. Absence of oblique fissure was about four (10%) in left lung specimens. According to Craig and Walker classification, Grade 1 and Grade 3 fissures were found to be more in both the lung specimens. Accessory fissure was observed in 5 (12.5%) specimens in the right lung and 10 (25%) specimens in the left lung. Single lobe was observed in both the lungs, 7.5% in the right lung and 5% in the left lung.

Conclusion: Variations of fissures and lobes and of hilar anatomy is of great significance. Knowledge of these variations is important for Radiologists and Cardiothoracic surgeons for interpreting the data and to plan for the surgeries.

Keywords: Accessory fissure, Hilar anatomy, Lobectomy

INTRODUCTION

The lungs are a pair of essential organs of respiration located within the thoracic cavity, on either side of heart and other mediastinal contents. Each lung is half – conical in shape, divided into lobes by fissures. Anatomically, left lung is divided into upper and lower lobes by oblique fissure whereas right lung is divided into upper, middle, lower lobes by oblique and horizontal fissures. In each lung, the oblique fissure begins from mediastinal surface above and behind the hilum and cuts the posterior border of the lung about 2.5 cm lateral to the junction of the T3 &T4 spine. Then, it runs along the costal surface, cuts the inferior border of the lung and will reappear on the mediastinal surface and ends at the lower end of the hilum. The horizontal fissure begins at the oblique fissure, courses along the costal surface, cuts the anterior border and appears to end at the hilum [1].

Finding of an accessory fissure in lung specimens is not uncommon but appreciating them on radiographs and Computed Tomography (CT) scans is difficult and hence, they are not appreciated as distinct entities or are completely misinterpreted. They usually occur at the boundaries between bronchopulmonary segments [2]. The commonly found accessory fissures are superior accessory fissure, inferior accessory fissure and left minor accessory fissure. The superior accessory fissure separates superior segment from the rest of the segments of lower lobe of lung, the inferior accessory fissure separates small infracardiac lobe from other segments of lower lobe of lung on the diaphragmatic surface and the left minor fissure separates the lingula from the other segments of upper lobe of left lung [2].

The fissures may vary in the degree of completeness and tend to divide the lobe into smaller divisions. Complete fissures have continuity of lobes at their bottom. The adjacent lobes are connected by a small portion of pulmonary tissues because of clefts it fails to reach the hilum in the incomplete fissures. The fissure may be absent altogether. The fissures are important for uniform expansion of lobes. They allow movements of lobes in relation to each other. This is more involved in the lower lobes at the time of breathing [3].

The appearance of accessory lung fissure may be seen as in relation to its completeness or its depth and that varies with X–ray and CT scan [4].

Knowledge of classical accessory lobes and fissures is necessary for radiological interpretation. This gives proper guidance to Cardio thoracic surgeons in performing segmental lung resection and lobectomies to have an uncomplicated perioperative outcome.

To assess the patterns of lobes and fissures of lung and to find out any variations in the fissures and lobes and hilar structures of the lungs in human cadavers and to find their clinical significance and to compare with them with the previous studies.

MATERIALS AND METHODS

Forty pairs of lung specimens (32 lung specimens from male cadavers and 8 lung specimens from female cadavers) free from pathological lesions, removed at the time of teaching for first year of MBBS from the 10% formalin fixed human cadavers from the Department of Anatomy, PSG Institute of Medical Sciences and Research, Coimbatore were included in the study. The study was conducted in the month of November 2016 to April 2017 after Ethical clearance (Proposal Number.16/291). The lung specimens were observed and were photographed for:

1. The patterns of lobes and fissures;
2. Variations in fissures, complete or incomplete;
3. Accessory fissure if any;
4. Hilar structures and its variations.

The anatomical classification proposed by Walker WS et al., was followed to determine the presence of completeness of fissures [5].

Abstract

Introduction Jugular foramen is one of the most fascinating foramina of the human skull. It is a complex, irregular bony canal located between the occipital bone and petrous part of the temporal bone. Many important structures, like 9th, 10th, 11th cranial nerves, meningeal branch of occipital and ascending pharyngeal arteries, internal jugular vein, and inferior petrosal sinus, are passing through it. The jugular fossa has a septum and a dome. The septum divides the foramen into two compartments: anteromedial compartment (pars nervosa) and posterolateral compartment (pars vascularis). The dome contains superior bulb of internal jugular vein. The architecture of the foramen varies in size, shape, and laterality besides differences related to sex and race. The morphometric measurements of jugular foramen are very important for neurosurgeries and head and neck surgeries.

Objectives The aim of the present study is to study the morphology of jugular foramen along with its dimensions, compartments, presence of partial or complete septa and dome.

Materials and Methods A total number of 60 jugular foramina were examined from 30 adult dry human skulls of unknown age and sex from the Department of Anatomy, PSG Institute of Medical Sciences and Research, Coimbatore. Measurements were taken using Digital Vernier calipers. Results were analyzed statistically.

Results The length, width, and surface area of jugular foramen of right side were measured and compared with the left side. Length and width of the jugular foramen was significantly higher on the right side. The presence of partial septum was found in 27 skulls (90%) on the right side and 29 skulls (99.7%) on the left side, respectively. Dome was present in 100% of the jugular foramina on the right side and 90% of the jugular foramina on the left side. Separate opening for inferior petrosal sinus was found in eight skulls (27%) on the right side and four skulls (13%) on the left side.

Conclusion This study provides a clear understanding of anatomy of jugular foramen and supports the reported morphometric variations. The morphometric variations of jugular foramen in the parameters of the skull are probably due to ethnic and racial factors. Knowledge of these variations is important for neurosurgeons and radiologists who deal with space occupying lesions of the structures surrounding jugular foramen. This study may be helpful for ENT surgeons while performing middle ear surgeries.

Morphometric Study of Atypical Lumbar Vertebrae and their Clinical Significance

MANICKA VASUKI KANDAVADIVELU ANAIMALAI[1], M NIRMALADEVI[2]

(cc) BY-NC-ND

ABSTRACT

Introduction: Lumbar pedicles are short and strong. They form an important part of lumbar spine and play role in transmission of weight from neural arch to the anterior part of vertebral column. Fractures, tumours and degenerative diseases of lumbar vertebrae are common. Pedicle screw fixation is needed to stabilise the vertebrae if required. Only few studies are available for atypical lumbar vertebrae.

Aim: To determine the various morphometric measurements of fifth lumbar vertebrae and to discuss the various applied aspects of the study.

Materials and Methods: This cross-sectional study was conducted for a period of one year from March 2016 to February 2017. Eighty-five adult human fifth lumbar vertebrae were identified with its atypical features and were examined. Various morphometric measurements- pedicle length, pedicle height and pedicle width, inter pedicle distance, transverse pedicle angle, sagital pedicle angle, chord length, vertebral body height, vertebral body width and vertebral canal measurements were taken using sliding vernier caliper with a least count of 0.1 mm. The data were entered in Microsoft excel and were analysed.

Results: A total of 85 fifth lumbar vertebrae were examined. Mean Pedicle Height of L5 vertebrae on both the sides were equal (8.4±3.74). Mean pedicle length of L5 vertebrae and mean transverse pedicular angle of L5 vertebrae were more on the right side than on the left side. Mean pedicle width, mean sagital pedicular angle and chord length of L5 vertebrae were more on the left side than on the right side in this study. All the measurements were compared with previous authors and found to have similar results.

Conclusion: Various morphometric measurements of pedicle of fifth lumbar vertebrae were taken in this study. These morphometric knowledge of the pedicles may be helpful for the orthopaedic surgeons and radiologists for proper selection of the pedicle screw and operative repair.

Keywords: Lumbar pedicle, Pedicular angle, Vertebral canal

INTRODUCTION

There are five lumbar vertebrae between the rib cage and the pelvis. The largest segments of the vertebral column are lumbar vertebrae and are characterised by the presence of accessory tubercles in transverse processes and mammillary tubercles in superior articular facets and by the absence of foramen transversarium in the transverse process (as only found in cervical region) and by the absence of facets on the sides of the body (as only found in thoracic region). They are designated L1-L5. The lumbar vertebrae support the weight of the body and permit movement [1].

Lumbar vertebral pedicles are short, thick and flat dorsal projections from superior part of the body at the junction of its lateral and dorsal surface. Pedicles form the concavity by the curved superior and inferior borders. Superior vertebral notch is shallower than inferior. When vertebrae articulate by the intervertebral disc and facet joints, these adjacent vertebral notches contribute to formation of intervertebral foramen. The foramen contains a segmental mixed spinal nerve and its sheaths, 2-4 recurrent meningeal nerves, variable number of spinal arteries and plexiform venous connections between the internal and external vertebral venous plexus. These structures particularly the nerves may be affected by trauma or diseases affecting the adjacent tissue. The complete perimeter of an intervertebral foramen consists of the notches, dorsal aspects of parts of adjacent vertebral bodies, the intervertebral disc and the capsule of the plane synovial facet joints [1].

The fifth lumbar vertebrae is the only atypical lumbar vertebrae differs from others by having massive body, its anterior surface is more extensive than posterior surface, transverse processes are substantial and they encroach on the sides of the body from the junctions of pedicles and laminae and the space between inferior articular processes are wider than that of superior articular processes [2]. Pedicles are thick, strong projections from the junction of lateral and dorsal surface of body of lumbar vertebrae. They are made up of inner cancellous and outer cortical bone. Pedicles have an important role in weight transmission from neural arch to anterior part of vertebral column in lumbar spine. Pedicle of fifth lumbar vertebrae helps in forward slide of L5 over S1. In the lumbar region, where the concavity is posterior, a part of compressive force of anterior column is transmitted to posterior [3].

Low back pain is a major public health problem all over the world. An estimated 75% of all the people may experience back pain at some time in their lives out of which most of them recover without surgery while 3-5% of the patient's present herniated disc and 1-2% have compression of nerve root. Treatment can be conservative or by surgical decompression-laminectomy in persons experiencing severe pain, claudication, neurological deficit or Myelopathy [4].

Fracture of lumbar pedicles is common in older age group due to osteoporosis and requires open surgical or percutaneous pedicle screw fixation to stabilise the vertebrae. Hence morphometric knowledge of lumbar pedicle is important [5]. Transpedicle fixation of the spine is a safe way of gaining effective vertebral stabilisation in the management of different spinal ailments fracture in lumbar spine, removal of tumours in vertebral bodies, gross spondylolesthesis and lumbar unsteadiness [6]. Fracture of the pedicle might result from the usage of relatively oversized screw. Hence, choice of the screw for operation is determined by the minimum diameter of the pedicle [7].

Transpedicle screws enable devices like plates, rods or wires to be applied to spine for fixation. The integrity of the pedicles and vertebral

Vascular foramina of navicular bone: a morphometric study

Vani Prathapamchandra, Praveena Ravichandran, Jayanthi Shanmugasundaram, Anbalagan Jayaraman, Rajasekar Sivaprakasam Salem
Department of Anatomy, Mahatma Gandhi Medical College & Research Institute, SBV University, Puducherry, India

Abstract: The navicular bone is supplied by more than one artery. The knowledge about the vascular foramina is important to understand the pathogenesis and management of navicular fractures. The objective of the present study is to analyze the morphology and morphometry of vascular foramina of dried human navicular bone in Indian population. The study was carried out by using 100 navicular bones (50 right and 50 left) collected from our institute and other medical institutes in and around Puducherry. The bones were macroscopically studied for vascular foramina with respect to its location, number, size, and shape. The data collected were statistically analyzed. The vascular foramina were present on dorsal, plantar, medial, and lateral surfaces of navicular bone. Kruskal-Wallis test followed by series of Mann-Whitney test for *post hoc* analysis showed the number of nutrient foramina observed on dorsal surface were significantly greater than those observed on the plantar (U=2,755, P=0.001), medial (U=43, P=0.001), and lateral (U=626.5, P=0.001) surfaces of the navicle. About 97.6% of foramina were circular and 2.5% were oval in appearance. About 96.7% of vascular foramina were <1 mm in size and 3.3% were ≥1 mm in size. Spearman's rank correlation coefficient done showed a strong, positive correlation between vascular foramina of <1 mm size and circular shape, which was statistically significant (r_s=0.981, P=0.001). We believe the present study has provided additional information on the vascular foramina of navicular bone and useful to surgeons in foot surgeries.

Key words: Navicular, Stress fractures, Vascular foramina

Received December 9, 2016; Revised April 20, 2017; Accepted May 6, 2017

Introduction

The navicular bone is one of the tarsal bones present on the medial side of the foot. The word navicular in Latin means a little ship [1]. It articulates with talus proximally and with the three cuneiforms distally. It also gives attachment to the tendon of tibialis posterior muscle [2]. The navicular bone derives its dorsal blood supply from a branch of dorsalis pedis artery and plantar blood supply from medial plantar branch of posterior tibial artery [3]. These branches enter the bone through the numerous vascular foramina present on the surface of the bone.

Navicular is the most frequently injured lesser tarsal bone and an important constituent in the transverse tarsal locking mechanism [1]. Acute navicular fractures are broadly classified into three types: avulsion fractures, tuberosity fractures, and body fractures [4]. Tuberosity and displaced body fractures are treated surgically while others are treated conservatively [5]. Navicular stress fracture is common among athletes and may have devastating consequences including avascular necrosis [6, 7].

Thus, the knowledge about the vascular foramina of the navicular bone becomes important for orthopaedic and vascular surgeons. An enhanced knowledge about the vascula-

AN INSIGHT INTO THE CIRCLE OF WILLIS, ITS VARIATION IN THE FORMATION AND COMPONENT VESSELS IN THE ADULT HUMAN CADAVERS

Prasanna LC, MD[1*], Andrade LS, PhD[1], Ravichandra P, MD[1], Hosapatna M, MD[1]

ABSTRACT

Introduction: *Circle of Willis, is an arterial circle, furnishing arterial supply to most of the brain and meninges. It is formed by the branches of anterior cerebral, middle cerebral and posterior cerebral arteries. However, its formation and a complete arterial circle, differs among individuals.*
Objectives: *In the present study, an attempt has been made to identify those variations and to segregate them into anterior and posterior circulation.*
Methods: *Thirty-two cadaveric brains were used for the study. The circle of Willis was identified and painted for better visualisation and then photographed.*
Results: *The results show that the variations of the anterior circulation exceeded those observed in the posterior circulation.*
Conclusions: *These variations would add on to the previous findings and thus help the neurosurgeons while operating this region.*
Key words: *Anterior cerebral artery; basilar artery; brain, cadaver; circle of Willis; communicating artery; internal carotid; posterior cerebral*

INTRODUCTION

The optimum functioning of an individual at any given point of time is highly dependent on constant neural activity going on in the brain, which reflects the high metabolic activity and the amount of energy requirement. This enormous demand is met with through a profuse network of blood vessels called the circle of Willis/circulus arteriosus cerebri which serve to convey an uninterrupted supply of nourishment and oxygen to the brain (1).

The circle is formed by the terminal branches of internal carotid and vertebro-basilar arterial systems in the interpeduncular fossa at the base of the brain. Although a complete circular channel almost always exists, one vessel is usually sufficiently narrowed to reduce its role as a collateral route rendering the circle functionally incomplete (2,3). The cerebral and communicating arteries may be absent, hypoplastic, double or even triple (4,5).

Considering the complexity of the developmental pattern in arterial circle, arterial variations occur mostly because of absence of a vessel normally present or abnormal persistence of an embryonic stage of a vessel (6).

Keeping in view the surgical importance of this region, the present study was undertaken to observe the formation of the Circle of Willis, in terms of origin and branching pattern of the component vessels, to evaluate any variations in the component vessels, and to note the frequency of occurrence of different patterns of variant circles (in terms of anterior and posterior circulations). The study not only adds clinically significant unreported variations to the literature but also finds out the prevalence of these variations in the study population.

MATERIAL AND METHODS

Thirty-two cadaveric specimens were procured from the routine dissection done for the undergraduate students in the Department of Anatomy, Kasturba Medical College, MAHE, Karnataka, India. After cleaning and carefully removing the overlying meninges without damaging the vessels, the pattern of formation and the existing anatomical variations of the constituent vessels of the circulus arteriosus cerebri was noted. Each specimen was photographed using a digital camera with the variations noticed. The observations were carried out by a single person. Ethical clearance was obtained from the institutional ethical committee (IEC). The number of the ethical clearance is IEC 331/2012.

ABSTRACT

BACKGROUND

In the modern medical era, laparoscopic approach to surgical conditions has reached to a height that it is performed even for malignant conditions. The minimal access surgery which has grown up from minimally invasive surgery has given us the faith that nearly all surgeries can be done by laparoscopy. The first laparoscopic cholecystectomy was done by Prof. Dr. Med Erich Muhe of Germany in the year 1985. About ten lakh cholecystectomies are performed ever year, of which 96% are done by laparoscopic method. Laparoscopic cholecystectomy is the most common laparoscopic procedure. By number of studies and research works, it is stated that laparoscopic cholecystectomy is superior to conventional open method because of its advantages like smaller incisions, early recovery, less post-operative pain and hospital stay with better cosmesis. However, laparoscopic cholecystectomy also has got its own disadvantages and complications. In 1992, an NIH consensus conference held in Bethesda approved laparoscopic cholecystectomy as the treatment of choice for symptomatic cholelithiasis. Conversion to open technique is a major morbidity of laparoscopy, as it loses its supremacy over open technique once the conversion takes place. With growing experience of laparoscopic cholecystectomy and completion of the learning curve, the indications for laparoscopic cholecystectomy have been extended approaching that of open cholecystectomy. Complications of laparoscopic cholecystectomy have been minimised to as low as 2 - 6%. However, a substantial proportion of patients had to be converted to open surgery because of technical difficulties or intraoperative complications. Conversion rates of 2.6% to 14% had been described in different studies. The factor to be considered with conversion is that it should never be considered a complication, but rather a correct judgement by the surgeon.

The aims of the present study are:

1. To study the incidence of conversion of laparoscopic cholecystectomy.
2. To analyse the reasons for the conversion of laparoscopic cholecystectomy owing to per operative complications like-
   a) Arterial injury,
   b) Hepatobiliary tract injury,
   c) Dense adhesions,
   d) Aberrant anatomy,
   e) Technical issues.

MATERIALS AND METHODS

This prospective observational study was conducted in patients who underwent laparoscopic cholecystectomy from November 2016 to November 2017 in the Department of General Surgery, Karpagam Faculty of Medical Sciences and Research, Coimbatore. There were totally 98 patients, of which 36 were males and 62 were females. The study has been done after the patient's informed consent. All these patients were evaluated in a proper manner as given in the proforma and had been assessed pre-operatively and operated under perfect anaesthetic fitness. This study mainly focussed on the patients who had been converted to open method. They were analysed further regarding the reasons for conversion to open method due to per-operative complications.

RESULTS

From November 2016 - November 2017, a total of 98 patients had undergone laparoscopic cholecystectomy in the Department of General Surgery, Karpagam Faculty of Medical Sciences and Research, Coimbatore. Out of 98 patients who underwent laparoscopic cholecystectomy, 13 patients (13.26%) were converted to open cholecystectomy owing to per-operative complications. All patients underwent cholecystectomy as an elective case. Though some morbidity was there in terms of post-operative complications, which we are not analysing, no mortality was reported.

CONCLUSION

After analysing the results of our study, we conclude that the incidence of conversion of laparoscopic cholecystectomy is 13.26%. The reasons for conversion in descending order of frequency are: 1. Dense adhesions (5.1%), 2. Difficult anatomy around Calot's triangle (3.06%), 3. Arterial injury (3.06%), 4. Hepatobiliary injury (1.02%) and 5. Technical issues (1.02%).

A CADAVERIC STUDY OF THE MYOCARDIAL BRIDGES

Suganya Saminathan[1], Vishnuvarthan Selvaraj[2]

[1]Assistant Professor, Department of Anatomy, Karpagam Faculty of Medical Sciences and Research, Coimbatore, Tamilnadu, India.
[2]Associate Professor, Department of General Surgery, Karpagam Faculty of Medical Sciences and Research, Coimbatore, Tamilnadu, India.

ABSTRACT

BACKGROUND

Myocardial bridging is a congenital anomaly, where a segment of an epicardial coronary artery is undercover of myocardial fibres for a variable distance and the underlying arterial segment is described as a mural coronary artery or a tunnelled artery. The history of myocardial bridges dates back to 1737 when it was first recognized by Reyman and then by Black in 1805. The first detailed post mortem examination of myocardial bridges was done by Geiringer in 1951 and the first radiological description was given by Portmann and Iwig in 1960. The bridged segment of the coronary artery is susceptible to various pathophysiological mechanisms leading to myocardial ischemia, especially when associated with other cardiovascular diseases. The myocardial bridges were initially thought to be innocent bystanders in the development of acute coronary syndromes. But in the last two decades, the outlook has changed with the increasing incidence of sudden cardiac deaths in young athletes, where myocardial bridges were the only finding at autopsy. The mechanism by which the myocardial bridges induce clinical symptoms is uncertain, but among the proposed are vasospasm, thrombus formation, endothelial dysfunction and impaired coronary flow reserve. Most important of these is the dynamic systolic compression of the tunnelled artery with sustained early diastolic diameter reduction.

The aim of this study is to provide more information on the incidence of myocardial bridges, arterial preponderance for myocardial bridging, the length of the bridged segment and multiple bridging.

MATERIALS AND METHODS

A descriptive study of fifty formalin fixed hearts from the department of anatomy were dissected by conventional dissection methods as guided by Cunningham.

RESULTS

Myocardial bridges were found in 18 (36%) hearts with a total of about 28 bridges. Most common artery involved was the anterior inter ventricular artery (66.6%), which even had multiple bridges over it. The mean length of the bridges was 26.54 mm.

CONCLUSION

From the present study, we infer that the presence of myocardial bridges in an unsuspected population is relatively higher. The definitive role of these bridges in acute coronary syndromes is yet uncertain. But owing to its higher rate of detection in those with myocardial ischemia, it is better to screen for the bridges along with other aetiological factors and treat the patients prophylactically. Of the imaging modalities, CT Coronary Angiography is found to be the investigation of choice. In the near future, holistic studies involving cadaveric, radiologic and clinical data are mandatory in researching the myocardial bridges.

BACKGROUND

Myocardial bridging is a congenital anomaly, in which an epicardial coronary artery lies in the myocardium for part of its course. The bridged segment of the coronary artery is susceptible to various pathophysiological mechanisms leading to myocardial ischemia, especially when associated with other cardio vascular diseases. Recently, myocardial bridges have become a main topic of interest owing to its probable causation of sudden cardiac death in young athletes.

Abstract

Objective: To study the normal and variant anatomy of the coronary artery ostia in south Indian population.

Introduction: Sudden cardiac deaths, especially in young are on the rise in recent days. Of all causes for sudden cardiac death, anomalous origins of coronary arteries also comprise a significant percentage. A cadaveric study of the origin of coronary arteries in an unsuspected population in south India paves way for understanding the normal variants & to determine the prevalence of anomalies and the need for screening for such anomalies.

Methods: Fifty adult heart specimens of unknown age and sex were dissected. The number of ostia and their positions within the respective sinuses were observed. Vertical and circumferential deviations of the ostia were observed.

Results: Of all hearts,the coronary arteries arose from the aortic sinuses in 99 hearts; no openings were present in the pulmonary artery or the non-coronary sinus. In one heart, the left coronary artery was absent, wherein the anterior inter ventricular artery and the left circumflex artery had independent origins from the aortic sinuses.The number of openings in the aortic sinuses varied from 2-3 in the present study; multiple ostia were seen in the right posterior sinus. The majority of the ostia lay below the sinutubular ridge (89% for RCA & 92% for LCA) and at or above the level of the upper margin of the cusps (84%). Left ostial openings were mainly centrally located (80%), whereas the right coronary ostia were often shifted towards the right posterior aortic sinus (59%).

Discussion: The usual location of the ostia was within the sinus and above the cusps, but below the sinutubular ridge. On occasion, normal variants like multiple ostia, vertical or circumferential shift in the position, and slit-like ostia may create confusion in interpreting the images and pose a difficulty during procedures like angiography, angioplasty, and coronary artery bypass surgery.

A Cadaveric Study on Coronary Dominance in South Indian Population

Suganya Saminathan

Assistant Professor of Anatomy, PSGIMSR, Coimbatore, Tamilnadu

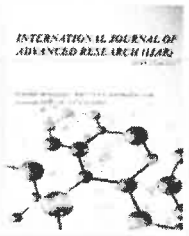
ABSTRACT

Background: Adequate insight about coronary dominance is important to understand coronary artery diseases, interpret the radiological images and to devise a proper treatment protocol in cardiovascular diseases. It determines the amount and the area of myocardium being perfused by the left or right coronary arteries.
Aim: The aim of the present study is to observe the origin of posterior interventricular artery which determines the coronary dominance.
Materials and Methods: The study was done on 50 formalin fixed adult heart specimens in the Institute of Anatomy, Madras Medical College irrespective of age, sex, socio-economic status, religion and education status. The coronary arteries were examined by gross dissection and analyzed statistically.
Results: Right dominance was seen in 26(52%) hearts, left dominance in 10 (20%) hearts and balanced or codominance was seen in 14(28%) hearts.
Discussion: The coronary artery dominance has an important clinical & surgical significance. Most of the studies have reported a higher percentage of right dominance including the present study.
Conclusion: The present study on coronary dominance would be of assistance to interventional cardiologist and cardiothoracic surgeons to plan ahead during angioplasty & coronary artery bypass surgeries. Coronary dominance is also considered as an indicator in the incidence of myocardial infarction & also used as a prognostic factor during recovery.

Key Words: codominance, coronary artery, coronary diseases, coronary dominance, coronary preponderance

INTRODUCTION

Coronary artery disease is one of the leading causes of mortality and morbidity across the world. Coronary artery disease is one of the major causes of death in developed countries. The incidence of coronary artery disease is increasing today in developing countries too, because of a sedentary life style, binge eating of junk food, reduced physical activity and stress. Recent trends show a rise in coronary artery associated death in young people. It is seen significantly both in males and females irrespective of socio economic status [1]. In the young, the primary cause of death is non atherosclerotic coronary abnormalities [1]. Dominance pattern of the heart has got important clinical significance. Left dominance was found to have significantly higher mortality than right dominance and codominance [2]. Dominance also plays important role in inferior wall infarcts of the heart. Inferior wall infarcts although less extensive than anterior infarcts, are more important as they can cause various degrees of atrioventricular blocks in approximately 30% of cases. The dominanat right coronary artery usually supplies atrioventricular node. Therefore an inferior wall infarcts caused by occlusion of right coronary artery will have higher risk of AV blocks [3].



The arterial supply to the heart is by two coronary arteries: Right coronary artery (RCA) and left coronary (LCA). There is a

Coracobrachialis, Struther's ligaments, median nerve, brachial artery.

Abstract

Coracobrachialis is the most medial of three anterior compartment muscles of arm. In some mammals it is tricipital in origin. The lower head is usually suppressed in man. Sometimes it is represented by a fibrous band, the ligament of Struther's. During our dissection regime of I[st] MBBS students in the department of anatomy, BJMC, we observed an accessory head of coracobrachialis on the right side of a male embalmed donated cadaver .The muscle was described as being functionally unimportant. However, the muscle has recently attracted interest with its potential use for contouring the infraclavicular area or covering the exposed axillary vessels specifically in postmastectomy reconstructive operations, muscle transfer for the treatment of paralysis, as a guide for axillary artery access and anaesthetic blockade of the brachial plexus.

Copy Right, IJAR, 2017,. All rights reserved.

Introduction:-

Coracobrachialis is the most medial of three anterior compartment muscles of arm.

It arises from the tip of coracoid process in common with the short head of biceps brachii and inserted by fleshy fibres to the medial border of the middle of the shaft of humerus where the nutrient foramen of the bone is usually located. The muscle is supplied by musculocutaneous nerve, a branch from the lateral cord. It is said that the nerve pierces the muscle and supplies it before piercing. It is a weak flexor of shoulder joint. Coracocobrachialis represents the adductor muscle of arm but such action is insignificant in man. In some mammals it is tricipital in origin. Upper 2 heads are fused to take origin from coracoid process and enclose the musculocutaneous nerve between them. The lower head is usually suppressed in man. Sometimes it is represented by a fibrous band, the ligament of struthers , which extends from an occasional bony projection, the supratrochlear spur, from the anteromedial surface of lower part of the humerus to the medial epicondyle. Median nerve or brachial artery may pass beneath the ligament which compress upon them producing vascular spasm or median nerve palsy[2]. The muscle was described as being functionally unimportant [3].

However, the muscle has recently attracted interest with its potential use for contouring the infraclavicular area[4,7] or covering the exposed axillary vessels specifically in postmastectomy reconstructive operations[5], muscle transfer for the treatment of paralysis, as a guide for axillary artery access and anaesthetic blockade of the brachial plexus[4,6].

Occipitalization of Atlas -

Dr. R. Raja Rajeshwari Devi[1*], Dr. Dipali Trivedi[2], Dr. Sucheta Chaudary[3]

[1]Third Year Resident, [2]Professor, [3]Professor & Head, Department Of Anatomy, B. J. Medical College, Ahmedabad, Gujarat.

Abstract:

Occipitalization of atlas is an osseous anomaly of the cranio-vertebral junction which occurs at the base of the skull in the region of the foramen magnum due to failure of segmentation and separation of the most caudal occipital sclerotome and the first cervical sclerotome during the first few weeks of foetal life. Atlas is the first cervical vertebra and the atlanto-occipital joint belongs to ellipsoid variety of synovial joints. It does not have a body like other vertebrae. Rarely, it gets occipitalized, where the lateral masses of the atlas vertebra fuse with the condyles of the occipital bone. One skull showing Occipitalization of Atlas was observed in the Department of Anatomy, B.J. Medical College, Ahmedabad, Gujarat. The knowledge of such a fusion may be of importance for radiologists, anaesthesiologists, orthopaedic and neurosurgeons because skeletal abnormalities at the cranio-cervical junction may result in sudden unexpected death. It can result in dysphagia, dysarthria or torticollis because of compression of cranial nerves. They should be aware that such an anomaly may exist without any typical symptomatic presentation, and thus, serious consequences of upper cervical spinal manipulative therapy may arise when a complete and adequate clinical assessment is missed.

Key words: Atlanto-Occipital joint, Atlas, Occipital bone, Occipitalization.

Introduction:

Atlas is the first cervical vertebra. It is ring like structure, consisting of anterior and posterior arches including two lateral masses along with the transverse processes. Two lateral masses bear a kidney shaped superior articular facets which articulate with occipital condyles to form atlanto-occipital joint of ellipsoid variety. Inferior articular facets of these lateral masses are almost circular and flat. It is oriented more obliquely to the transverse plane than the superior articular facet and faces more medially. Inferior articular facets of atlas form lateral atlanto-axial plane joint[1]. The anterior arch which forms anterior 2/5 of ring is slightly convex anteriorly and bears anterior tubercle. The anterior longitudinal ligament and longus colli muscles are attached to anterior tubercle. Its upper border provides attachment to the anterior atlanto-occipital membrane which often gets ossified. The posterior surface of the anterior arch bears concave circular facet for dens[1]. This condition was initially described by Rokitansky in 1844 and was demonstrated radiologically by Schuller in 1911 [2]. According to Yochum and Rowe[8] occipitalization

Abstract

Introduction: Knowledge of the normal and variant anatomy and anomalies of coronary circulation are vital component in the management of coronary artery disease. Any coronary artery disorder may reduce the blood supply to the heart and may lead to Myocardial infarction and death.

The aim of the study was to identify right coronary artery branching pattern and its variations. This may indirectly affect the patient's prognosis. This study describes the presence of normal arterial pattern and variations of right coronary artery in fifty heart specimens.

Materials and Method: This study was carried out on fifty formalin fixed adult human cadaveric heart specimens of both sexes. Visceral pericardium and subepicardial fats were removed. The right coronary artery and its branches were carefully dissected and followed till their termination.

Results: The right coronary artery was found to be arising from pulmonary trunk in three heart specimens in our study. Third coronary artery was found in one specimen. Sinu atrial nodal artery was arising from right coronary from right coronary artery in 94% and from left coronary artery in 6% Right dominance was observed in 35(70%) specimens. Fistula between right coronary artery and pulmonary artery was found in one specimen.

Conclusion: Branching pattern of right coronary artery is important for interpretation of coronary angiography and surgical revascularization of myocardium.

Keywords: Coronary artery, Sinu – atrial nodal artery, Fistula, pulmonary artery

Introduction

Coronary arteries represent the only supply to the myocardium. The two main coronary arteries, right and left coronary arteries arise from ascending aorta. Right coronary artery arises from right anterior aortic sinus and left coronary artery arises from left posterior aortic sinus. Patency of left coronary artery is vital for sufficient perfusion of the heart. The left coronary artery is responsible for irrigation, not only of most of the left ventricle, but also considerable portion of right ventricle.[1]

Right coronary artery runs between pulmonary trunk and right auricle and then runs downwards and is divided into two segments. First segment runs along the right border of the heart up to inferior border of heart. It gives right conus artery and supplies infundibulam of the right ventricle. If the right conus artery arises separately from the aortic sinus, then it is called as Third coronary artery. The second segment runs up to the apex as right marginal artery and supplies right ventricle. Sometimes it may runs in the posterior interventricular groove and may give rise to Posterior interventricular branch. Hence according to the origin of posterior interventricular artery, the coronary artery dominance has been considered. Right coronary artery ends in the crux by anastomosing with circumflex artery. It supplies the right atrium, right ventricle, atrioventricular septum and part of left ventricle.

Sinu atrial nodal artery may arise as atrial rami from initial segment of right coronary artery in 65% of the cases and from circumflex artery in 35% of the cases. Atrioventricular nodal artery arises as first septal ramus of posterior interventricular artery in 90% of the cases and 10% from the left coronary artery.[2]

Numerous studies on the variations of the arteries have been reported, but still it is better to study them further with respect to their clinical significance.

Coronary anomalies are a poorly understood topic in modern cardiology. Clinicians should be aware of such anomalies because some of them may produce sudden death.

The incidence of congenital coronary artery anomalies is 5–6%. By definition, the term anomalous or abnormal is used to define any variant form observed in less than 1% of the general population.[3]

The aim of the study is to identify the normal pattern of the coronary arteries and its variations. Though the modern techniques of revascularisation and coronary bypass surgeries are available, the knowledge about the anatomy of coronary arterial pattern and its variations are important for the cardiologists and cardio – thoracic surgeons.

Materials and Method

Fifty formalin fixed heart specimens of both sexes with intact coronary arterial pattern were studied in Anatomy department, PSG IMS & R, Coimbatore. The right coronary artery and its branches were carefully dissected out till their termination and were analysed for normal and abnormal patterns of coronary arteries.

Anatomical Study of Left Coronary Artery and its Variations–Cadaveric Study

ANAIMALAI KANDAVADIVELU MANICKAVASUKI[1], MEENAKSHISUNDARAM JAMUNA[2], THANASINGH DEBORAH JOY HEBZIBAH[3], MURUGESAN NIRMALADEVI[4], BEULAH PRIYALATHA SWAMICKEN[5], KUTTAN RADHIKA[6] K KALYANA SUNDARAM[7]

ABSTRACT

Introduction: Variations of the anatomy of the Coronary arteries are quiet common and have been reported previously in the literature. Right and Left coronary arteries which supply blood to the heart originates from the ascending aorta. Any coronary artery disorder may have serious implications by reducing the blood supply to heart leading to myocardial infarction and death.

Aim: To identify left coronary artery branching pattern and its variations.

Materials and Methods: Fifty formalin fixed wet specimens of heart of both sexes with intact coronary arterial pattern were collected and studied. The left coronary artery and its branches were carefully dissected out and were analysed for variable pattern in each specimen.

Results: Left coronary artery (LCA) was found to be hypoplastic in six (12%) specimens. In one specimen (2%), hypoplastic LCA was crossed by a vein and had communication with the vein. Trifurcation of LCA was seen in 17 (34%) specimens, Circumflex artery was short in one (2%) specimen. Kugel's artery was observed in three (6%) specimens. Median artery was found in seven specimens (14%). The left coronary artery and circumflex artery were absent in one (2%) specimen. In case where left coronary artery was absent, left anterior descending artery and circumflex artery were taking origin directly from left anterior aortic sinus. Left anterior descending artery showed variation in the form of short course (2 cm), discontinuous and embedded within myocardial tissue in 2% of cases each. However the circumflex artery also showed short course in one (2%) case.

Conclusion: The variations of the left coronary artery observed in the study are important for interpretation of coronary angiography, surgical revascularization of myocardium and embryological interpretations.

Keywords: Angiography, Circumflex artery, Kugel's artery, Left Anterior descending artery

INTRODUCTION

Left coronary artery (LCA) originates from left posterior aortic sinus. Patency of left coronary artery is vital for sufficient perfusion of the heart. The left coronary artery supplies most of the left ventricle and considerable portion of right ventricle [1].

LCA bifurcates into left anterior descending and circumflex artery and passes between pulmonary trunk and left auricle. The left anterior descending artery (LAD) runs in the left anterior interventricular groove and ends at the apex or may run up to crux of the heart [2]. Circumflex artery (CX) then runs in the posterior atrioventricular groove and ends at the crux of heart by anastomosing with right coronary artery (RCA) or may end before the crux. Sometimes posterior interventricular artery may arise from circumflex artery and may run in the posterior interventricular groove as left coronary dominance [2].

Numerous studies on the variations of the arteries have been reported [3,4]. Coronary artery (CA) variations is a topic of interest in modern cardiology. Cardiologists, cardiothoracic surgeons and radiologists should be aware of such anomalies because some of them may produce sudden death. Such rare coronary anomalies are poorly understood thus a detailed variation in them will add onto the existing clinical knowledge. The incidence of congenital coronary artery anomalies is 5–6%. By definition, the term anomalous or abnormal is used to define any variant form observed in less than 1% of the general population [3]. The incidence of all coronary anomalies is 0.23% in autopsy series and ranges between 0.3 to 5.6% in angiographic series [4]. The recent introduction of selective coronary angiography provides information about the normal coronary arterial pattern and also its variations [3].

The frequency of various anomalies of left coronary artery and the arterial dominance of the heart were observed in current study.

Numerous studies [3,4] on the variations of the arteries have been reported, but still it is better to study them further with respect to their clinical significance. The aim of the study was to identify the normal arterial branching pattern of left coronary artery and its variations in fifty heart specimens.

MATERIALS AND METHODS

The Cross sectional observational study was conducted from September 2016 to November 2016. The study was carried out after obtaining ethical clearance from Institutional ethical committee. Fifty formalin fixed heart specimens of both sexes with intact coronary arterial pattern were studied. Specimens with damaged arterial pattern were excluded. The left coronary artery and their branches were carefully dissected out till their termination and were analysed for variable patterns.

Length of the arteries were measured with the help of thread and Vernier caliper from the point of origin of the arteries to the point of termination. The course of artery was delineated and thread was passed around the vessel. Then thread with mark was measured using the Vernier caliper. Percentage incidence of various patterns was recorded and tabulated.

ABSTRACT

Introduction: Seven cervical vertebrae constitute the skeletal framework of the neck. Along with the other identification points, the cardinal feature of a cervical vertebra whether typical or atypical is the presence of Foramen transversarium on the transverse process. This foramen transmits the Vertebral artery, Vertebral vein and Sympathetic nerves. These foramina are known to have variations in size, shape and numbers and may be absent, incomplete or duplicate, which may lead to various symptoms. Their etiology is related with the variations in the course of the Vertebral artery due to developmental reasons.

Materials and methods: Three hundred dry human cervical vertebrae were collected and studied in the department of Anatomy, PSG Institute of Medical Sciences and Research, Coimbatore. We included all the Cervical vertebrae including Atlas, Axis and all other cervical vertebrae. We observed the presence, size, shape and variations of Foramen transversarium of cervical vertebrae during our study.

Observations and results: Out of three hundred Cervical vertebrae, One hundred and twenty five cervical vertebrae (42%) had variations of Foramen transversarium like Complete / incomplete Accessory foramen, triple foramen on one side, absence of foramen on one side and unequal size of foramen on both the sides. The different types of shapes of foramen transversarium were also analysed and tabulated. The areas of foramen transversarium were measured after measuring all the diameters.

Conclusion: Variations in the Foramen transversarium may indicate, the variation in the course of the Vertebral artery. The present study was important clinical implications for Head and neck and vascular surgeries. These variations should be kept in our mind during surgeries on cervical spine.

KEY WORDS: Foramen transversarium, shape, cervical vertebrae, accessory, absent and variations.

Anatomical Study of Lobes and Fissures of Lungs and its Clinical Significance-A Cadaveric Study

A K MANICKA VASUKI[1], K KAILASH KRISHNAN[2], M JAMUNA[3], DEBORAH JOY HEPZIBAH[4], K KALYANA SUNDARAM[5]

ABSTRACT

Introduction: The human lungs are divided by fissures into lobes which permit movements of lobes to one another. The fissures act as barriers to avoid the spread of the diseases. Knowledge of variations in the lobes and fissures of the lungs is important for the Radiologists to interpret the radiological images and for the cardiothoracic surgeons to plan for segmental resection or lobectomy.

Aim: To study the patterns of fissures and lobes of the lungs and their variations and to find their clinical implications and to compare with the previous studies.

Materials and Methods: Forty pairs of lungs were used for the study. They were obtained from formalin fixed cadavers. The patterns of lobes, fissures and hilar anatomy of lungs and its variations were noted and specimens were photographed.

Results: In the present study, incomplete horizontal fissure was found to be in 23(57.5%) right lung specimens and incomplete oblique fissure was observed in 20(50%) left lung specimens. Absence of horizontal fissure was about 10(25%) and oblique fissure was about six (15%) in right lung specimens. Absence of oblique fissure was about four (10%) in left lung specimens. According to Craig and Walker classification, Grade 1 and Grade 3 fissures were found to be more in both the lung specimens. Accessory fissure was observed in 5 (12.5%) specimens in the right lung and 10 (25%) specimens in the left lung. Single lobe was observed in both the lungs, 7.5% in the right lung and 5% in the left lung.

Conclusion: Variations of fissures and lobes and of hilar anatomy is of great significance. Knowledge of these variations is important for Radiologists and Cardiothoracic surgeons for interpreting the data and to plan for the surgeries.

Keywords: Accessory fissure, Hilar anatomy, Lobectomy

INTRODUCTION

The lungs are a pair of essential organs of respiration located within the thoracic cavity, on either side of heart and other mediastinal contents. Each lung is half – conical in shape, divided into lobes by fissures. Anatomically, left lung is divided into upper and lower lobes by oblique fissure whereas right lung is divided into upper, middle, lower lobes by oblique and horizontal fissures. In each lung, the oblique fissure begins from mediastinal surface above and behind the hilum and cuts the posterior border of the lung about 2.5 cm lateral to the junction of the T3 &T4 spine. Then, it runs along the costal surface, cuts the inferior border of the lung and will reappear on the mediastinal surface and ends at the lower end of the hilum. The horizontal fissure begins at the oblique fissure, courses along the costal surface, cuts the anterior border and appears to end at the hilum [1].

Finding of an accessory fissure in lung specimens is not uncommon but appreciating them on radiographs and Computed Tomography (CT) scans is difficult and hence, they are not appreciated as distinct entities or are completely misinterpreted. They usually occur at the boundaries between bronchopulmonary segments [2]. The commonly found accessory fissures are superior accessory fissure, inferior accessory fissure and left minor accessory fissure. The superior accessory fissure separates superior segment from the rest of the segments of lower lobe of lung, the inferior accessory fissure separates small infracardiac lobe from other segments of lower lobe of lung on the diaphragmatic surface and the left minor fissure separates the lingula from the other segments of upper lobe of left lung [2].

The fissures may vary in the degree of completeness and tend to divide the lobe into smaller divisions. Complete fissures have continuity of lobes at their bottom. The adjacent lobes are connected by a small portion of pulmonary tissues because of clefts it fails to reach the hilum in the incomplete fissures. The fissure may be absent altogether. The fissures are important for uniform expansion of lobes. They allow movements of lobes in relation to each other. This is more involved in the lower lobes at the time of breathing [3].

The appearance of accessory lung fissure may be seen as in relation to its completeness or its depth and that varies with X–ray and CT scan [4].

Knowledge of classical accessory lobes and fissures is necessary for radiological interpretation. This gives proper guidance to Cardio thoracic surgeons in performing segmental lung resection and lobectomies to have an uncomplicated perioperative outcome.

To assess the patterns of lobes and fissures of lung and to find out any variations in the fissures and lobes and hilar structures of the lungs in human cadavers and to find their clinical significance and to compare with them with the previous studies.

MATERIALS AND METHODS

Forty pairs of lung specimens (32 lung specimens from male cadavers and 8 lung specimens from female cadavers) free from pathological lesions, removed at the time of teaching for first year of MBBS from the 10% formalin fixed human cadavers from the Department of Anatomy, PSG Institute of Medical Sciences and Research, Coimbatore were included in the study. The study was conducted in the month of November 2016 to April 2017 after Ethical clearance (Proposal Number.16/291). The lung specimens were observed and were photographed for:

1. The patterns of lobes and fissures;
2. Variations in fissures, complete or incomplete;
3. Accessory fissure if any;
4. Hilar structures and its variations.

The anatomical classification proposed by Walker WS et al., was followed to determine the presence of completeness of fissures [5].

Abstract

Background and Aims: Profunda femoris artery is the largest branch of femoral artery. It is the principal supply to the muscles of the thigh as well as head and neck of femur. Its branches form anastomosis around the head of the femur. Profunda femoris artery is also used for arteriography. It is frequently used in vascular reconstructive procedures in the proximal thigh. It forms main route of collateral circulation in occlusion of femoral artery. The study of variation of Profunda femoris artery is of great value for radiologists and surgeons during diagnostic and surgical intervention.

Aim of the study is to observe the origin of Profunda femoris artery, to measure the distance between midinguinal point and site of origin of Profunda femoris artery and to study the anatomy of Profunda femoris artery and its branches and to find out any variations in its course and its branches.

Materials and Methods: The study was conducted as a prospective study from April 2018 to October 2018. All the lower limbs with the intact Femoral artery and Profunda femoris artery and their branches were included. Femoral artery and its branches had got cut during dissection were not included in the study. Thirty two Profunda femoris arteries (20 on the right side and 12 on the left side) were studied in the department of Anatomy. The femoral triangle was exposed by making incisions along the inguinal ligament from pubic symphysis to anterior superior iliac spine. Midpoint was taken as Midinguinal point (MIP). MIP was marked with a coloured pen. The distance between MIP and the site of origin of

Abstract

Introduction Jugular foramen is one of the most fascinating foramina of the human skull. It is a complex, irregular bony canal located between the occipital bone and petrous part of the temporal bone. Many important structures, like 9th, 10th, 11th cranial nerves, meningeal branch of occipital and ascending pharyngeal arteries, internal jugular vein, and inferior petrosal sinus, are passing through it. The jugular fossa has a septum and a dome. The septum divides the foramen into two compartments: anteromedial compartment (pars nervosa) and posterolateral compartment (pars vascularis). The dome contains superior bulb of internal jugular vein. The architecture of the foramen varies in size, shape, and laterality besides differences related to sex and race. The morphometric measurements of jugular foramen are very important for neurosurgeries and head and neck surgeries.

Objectives The aim of the present study is to study the morphology of jugular foramen along with its dimensions, compartments, presence of partial or complete septa and dome.

Materials and Methods A total number of 60 jugular foramina were examined from 30 adult dry human skulls of unknown age and sex from the Department of Anatomy, PSG Institute of Medical Sciences and Research, Coimbatore. Measurements were taken using Digital Vernier calipers. Results were analyzed statistically.

Results The length, width, and surface area of jugular foramen of right side were measured and compared with the left side. Length and width of the jugular foramen was significantly higher on the right side. The presence of partial septum was found in 27 skulls (90%) on the right side and 29 skulls (99.7%) on the left side, respectively. Dome was present in 100% of the jugular foramina on the right side and 90% of the jugular foramina on the left side. Separate opening for inferior petrosal sinus was found in eight skulls (27%) on the right side and four skulls (13%) on the left side.

Conclusion This study provides a clear understanding of anatomy of jugular foramen and supports the reported morphometric variations. The morphometric variations of jugular foramen in the parameters of the skull are probably due to ethnic and racial factors. Knowledge of these variations is important for neurosurgeons and radiologists who deal with space occupying lesions of the structures surrounding jugular foramen. This study may be helpful for ENT surgeons while performing middle ear surgeries.

Electrocardiographic Changes in COVID-19 Patients: A Hospital-based Descriptive Study

Deepalakshmi Kaliyaperumal[1], Kumar Bhargavi[2], Karthikeyan Ramaraju[3], Krishna S Nair[4], Sudha Ramalingam[5], Murali Alagesan[6]

Abstract

Background: Coronavirus disease-2019 (COVID-19) infection is a multisystem disease not restricted to the lungs. It has a negative impact on the cardiovascular system by causing myocardial damage, vascular inflammation, plaque instability, and myocardial infarction. The presence of myocardial injury is a poor prognostic sign. Electrocardiogram (ECG), a simple bedside diagnostic test with high prognostic value, can be employed to assess early cardiovascular involvement in such patients. Various abnormalities in ECG like ST-T changes, arrhythmia, and conduction defects have been reported in COVID-19. We aimed to find out the ECG abnormalities of COVID-19 patients.

Methods: We performed a cross-sectional, hospital-based descriptive study among 315 COVID-19 in-patients who underwent ECG recording on admission. Patients' clinical profiles were noted from their records, and the ECG abnormalities were studied.

Results: Among the abnormal ECGs 255 (81%), rhythm abnormalities were seen in 9 patients (2.9%), rate abnormalities in 115 patients (36.5%), and prolonged PR interval in 2.9%. Short QRS complex was seen in 8.3%. QT interval was prolonged in 8.3% of the patients. Significant changes in the ST and T segments (42.9%) were observed. In logistic regression analysis, ischemic changes in ECG were associated with systemic hypertension and respiratory failure.

Conclusion: In our study, COVID-19 patients had ischemic changes, rate, rhythm abnormalities, and conduction defects in their ECG. With this ongoing pandemic of COVID-19 and limited health resources, ECG-a simple bedside noninvasive tool is highly beneficial and helps in the early diagnosis and management of cardiac injury.

Keywords: Coronavirus disease-2019, Electrocardiogram change, Rate abnormalities, ST-T changes.

Indian Journal of Critical Care Medicine (2022): 10.5005/jp-journals-10071-24045

Introduction

A cluster of pneumonia cases were reported due to "severe acute respiratory syndrome coronavirus 2" (SARS-CoV-2) at the end of 2019 in the city of Wuhan, in the Hubei Province of China. Soon coronavirus disease-2019 (COVID-19) was declared as a pandemic owing to its rapid spread across the countries.[1] Initially regarded as a respiratory infection, COVID-19 is now known to affect all major systems in the body. Quite a lot is discussed in literature last year about COVID-19 and its effect on lungs and systemic response. However, very little is debated about cardiovascular involvement in COVID. It has been observed that lung involvement is more severe in patients with preexisting cardiac involvement. However, in sharp contrast new-onset cardiac involvement is also noted in a few patients and few patients do present with cardiac symptoms alone without lung involvement.[2] The spectrum of presentation is wide-ranging from patients having no cardiac disease at all, asymptomatic but with elevated cardiac markers, having symptoms of overt cardiac disease such as angina, cardiogenic shock, heart failure, cardiac arrhythmias, and sudden cardiac death.

Arrhythmia and acute cardiac injury were reported in 16.7 and 7.2% of the COVID patients.[3] In addition to the systemic inflammatory response, the physiological mechanisms identified to cause cardiac involvement in COVID-19 patients are hypoxemia-related myocardial cell injury and endothelial cell damage due to upregulated expression of angiotensin-converting enzyme 2 (ACE 2) in the heart and lungs.[4]

The electrocardiogram (ECG) changes reflect cardiac involvement with diverse manifestations. Arrhythmia and conduction defects are found to be more prevalent among SARS-CoV-2-infected individuals.[5] Myocardial ischemia, myocarditis, shock, hypoxia, and electrolyte abnormalities were the factors identified to cause arrhythmias.[6] The presence of cardiac involvement may imply poor prognosis and an adverse outcome.[7] Therefore, it is pertinent to assess and monitor the cardiac abnormalities paving way for a prompt action. ECG, a simple bedside diagnostic test with high prognostic value, can be employed to assess cardiovascular involvement in COVID-19 patients. We aimed to find out the ECG abnormalities of patients with SARS-CoV-2 infection.

Characterization of cardiac autonomic function in COVID-19 using heart rate variability: a hospital based preliminary observational study

https://doi.org/10.1515/jbcpp-2020-0378
Received November 13, 2020; accepted February 18, 2021; published online March 11, 2021

Abstract

Objectives: The novel corona virus disease, which was initially reported in China in late 2019, has become a global pandemic affecting 330 million cases. COVID-19 affects predominantly the respiratory system, in addition to other organ systems, mainly the cardiovascular system. One of the hypotheses is that virus entering the target cells by binding to angiotensin converting enzyme 2 affecting hypothalamic pituitary axis could lead to dysautonomia which is measured by heart rate variability (HRV). HRV is a non-invasive measure of autonomic function that facilitates identification of COVID-19 patients at the risk of developing cardiovascular complications. So, we aimed to assess HRV in COVID patients and compare between COVID patients and normal controls.

Methods: In a case control design, we compared 63 COVID-19 infected patients with 43 healthy controls matched for age and gender. Along with clinical characterization, heart rate variability was evaluated using ambulatory 5 min ECG in lead II and expressed in frequency and time domain measures. Statistical analysis was performed using SPSS 17.0.

Results: Mean age of the study population was 49.1 ± 14.2 years and 71 (66.9%) were males. Frequency domain measures high (HF) and low (LF) frequency powers were significantly decreased in COVID-19 patients compared to controls. HF/LF and LF/HF ratios were not different between groups. Time domain measures rMSSD (root mean square of successive RR interval differences) and SDNN (standard deviation of NN intervals) were significantly increased among COVID-19 subjects. COVID-19 infection was associated with increased parasympathetic activity as defined by rMSSD>40 {adjusted odds ratio 7.609 (95% CI 1.61–35.94); p=0.01} and SDNN>60 {adjusted odds ratio 2.620 (95% CI 1.070–6.44); p=0.035} after adjusting for age, gender and comorbidities.

Conclusions: Our study results showed increased parasympathetic tone in COVID patients. Early diagnosis of autonomic imbalance in COVID patients is needed to plan management and limit progression of disease.

Keywords: heart failure; pulmonary hypertension; right heart.

Introduction

In December 2019, a novel coronavirus disease (nCoV) epidemic emerged in Wuhan City, Hubei Province, China. Owing to its high transmissibility and infectivity rate it spread across the world and WHO declared it as a pandemic on March 11, 2020 [1, 2]. As this virus predominantly affects the respiratory system it has been renamed as severe acute respiratory syndrome coronavirus 2 (SARS CoV-2) and the disease caused by this virus has been named as corona virus disease 19 (COVID-19) [3].

COVID-19 shows wide range of clinical presentations ranging from asymptomatic/mild symptoms (fever, cough, dyspnea, myalgia, fatigue, anosmia, dysgeusia and diarrhea) to severe illness like acute respiratory distress syndrome (ARDS), arterial and venous thrombosis, myocarditis and varieties of neurological manifestations [4–7]. A report from WHO says that "80% of infections are mild or asymptomatic, 15% are severe infections and 5% are critical infections" [8]. Co-morbid conditions like obesity, type 2 diabetes mellitus, coronary artery disease, chronic liver disease, chronic kidney disease and chronic respiratory disease are known to be risk factors for developing severe disease [9–11]. Wide spectrum of manifestations is explained by SARS CoV-2 having target cells in multiple organs and systems like respiratory tract including lung parenchyma,

Association between Quality of Sleep and Academic Performance in Medical Students: A Preliminary Study

K. Deepalakshmi[1], S. Vijayabaskaran[2], R. Thamaraiselvi R.[3], R. Nagashree[4]

[1]Associate Professor, [2]Assistant Professor, Department of Physiology, PSG Institute of Medical Sciences and Research, Coimbatore, [3]Tutor, Department of Physiology, Stanley Government Medical College, Chennai, [4]Professor, Department of Physiology, PSG Institute of Medical Sciences and Research, Coimbatore

Abstract

Background: Medical students are more prone to daytime sleepiness, sleep deprivation and irregular sleep schedules, as they have less free time, longer courses and working hours compared to other professional students.

Aim: To assess the quality of sleep and to find out the association between sleep quality and academic performance among medical students.

Methodology: This cross sectional study was conducted among 176 medical students. They were subjected to Pittsburgh Sleep Quality Index (PSQI) questionnaire to assess their sleep quality over a one-month period. A PSQI global score of 5 and greater than 5 was considered indicative of poor sleep. Academic performance was assessed from their internal assessment scores conducted during that period. The data was analyzed using the unpaired students 't' test and Pearson's correlation test

Results: Our study included 176 students from all the phases of MBBS curriculum. 24 percentage students had poor quality of sleep. In our study, there was no statistically significant difference in the performance of good sleepers (57.94 ±18.06) and poor sleepers (58.80 ±17.37) with a p value of 0.785. Our study results showed a negative correlation between global PSQI scores and assessment scores of the students ($r = 0.57$ and $P = 0.449$).

Conclusion: In our study association between sleep quality and academic performance was not statistically significant. Assessment of sleep quality helps to indentify the students at risk and plan the specific programs to improve the quality of sleep.

Keywords: *Sleep quality, academic performance, medical students.*

Introduction

Medical students are exposed to multitude of changes when they enter into their professional life after completing their school education. Owing to highly demanding professional and academic requirements medical students are considered to be a vulnerable population of poor quality of life.[1] Medical students have compromised quality of life as they have to undergo long and intensive academic years.

Medical students are more prone to daytime sleepiness, sleep deprivation and irregular sleep schedules as they have less free time, longer courses and working hours compared to other professional students. Over the period of time, poor sleep quality will lead to chronic inability to recover from stressful conditions

COMPARISON OF TIME DOMAIN MEASURES OF SHORT TERM HEART RATE VARIABILITY IN TYPE 2 DIABETIC PATIENTS WITH AND WITHOUT MICROALBUMINURIA- A PRELIMINARY STUDY

K Deepalakshmi*, S Vijayabaskaran **,R Nagashree***,

*Associate Professor, ** Assistant Professor, *** Professor Department of Physiology, PSG Institute of Medical Sciences and Research, Coimbatore 641004

Abstract: Background & objectives: Diabetes is a complex and multi-factorial endocrine disorder with increased prevalence worldwide. Microalbuminuria is an independent marker of endothelial dysfunction and increases the risk of arrhythmia and atherosclerosis that affects cardiac autonomic function. Cardiovascular pathology remains a primary cause of death in patients with diabetes mellitus .So we aimed to compare time domain measures of short term Heart Rate Variability (HRV) in type 2 diabetic patients with and without microalbuminuria **Methods:** This prospective comparative study was conducted among diabetic patients with (n=14) and without (n=15) microalbuminuria. Patients with hypertension, dyslipedemia, coronary artery disease, cerebrovascular accident, family history of young MI, hyper or hypothyroidism and on beta-blocker treatment were excluded. Study participants were subjected to general clinical examination. Presence of microalbuminuria and their HbA_1C values were noted from their clinical records. Heart rate variability was assessed using an ambulatory ECG system in lead II for 5 minutes. The series of RR intervals obtained was subjected to time domain analysis. Time domain measures SDNN, rMSSD and NN50and pNN50 were obtained. **Results:** 29 diabetic patients participated in the study, out of which 14 were diabetics with microalbuminuria, and 15 were without microalbuminuria. On analysis of short-term time domain measures of HRV, the mean SDNN was decreased (51 ± 11.5) in diabetic patients with microalbuminuria, when compared to diabetic patients without microalbuminuria (54.96 ± 10.93) with p value 0.45. pNN50 and rMSSD was decreased in diabetic patients with microalbuminuria (1.09 ± 2.73, 14.32±8.17) when compared to diabetic patients without microalbuminuria (1.82 ± 3.06, 18.99 ± 7.71) with p value 0.51 & 0.13 respectively .

Conclusion: Our findings indicate cardiac autonomic function was altered in diabetic population with microvascular involvement

Key Words: Microalbuminuria, Heart rate variability, Diabetes Mellitus

Introduction:

Diabetes mellitus is a complex and multi-factorial endocrine disorder affecting all age groups .Its prevalence has increased worldwide and it was estimated to be 2.8% in 2000 and 4.4% in 2030.[1] Microalbuminuria is a independent marker of endothelial dysfunction and known to cause cardiovascular morbidity and mortality among individuals with diabetes.[2] Microalbuminuria increases the risk of arrhythmia and atherosclerosis which affects cardiac autonomic function.[3]

Early recognition of autonomic dysfunction plays a significant role in prediction of cardiovascular mortality in diabetes mellitus. Decreased Heart Rate Variability (HRV) is associated higher risk (32–45%) of cardiovascular morbidity and mortality in diabetic individuals and as well in healthy controls.[4,5,6]

HRV is a reliable non invasive tool used in the assessment of cardiac autonomic function. Evaluation of HRV by time domain measure is the simplest and most popular method.[7] Parameters considered during time a domain analysis are standard deviation of all R-R intervals (SDNN), root mean square of successive RR- interval differences (RMSSD) and number of intervals differing by > 50ms from adjacent interval (NN50) and

ABSTRACT

Background: Shift work has become a social and economic necessity, as most sectors like the healthcare require round the clock operation. Extended and variable working hours leads to desynchronization of the body's circadian rhythm. Thus, shift work is commonly associated with various physical and mental disorders like insomnia, fatigue, depression, anxiety, cognitive impairment, etc. The aim of the study was to assess the prevalence of sleep deprivation and hence, the levels of fatigue, depression and anxiety among shift working nurses.
Methods: This cross-sectional study was conducted among shift working nurses. Sleep deprivation among 97 female and 3 male healthy nurses of age 20-50 years was assessed by Epworth Sleepiness Scale (ESS). Fatigue Severity Scale, Patient Health Questionnaire (PHQ-9) and Hamilton Anxiety Rating Scale (HAM-A) were used for assessing fatigue, depression and anxiety respectively. Level of Sleep deprivation, Depression and Anxiety were expressed in Proportion. Difference in fatigue levels during day and night shift was analyzed using Wilcoxon Signed-Ranks Test.
Results: Analysis of ESS, showed, 69% of shift working nurses had poorer sleep quality. The level of fatigue experienced following a night shift work was significantly higher than that following day shift work ($Z = 3.34$, $p = 0.0008$). Moderate to severe depression and anxiety was observed in 15% and 16% of the nurses working in shift.
Conclusions: Thus, shift work is inevitably associated with sleep deprivation. There exists an increased prevalence of fatigue, depression and anxiety among shift working nurses.

Keywords: Anxiety, Depression, Fatigue, Shift work, Sleep deprivation

INTRODUCTION

Sleep plays vital role in promoting good physical, mental and emotional health. Adequate quantity and quality of sleep each night is necessary for the maintenance of homeostasis. Sleep deprivation (SD) is a condition where 'an individual is either partially or completely prevented from obtaining their usual amount of sleep in 24 hours'.[1] This serious health hazard is likely to result from inadequate quantity of sleep, poor quality of sleep, or sleep at the wrong time of the day. SD is common public health problem that affect individuals of all age groups. The need for nonstop work in certain sectors like industrial set up and health care has forced the workers into shift work.[2] Cognitive performance worsens with progressive sleep deprivation, as evidenced by its effects on general intellect, mental speed, response inhibition, reaction time, attention, working memory and other complex cognitive functions like decision making and multitasking.[3] Shift work has resulted in lifestyle modifications that affect the biological clock, i.e. the circadian rhythm. Disruption of this natural rhythm for a

Effect of Age and Hypertension on Cognition: A Cross-sectional Study

DEEPALAKSHMI KALIYAPERUMAL[1], VIJAYABAS KARAN SHANMUGA VARADHARAJAN[2], VARSHA VISWANATHAN[3], MURALI ALAGESAN[4]

ABSTRACT

Introduction: Cognitive impairment has evolved as major health and social issue. As age advances cognitive tasks involving processing speed, working memory and executive function get affected. Cognitive impairment is also influenced by modifiable risk factors such as hypertension, diabetes mellitus and hypercholesterolemia.

Aim: To find out the effect of age and hypertension on cognition.

Materials and Methods: The total study participants were divided into three groups based on their age as group I (18-29) group II (30-59) and group III (above 60) with 20 participants (n= 20) in each group. Their cognition was assessed using Mini Mental State Examination, Picture word Learning test, Stroop colour word test, Letter digit coding test, Verbal fluency and Logic memory tests. Disease history and known co morbidities (hypertension) were noted. Post-hoc test (Bonferroni) was employed to assess age-wise comparison of cognition and Pearson's chi-square test was used to compare cognition between hypertensive and normotensives.

Results: Group II had impaired cognition when compared with group I (p-value- 0.000). Group III had impaired cognition when compared with group I (p-value- 0.000) and group II (p-value 0.001). The hypertensives in group II and III had statistically significant impairment in cognition when compared with normotensives (p-value -0.001) in the same group.

Conclusion: Cognitive functions are impaired as a result of increase in age. Furthermore, there is also a significant decrease in cognitive functions amongst those suffering from hypertension. Hence, we conclude there is decrease in cognitive function as age advances and the co-existence of hypertension hastens this decline.

Keywords: Cognitive impairment, Mini mental state examination, Old age

INTRODUCTION

The word cognition comes from the Latin verb *cognosco* meaning 'I know, perceive' or 'to recognise or conceptualise. Cognitive functions are those which include cerebral activities that lead to knowledge and encompass reasoning, memory, attention and language. Ageing can also have diverse effects on cognitive function. The spectrum of cognitive decline ranges from normal cognitive ageing (healthy" or "successful" Ageing), mild Cognitive impairment (does not prevent them from performing daily activities) and severe cognitive deficits (impede the ability to live independently [1]. Cognitive impairment has evolved as major health and social issue as the life span of both men and women has increased dramatically. Cognitive impairment accounts for about 40% of hospital admissions among the older individuals [2]. As age advances cognitive tasks involving rapid processing and transformation of information, which includes processing speed, working memory and executive function gets affected [3].

These age-related cognitive declining results from structural and functional changes that affect neuronal structure like loss of synapses and dysfunction of neuronal networks [4]. Cognitive impairment is also influenced by modifiable risk factors such as hypertension, diabetes mellitus and hypercholesterolemia [5]. Among these factors hypertension, which causes vascular changes resulting in cerebral infarction and diffuse ischaemic changes contribute to cognitive impairment [6].

Age related cognitive decline is already stated by several studies [7,8] earlier; but none of them used six tests which examine the different domains of cognition and there are only a few studies [9,10] that have included co-morbid condition such as hypertension to study the decline in cognition as age advances.

Hence, we aimed to conduct a study to find out the effect of age on cognition with the help of series of cognitive assessment tests. In this study we also analysed the effect of more common and prevalent (33.8% in urban parts of India) [11] co-morbid condition, hypertension on cognition especially amongst the vulnerable elderly group of individuals.

MATERIALS AND METHODS

This cross-sectional study was conducted during the month of January 2014 for the period of two months among students, staff and patients of PSG Institute of Medical Sciences and Research, Coimbatore after obtaining the ethical clearance from institutional ethical committee (Ethics registration file No 13/328). A total of 60 participants after getting their written informed consent were included in the study. Participants were grouped based on their age Group-I (18-29), Group II (30-59), Group III (above 60). Participants younger than 18 years of age and those suffering from co-morbidities apart from hypertension such as diabetes mellitus; chronic respiratory diseases, chronic liver diseases, thyroid diseases, renal and neurological disorders were excluded from the study. Hypertensive participants (Systolic BP of more than 140mm Hg, Diastolic BP of more than 90 mm Hg) for more than two years duration and on anti hypertensive treatment were included the study.

Study participants were assessed for their cognitive performance by using a series of tests. An initial interview of subjects was conducted where they were asked about their education, occupation and age at retirement for group III. Disease history and known co-morbidities (hypertension) were noted.

Mini Mental State Examination [12]

It is an 11 question measure that tests five areas of cognitive function: orientation, registration, attention and calculation, recall and language. The maximum score is 30, a score of 23 or lower is indicative of cognitive impairment.

ABSTRACT

Background: Abnormal esophageal motility and low Lower Esophageal Pressure (LES) play an integral role among various etiologies implicated in pathogenesis and severity of Gastro Esophageal Reflux Disease (GERD). Delayed clearance of refluxate leads to prolonged mucosal exposure to gastro duodenal contents which promotes esophagitis and its complications. To find out the association of ineffective esophageal motility (IEM) and low Lower Esophageal Sphincter (LES) pressure with endoscopic esophagitis in patients presenting with symptoms of GERD. Settings and designs: Prospective cross sectional study done in a tertiary medical care center in south India from October 2016 to March 2017.

Methods: This cross sectional study was carried out among patients presenting with symptoms of GERD (heart burn and regurgitation,) at least twice per week for past three months. Based on their endoscopy findings patients with GERD are grouped into two having erosive and nonerosive reflux disease. After general and systemic clinical examination, High resolution Manometry was performed, and data was analyzed using Trace 1.2.3a V software. Statistical methods: Data was analysed using SPSS version 19. Chi square test was used to analyze categorical variables and independent 't' test was used for continuous variables.

Results: A total of 66 patients with GERD symptoms were subjected to esophageal manometry. Out of these 66 patients 42 were males and 22 were females with their mean age 40.82±12.86 years. Among 66 patients presented with GERD symptoms 26.7% were found to have ineffective esophageal motility and only 11.7% had low LES pressure. Ineffective esophageal motility was also found to be more common among older age group individuals with their mean age being 44.64 ±14.154. Among the patients with erosive reflux disease (70.21%), 66.7% had low LES pressure and 75 % had IEM; the association was not statistically significant.

Conclusions: The incidence of Ineffective esophageal motility in patients with GERD is found to be higher than that of low LES pressure. There was no significant association observed between IEM and low LES pressure with endoscopic esophagitis in patients with GERD.

Effects of Sleep Deprivation on the Cognitive Performance of Nurses Working in Shift

DEEPALAKSHMI KALIYAPERUMAL[1], YAAL ELANGO[2], MURALI ALAGESAN[3], ISWARYA SANTHANAKRISHANAN[4]

ABSTRACT

Introduction: Sleep deprivation and altered circadian rhythm affects the cognitive performance of an individual. Quality of sleep is compromised in those who are frequently involved in extended working hours and shift work which is found to be more common among nurses. Cognitive impairment leads to fatigability, decline in attention and efficiency in their workplace which puts their health and patients' health at risk.

Aim: To find out the prevalence of sleep deprivation and its impact on cognition among shift working nurses.

Materials and Methods: Sleep deprivation among 97 female and three male healthy nurses of age 20–50 years was assessed by Epworth Sleepiness Scale (ESS). Cognition was assessed by Montreal Cognitive Assessment (MoCA) questionnaire. Mobile applications were used to test their vigilance, reaction time, photographic memory and numerical cognition. The above said parameters were assessed during end of day shift and 3-4 days after start of night shift.

Results: Poor sleep quality was observed among 69% of shift working nurses according to ESS scores. The cognitive performance was analysed using Wilcoxon signed rank test. The MoCA score was found to be lesser among 66% of nurses during night (25.72) than day (26.81). During the night, 32% made more mathematical errors. It was also found that, 71%, 83% and 68% of the nurses scored lesser during night in the Stroop's colour test, vigilance test and memory tests respectively. Thus, impairment in cognitive performance was statistically significant ($p<0.001$) among shift working nurses.

Conclusion: Cognitive performance was found to be impaired among shift working nurses, due to poor sleep quality and decreased alertness during wake state. Thus, shift work poses significant cognitive risks in work performance of nurses.

Keywords: Circadian rhythm, Night shift, Sleep quality

INTRODUCTION

Sleep plays an integral part in the health and well-being of the individual. Sleep is controlled by the Supra Chiasmatic Nucleus (SCN) of the hypothalamus, endogenous clock which regulates the production of melatonin, a hormone that induces sleep [1]. Physiological systems that follow circadian rhythm like sleep-wake cycle, hormone secretions, core body temperature are influenced by signals from the environment especially light [2]. Altered circadian rhythm results in physiological and psychological variations [3].

The recommended sleep duration for a healthy adult is seven to nine hours per day [4]. Shift work results in a conflict between a days oriented circadian physiology and requirement for work and sleep at the wrong biological time of day. Internally driven circadian biological clocks regulate the periods of sleepiness and wakefulness. Disruption of circadian rhythm and inadequate sleep are associated with derangement of physiological functions and leads to obesity, cardiovascular disease, and cognitive impairment. Thus, shift work, night work, and longer, irregular working hours are associated with reduced sleep duration and poor quality of sleep [5,6].

Sleep Deprivation (SD) is defined as, "obtaining inadequate sleep to support adequate daytime alertness" [7]. Long-term SD has a detrimental effect on cognitive function, attention, learning, and working memory and is associated with exaggerated neural reactivity [8]. Moreover, it is also associated with mal adaptations of physiological and behavioral functions. Sleep deprivation affects the ability of health workers who are involved in multitude of life saving tasks which need more attention and concentration. Extended work shifts of twelve hours or longer is common with nurses, whose insufficient sleep puts patients' health and their health at risk [9]. SD among nurses is the major cause for making an error in patient care and significant decrease in vigilance of the job [10]. The aim of this study was to assess the prevalence of SD among nurses working in shift and its impact on their cognitive performance.

MATERIALS AND METHODS

This cross-sectional study was conducted among staff nurses of Peelamedu Samanaidu Govindasamy Hospitals, Coimbatore, Tamil Nadu, India, who were on a rotating work schedule i.e., staff posted to day shift for one month and the same staff posted to night shift for the next one month during August 2016 to September 2016 after obtaining the ethical clearance from the Institution Ethical Committee.

Sample Size

Hundred staff nurses were chosen whose age ranged from 20 years to 50 years. Sample size (96), was calculated considering prevalence of sleep deprivation among staff nurses as 51% with 20 % precision [11].

Inclusion Criteria

Staff nurses of all departments like Medicine, Surgery, OBG, Paediatrics, etc., who were working eight hours shift a day for six days a week, not suffering from any known medical or mental illness and had a previous work experience of at least one year in rotating shift work, were included.

Exclusion Criteria

Staff nurses with a history of medical illness especially neurological diseases, sleep disorders (insomnia, somnolence, etc.,) and smoking, alcohol, any other drug consumption or any medications (within the last 14 days), those who do overtime and other jobs during off duty were excluded from the study.

The participants were informed about the test procedure and a written consent was obtained from them. The staff nurses were assessed for sleep deprivation using the Epworth Sleepiness Scale (ESS) [12]. The ESS was used to measure day time sleepiness and

ABSTRACT

Background: Microalbuminuria is considered as an early marker and strongly associated with risk of cardiovascular complications in diabetic patients. Autonomic imbalance due to micro vascular damage to parasympathetic and sympathetic fibers results in reduced heart rate variability; also predicts increased risk for cardiovascular events in diabetics. Hence it is necessary to identify an early and effective predictor of diabetic micro vascular complications. Objective of the study was to compare heart rate variability of controls with type 2 diabetes with and without microalbuminuria.

Methods: This comparative study was conducted among individuals without diabetes, hypertension and dyslipidemia (controls) and Type II diabetics with and without microalbuminuria (cases). Cases and controls were subjected to general clinical examination; microalbuminuria and HbA1C were noted. heart rate variability was assessed using digital physiograph. Frequency (HF, LF, LF/HF ratio) domain readings were noted.

Results: Mann Whitney U test was employed to analyze nonparametric data. Diabetics with microalbuminuria when compared with controls showed statistically significant (p-value=0.015) reduction in vagal activity. When compared with diabetics without microalbuminuria (180.4±151.7) they showed reduction in HF with no statistical significance. When diabetic group without microalbuminuria (0.56±0.31) was compared with controls they showed alternation in LF/HF ratio which has no statistical significance. Diabetics with microalbuminuria when compared with controls showed a statistically significant (p-value=0.009) alternation in LF /HF ratio implying an autonomic imbalance.

Conclusions: This study shows there is significant vagal inhibition and autonomic imbalance in diabetic patients with microalbuminuria compared to controls. To ascertain the role of HRV as an early predictor of cardiovascular complications we propose to conduct study with a larger sample size in future.

Keywords: Autonomic imbalance, Diabetes mellitus, Heart rate variability, Microalbuminuria

INTRODUCTION

The magnitude of non-communicable diseases (cardiovascular diseases, diabetes, malignancies and chronic respiratory diseases) has brought about a negative socioeconomic impact and sufferings to the mankind.[1] 36 million deaths have been reported every year due to diabetes and its complications. Moreover, 9 million people succumb to death prematurely.[2] Improved and effective medications have increased the lifespan of diabetic population. Hence there is a need to identify and intervene at the earliest in order to prevent complications and provide them a better quality of living. Microalbuminuria is considered as an early marker. It

Students and faculty perspectives towards early clinical experience in learning neurosciences

K. Deepalakshmi[1], P. Sathyavathi[2], Pananghat A. Kumar[3], Anith Kumar Mambatta[4], Denesh Narasimhan [4]

Date of Submission: 16.12.2016 **Date of Acceptance: 04.03.2017**

Abstract

Background: Medical education has undergone major changes over a period which redefines conventional teaching strategies. It is necessary to reinforce and link basic sciences with clinical aspects in order to enhance better understanding, knowledge retention, application and development of clinical skills. With this view we introduced a method of exposing students to clinical environment early in their curriculum. Our study aimed at determining post exposure academic performance of students and faculty perceptions towards early clinical experience (ECE) in a hospital setting. **Methods**: Validated teaching module comprising of specific learning objectives, lesson plan, students and facilitators guide was developed and implemented to 150 students. After conventional didactic lectures in Anatomy and Physiology on Facial nerve, students were taken to hospital wards in five batches of 30 each. They observed interaction between physician and patients to appreciate clinical signs of facial nerve palsy. Pre and post tests were conducted to assess effectiveness of ECE. Students and faculty were provided with feedback questionnaires to know their perceptions towards the program. **Results**: Out of 150 students 119 students attended all sessions. Descriptive statistics was employed to assess their responses. Significant difference in scores of the students before (2.91±2.35) and after (5.93±3.07) ECE was observed with p value <0.01. 87% of students agreed that module was student centered, facilitated active learning and fostered critical thinking. Faculty involved revealed that this module satisfied current disciplinary (Anatomy and Physiology) and interdisciplinary (clinical) expectations. **Conclusion**: This active teaching learning strategy was well conceived by students and faculty. It helps in integration of basic and clinical sciences and paves way for application of basic science concepts in clinical practice.

Introduction:

Medical Science is an ever evolving field which invariably demands a periodic revisit of learning as well as teaching methods. Globally more emphasis is being laid on early clinical exposure of students, which includes both horizontal and vertical integration that eventually is expected to bring contextual learning. The traditional undergraduate medical curriculum in India is designed such that the students are exposed to clinical subjects during the second year of their course after prior exposure to basic sciences in the form of didactic lectures. On observing and screening the pattern of present medical education curriculum, the academicians have strongly recommended that the students need to be introduced to clinical medicine early in their

Correlation of Reciprocal Changes and QRS Amplitude in ECG to Left Ventricular Dysfunction, Wall Motion Score and Clinical Outcome in First Time ST Elevation Myocardial Infarction

SILPITA KATRAGADDA[1], MURALI ALAGESAN[2], SHANMUGASUNDARAM RATHAKRISHNAN[3], DEEPALAKSHMI KALIYAPERUMAL[4], ANITH KUMAR MAMBATTA[5]

ABSTRACT

Introduction: Electrocardiogram (ECG) is the simplest tool for diagnosing ST Elevation Myocardial Infarction (STEMI). We can use a12 lead ECG for prognostication purposes also.

Aim: The aim of the study was to find out the role of ECG as a prognostic marker in terms of clinical outcome and wall motion abnormality.

Materials and Methods: It was a prospective study done in PSG Institute of Medical Sciences and Research, Coimbatore, Tamil Nadu, India, from January 2014 to September 2014. Patients aged above 18 years admitted with first episode of ST EMI as per the inclusion and exclusion criteria were recruited for the study. Presence of reciprocal changes and QRS amplitude was measured from ECG. Presence of Left Ventricular Dysfunction (LVD) and wall motion score were calculated from ECG along with clinical outcome during first follow up visit. Statistical analysis was done using SPSS software. Probability was calculated using chi-square test, independent t-test and ANOVA analysis.

Results: A total of 120 patients were recruited for the study of which six were excluded based on the exclusion criteria. Among 114 patients analysed, 55 had reciprocal changes; 38 of them developed LVD which was statistically significant (p=0.002). Of the 78 patients with Anterior Wall Myocardial Infarction (AWMI), 35 had reciprocal changes; 15 (42.9%) of them had NYHA Class 1 symptoms, 14 (40%) had Class II and 4 (11%) had class III symptoms at follow up. The association was statistically significant (p=0.001). Similar statistically significant association was found in patients with Inferior Wall Myocardial Infarction (IWMI) who had reciprocal changes and NYHA symptoms at follow up (p=0.004). The mean wall motion score in patients with AWMI and reciprocal changes was 24.83 ± 4.1; whereas without reciprocal changes was 23.98 ± 3.6; the association was not statistically significant. The mean QRS amplitude of all patients with LVD was 33.25 ±16.34. The association between QRS amplitude and LVD was not statistically significant. The overall mean wall motion score was 24.86 ± 3.91. The association between QRS amplitude and wall motion score was statistically significant (r value = 0.210). The association between QRS amplitude and wall motion score was statistically significant when we analysed AWMI (r= -0.147, p=0.199) and IWMI (r= -0.359, p=0.031) separately.

Conclusion: ECG can be used as a tool for prognostication in acute STEMI. The presence of reciprocal changes in the ECG can signify poorer outcome on follow up. Lower QRS amplitude can be used as a predictor of larger infarct.

Keywords: Coronary artery disease, Heart failure, Prognostic marker

INTRODUCTION

Myocardial infarction is one of the most important causes for hospitalization and is commonly seen in all populations worldwide [1]. The clinical approach to a patient suspected to have an acute coronary syndrome consists of detailed history taking, ECG changes, cardiac biochemistry evidence and imaging. The reliability of each of these modalities as a diagnostic tool is dependent on multiple factors, the most significant being the window period between the time of infarction and the time the patient seeks medical attention [2]. The current approach to patients presenting with typical or atypical features of myocardial ischemia or infarction starts with making the provisional diagnosis of acute coronary syndrome [3,4]. Depending on the changes seen on the 12 lead ECG, acute coronary syndrome is classified into STEMI, Non ST Elevation Myocardial Infarction (NSTEMI) or unstable angina [5].

Inspite of major leaps in the diagnostic tools and treatment of myocardial infarction, STEMI persists as one of the leading cause for mortality and morbidity in both the developed and developing world [6]. The prevalence of coronary disease and myocardial infarction is also on rise in the developing countries, with further worsening of adverse cardiovascular events due to disadvantages like inadequate primary prevention policies and limited availability of medical help [7].

There has been extensive research done in the field of cardiovascular medicine focused on ST elevation myocardial infarction and the dynamics of complications surrounding it. One particular area of interest in recent studies appears to be the study of extent of infarct over imaging modalities and its correlation with various events in the course of infarction [8,9]. Other parameters gaining importance are non traditional ECG changes like reciprocal changes, ST depression, QRS morphology, q waves etc., [10-17].

The simplest and oldest diagnostic tool for myocardial infarction is the 12 lead ECG. In daily practice, even though the ECG remains an important test in diagnosis and detection of progression of disease, there still remains ample potential for its role as a prognostic marker [18,19]. The fundamental advantage that stands to be gained by

CORRELATION OF LIPID PROFILE AND RR INTERVAL WITH TSH IN HYPERTHYROIDS AND EUTHYROIDS

Rashmi Ramanathan, Mohan Jayapal, Manishankar subramaniyam, Nagashree Ramasamy, Jyothi Sivalingiah, Rajeswari M..

ABSTRACT

Abstract

Aim: Excess thyroid hormones has a profound effect on carbohydrate, protein, lipid metabolism and also on Cardiovascular system. The current study was aimed to determine the association between serum lipid profile, RR interval with TSH in hyperthyroids and euthyroids

Methodology: Study was carried out in PSG Hospitals ,Coimbatore among 30 untreated hyperthyroids and 30 age matched Euthyroids. Thyroid profile including Triiodothyronine (T3), Thyroxine (T4) and Thyroid stimulating hormone (TSH) were measured by using ECLIA (Electro Chemi Luminescence Immuno Assay). Serum Lipid profile including Cholesterol, Triglycerides, LDL, and HDL were measured by Immuno Turbidimetry method. ECG was recorded using in lead II for 5 minute. Heart rate and RR interval were noted for all the subjects.

Results: All lipid parameters were significantly reduced in Hyperthyroids than controls. Among the Euthyroids, Significant ($p<0.05$)

Key words: Lipid Profile, TSH, RRinterval, Hyperthyroids

Effect of Obesity on semen parameters

Nagashree R[1], Praveena M[2]

[1]Professor & Head of the Department, [2]Final year PG, Department of Physiology, PSG Institute of Medical Science & Research, Coimbatore

Abstract

Background: Obesity is a non-communicable disease and has grown to pandemic in recent years in western as well as in developing countries. It should be considered as an etiology of male infertility, as there is an increase in incidence of overweight and obesity in men of reproductive age. **Aim: To** study the effect of obesity on semen parameters. **Materials and methods:** This was a cross sectional study, which involved 75 male participants, aged between 20 to 50 years. Paternal height and weight, life style habits and semen analysis data were collected from medical records of fertility department. Men were divided into three groups based on their body mass index (BMI). Group1 (n = 25)- Normal (18.5 -24.99 kg/m^2), Group 2(n = 25) - Overweight (25.0 -29.99 kg/m^2), Group 3 (n = 25)- Obese (BMI>30 kg/m^2). Semen parameters were analysed by applying WHO 2010 criteria as normal cut off values. The data obtained was analysed using logistic regression. **Result: T**his study showed statistically significant association between obesity and abnormal sperm concentration, low sperm motility, low sperm vitality with an adjusted odds ratio of 26.36 (3.05 – 227.74),14.34 (1.18–174.00),8.59 (2.34 – 31.49) respectively after adjusting for age, smoking habits, intake of alcohol and physical activity. **Conclusion:** This study finding strongly indicates that obesity has an association with semen parameters. In future, it is needed to work in that direction to reduce such factors, which can affect the fertility of males.

Introduction

Obesity is a global health problem not only in Western countries but also in developing countries like India.[1] American Medical Association (2013), recently classified obesity as a disease. It affects not only cardiovascular system but also has a role in many other related health disorders. It accounts for 7.5% of the total burden of disease. In India, the prevalence of obesity is 12.6% in women as compared to 9.3% in men.[2]The rate of obesity in reproductive-age men has nearly tripled. Obesity reaches epidemic proportions with 1.6 billion adults being classified as overweight and an extra 400 million adults classified as obese.[3]Obesity adversely affects male reproduction by endocrine, thermal, genetic and sexual mechanisms.[3] It has

Association between Quality of Sleep and Academic Performance in Medical Students: A Preliminary Study

K. Deepalakshmi[1], S. Vijayabaskaran[2], R. Thamaraiselvi R.[3], R. Nagashree[4]

[1]Associate Professor, [2]Assistant Professor, Department of Physiology, PSG Institute of Medical Sciences and Research, Coimbatore, [3]Tutor, Department of Physiology, Stanley Government Medical College, Chennai, [4]Professor, Department of Physiology, PSG Institute of Medical Sciences and Research, Coimbatore

Abstract

Background: Medical students are more prone to daytime sleepiness, sleep deprivation and irregular sleep schedules, as they have less free time, longer courses and working hours compared to other professional students.

Aim: To assess the quality of sleep and to find out the association between sleep quality and academic performance among medical students.

Methodology: This cross sectional study was conducted among 176 medical students. They were subjected to Pittsburgh Sleep Quality Index (PSQI) questionnaire to assess their sleep quality over a one-month period. A PSQI global score of 5 and greater than 5 was considered indicative of poor sleep. Academic performance was assessed from their internal assessment scores conducted during that period. The data was analyzed using the unpaired students 't' test and Pearson's correlation test

Results: Our study included 176 students from all the phases of MBBS curriculum. 24 percentage students had poor quality of sleep. In our study, there was no statistically significant difference in the performance of good sleepers (57.94 ±18.06) and poor sleepers (58.80 ±17.37) with a p value of 0.785. Our study results showed a negative correlation between global PSQI scores and assessment scores of the students (r = 0.57 and P =0.449).

Conclusion: In our study association between sleep quality and academic performance was not statistically significant. Assessment of sleep quality helps to indentify the students at risk and plan the specific programs to improve the quality of sleep.

Keywords: *Sleep quality, academic performance, medical students.*

Introduction

Medical students are exposed to multitude of changes when they enter into their professional life after completing their school education. Owing to highly demanding professional and academic requirements medical students are considered to be a vulnerable population of poor quality of life.[1] Medical students have compromised quality of life as they have to undergo long and intensive academic years.

Medical students are more prone to daytime sleepiness, sleep deprivation and irregular sleep schedules as they have less free time, longer courses and working hours compared to other professional students. Over the period of time, poor sleep quality will lead to chronic inability to recover from stressful conditions

COMPARISON OF TIME DOMAIN MEASURES OF SHORT TERM HEART RATE VARIABILITY IN TYPE 2 DIABETIC PATIENTS WITH AND WITHOUT MICROALBUMINURIA- A PRELIMINARY STUDY

K Deepalakshmi*, S Vijayabaskaran **,R Nagashree*,**

*Associate Professor, ** Assistant Professor, *** Professor Department of Physiology, PSG Institute of Medical Sciences and Research, Coimbatore 641004

Abstract: Background & objectives: Diabetes is a complex and multi-factorial endocrine disorder with increased prevalence worldwide. Microalbuminuria is an independent marker of endothelial dysfunction and increases the risk of arrhythmia and atherosclerosis that affects cardiac autonomic function. Cardiovascular pathology remains a primary cause of death in patients with diabetes mellitus .So we aimed to compare time domain measures of short term Heart Rate Variability (HRV) in type 2 diabetic patients with and without microalbuminuria **Methods:** This prospective comparative study was conducted among diabetic patients with (n=14) and without (n=15) microalbuminuria. Patients with hypertension, dyslipedemia, coronary artery disease, cerebrovascular accident, family history of young MI, hyper or hypothyroidism and on beta-blocker treatment were excluded. Study participants were subjected to general clinical examination. Presence of microalbuminuria and their HbA_1C values were noted from their clinical records. Heart rate variability was assessed using an ambulatory ECG system in lead II for 5 minutes. The series of RR intervals obtained was subjected to time domain analysis. Time domain measures SDNN, rMSSD and NN50and pNN50 were obtained. **Results:** 29 diabetic patients participated in the study, out of which 14 were diabetics with microalbuminuria, and 15 were without microalbuminuria. On analysis of short-term time domain measures of HRV, the mean SDNN was decreased (51 ± 11.5) in diabetic patients with microalbuminuria, when compared to diabetic patients without microalbuminuria (54.96 ± 10.93) with p value 0.45. pNN50 and rMSSD was decreased in diabetic patients with microalbuminuria (1.09 ± 2.73, 14.32±8.17) when compared to diabetic patients without microalbuminuria (1.82 ± 3.06, 18.99 ± 7.71) with p value 0.51 & 0.13 respectively .

Conclusion: Our findings indicate cardiac autonomic function was altered in diabetic population with microvascular involvement

Key Words: Microalbuminuria, Heart rate variability, Diabetes Mellitus

Author for correspondence: Dr K Deepalakshmi Department of Physiology, PSG Institute of Medical Sciences and Research, Coimbatore 641004

e- mail: drdeepalakshmik@gmail.com

Introduction:

Diabetes mellitus is a complex and multi-factorial endocrine disorder affecting all age groups .Its prevalence has increased worldwide and it was estimated to be 2.8% in 2000 and 4.4% in 2030.[1] Microalbuminuria is a independent marker of endothelial dysfunction and known to cause cardiovascular morbidity and mortality among individuals with diabetes.[2] Microalbuminuria increases the risk of arrhythmia and atherosclerosis which affects cardiac autonomic function.[3]

Early recognition of autonomic dysfunction plays a significant role in prediction of cardiovascular mortality in diabetes mellitus. Decreased Heart Rate Variability (HRV) is associated higher risk (32–45%) of cardiovascular morbidity and mortality in diabetic individuals and as well in healthy controls.[4,5,6]

HRV is a reliable non invasive tool used in the assessment of cardiac autonomic function. Evaluation of HRV by time domain measure is the simplest and most popular method.[7] Parameters considered during time a domain analysis are standard deviation of all R-R intervals (SDNN), root mean square of successive RR- interval differences (RMSSD) and number of intervals differing by > 50ms from adjacent interval (NN50) and

Hypolipidemic Effects of Fenugreek and Atorvastatin-Comparative Study on High Fat Fed Dyslipidemic Rats

HEMAVARDHINI CHENNAPPAN SEKAR[1], GV LATHADEVI[2]

ABSTRACT

Introduction: Dyslipidemia is the current medical problem of utmost concern with an increased prevalence among the males between 31-40 years. Various extracts from fenugreek (*Trigonellafoenum-graecum*), methi (in Hindi), have known to have effect on the metabolic parameters, lipid lowing properties being one of them.

Aim: The objective of this study was to evaluate the efficacy of fenugreek, one of the commonest Indian spice in lowering the serum lipid levels and comparing its efficacy with lipid lowering properties of a pharmacological agent-atorvastatin so that it could be incorporated as a part of life style modifications among the dyslipidemic individuals.

Materials and Methods: Twenty four adult male Wistar rats were divided equally into four groups. Group A was kept as the control and fed on normal diet. Hyperlipidemia was induced in Groups B, C and D with high fat diet containing groundnut oil cake and dried coconut for 12 weeks. The hyperlipidemic rats were then subjected to the various hypolipidemic regimens. Group B- 2mL emulsion of fenugreek (1 gm/kg/day) orally, Group C- 2mL emulsion of atorvastatin (30 mg/kg/day) orally, Group D- 4mL emulsion of fenugreek and atorvastatin combined. The serum samples were analysed for lipid profile at the beginning and end of four weeks. The statistical analysis for the data collected was done using One-way Anova analysis in the software- SPSS Version 20.0.

Results: Administration of fenugreek to hyperlipidemic rats (Group B) showed a significant reduction of serum triglycerides, cholesterol and body weight ($p<0.05$) and a significant increase in the serum High Density Lipoprotein (HDL) levels ($p<0.05$). The serum Low Density Lipoprotein Cholesterol (LDL-C) values showed a statistical reduction in Group C ($p<0.01$) administered with atorvastatin monotherapy. In Group D the combination therapy with fenugreek and atorvastatin showed a statistical significant increase of High Density Lipoprotein Cholesterol (HDL-C) $p<0.01$.

Conclusion: Fenugreek is proved to be a potent hypolipidemic agent. Lifestyle modification with dietary supplement of fenugreek can be taken as an effective hypolipidemic element initially to combat the increasing risks of dyslipidemia. If they do not respond then the individuals can switch over to pharmacological agents like atorvastatin along with fenugreek to control dyslipidemia.

Keywords: Dietary supplement, Lifestyle modification, Metabolic disorder, Statins, Trigonellafoenum-graecum

INTRODUCTION

Dyslipidemia as defined by the abnormal levels of lipid parameters such as LDL-C, triglycerides, HDL-C and atherogenic indices in the blood, is the current medical as well as social problem of utmost concern leading to increasing morbidity and mortality. Studies have shown that regional disparity exists in India with the highest rates of hypercholesterolemia observed in Tamil Nadu (18.3%) among which the urban residents had the highest prevalence of lipid abnormalities compared to rural residents [1,2]. Studies have also revealed that dyslipidaemia is more common among the males aged 30-40 years leading to increased prevalence of young infarcts due to coronary artery disease in this group [3,4]. Current AACE guidelines on the prevention and management of dyslipidemia suggest that it is the major prerequisite for the development of coronary artery disease and may even be the primary risk factor occurring before other major risk factors comes into play [5].

Several methods for combating this life threatening metabolic disorder have been emphasized upon in various researches in the recent times. The armamentarium for managing it now includes "statins" that can decrease the LDL-C levels by up to 55% [6]. Statins are hypolipidemic agents with anti-atherosclerotic properties [7]. A study on comparison of safety and efficacy among statins showed that atorvastatin is more effective when compared to simvastatin and pravastatin in patients with hyperlipidemia [8,9]. Multiple clinical trials conducted across the world show that a significant number of patients on statins continue to have a high residual risk of coronary artery disease [10,11]. The various adverse effects associated with the statin group of drugs provide a clinical challenge in management of dyslipidemia with such pharmacological modalities.

The modern medicine draws its potential from the rich legacy of traditional medicine. Fenugreek (*Trigonellafoenumgrae*-cum) is one of the oldest medicinal plants, dating back to the Hippocrates and ancient Egyptian times and known to have immense therapeutic value as proven by several experiments on animal and human models [12]. It is also said to have a high levels of iron hence it can be an useful supplement in iron-deficient patients [13]. In vivo studies using fenugreek extracts has an inhibitory effect on the growth of cancer cells and reduces inflammation [14]. The other beneficial nutritive effects of fenugreek seeds include hypolipidemic and anti-diabetic effects [15]. Lipid lowering effects of fenugreek have been attributed to the various chemical extracts such as ethyl acetate extract which was found to have-Naringenin, the abundant flavonoid compound found to have significant hypocholesterolemic effects [16].

This study was aimed at determining the hypolipidemic potential of fenugreek in comparison to the pharmacological agents like atorvastatin in order to include fenugreek as part of the dietary modification in the hypolipidemic regimen taken up by the dyslipidemic individuals.

A study on the quality of life in children and adolescents with type I Diabetes Mellitus.

Raja priya S[1], Lathadevi GV[2], Meena Kumari M[3]

[1]III year post graduate, [2]Professor, Department of Physiology, [3]Consultant Paediatric endocrinologist, Department of Endocrinology, PSG Institute of Medical Science & Research, Coimbatore

Abstract

Background: Diabetes mellitus is expected to increase from 425 million in 2017 to 629 million by 2045 worldwide. Diabetes mellitus diagnosed during childhood presents an increased risk of complications in an early and productive stage of life, leading to a reduction in mean life expectancy of 10 to 20 years which is especially prevalent in developing countries. Children and adolescents with Type 1 diabetes Mellitus are at a heightened risk for mental health issues, including diabetes distress, depression, anxiety, and disordered eating. Health-Related Quality of Life (HRQOL) is an essential health outcome in clinical trials and healthcare. **Aim:** To evaluate the quality of life in children and adolescents with Type 1 Diabetes Mellitus for an effective management using Pediatric Quality of Life Inventory (PedsQL) tool questionnaire. **Materials and Methodology:** This was a prospective study. After ethical approval, 60 subjects who qualify the inclusion criteria were enrolled. The PedsQL tool questionnaire were given separately to child and parent. The child self-report and parent proxy-report were obtained and the PedsQL 4.0 Generic Core Scales were calculated. Statisticalanalysis was done using paired student 't' test. **Results:** The PedsQL score of children was 77.94 ± 15.59 and that of parents was 74.12 ± 17.78. There was a significant difference between the child's self-report and the parents'- proxy report. The p value was statistically significant (p =0.000). **Conclusion:** These findings emphasizes the importance of the psychosocial assessment and regular counselling to the children and adolescents with Type 1 DM which is a chronic disease along with their routine medical treatment which insists on good glycemic control.

Introduction

Diabetes mellitus (DM) is one of the most common metabolic diseases worldwide. Its prevalence has increased in the past decade. Almost 90% of cases classified as Type 1 DM, with an autoimmune cause are children aged under 15 years. It represents one of the major chronic disease in pediatric age group. The Diabetes Atlas 2017 estimates that there are 128,500 children and adolescents with diabetes in India.[1]

Type 1 DM, formerly known as juvenile or insulin-dependent diabetes is characterized by deficient insulin production. Symptoms include excessive

ABSTRACT

In browsing through the list of Nobel Prize Laureates, only about 5.3% of women have won the Alfred Nobel Prize for Physiology and Medicine. In countries with highest number of Nobel laureates like USA & UK, only about 4% of them are Females. This review article analyses the role played by the "female gender" in receiving the nobel prize for Physiology and Medicine.

INTRODUCTION

Nobel Prize is one of the highly prestigious awards to be won by the mankind. Each recipient receives a medal, a diploma and a cash prize of about 8 million Swedish Krono that has varied through the years **(Figures 1-3)**. Now cash prize is equivalent to 6 crore and 25 lakhs. Nobel prize medals are handmade with recycled gold with careful precision. So far only 48 women have received (822 men) the distinction and among them, only 12 women got the honor for Physiology/Medicine whereas 211 individuals have received Nobel Prize for Physiology/Medicine.

The first woman to receive the Nobel Prize for Physiology/Medicine was in the year 1947. It is about 46 years after inception of the prize (1901).

PLATELET INDICES AS A TOOL IN ASSESSING THE PROGRESSION OF TYPE 2 DIABETES MELLITUS

Physiology

Dr. S. Nirangjhana MBBS., Postgraduate, Department of Physiology, PSG Institute of Medical Sciences & Research, Coimbatore-641004

Dr. N. Shuba* MD., Associate Professor of Physiology, PSG Institute of Medical Sciences & Research, Coimbatore-641004*Corresponding Author

ABSTRACT

Background: Type 2 Diabetes mellitus is considered as a prothrombotic state that increases the risk for microvascular complications. Studies associating platelet indices with severity of diabetes have yielded inconsistent results.

Aim: To compare platelet indices such as platelet count, mean platelet volume (MPV), platelet distribution width (PDW), plateletcrit (PCT) between diabetic and non-diabetic population.

Materials and methods: The cross-sectional study was conducted in the Department of Medicine with 30 diabetic patients and 30 controls. Platelet indices were measured using Beckman Coulter LH 780. SPSS software was used for statistical analysis.

Results: MPV, Platelet count and PDW were significantly increased in diabetic subjects compared to non diabetic subjects. MPV and Platelet count showed significant positive correlation with HbA1c in diabetic patients.

Conclusion: Platelet indices especially MPV, PDW assesses the thrombogenic state and hence can be used to monitor treatment.

KEYWORDS

Diabetes mellitus, Mean platelet volume, Platelet distribution width.

INTRODUCTION

Diabetes mellitus is a clinical syndrome characterized chiefly by hyperglycemia resulting from absolute or relative deficiency of insulin [1]. The resultant metabolic dysfunction in diabetes leads to microvascular and macrovascular complications. These vascular complications in turn results in secondary damage to multiple organ systems [2].

The prevalence of diabetes has risen worldwide from 108 million cases in 1980 to 422 million cases in 2014. According to WHO, Diabetes was the seventh leading cause of death in 2016. A recent estimate in 2016 has suggested that diabetes causes almost 1.6 million deaths globally [3]. Type 2 diabetes mellitus is the predominant form of diabetes worldwide accounting for 90% of cases. India has the second-largest prevalence of diabetes accounting for 62.1 million cases in 2013 [2].

Type 2 Diabetes mellitus is considered as a prothrombotic state with enhanced platelet reactivity that increases the risk for microvascular complications like retinopathy [4]. Insulin antagonizes the effect of platelet agonists like collagen, adenosine diphosphate, epinephrine and platelet-activating factor. Hence insulin resistance leads to increased reactivity of platelets [5].

Platelet indices such as platelet count, mean platelet volume (MPV), platelet distribution width (PDW), plateletcrit (PCT) have been used to assess the platelet activity. MPV indicates the average size and activity of platelets. This in turn reflects either a change in platelet stimulation or a change in the rate of platelet production [6].

Increase in MPV has been demonstrated in metabolic syndrome and stroke, which are prothrombotic states [6]. Platelet distribution width (PDW) which indicates heterogeneity in platelet size and shape is a sign of active platelet release [7].

Investigations such as fibrinogen, prothrombin time (PT), activated partial thromboplastin time (aPTT) assesses the prothrombotic state. Many of these tests cannot be employed for screening prothrombotic state in diabetes routinely.

Hence in their place; platelet indices that include MPV, PDW which are done during routine hematological analysis can be used [4].Not many studies have been conducted in South India emphasizing the association of platelet indices with glycemic control in diabetes mellitus. Studies associating platelet indices with progression of diabetes have yielded inconsistent results. Hence this study was chosen to compare platelet indices between diabetic and non-diabetic population and to correlate platelet indices with HbA1c in diabetic patients.

MATERIALS AND METHODS

This cross-sectional comparative study was conducted in the Department of Medicine, from May 2018 to April 2019 after getting Institutional Ethics Clearance. Sample size was calculated with Open Epi software version 3.01 using 80% power, 95% confidence interval and by substituting mean ± SD values of platelet indices obtained from a study conducted by Shilpi K, et al [4]. The calculated sample size was 60 with 30 subjects without diabetes mellitus in Group A and 30 subjects with type 2 diabetes mellitus in Group B.

Inclusion criteria

- Age of the subjects: 35-70 years
- Gender: Both males and females
- Subjects with type 2 diabetes mellitus on treatment. Diagnosis of type 2 diabetes mellitus was made using WHO criteria [11]

Exclusion criteria

- Subjects who were pregnant.
- Subjects with acute infections, trauma or recent myocardial infarction.
- Subjects with hematological disorders like anemia (hemoglobin values <12g/dl in females and <13g/dl in males), polycythemia, lymphoma, multiple myeloma or with bleeding disorders.
- Subjects with autoimmune disorders such as rheumatoid arthritis, systemic lupus erythematosus.
- Subject with hypertension, thyroid disorders like hypothyroidism
- Subjects with cardiac failure, hepatic failure, renal failure, malignancies or poor general conditions.
- Subjects on antiplatelet medications like aspirin, clopidogrel.
- Subjects who were not willing to participate.

After getting informed and written consent, the data was collected using a data collection tool. Under sterile aseptic precautions, 2ml of venous blood was drawn from the antecubital veins of the subjects. The withdrawn blood was anticoagulated with EDTA. Platelet indices were computed using Beckman Coulter LH 780. Plasma glucose level was measured by the glucose oxidase method and HbA1c was measured by HPLC, if they have not been already done in the study population.

The data collected were analyzed using IBM SPSS software version 24. Normally distributed variables were presented as mean ± SD. Categorical variables were presented as frequencies and proportions. Independent t-test was used to compare the variables between the two groups. Karl Pearson's correlation was used to compare the continuous variables which were normally distributed. p-value < 0.05 was considered to be statistically significant.

RESULTS

The mean age of the subjects in groups A (non-diabetic) and B

COMPARISON OF SENSORY NERVE CONDUCTION BETWEEN OVERWEIGHT AND OBESE DIABETIC PERIPHERAL NEUROPATHY PATIENTS BASED ON ASIAN INDIAN BODY MASS INDEX STANDARDS

Physiology

Dr. S. Nirangjhana* MBBS., Postgraduate, Department of Physiology, PSG Institute of Medical Sciences & Research, Coimbatore-641004 *Corresponding Author

Dr. N. Shuba MD., Associate Professor of Physiology, PSG Institute of Medical Sciences & Research, Coimbatore-641004

ABSTRACT

Background: Obesity is a major component of metabolic syndrome that accentuates the inflammatory and oxidative stress in diabetic peripheral neuropathy (DPN). Based on the Asian Indian BMI standards, the prevalence of overweight is on the rise in India.

Aim: To compare the sensory nerve conduction parameters such as latency, amplitude and nerve conduction velocity in the median, ulnar and sural nerves between overweight and obese DPN patients.

Materials and methods: This cross-sectional study was conducted in the Department of Neurology with 80 type 2 DPN patients with Body mass index (BMI) > 23 Kg/m2. Sensory nerve conduction studies were performed. SPSS software was used for statistical analysis.

Results: Except for sural nerve, the nerve conduction studies in other nerves did not show a statistical significant difference between overweight and obesity.

Conclusion: Overweight affects sensory nerve conduction study in diabetic peripheral neuropathy similar to obesity.

KEYWORDS

Diabetic peripheral neuropathy, Overweight, BMI

INTRODUCTION

Type 2 diabetes mellitus is the predominant form of diabetes worldwide accounting for more than 90% of diabetic cases [1]. Among the microvascular complications of diabetes; diabetic neuropathy occurs in more than 50% of individuals with type 2 diabetes mellitus [2]. Diabetic neuropathy can manifest in the forms of polyneuropathy, mononeuropathy and/ or autonomic neuropathy. Out of these forms, distal symmetric polyneuropathy (DSPN) accounts for about 75% of the caseload in diabetic neuropathies [3]. A prevailing view for the pathogenesis of diabetic peripheral neuropathy is the inflammatory and oxidative stress that occurs as a result of metabolic syndrome [3]. Obesity is a major component of metabolic syndrome [4].

Based on the BMI classification criteria for Asian Indians, the prevalence of overweight and obesity (BMI $\geq$23 kg/m ^{2}) in India is on the rise [5]. For long it was known that obesity is a major risk factor for amplifying the severity of diabetic neuropathy. Now with the advent of newer guidelines for BMI classification [6] even diabetic patients with overweight (BMI 23-27.4 Kg/m^2) could be under risk for worsening severity of peripheral neuropathy on par with obesity.

Hence using nerve conduction study as a tool, we decided to compare the sensory nerve conduction study parameters such as latency, amplitude, and nerve conduction velocity in the median, ulnar and sural nerves between overweight and obese diabetic peripheral neuropathy patients (DPN) patients. Since the sensory component of the nerves is more affected in diabetic peripheral neuropathy [7], we have chosen sensory nerve conduction study. The null hypothesis employed here is that there is no difference in sensory nerve conduction between overweight and obese DPN patients. Sensory nerve conduction study parameters in DPN patients with both overweight and obesity were also correlated with BMI.

MATERIALS AND METHODS

This cross-sectional study was conducted in the Department of Neurology from December 2017 to December 2018 in 80 DPN outpatients after getting Institutional Ethics Clearance. The sample size was calculated with Open Epi software version 3.0 using the prevalence of overweight and obesity from ICMR-INDIAB study 2015 [8] and 95% confidence interval.

Inclusion criteria

- Age: 35-70 years
- BMI $\geq$ 23 Kg/m^2 (Subjects with BMI 23-27.4 Kg/m^2 were considered overweight and those with BMI > 27.5 Kg/m^2 were considered to be obese)
- Gender: Both males and females
- Subjects with a history of type 2 diabetic peripheral neuropathy for more than 1-year duration on treatment.

Exclusion criteria

- Subjects with hemolytic or aplastic anemias
- Subjects with vitamin B12 deficiency
- Subjects with thyroid disorders
- Subjects with inflammatory conditions such as connective tissue disease, CIDP (Chronic Inflammatory Demyelinating Polyneuropathy) or neuromuscular disease
- Subjects with signs of peripheral vascular disease
- Subjects with a history of cerebral infarction, cervical spondylosis or lumbar spondylosis.
- Subjects diagnosed with malignancies.
- Subjects with cardiac failure, hepatic failure or poor general conditions.

After getting informed and written consent, the data was collected. Recorders Medicare System (RMS) EMG EPM 2K version 1 was used to record the sensory nerve conduction parameters such as latency, amplitude and nerve conduction velocity (NCV). Onset latency (ms) was measured from the onset of stimulus artifact to the initial negative peak in antidromic conduction. Amplitude (μV) was measured from the baseline to the negative peak of the biphasic response obtained after supramaximal nerve stimulation and NCV (m/s) was measured by applying a stimulus at a single stimulus site. The formula utilised for calculating NCV was

$$\text{Conduction velocity} = \frac{\text{Distance between stimulating and recording electrodes (cm)}}{\text{Onset of latency (msec)}} \times 10$$

Fasting (FBS) and postprandial plasma glucose levels (PPBS) were estimated using hexokinase, UV, kinetic methods. Glycosylated hemoglobin (HbA1c) was assessed using high-pressure liquid chromatography (HPLC).

Serum cholesterol and triglycerides (TGL) were measured using enzymatic endpoint methods. Serum high-density lipoproteins (HDL) and low-density lipoproteins (LDL) levels were measured using direct enzymatic assays. Serum urea and creatinine were determined using enzymatic methods. Estimated glomerular filtration (eGFR) was calculated based on chronic kidney disease epidemiology collaboration (CKD – EPI) equation (2009).

The data collected were analyzed using SPSS IBM software version 24. Shapiro-Wilk test was used to test the normality of variables. Normally distributed data are presented as mean $\pm$ standard deviation (SD) and variables with skewed distribution are presented as median (interquartile range).

Independent t-test was used to compare the variables with normal distribution between DPN with overweight and those with obesity. Mann-Whitney U test was used to compare the variables with skewed

ABSTRACT

Background: Stroke serves as the leading cause of death and physical disability. This study was conducted to find the relationship between platelet indices and severity of acute ischemic stroke.

Materials and methods: This was a cross-sectional study conducted among 60 ischemic stroke patients divided into severe and mild stroke based on modified Rankin Score(mRS) with 30 patients in each group and 30 normal individuals. Platelet indices(Platelet count and Mean Platelet Volume) were obtained from CBC report.

Results: There was a significant decrease in platelet count and increase in Mean Platelet Volume(MPV) in stroke patients when compared with normal persons and also in severe stroke patients when compared with mild stroke patients with p values 0.001 and < 0.001 respectively in both comparisons.

Conclusion: Patients with severe stroke had lowest platelet count and the highest MPV in our study. There is a positive association between platelet indices and the severity of acute ischemic stroke. Platelet indices can serve as an important predictor for the prognosis of acute ischemic stroke. It also helps in risk stratification in ischemic stroke patients so that they can be given more vigilant and aggressive care that can lead to decrease in morbidity and mortality.

KEYWORDS

Acute ischemic stroke, Platelet Indices, Platelet count, Mean Platelet volume

INTRODUCTION:

Central nervous system infarction is brain, spinal cord or retinal cell death attributable to ischemia, based on neuropathological, neuroimaging and/or clinical evidence of permanent injury (1). Stroke is the second leading cause of death, after ischemic heart disease accounting for 9% of deaths worldwide (2). Ischemic stroke is an episode of neurological dysfunction caused by cerebral, spinal or retinal infarction (1). As per Global burden of disease data on stroke on 2013, there were about 25.7 million stroke survivors, 6.5 million stroke deaths and 10.3 millions new strokes. Thus stroke is disease of immense public health importance with serious economic and social consequences (3). The two major mechanisms causing stroke are ischemia and haemorrhage. About 85% of all strokes are ischemic in origin (4).About one-fifth of patients with an acute stroke die within one month of the event and at least half of those who survive are left with a physical disability(5).

Cortical strokes which are 60% of ischemic stroke follow in situ cerebral thrombosis or cardiac source in which platelet play an important role. However lacunar stroke comprising 25% of ischemic stroke is due to lipohyalinosis of end arteries, which is unlikely to involve platelets (6). In recent years, there is an increased interest on research documenting the platelet indices (platelet count, mean platelet volume (MPV), platelet distribution width) in association with various ischemic strokes. Increased platelet reactivity is considered to be a relevant pathophysiological factor in approximately 50% of all strokes (7). Large platelets due to greater content in granules are more reactive than ordinary size platelets, produce more prothrombotic factors and show greater aggregation to Adenosine diphosphate (ADP), collagen and secrete more thromboxane A2 (TXA2). Increased platelet size has been described in patients with vascular risk factors such as diabetes, hypercholesterolemia and metabolic syndrome (8).

Platelet indices are calculated during routine blood analysis along with Complete Blood Count but these are generally not considered by clinicians. Mean Platelet Volume and platelet count are inversely associated so that the total platelet mass remains approximately constant (9).Studies have detected increased MPV in different subtypes of stroke both in acute phase and long after disease. Also stroke patients with high mortality have been found to have low platelet count (8). Moreover, studies on association of MPV with severity of ischemic stroke yielded inconsistent results (10).

Our study finds the association between the platelet indices(Platelet count and Mean Platelet Volume) and severity of acute ischemic stroke thus helps to know the diagnostic value of platelet indices in ischemic stroke. It also helps in risk stratification of patients with ischemic stroke, so that such patients can be given more vigilant and aggressive care that can lead to decrease in morbidity and mortality.

MATERIALS AND METHODS:

This was a cross sectional study, conducted among 60 acute ischemic stroke patients admitted in PSG Hospitals, Coimbatore, Tamilnadu and 30 healthy persons. The study was conducted after obtaining clearance from Institutional Human Ethical Committee, of our institution and obtaining written informed consent from the subjects.

Study population: Patients presenting with acute ischemic stroke (without previous history of stroke) in the age group of 40-70 years admitted in Neurology ward are cases. Controls were healthy persons attending Master Health Check up department.

Inclusion criteria:

- Patients with acute ischemic stroke for the first time proven by CT scan
- Patients admitted within 24 hours of onset of symptoms in neurology ward
- Patients of both genders within the age group of 40-70 years
- Known case of diabetes mellitus and hypertension under control

Exclusion criteria:

- Patients with previous history of stroke
- Transient ischemic attack
- Patients with haemorrhagic stroke, cerebral venous sinus thrombosis
- Patients with late admission of stroke (> 24 hours after stroke onset)
- Patients with co-morbidities like chronic renal disease, chronic liver disease, bypass heart surgery.
- Patients who are on drugs which modify platelet morphology like NSAIDS for long time.
- Patients with haematological malignancies and patients showing atypical cells in peripheral smear were excluded.

Sample size: 90 subjects, 60 acute ischemic stroke patients divided into 2 groups (groupI and group II) of 30 patients in each group and 30 healthy subjects(group III)

Calculation of sample size was done by using Open Epi software version 3.01, by using simplified formula for difference in means of

ASSOCIATION OF PLATELET INDICES WITH DISEASE ACTIVITY IN RHEUMATOID ARTHRITIS

ABSTRACT

BACKGROUND

Rheumatoid Arthritis (RA) is a chronic autoimmune inflammatory disease of unknown aetiology that mainly affects peripheral joints in a symmetric pattern. Prevalence of RA is approximately 1% worldwide, being two to three times more common in women than men. Effective management in RA requires close monitoring of disease activity. Platelet activation is an important event in synovial inflammation, but very few studies have used platelet indices to assess inflammation.

Thus, the aim of the study was to correlate the platelet indices (platelet count, mean platelet volume and platelet distribution width) with disease activity in Rheumatoid Arthritis.

MATERIALS AND METHODS

This descriptive comparative study was conducted among 60 RA patients and 30 healthy controls within the age group of 30 to 70 years. Every consecutive RA patient who attended the Rheumatology Outpatient Department was included in the study. The severity of RA was assessed by the Disease Activity Score Calculator for Rheumatoid Arthritis (DAS-28). The platelet indices assessed in the study include platelet count, Mean Platelet Volume (MPV) and Platelet Distribution Width (PDW) obtained from their CBC report. The study population was divided into three groups. Group I (Moderate disease activity) with DAS-28 score of 3.2-5.1; Group II (High disease activity) with DAS-28 score above 5.1. Thirty patients in Group I and thirty in Group II were taken for the study. Group III: 30 healthy controls who attended the Master Health Check-Up Department. Data analysis was done by using SPSS software and independent t-test. P value < 0.05 was taken as statistically significant.

RESULTS

There was statistically significant increase in platelet count, decrease in MPV and PDW in high-grade RA patients when compared with normal individuals (p= 0.004, p= 0.001, p= 0.019 respectively). We also found similar statistical significance between high and moderate grade RA patients (p= 0.001 for platelet count, p= 0.007 for MPV and p= 0.012 for PDW).

CONCLUSION

Our study suggests that platelet indices can be considered as inflammatory markers for disease activity in RA. However, further studies with larger number of patients are warranted to cross validate our findings.

BACKGROUND

Rheumatoid Arthritis is a chronic autoimmune inflammatory disease characterised by tenderness, swelling and stiffness of the joints with progressive destruction of cartilage and bone.[1] RA affects approximately 0.92% of the adult population of India with 20 to 40 new cases per lakh population every year[2] and is two to three times more common in women than men as other autoimmune diseases.[3]

Early diagnosis and aggressive therapy can usually prevent permanent disability and improve the quality of life.[2] Effective management in RA requires close monitoring of disease activity.

To determine the disease activity, clinicians use clinical signs and symptoms, radiological findings and Rheumatoid Factor (RF) values and C-Reactive Protein (CRP) and Erythrocyte Sedimentation Rate (ESR). Other blood tests are required for assessment of systemic involvement (Liver and kidney function) and monitoring of adverse drug events. So far, immune cells were considered to play the central role in RA pathophysiology and until recently platelets have not been expected to have a role in the pathogenesis of the disease. Inflammation creates an imbalance of normal physiological anticoagulant mechanism, induces activation of coagulation system with interleukin-6 and tumour necrosis factor alpha (TNFα) thus affecting platelet indices.[4]

Dense platelet bodies contain adenosine nucleotides, calcium and serotonin that exert effects in the initial phase of inflammation. They release pre-stored inflammatory mediators and can also produce eicosanoids such as thromboxane A_2, prostaglandin $F_2\alpha$ ($PGF_2\alpha$) and PGE_2, to regulate inflammatory response and can synthesize peptide mediators such as interleukin (IL)-1β on stimulation.[5,6]

From the 1950s, many attempts were made to design a disease activity measurement tool. Tools available are in the form of patient questionnaires, joint counts or lab tests. Most

EFFECTS OF AGE, GENDER AND EDUCATION LEVEL ON COGNITION IN ELDERLY PEOPLE

Shuba N[1], Prakash B[2]

[1]Associate Professor, Department of Physiology, PSG IMS&R, Coimbatore.
[2]Former Professor, Department of Neurology, PSG Hospitals, Coimbatore Consultant Neurologist, KMCH, Coimbatore.

ABSTRACT

BACKGROUND

With rapidly increasing number of older people in our community cognitive impairment is a growing public health concern in India. It affects the quality of life for the person affected and the caregiver. By preserving the function, we can help older adults to remain independent for as long as possible.

The aim of this study is to investigate the cognitive function in elderly people in various age groups and to find correlation of gender and education with cognition.

MATERIALS AND METHODS

This is a cross-sectional study conducted on 100 elderly people above 60 years at PSG Hospitals, Coimbatore. Cognition was assessed by Mini-Mental State Examination (MMSE) and Modified Mini-Mental Status examination (3MS) and was scored for 30 and 100 respectively. Correlation of age, gender and education with cognition scores was found. Statistical analysis was done using SPSS software by independent t test and chi square test and p value <0.05 was considered to be statistically significant.

RESULTS

We found statistically significant decline in cognition scores in elderly people as age advances by both tests ($p < 0.001$). Correlation of gender with cognition scores was not found to be significant ($p = 0.254$ and 0.268) and correlation of education with cognition scores showed decreased cognition in persons with lower level of education.

CONCLUSION

In general, we detected a significant decline in cognitive scores as age advances by both MMSE and 3MS. Higher education and younger age group were associated with better cognitive performance. By identifying those people at risk and by evaluation of any causes for cognitive decline and by proper treatment at an early stage, dementia can be prevented.

KEYWORDS

Cognition, Dementia, Education, Gender, MMSE, 3MS.

HOW TO CITE THIS ARTICLE: Shuba N, Prakash B. Effects of age, gender and education level on cognition in elderly people. J. Evolution Med. Dent. Sci. 2017;6(95):6952-6956, DOI: 10.14260/jemds/2017/1509

BACKGROUND

The elderly population in India above 60 years was 8% in 2010, is expected to increase to 19% in 2050 according to United Nations Population Division (UN 2011). By 2050, India's 60 and older population is expected to encompass 323 million people.[1] Ageing entails many physical, biological, chemical, and psychological changes. Ageing can have diverse effects on cognitive function. Cognitive impairment affects the quality of life for the person affected and the caregiver.

In 2010, 3.7 million Indians over 60 years had dementia and are expected to double by 2030. Prevalence rates of mild cognitive impairment varies from 3% to as high as 59% with a conversion rate to dementia varying from 8% to 15% shows the need for diagnostic tests for dementia.[2]

Mini-Mental state Examination (MMSE), by Folstein et al in 1975 is the most widely used standardised instrument for cognitive impairment in the world.[3] Modified Mini-Mental status Examination (3MS) was developed by Teng and Chui in 1987, it is an expanded version of MMSE.

'Financial or Other Competing Interest': None.
Submission 08-11-2017, Peer Review 08-12-2017,

The 3MS is significantly a better predictor of functional outcome than the MMSE and is found to have higher sensitivity.[4] Even though various studies show decline in cognition as age advances, there are not much studies involving correlation of various factors with cognition in elderly people. This study finds the correlation of various physiological factors among elderly people with cognitive impairment.

We tested the hypothesis that age, gender and education play an important role in cognitive function in elderly people. By preserving function, we can help older adults remain independent for as long as possible, which can improve their quality of life and delay the need for costly longterm care. By this study elderly people who are at risk of developing dementia and Alzheimer's disease can be identified and by initiating effective treatment and care, the disease can be prevented or progression of the disease can be slowed down.

Objective

The objective of the study is to assess the cognitive function in elderly people above 60 years by MMSE and 3MS, and to find correlation of gender and education level with cognitive impairment.

MATERIALS AND METHODS

This is a cross-sectional study done by collecting data afresh from study participants. Clearance from Human Ethics Committee, PSG IMS&R was obtained and the study was

Full Text

Sir,

A 45-year-old woman went to bed well by 10 pm after finishing strenuous household works. She woke up around 4 am due to chest and back discomfort with sweating. She could not turn over or sit-up. The lower limbs were felt cold, numb, and weak. The emergency department physician had suggested X-ray of the spine to check for compressive pathology. She had cardiac arrest at the radiology department, where she was revived and shifted to intensive care unit, sedated, and intubated. After 6 h of stabilization, she could be extubated. There was no history of fever, diarrhea, trauma, visual impairment, chest pain, palpitation, or dyspnea preceding the event. However, she had episodes of unexplained chest discomfort at rest for the previous 2 weeks. There was no other significant medical history. Clinically, she was conscious and afebrile, but was in discomfort due to back pain, and could not lie down properly. She could not describe her problems and was not able to localize the tender spot in the spine. Her peripheral pulses were well felt in all the four limbs. The pulse rate was 76/min, and blood pressure was 140/50 mm of Hg, with a collapsing pulse in the upper limbs. Early diastolic murmur was made out by auscultation. Respiratory system and abdominal examination were normal. Neurologically, cranial nerve and upper limb examinations were normal. No Horner's syndrome was noted. She had weakness of Medical Research Council grade 0/5 in both lower limbs from hip downward with hypotonia. Deep tendon reflexes in the upper limbs were brisk, which could not be elicited in lower limbs. She was able to describe the absent pinprick below her D-10 dermatome but could not cooperate well for posterior column examination. Plantar reflexes were absent on both the sides. In view of the above findings, the clinical diagnoses of myocardial infarction (MI), aortic regurgitation (AR), with anterior spinal artery (ASA) embolism causing paraplegia were made. Aortic disease was not considered initially as the peripheral pulses were normal. The patient did not have typical pain of dissection. Early diagnosis of Aortic Dissection (AD) at critical setup is often difficult [1] Furthermore, paraplegia as a presenting manifestation of AD is rare.[2] Other differential diagnoses of spinal arteriovenous malformation, dural arteriovenous fistula, epidural abscess, and spinal cord demyelination were also considered. However, a single consolidated diagnosis which explains all the findings could not be arrived at this point. The patient was subjected to investigations. X-ray of the dorsal spine did not reveal vertebral collapse or other abnormalities. Her routine blood investigations, liver function tests, and electrolytes were normal. Electrocardiogram showed anterior wall MI. The troponin-T level was high (80.97 pg/ml). Her echocardiogram showed mild left ventricular dysfunction, global hypokinesia, ejection fraction of 45%, mild AR, mild mitral regurgitation with dissection flap in ascending and arch of aorta extending into descending aorta. Three attempts of doing magnetic resonance imaging (MRI) went in vain as she could not lie down for more than few minutes and not sedated in view of hemodynamic instability. However, we could complete computed tomography (CT) angiogram of the aorta which revealed a Stanford-A, de-Bakey type-1 dissection of the aorta with entry point at the coronary sinus, extending upward to involving root, arch of aorta, descending thoracic and abdominal aorta extending into both common iliac and proximal external iliac arteries. All the three major branches of arch of aorta were involved. The true lumens of left main, right coronary arteries were compressed and small throughout their length. The left renal artery was arising from the true lumen at the site of narrowing [Figure 1]. Patient was advised to undergo emergency surgery under high life risk with poor outcome of paraplegia, which was explained in detail and her attendees agreed after prolonged counseling. The operation was performed through a midline sternotomy. Cardiopulmonary bypass was achieved. The aortic dissection was found to have originated in the right coronary sinus in close relation to the right coronary ostium. The left main coronary ostium looked clear without any obstructions. Under moderate hypothermia, the aortic root was replaced with a St. Jude Medical valved Dacron conduit. A reversed saphenous vein graft was sutured to the right coronary artery and connected proximally to the aortic graft. The distal aorta was anastomosed to the Dacron graft. The patient was weaned off bypass with stiff ionotropic support and shifted to the intensive care unit. She made slow but steady recovery with good hemodynamics, with no fresh focal neurologic deficit and gradual improvement in creatinine. She was transferred to the postoperative ward on day 8 and fit for discharge on the 14th postoperative day. Despite adequate physiotherapy, medial nursing, and nutritional care, she had developed sacral sores and the sensory level had ascended to D-2 dermatome. There was no improvement in lower limb power. She also continued to have double incontinence. A CT scan of the brain done on the 5th postoperative day did not show any abnormality. The marfanoid features were noted later after the diagnosis of AD was made. She had wrist sign, thumb sign, probable malar hypoplasia, and arm span-height ratio being 171.165 (>1.04) [Figure 2]. The patient's only son also had marfanoid features. The dissected aorta was sent for histopathology. The gross sample was 2 cm in length and 3 cm in diameter. Microscopy revealed focal loss of elastic and mucoid material of media. There are areas of disruption of elastic laminae replaced by smooth muscle, mucoid material, and collagen. The above features suggest aortic dissection secondary to cystic medial degeneration of ascending aorta [Figure 3].{Figure 1}{Figure 2}{Figure 3}

Discussion

Acute AD is a cardiothoracic emergency and acute paraplegia is neurological emergency. The diagnostic difficulties encountered in our patient include poor description of t the diagnosis he pain due to her restlessness as she had recent cardiac arrest, missing marfanoid features clinically due to supine position and sickness. Normal peripheral pulses and the inability to perform MRI also had made the diagnosis difficult. Embolic spinal cord infarction was initially suspected due to the occurrence of simultaneous MI with elevated troponin-T. Echocardiogram had given the first clue about aortic dissection. Unfortunately, MRI of the spine could not be done post operatively also due to recent surgery and staples. This case was presented due to its rare combination of paraplegia due to spinal cord infarction, caused by aortic dissection, secondary to Marfan syndrome associated with acute MI and cardiac arrest, without compromising carotid and renal circulations, and to share the difficulties encountered in making a prompt initial diagnosis. The clinical features of Marfan syndrome include ectopia lentis, joint laxity, dolichostenomelia, scoliosis, and pectus deformities. Retinal detachment, early cataract, and glaucoma are other features. The life expectancy is reduced in severe forms who have greater diameter of aortic root and arch (60%). If the difference in aortic root diameter is more than 5 mm in a patient with family history, prophylactic aortic root replacement should be considered. The aortic dissection is one of the major Ghent criteria [3] for the diagnosis of Marfan syndrome.

Role of Vitamin D in the Outcome of Ischemic Stroke- A Randomized Controlled Trial

SHUBA NARASIMHAN[1], PRAKASH BALASUBRAMANIAN[2]

ABSTRACT

Introduction: Vitamin D deficiency has reached epidemic proportions in India with prevalence rates of 70-100% in the general population. Low vitamin D levels are associated with worse outcomes in ischemic strokes. The outcome of stroke after vitamin D replenishment has not been much studied.

Aim: To compare the stroke outcome between patients receiving vitamin D supplementation and patients without vitamin D supplementation by Scandinavian Stroke Scale (SSS) and thus, to assess the long term outcome of ischemic stroke patients with low vitamin D level by supplementation of vitamin D.

Materials and Methods: This is a non blinded randomized controlled trial conducted in ischemic stroke patients. The patients were divided into two groups (A and B) where Group A received a single dose of 6 lac IU of Cholecalciferol Intramascular (IM) injection and Group B were not given vitamin D. Finally 30 patients in each group were analyzed. SSS was applied to evaluate the stroke severity at the onset and at the follow up after three months in both groups. The difference in SSS was analyzed using SPSS software. Independent t-test was applied and p-value < 0.05 was taken as significant.

Results: Mean±SD of vitamin D levels in Group A and Group B were 17.98±3.81ng/ml and 18.44±4.69 ng/ml respectively. Mean±SD of SSS at time of admission and after three months for Group A was 32.50±11.61 and 38.89±8.34; and for Group B 35.82±8.56 and 38.32±7.10. The difference in SSS from time of admission and after three months, in Group A (6.39±...) Group B (2.50±2.20) were analyzed statistically and found to be highly significant (p<0.001).

Conclusion: The results showed that there is a significant improvement in the stroke outcome after three months in those patients who were supplemented with vitamin D. Thus screening for vitamin D deficiency in stroke patients is essential and vitamin D replenishment will improve the stroke outcome.

Keywords: Scandinavian stroke scale, Stroke severity, Vitamin D deficiency, Vitamin D supplementation

INTRODUCTION

Vitamin D deficiency has reached an epidemic in India with prevalence rate being 70-100% in the general population [1]. Vitamin D deficiency is widely prevalent in tropical countries like India despite abundant sunlight [1]. It is the most under diagnosed and untreated nutritional deficiency in the world. Vitamin D deficiency is associated with increased risk of vascular disease and ischemic stroke in healthy individuals [2,3]. Vitamin D deficiency is associated with ischemic stroke risk and contributing factors being hypertension, hyperlipidemia, diabetes mellitus and ischemic heart disease [4]. Stroke is the second leading cause of death worldwide, accounting for 9% of deaths. There are an estimated 5.7 million stroke deaths which are expected to increase to 7.8 million by 2030 [5,6]. Vitamin D deficiency in stroke patients preceded stroke and prevalence of vitamin D deficiency was more in stroke patients than general medical patients [7]. Vitamin D supplementation in post stroke patients is helpful in prevention of recurrent stroke and is suggested to reduce neurological, psychological and musculoskeletal disorders [8]. It also reduces morbidity, mortality and improves functional outcome after stroke [9]. American Stroke Association International Stroke Conference 2015 has found that stroke patients with low vitamin D levels have large ischemic infarcts, suffer severe strokes and have poor health outcomes after stroke than those with normal vitamin D level [10].

There are various methods and scales to assess severity of stroke. SSS is reliable and widely used to assess functional outcome in patients with ischemic cerebrovascular disease and has been successfully used in several clinical trials [11].

Even though studies have shown association of vitamin D deficiency in stroke, studies have not been done by supplementation of vitamin D to ischemic stroke patients, which form the basis of our study. We tested the hypothesis that there is improved functional outcome in ischemic stroke patients supplemented with high dose of vitamin D compared with ischemic stroke patients receiving regular conventional treatment. Thus, we have assessed the long term outcome of ischemic stroke patients with low vitamin D level, by supplementation of vitamin D.

MATERIALS AND METHODS

This is a non blinded, randomized controlled trial conducted at PSG Hospitals, Coimbatore, Tamil Nadu, India. On obtaining approval from Institutional Human Ethics committee, the study was conducted in ischemic stroke patients admitted in Neurology ward from April-2014 to March- 2016. Informed written consent was obtained from the patients.

At the time of planning for the study, there were no trials of vitamin D supplementation in ischemic stroke patients. Therefore, sample size was based on Mean±SD estimates of vitamin D level in ischemic stroke patients and normal persons as per advice by statistician and the study done by Wu C et al., was used for calculation of sample size [12]. Sample size was calculated by Open Epi software version 3.01, by using simplified formula for difference in means of power 80%, confidence interval 95% and α level of 0.05 and was found to be 28 persons in each group.

The study included both males and females of age group from 50 to 80 years with vitamin D insufficiency (Serum 25- hydroxy vitamin D level 21-29 ng/ml) and vitamin D deficiency (Serum 25- hydroxy vitamin D level ≤ 20 ng/ml). Diagnosis of stroke was based on clinical assessment supported by Computed Tomography (CT) scan and Magnetic Resonance Imaging (MRI). Ischemic stroke

Association between Quality of Sleep and Academic Performance in Medical Students: A Preliminary Study

K. Deepalakshmi[1], S. Vijayabaskaran[2], R. Thamaraiselvi R.[3], R. Nagashree[4]

[1]Associate Professor, [2]Assistant Professor, Department of Physiology, PSG Institute of Medical Sciences and Research, Coimbatore, [3]Tutor, Department of Physiology, Stanley Government Medical College, Chennai, [4]Professor, Department of Physiology, PSG Institute of Medical Sciences and Research, Coimbatore

Abstract

Background: Medical students are more prone to daytime sleepiness, sleep deprivation and irregular sleep schedules, as they have less free time, longer courses and working hours compared to other professional students.

Aim: To assess the quality of sleep and to find out the association between sleep quality and academic performance among medical students.

Methodology: This cross sectional study was conducted among 176 medical students. They were subjected to Pittsburgh Sleep Quality Index (PSQI) questionnaire to assess their sleep quality over a one-month period. A PSQI global score of 5 and greater than 5 was considered indicative of poor sleep. Academic performance was assessed from their internal assessment scores conducted during that period. The data was analyzed using the unpaired students 't' test and Pearson's correlation test

Results: Our study included 176 students from all the phases of MBBS curriculum. 24 percentage students had poor quality of sleep. In our study, there was no statistically significant difference in the performance of good sleepers (57.94 ±18.06) and poor sleepers (58.80 ±17.37) with a p value of 0.785. Our study results showed a negative correlation between global PSQI scores and assessment scores of the students ($r = 0.57$ and $P = 0.449$).

Conclusion: In our study association between sleep quality and academic performance was not statistically significant. Assessment of sleep quality helps to indentify the students at risk and plan the specific programs to improve the quality of sleep.

Keywords: *Sleep quality, academic performance, medical students.*

Introduction

Medical students are exposed to multitude of changes when they enter into their professional life after completing their school education. Owing to highly demanding professional and academic requirements medical students are considered to be a vulnerable population of poor quality of life.[1] Medical students have compromised quality of life as they have to undergo long and intensive academic years.

Medical students are more prone to daytime sleepiness, sleep deprivation and irregular sleep schedules as they have less free time, longer courses and working hours compared to other professional students. Over the period of time, poor sleep quality will lead to chronic inability to recover from stressful conditions

COMPARISON OF TIME DOMAIN MEASURES OF SHORT TERM HEART RATE VARIABILITY IN TYPE 2 DIABETIC PATIENTS WITH AND WITHOUT MICROALBUMINURIA- A PRELIMINARY STUDY

K Deepalakshmi*, S Vijayabaskaran **,R Nagashree***,

*Associate Professor, ** Assistant Professor, *** Professor Department of Physiology, PSG Institute of Medical Sciences and Research, Coimbatore 641004

Abstract: Background & objectives: Diabetes is a complex and multi-factorial endocrine disorder with increased prevalence worldwide. Microalbuminuria is an independent marker of endothelial dysfunction and increases the risk of arrhythmia and atherosclerosis that affects cardiac autonomic function. Cardiovascular pathology remains a primary cause of death in patients with diabetes mellitus .So we aimed to compare time domain measures of short term Heart Rate Variability (HRV) in type 2 diabetic patients with and without microalbuminuria **Methods:** This prospective comparative study was conducted among diabetic patients with (n=14) and without (n=15) microalbuminuria. Patients with hypertension, dyslipedemia, coronary artery disease, cerebrovascular accident, family history of young MI, hyper or hypothyroidism and on beta-blocker treatment were excluded. Study participants were subjected to general clinical examination. Presence of microalbuminuria and their HbA_1C values were noted from their clinical records. Heart rate variability was assessed using an ambulatory ECG system in lead II for 5 minutes. The series of RR intervals obtained was subjected to time domain analysis. Time domain measures SDNN, rMSSD and NN50and pNN50 were obtained. **Results:** 29 diabetic patients participated in the study, out of which 14 were diabetics with microalbuminuria, and 15 were without microalbuminuria. On analysis of short-term time domain measures of HRV, the mean SDNN was decreased (51 ± 11.5) in diabetic patients with microalbuminuria, when compared to diabetic patients without microalbuminuria (54.96 ± 10.93) with p value 0.45. pNN50 and rMSSD was decreased in diabetic patients with microalbuminuria (1.09 ± 2.73, 14.32±8.17) when compared to diabetic patients without microalbuminuria (1.82 ± 3.06, 18.99 ± 7.71) with p value 0.51 & 0.13 respectively .

Conclusion: Our findings indicate cardiac autonomic function was altered in diabetic population with microvascular involvement

Key Words: Microalbuminuria, Heart rate variability, Diabetes Mellitus

Introduction:

Diabetes mellitus is a complex and multi-factorial endocrine disorder affecting all age groups .Its prevalence has increased worldwide and it was estimated to be 2.8% in 2000 and 4.4% in 2030.[1] Microalbuminuria is a independent marker of endothelial dysfunction and known to cause cardiovascular morbidity and mortality among individuals with diabetes.[2] Microalbuminuria increases the risk of arrhythmia and atherosclerosis which affects cardiac autonomic function.[3]

Early recognition of autonomic dysfunction plays a significant role in prediction of cardiovascular mortality in diabetes mellitus. Decreased Heart Rate Variability (HRV) is associated higher risk (32–45%) of cardiovascular morbidity and mortality in diabetic individuals and as well in healthy controls.[4,5,6]

HRV is a reliable non invasive tool used in the assessment of cardiac autonomic function. Evaluation of HRV by time domain measure is the simplest and most popular method.[7] Parameters considered during time a domain analysis are standard deviation of all R-R intervals (SDNN), root mean square of successive RR- interval differences (RMSSD) and number of intervals differing by > 50ms from adjacent interval (NN50) and

Effect of Age and Hypertension on Cognition: A Cross-sectional Study

DEEPALAKSHMI KALIYAPERUMAL[1], VIJAYABAS KARAN SHANMUGA VARADHARAJAN[2], VARSHA VISWANATHAN[3], MURALI ALAGESAN[4]

ABSTRACT

Introduction: Cognitive impairment has evolved as major health and social issue. As age advances cognitive tasks involving processing speed, working memory and executive function get affected. Cognitive impairment is also influenced by modifiable risk factors such as hypertension, diabetes mellitus and hypercholesterolemia.

Aim: To find out the effect of age and hypertension on cognition.

Materials and Methods: The total study participants were divided into three groups based on their age as group I (18-29) group II (30-59) and group III (above 60) with 20 participants (n= 20) in each group. Their cognition was assessed using Mini Mental State Examination, Picture word Learning test, Stroop colour word test, Letter digit coding test, Verbal fluency and Logic memory tests. Disease history and known co morbidities (hypertension) were noted. Post-hoc test (Bonferroni) was employed to assess age-wise comparison of cognition and Pearson's chi-square test was used to compare cognition between hypertensive and normotensives.

Results: Group II had impaired cognition when compared with group I (p-value- 0.000). Group III had impaired cognition when compared with group I (p-value- 0.000) and group II (p-value 0.001). The hypertensives in group II and III had statistically significant impairment in cognition when compared with normotensives (p-value -0.001) in the same group.

Conclusion: Cognitive functions are impaired as a result of increase in age. Furthermore, there is also a significant decrease in cognitive functions amongst those suffering from hypertension. Hence, we conclude there is decrease in cognitive function as age advances and the co-existence of hypertension hastens this decline.

Keywords: Cognitive impairment, Mini mental state examination, Old age

INTRODUCTION

The word cognition comes from the Latin verb *cognosco* meaning 'I know, perceive' or 'to recognise or conceptualise. Cognitive functions are those which include cerebral activities that lead to knowledge and encompass reasoning, memory, attention and language. Ageing can also have diverse effects on cognitive function. The spectrum of cognitive decline ranges from normal cognitive ageing (healthy" or "successful" Ageing), mild Cognitive impairment (does not prevent them from performing daily activities) and severe cognitive deficits (impede the ability to live independently [1]. Cognitive impairment has evolved as major health and social issue as the life span of both men and women has increased dramatically. Cognitive impairment accounts for about 40% of hospital admissions among the older individuals [2]. As age advances cognitive tasks involving rapid processing and transformation of information, which includes processing speed, working memory and executive function gets affected [3].

These age-related cognitive declining results from structural and functional changes that affect neuronal structure like loss of synapses and dysfunction of neuronal networks [4]. Cognitive impairment is also influenced by modifiable risk factors such as hypertension, diabetes mellitus and hypercholesterolemia [5]. Among these factors hypertension, which causes vascular changes resulting in cerebral infarction and diffuse ischaemic changes contribute to cognitive impairment [6].

Age related cognitive decline is already stated by several studies [7,8] earlier; but none of them used six tests which examine the different domains of cognition and there are only a few studies [9,10] that have included co-morbid condition such as hypertension to study the decline in cognition as age advances.

Hence, we aimed to conduct a study to find out the effect of age on cognition with the help of series of cognitive assessment tests. In this study we also analysed the effect of more common and prevalent (33.8% in urban parts of India) [11] co-morbid condition, hypertension on cognition especially amongst the vulnerable elderly group of individuals.

MATERIALS AND METHODS

This cross-sectional study was conducted during the month of January 2014 for the period of two months among students, staff and patients of PSG Institute of Medical Sciences and Research, Coimbatore after obtaining the ethical clearance from institutional ethical committee (Ethics registration file No 13/328). A total of 60 participants after getting their written informed consent were included in the study. Participants were grouped based on their age Group-I (18-29), Group II (30-59), Group III (above 60). Participants younger than 18 years of age and those suffering from co-morbidities apart from hypertension such as diabetes mellitus; chronic respiratory diseases, chronic liver diseases, thyroid diseases, renal and neurological disorders were excluded from the study. Hypertensive participants (Systolic BP of more than 140mm Hg, Diastolic BP of more than 90 mm Hg) for more than two years duration and on anti hypertensive treatment were included the study.

Study participants were assessed for their cognitive performance by using a series of tests. An initial interview of subjects was conducted where they were asked about their education, occupation and age at retirement for group III. Disease history and known co-morbidities (hypertension) were noted.

Mini Mental State Examination [12]

It is an 11 question measure that tests five areas of cognitive function: orientation, registration, attention and calculation, recall and language. The maximum score is 30, a score of 23 or lower is indicative of cognitive impairment.

ABSTRACT

Background: Microalbuminuria is considered as an early marker and strongly associated with risk of cardiovascular complications in diabetic patients. Autonomic imbalance due to micro vascular damage to parasympathetic and sympathetic fibers results in reduced heart rate variability; also predicts increased risk for cardiovascular events in diabetics. Hence it is necessary to identify an early and effective predictor of diabetic micro vascular complications. Objective of the study was to compare heart rate variability of controls with type 2 diabetes with and without microalbuminuria.

Methods: This comparative study was conducted among individuals without diabetes, hypertension and dyslipidemia (controls) and Type II diabetics with and without microalbuminuria (cases). Cases and controls were subjected to general clinical examination; microalbuminuria and HbA1C were noted. heart rate variability was assessed using digital physiograph. Frequency (HF, LF, LF/HF ratio) domain readings were noted.

Results: Mann Whitney U test was employed to analyze nonparametric data. Diabetics with microalbuminuria when compared with controls showed statistically significant (p-value=0.015) reduction in vagal activity. When compared with diabetics without microalbuminuria (180.4±151.7) they showed reduction in HF with no statistical significance. When diabetic group without microalbuminuria (0.56±0.31) was compared with controls they showed alternation in LF/HF ratio which has no statistical significance. Diabetics with microalbuminuria when compared with controls showed a statistically significant (p-value=0.009) alternation in LF /HF ratio implying an autonomic imbalance.

Conclusions: This study shows there is significant vagal inhibition and autonomic imbalance in diabetic patients with microalbuminuria compared to controls. To ascertain the role of HRV as an early predictor of cardiovascular complications we propose to conduct study with a larger sample size in future.

Keywords: Autonomic imbalance, Diabetes mellitus, Heart rate variability, Microalbuminuria

INTRODUCTION

The magnitude of non-communicable diseases (cardiovascular diseases, diabetes, malignancies and chronic respiratory diseases) has brought about a negative socioeconomic impact and sufferings to the mankind.[1] 36 million deaths have been reported every year due to diabetes and its complications. Moreover, 9 million people succumb to death prematurely.[2] Improved and effective medications have increased the lifespan of diabetic population. Hence there is a need to identify and intervene at the earliest in order to prevent complications and provide them a better quality of living. Microalbuminuria is considered as an early marker. It

Received: July 13, 2021; **Accepted:** August 06, 2021

ABSTRACT

Background: Gastrointestinal (GI) autonomic neuropathy and reflux esophagitis are common in chronic diabetics. To gauge the adequacy of peristalsis, high-resolution esophageal manometry is considered as a reliable test. **Aim and Objective:** To compare the GI symptoms and high-resolution manometry parameters between type II diabetes patients and normal volunteers. Materials and Methods: This comparative study was conducted on 35 known type II diabetes mellitus patients (hemoglobin A1c [HbA1c] levels ≥6.5%) and 35 normal volunteers between the age group of 35 and 70 years. Sociodemographic details, drug history, disease duration, and GI symptoms were elicited among the study participants. HbA1c and High-resolution manometry were measured for all the participants. **Results:** The frequency of epigastric pain (31.48%), heartburn (34.28%), pharyngeal irritation (31.43%), and loose stools (37.14%) were significantly higher in the diabetics. Significant difference ($P < 0.05$) was observed in mean basal expiratory pressure (MBEP) and mean basal inspiratory pressure (MBIP) values between diabetics and controls. There was a positive significant correlation between esophagogastric junction contractile integral and MBIP ($r = 0.557$), MBEP ($r = 0.583$), Median Integrated Relaxation pressure ($r = 0.410$). **Conclusion:** Hyperglycaemia seems to be an independent risk factor for gastroesophageal reflux disease (GERD). Obesity significantly increments the occurrence of GERD in diabetics. Strict adherence to preventive measures such as weight reduction, diet management, glycaemic control will have a great impact on the occurrence of GERD in diabetics.

KEY WORDS: High-resolution Manometry; Hemoglobin A1c; Type 2 Diabetes Mellitus; Gastrointestinal Symptoms

INTRODUCTION

Diabetes Mellitus (DM) is a metabolic disorder with high blood glucose levels, either the pancreas does not produce adequate insulin or due to insulin resistance.[1] India is known as the "diabetes capital" of the world due to its growing prevalence and the causes may be attributed to lifestyle changes, genetic predisposition, and urbanization. Majority of diabetics may encounter episodes of gastrointestinal (GI) symptoms like heartburn and acid regurgitation.[2] The GI symptoms such as diarrhea, epigastric pain, nausea, heartburn, vomiting, dysphagia, constipation heartburn, and fecal incontinence are collectively known as Diabetic enteropathy.[3] Autonomic dysfunction can be the primary cause if a type II Diabetic person presents with upper GI symptoms most often.[4] Gastroesophageal reflux disease (GERD) was predominantly observed in diabetics than the euglycemic population.[5]

His angle and flap valve, Crural diaphragm, lower esophageal sphincter (LES) are the components of Esophagogastric

Plasma Total Thiols and Total Thiol/Albumin Ratio in Patients Suffering from Depression

AS MEENAKSHI SUNDARAM[1], KRISHNANANDA PRABHU[2]

BY-NC-ND

ABSTRACT

Introduction: Increased oxidative stress has been reported in patients who suffer from depressive disorders. Albumin acts as a target for plasma protein oxidation during oxidative stress. The plasma thiols act as significant in-vivo antioxidants. Major SH-groups are found on the surface of albumin molecules. Since depressive disorders are related to oxidative stress. Only a few studies have been done that correlate plasma total thiols with major depressive disorder. The authors intended to draw a relationship between oxidative stress, thiols and major depressive disorder by estimating total plasma thiols and calculating the ratio of thiol/albumin. The study may throw some light in understanding whether the use of anti-oxidant supplements to counter oxidative stress in depressed patients.

Aim: To estimate plasma thiols, albumin and obtain a plasma thiol/albumin ratio in people suffering from depression and compare the levels with the control group.

Materials and Methods: This case control study was conducted in Kasturba Medical College, Manipal. Plasma thiols were estimated using Ellman's method. Plasma albumin levels were estimated using Bromo cresol green dye binding method. Mann-Whitney U test was used for analysing the data for total thiols and thiol/albumin ratio. A p-value <0.05 was considered significant.

Results: The study group was made up of 43 (22 males and 21 females) patients and the control group was made up of 40 (18 males and 22 females) healthy controls. Plasma thiol levels and the plasma total thiol/albumin ratio were significantly elevated (p<0.001) in cases (depression) as compared to that of the controls.

Conclusion: Plasma total thiols can be used as an early marker for understanding the risk for major depressive disorders and also be used as a prognostic indicator in the follow up of patients suffering from major depressive disorder who are under treatment.

Keywords: Major depressive disorder, Malon-di-aldehyde, Reactive oxygen species

INTRODUCTION

Elevated oxidative stress identified by elevated free radicals has been studied in patients with unipolar depressive disorder. As a common understanding, 12% of patients presenting to primary health care set up suffer from depression [1,2]. Antioxidant effects seen in antidepressants that are offered as a treatment of depression supports the concept that free radical stress may have a part in the pathology of depressive disorders. The stress may cause neuro-degeneration and lowered neurogenesis. There are data suggested that elevation in oxidative stress can be related to major depression and is proved by an elevated serum Malondialdehyde (MDA) levels and Super oxide dismutase (SOD) levels [3]. High levels of antioxidant enzymatic activity (SOD and glutathione peroxidase) have been found in patients with depression [4]. Albumin gets to be a target during oxidative stress for oxidation of plasma proteins. Since thiols are found to exhibit in-vivo anti-oxidant properties and the major free sulphydryl groups are present over albumin [4,5] the study was intended to estimate the same and correlate them with the depressive disorders. The study can help us to understand if in future anti-oxidants or the drugs that can increase total thiols, may be helpful in the treatment of depression.

MATERIALS AND METHODS

This was a case-control study conducted between September 2010 and September 2012.

The study was conducted at:

1. Departments of Biochemistry and Psychiatry, Kasturba Medical College and Hospital.
2. Department of Psychiatry, Dr. A. V. Baliga Memorial Hospital, Udupi.

After obtaining the approval from the Institutional Ethics Committee (Approval number: I.E.C./44/2011). of Kasturba Hospital, Manipal and the Director of Dr. A. V. Baliga Hospital, Udupi, study has been done in accordance with Helsinki guidelines for human studies. The study was conducted after getting the proper informed written consent of the cases' legal guardians and healthy controls.

Inclusion criteria: Cases: Patients of both sexes of age group 30 to 70 years, who were freshly diagnosed clinically as suffering from depressive disorders and not on any treatment for depressive disorders.

Controls: Healthy subjects of both sexes of age group 30 to 70 years, who have scored less than four major points (or) fourteen minor points after answering the Goldberg's general health questionnaire-28 [6].

Exclusion criteria: Subjects less than 30 years and more than 70 years of age/those suffering from depression but having symptoms of psychosis/with disorders suggestive of psychosis (schizophrenia)/tuberculosis/diabetes mellitus/Acquired Immunodeficiency Syndrome (AIDS)/thyroid gland based illness/seizure disorders /long standing defects in kidney, liver or brain function and any chronic illnesses and subjects who were on treatment for any of the above conditions. Subjects who were chronic alcohol and nicotine consumers were excluded too.

Serum Separation

Samples were collected by venepuncture into the Lithium heparin containers in the fasting period from each patient before admission.

Blood was allowed to clot in an upright position for atleast 30 minutes but not longer than one hour before centrifugation. Centrifugation was done for atleast 15 minutes at 2200-2500 RPM within one hour of collection.

Can Early Thyroid Profiling Help Avert Spontaneous Abortions/Early Pregnancy Loss: A Retrospective Study

Meenakshi Sundaram Andra Suryanarayana [1], Kishore Vellingiri [2], Saransh Kumar Agarwal N [3], Bhushan Mohan [3]

1. Biochemistry, PSG Institute of Medical Sciences and Research, Coimbatore, IND 2. Orthopaedics, Sri Devaraj Urs Academy of Higher Education and Research, Kolar, IND 3. Medicine and Surgery, PSG Institute of Medical Sciences and Research, Coimbatore, IND

Corresponding author: Kishore Vellingiri, kishorembbs13@gmail.com

Abstract

Presence of thyroid autoantibodies in euthyroid women can result in various complications such as miscarriages and pre-eclampsia. Women who are hypothyroid have an increased risk of anaemia, infertility, and preterm birth. Spontaneous miscarriages have been reported in association with women with antithyroid antibodies. This can be utilised as a supplementary marker for the mother's immune system failure. The goal of this study was to compare the thyroid profiles of pregnant women who had a normal delivery to those who had a high-risk obstetric history, and to see if early thyroid profiling can help prevent poor pregnancy outcomes. In conclusion, our analysis has demonstrated that women with abnormal values of T4, T3, anti-thyroid peroxidase (TPO), and TSH were associated with fetal demise when compared to women with normal values of T4, T3, anti-TPO, and TSH. Anti-TPO levels were shown to be elevated in women with a poor obstetric history, making early thyroid profiling improve outcomes in pregnancy. Hypothyroidism with increased TSH and anti-TPO levels may have a negative impact on obstetric history, resulting in the loss of an early pregnancy.

Introduction

Thyroid peroxidase (TPO) is an enzyme found in the thyroid gland's apical membrane that aids in the conversion of iodine ions (I-) to iodine (I) atoms, a process known as organification. For the formation of thyroxine (T4) and triiodothyronine, these iodine atoms will bind to the tyrosine residues connected to thyroglobulin molecules (T3). TPO plays a supportive role in the formation of the thyroglobulin molecule as well as thyroid hormone coupling events. Anti-TPO antibodies, which belong to the IgG immunoglobulin class, are autoantibodies directed against thyroid peroxidase protein [1]. These antibodies are seen in patients with thyroid dysfunction (hypothyroidism or hyperthyroidism), but there is also evidence of these antibodies in healthy individuals. In Hashimoto's thyroiditis, anti-TPO antibodies can be one of the autoantibodies targeting the gland [2]. Euthyroid women with autoantibodies can cause complications in pregnancy such as repeated miscarriages and pre-eclampsia, according to one study [3]. Euthyroid women are also at a higher risk of anemia, infertility, and preterm deliveries [4]. According to one study, spontaneous miscarriages are linked to a higher incidence of antithyroid antibodies [5]. This can be used as a secondary marker for immune system failure in the mother [6]. The goal of this study was to compare the thyroid profiles of pregnant women who had a normal delivery with those who had a complicated obstetric history, and to see if early thyroid profiling can help prevent bad pregnancy outcomes.

Materials And Methods

From December 2019 to December 2020, investigators at PSG Institute of Medical Sciences and Research in Coimbatore conducted a retrospective analysis. After receiving approval from the institutional ethics committee, we reviewed data from 164 patients, including 81 patients with thyroid problems and 83 healthy pregnant women. Age, BMI, anti-TPO levels, T3, T4 levels, mode of delivery, and thyroid medication were all taken into consideration. The information obtained on chart review of the 164 patients was documented on a password-protected online tool and accessed by the investigators only. None of the patients protected health information (PHI) were documented as per the institutional Health Insurance Portability and Accountability Act (HIPAA) policy. The mean, standard median, and confidence interval were used to express all quantitative data. A student t-test was used to quantify the magnitude of the mean difference between groups, and a p-value of 0.05 was considered statistically significant.

Results

The mean age group in normal individuals was 27.67 years old, while thyroid patients were 27.43 years old.

Plasma Myeloperoxidase and Total Sialic Acid as Prognostic Indicators in Acute Coronary Syndrome

SUMITRA GOVINDARAJAN[1], VM MITHUN RAGHAVAN[2], ANAND C VASUDEVA RAO[3]

ABSTRACT

Introduction: Acute Coronary Syndrome (ACS) is the leading cause of death worldwide. Oxidative stress and inflammation play important role in the destabilization of plaques leading to ACS. Markers which reflect this pathophysiologic mechanism may have prognostic value. Myeloperoxidase (MPO) and Sialic acid are markers of inflammation and oxidative stress. Both these markers are increased in patients with ACS. Their prognostic value in ACS is not well established.

Aim: To analyse the prognostic value of plasma myeloperoxidase and total sialic acid levels in patients with suspected acute coronary syndrome.

Materials and Methods: A prospective study was conducted on 93 consecutively admitted patients with chest pain from July 2011 to September 2011. Plasma MPO and total sialic acid levels on admission were estimated spectrophotometrically. These were compared with extent of disease, development of complications during the hospital stay, left ventricular ejection fraction and mean duration of stay in hospital.

Results: Plasma MPO and total sialic acid levels were significantly higher in patients with myocardial infarction than those with unstable and stable angina ($p<0.001$ and $p<0.007$ respectively). The levels of plasma MPO and sialic acid levels were significantly higher in patients who developed complications like heart failure, arrhythmias, renal failure during their stay in hospital ($p<0.011$ and $p<0.006$ respectively). Ejection fraction was significantly low in patients with high MPO levels ($p<0.011$).

Conclusion: In patients with ACS, plasma MPO and total sialic acid levels on admission could predict the development of complications during their hospital stay. MPO levels correlated with ejection fraction in patients with ACS.

Keywords: Left ventricular ejection fraction, Major adverse cardiac event, Myocardial infarction

INTRODUCTION

Ischemic Heart Disease (IHD) is the leading cause of death worldwide, accounting for 12.7% of global mortality [1]. Acute Coronary Syndrome (ACS) covers a wide spectrum of clinical conditions ranging from unstable angina to Non-ST Elevation Myocardial Infarction (N-STEMI) and ST Elevation Myocardial Infarction (STEMI). Insufficient coronary perfusion due to variable degrees of acute plaque change, thrombosis and vasospasm over chronic, progressive atherosclerotic narrowing of the coronary arteries is the underlying pathology. Although they share this pathophysiology, outcomes and effective management strategies differ by the patient's place in the spectrum [2]. As new treatments and management guidelines emerge for care of patients with ACS, risk stratification is the cornerstone in the initial evaluation of these patients [2]. Simple prognostic markers that reflect pathophysiologic mechanism may aid in tailoring the therapy to match the intensity of patient's disease [3].

Oxidative stress and inflammation play vital roles in pathogenesis and progression of Coronary Artery Disease (CAD) leading to Acute Coronary Syndromes (ACS) [4]. Inflammation is implicated in all stages of atherosclerosis, from early lipid deposition to plaque rupture. Inflammation mediates the weakening of fibrous cap and makes the plaque more susceptible to rupture, thus precipitating ACS [5]. A study shows that the inflammatory process persists even after the resolution of clinical symptoms and there is a link between recurrent ischemic episodes and persistent inflammation [6]. Thus, inflammatory biomarkers may provide independent information regarding pathophysiology, prognosis and help in formulating optimal therapeutic strategies.

Myeloperoxidase (MPO) is present in neutrophils and monocytes and is released when they undergo degranulation [7]. It is a marker of inflammation and oxidative stress that has been consistently demonstrated to be elevated in patients with ACS [7]. Several experimental and epidemiologic studies indicate MPO as a candidate marker for clinical application [7]. In addition to being a causative factor for CVD and acute cardio vascular events, MPO can also extend the prognostic information gained from traditional biochemical markers. So, further investigation is needed to expand our knowledge on the prognostic role of MPO in ACS.

Sialic acids are 10 carbon derivatives of neuraminic acid. They comprise the terminal sugar of the oligosaccharide chain in glycolipids and glycoproteins. Studies have shown that serum total sialic acid is elevated in cardiovascular disease; which is attributed to the increase acute phase reactants in these patients [8]. Following acute myocardial infarction, shedding or secretion from damaged cell can lead to elevated sialic acid [9]. Though many studies have evaluated its role in pathogenesis of atherosclerosis its role as a prognostic marker has not been studied.

The purpose of the present study was to analyse the prognostic value of plasma myeloperoxidase and total sialic acid levels in patients with suspected acute coronary syndrome. In samples of patients with suspected ACS, myeloperoxidase and total sialic acid levels were measured and their concentrations were compared with certain prognostic markers of ACS.

MATERIALS AND METHODS

This prospective study was conducted at the Department of Biochemistry, PSG Institute of Medical Sciences and Research, Coimbatore, India. It was approved by the Institutional Human Ethics Committee (ethical clearance letter no:11/206).

Study subjects

Consecutively admitted patients with chest pain in PSG Hospitals from July 2011 to September 2011 were studied. Patients with cardiac chest pain as shown by ECG changes or elevated cardiac Troponin T levels (> 0.03ng/ml) were included in the study. Patients

Abstract

The emergence of Corona Virus Disease-2019 (COVID-19) pandemic had unprecedented effects on medical education worldwide. Sustaining student engagement in virtual learning is an arduous task. Team based learning (TBL) is a learner-centered approach that can facilitate better student engagement. Adapting TBL to online platform may address the challenges faced in virtual learning. This study was conducted to implement and evaluate online TBL among first year MBBS students in Biochemistry. After obtaining informed consent, three online TBL sessions were planned. The Individual Readiness Assessment Test, Group Readiness Assessment Test, and team application were assigned in Google classroom. The students used online platforms for their team interactions. After submitting their assignments, they joined online discussion with facilitator. Peer evaluation was done via Google forms. At the end of all the sessions, the students' perceptions on the process were collected using a structured anonymous feedback with open comments. Analysis of their feedback showed that the students found the process useful and it helped in fostering their team skills. Five major themes emerged on content analysis of the open comments; 'Enriched team skills', 'Gain in knowledge', 'Impact on attitude', 'Interaction during pandemic', and 'Emotional responses'. Students perceived that the online TBL is effective in improving their engagement, learning, and team skills.

1 | INTRODUCTION

Indian Medical curriculum faced two challenges in the year 2019, first, being the most anticipated shift from traditional curriculum towards Competency Based Medical Education and second, the emergence of COVID-19 pandemic. When the new curriculum was rolled out, colleges had to close mid-academic year due to COVID-19 lockdown restrictions across the country. The break in academics, initially expected to be for a brief period, continued for more than a year.

Medical schools had to witness a sudden transition from conventional face-to-face learning to virtual learning. This was a demanding task and the stakeholders faced many challenges in the process. Lack of technical and time management skills, inadequate infrastructure, and poor communication at various levels were some of the challenges faced by the faculty and institutions.[1] Students faced several problems; anxiety, distractions, isolation, lack of interaction with peers, and difficulty in staying focused in online class.[2]

Team based learning (TBL) is a highly learner-centered, group based instructional approach that can

Awareness about Research Ethics among General Practitioners not Attached with Research Institutions

SUBRAMANIAN KAVITHA[1], GOVINDARAJAN SUMITRA[2], DURAIRAJ VIJAYA[3], MARUDACHALAM KAVITHA[4], SUBRAMANIAN BHUVANESHWARI[5]

Keywords: Bioethics, Workshops, Private doctors

Dear sir,

Research in medical field is important to help and improve our knowledge in medicine. Especially there is increase in research in India in the past few decades. Research ethics is an important factor in any research protecting the welfare of participants. Many International guidelines exist for the same [1,2]. Complaints regarding research show that there is increase of awareness among public as well as the practices of doctors. General practitioners working in a hospital do conduct clinical trials. This study was designed with the aim to evaluate the awareness and knowledge of general practitioners about research ethics.

After obtaining approval from Institutional Ethics committee, a cross sectional study was conducted among 25 general practitioners in the local town. They were explained about the study and asked for willingness to participate. After getting informed written consent, they were recruited. A questionnaire was made by the authors based on literature. First part of questionnaire included demographic data, details about research involving human participants in the past and present and participation in any programs on research ethics. Second part contained a series of questions or statements which tested the knowledge of the doctors in research ethics.

Twenty five general practitioners or working in hospitals participated in the study. All the participants filled up the questionnaire and returned it to us whose identity was blinded. Mean age of the participants was 41.5 years. Of 25, three were MBBS, three were PG Diploma, 15 were MD/MS/ DNB holders and two were super specialty. Currently one was involved in research.

Eight participants had conducted clinical trials before and 76% were interested in future research. 8% participants had undergone formal training but, 52% felt that they are familiar with Research Ethics. All the 25 participants were aware that patient confidentiality has to be maintained. A 96% participants knew that ethical clearance has to be obtained for all the projects and all potential risks has to be explained to patients before enrolling them in the study. A 92% participant knew that patients had the right to withdraw from study without forgoing their right for treatment.

A total of 16% participants responded that stored samples can be used in other research projects without patient permission. A 16% were also not clear about conflict of interest while conducting clinical trials, 16% felt that ethical committee need not be informed about the progress of the study. Considerable number of participants (28%), were unclear about consent issues in vulnerable populations namely – children, students, etc.

Medicine is a growing field and research and it forms the platform for expansion of knowledge. Doctors working in research institutes undergo formal training in research ethics and general practitioners have less access to the same. Most of the participants knew the importance of patient confidentiality which is similar to the study conducted by Gopinath NM et al., to study the knowledge about research ethics among dental faculty [3]. But they were not aware of the ethical issues involving vulnerable population. Participants were knowledgeable about the need for ethics committee approval before starting the research but they felt that reporting study progress only delayed research. This is similar with El-Dessouky HF et al., study among dental faulty [4].

Though half of the participants said they are knowledgeable about research ethics, only 2 out of 25 participants had undergone any formal training which indicates a need for workshops or Seminars to general practitioners.

Knowledge about research ethics involving human subjects among Doctors not associated with research institutions is fairly good even though majority of them have not undergone formal training. Probably this knowledge was acquired during their PG training. However complete knowledge about research ethics involving human subjects is mandatory for all Doctors. This gap can be covered by conducting periodic training on Research ethics for all medical practitioners.

Breast disease

ABSTRACT

Objective: Matrix metalloproteinases (MMPs), particularly MMP-2 and MMP-9, have been reported as putative tumor markers because of their involvement in cancer invasion and metastasis. The aim of our study was to elucidate the possible role of MMP-2 and -9 as serum prognostic biomarker for breast cancer classification and correlate it with the clinicopathological variables.

Design and Methods: Our study consisted of 60 females with primary breast cancer, 40 cases of benign breast disease and 60 healthy female volunteers as controls. The serum MMP-2 and -9 levels were quantitatively measured by ELISA technique.

Results: A significantly raised MMP-2 and MMP-9 levels were observed in breast cancer patients. Significant rise in serum MMP-9 concentration was found in patients presenting with metastasis as well as in those cases who presented with a duration of less than 1 year. ROC analyses depicted a serum cutoff value of 315 ng/mL for MMP-9 to discriminate the breast cancer patients from the control group.

Conclusion: Our results suggest that serum MMP-9 level is a better marker than serum MMP-2 in predicting the breast cancer development and progression.

Introduction

Breast cancer continues to be one of the leading cause of cancer related mortality in women in the Western world [1]. It is well documented that breast cancer patients with the same stage of disease can have markedly different outcome and therapy responses [2]. The current screening methods like mammography, self breast examination and clinical breast examination are not sufficient for an early diagnosis in all these patients. Hence there is a need for biomarkers that can complement existing screening tools and used in clinical decision making to predict the responsiveness to therapies. An ideal biomarker should correlate well with disease and be easily detectable in blood. So far no single soluble biomarker for breast cancer with these attributes has been identified.

The mammary tissue microenvironment, consisting of structural, biochemical and cellular entities, is known to contribute to tumor cell fate [3]. Degradation of the stromal connective tissue and basement membrane components are key elements in tumor invasion and metastasis. Tumor invasion and metastasis are the major causes of treatment failure or death for carcinoma patient, and hence, molecules involved in these processes are obvious candidates to be identified as new prognostic markers in breast cancer. The matrix metalloproteinases (MMPs) in humans are a family of 23 members that have been associated with remodeling of the extracellular matrix (ECM). Because of their involvement in processing of ECM, MMPs were implicated in cancer invasion and metastasis [4,5]. Because tissue MMP may also be secreted into the blood stream and increase the circulating levels, it is believed that MMP profile in the blood could serve as biological markers for disease onset, progression and monitoring [6]. Gelatinase A (MMP-2) and gelatinase B (MMP-9) differ from other MMPs because of their ability to degrade gelatin and type IV collagen, the main component of basement membrane (BM), which is the main barrier separating in situ and invasive carcinoma [7]. Recent evidence suggests that MMP-2 and MMP-9 may also be involved in breast cancer initiation and growth through complex interactions with the main oncogenes and tumor suppressor genes involved in early stages of tumorigenesis [8]. Recent studies in breast cancer patients have shown that an increase activity level of both MMP-2 and MMP-9 in their sera is a strong and independent indicator of biologically aggressive disease with an unfavorable outcome and that their increased level in patients with advanced TNM staging might reflect the severity of invasive breast cancer [9–11]. Especially in breast, colorectal, bladder and ovarian cancers, serum MMP-9 levels have been shown to have prognostic significance [12]. Few studies have associated MMP-2 positivity with unfavorable prognosis in both premenopausal and postmenopausal node positive breast carcinoma patients [13–15], while few others have suggested that MMP-2 negativity may be linked with a favorable prognosis in node negative breast carcinoma [16]. Although available reports suggest that elevated levels of MMP-2 and MMP-9 occur in serum and plasma of

Abstract

Team teaching is an innovative method to engage the large group and make lectures more interesting. The aim of the study is to evaluate the impact of team teaching in first year biochemistry lecture classes. After obtaining ethical clearance, 150 first year medical undergraduate students participated in the study on a voluntary basis. Topic identified for team teaching was "Protein biosynthesis" in Biochemistry, which was designed to be carried out in 5 h of lecture by three teachers. At the end of the team teaching module and traditional lectures, a structured anonymous feedback was obtained from the students. At the end of each class, students' understanding of the lecture was assessed by an MCQ test comprising 5–6 items, which mainly tested the recollection and understanding levels of Bloom's taxonomy. This was compared with traditional lectures. The mean MCQ test score was significantly higher for team teaching when compared to traditional teaching. The students had increased attention span and were able to answer questions from later part of the class in team lectures. The students had reported that lectures taught by team were more interesting and informative. They also felt that the team was more receptive to the doubts raised, stimulated discussion on the topic and had a better rapport with the class.

1 | INTRODUCTION

Lecture is still the dominant teaching strategy in Medical schools worldwide.[1] Although lecture has the advantage of organized presentation of concepts to a large body of audience with economical use of time, it has always suffered the disrepute of being boring and unattractively long. Attention span for most of the adult learners is said to be around 20 min.[2] Capturing the attention of the large group and maintaining it through the lecture, encouraging active learning are some of the challenges faced by the lecturer. Many strategies have been explored to make the lectures more interactive and interesting. With an easily distracted audience of 150 (annual intake in most medical colleges in India), taking an effective lecture is a Herculean task.[3]

Collaborative teaching or Co-teaching involves a group of instructors working purposefully, regularly, and cooperatively to help a group of students learn. There are many possible models of Co-teaching—supportive, parallel, alternative, complementary, and team teaching. Team teaching is defined as "well planned, team taught lessons,

CASE REPORT

A Case of Light Chain Deposition Disease (LCDD) in a Young Patient

Mala Mahto · Sudhesna Mohapatra · G. Sumitra · Smita Kaushik · T. K. Mishra · Alpana Saxena

Received: 14 November 2010 / Accepted: 28 December 2010 / Published online: 11 January 2011

Abstract Light chain disease is a variant of multiple myeloma in which the malignant population of marrow cells produces free monoclonal light chains but no heavy chain or complete immunoglobulin. The monoclonal light chains are small enough to be freely filtered by the kidneys and become Bence–Jones protein. Light chain disease comprises about 18% of multiple myeloma patients. Here we present a case report of a 38-year-old man who initially presented with complaints of pain in back and low grade fever off and on. He was found to have collapse of D9 and D12 vertebrae along with ascites and right pleural effusion and massive proteinuria. Multiple myeloma was considered as a differential diagnosis based on the investigations but eventually the patient was lost to follow up. This case is reported here as the light chain variant of multiple myeloma leading to deposition disease is less commonly reported and presents considerable difficulties in diagnosis.

Keywords Multiple myeloma · Light chain disease · Bence–Jones protein

Introduction

Light chain disease (LCD) is a variant of multiple myeloma in which the malignant plasma cells of the bone marrow produce free monoclonal light chains [1]. These light chains can be deposited in many organs leading to light chain deposition disease [2]. Renal involvement is most frequent and it manifests as nephrotic range proteinuria and renal insufficiency. Light chain deposition disease is found in 5% of the myeloma patients at autopsy. The monoclonal light chains are small enough to be freely filtered by the kidneys and become Bence–Jones protein. The clinical features [3] include:

1. A more malignant course as compared to classical myeloma.
2. Extremely rapid doubling time.
3. Tendency for more osteolytic lesions.
4. Increased hypercalcemia.
5. Higher incidence of renal failure (including azotemia at presentation) as compared to other patients with multiple myeloma.
6. Higher incidence of amyloidosis and plasma cell leukaemia in the terminal stages of the disease. Renal failure is the principle cause of death in these patients.

Here we report a variant of multiple myeloma manifesting as excess kappa light chain production leading to extramedullary involvement in the form of hepatosplenomegaly, ascites, pleural effusion and renal failure.

Case Report

A 38-year-old male presented to the hospital with complaints of back ache for 2 months associated with low grade fever off and on. There were no complaints of bowel and bladder. He admitted to having a decreased appetite associated with weight loss. There was no history of any trauma or swelling in any part of the body.

Clinical examination of the abdomen revealed hepatosplenomegaly and presence of free fluid. On CNS examination power was 4/5 in bilateral lower limbs. B/L Plantars

Abstract

Purpose: To study the impact of an early clinical exposure program designed to provide a wide variety (cognitive, affective and psychomotor) of learning experiences for the preclinical year students.
Method: One hundred and fifty preclinical students were posted in small groups to selected departments – Transfusion medicine, Catheterization lab, Simulation lab, Radiology, Neurology, Nephrology, Respiratory medicine and General surgery. Each student had atleast ten hours of clinical exposure under this program. The program was evaluated through a series of pre and post-test questionnaires, which were designed based on the learning objectives of each session. Students who wished to participate in the program evaluation gave informed consent, took up the pre / post test and were also asked to give their written open comments about the program.
Results: There was a significant increase in the post-test scores (ranging from 9.14 ± 2.67 to 36.65 ± 6.62) when compared to the pre-test scores (ranging from 7.94 ± 2.31 to 28.69 ± 6.11) for all the sessions (p value < 0.001, $n = 144$). Analysis of the open feedback showed that the program had significant impact on the cognitive, psychomotor and affective domains. "Application of basic sciences in clinical practice", "motivation to learn", "got familiar with various specialties", "insight about what the patient undergoes" were the themes identified from the open comments.

Effect of Red Yeast Rice and Coconut, Rice Bran or Sunflower Oil Combination in Rats on Hypercholesterolemic Diet

SUMITRA GOVINDARAJAN[1], KISHORE VELLINGIRI[2]

ABSTRACT

Introduction: Dietary supplements provide a novel population based health approach for treating hyperlipidemias. Red yeast rice is known to have lipid lowering effects. Combination of red yeast rice with various oils is taken by different population around the world.

Aim: In this present work, we aimed to compare the effects of red yeast rice with different oil (coconut, rice bran and sunflower oil) supplementations on lipid levels and oxidative stress in rats fed on hypercholesterolemic diet.

Materials and Methods: A Randomized controlled study was conducted on 28 male Sprague Dawley rats. It included 4 arms-Control arm (hypercholesterolemic diet), Test arm A (hypercholesterolemic diet +Red yeast rice + Rice bran oil), arm B (hypercholesterolemic diet +Red yeast rice + Coconut oil) and arm C (hypercholesterolemic diet +Red yeast rice + Sunflower oil). At the end of one month, serum cholesterol, triglycerides, MDA and paroxanase was measured. The mean values of analytes between the different groups were compared using student 't-' test.

Results: The rats fed with red yeast rice and rice bran oil combination showed significantly lower levels of serum cholesterol, triglycerides and MDA when compared to the controls. The serum paroxanase levels were significantly higher in this group when compared to the controls. The rats fed with red yeast rice and coconut oil combination showed significantly lower serum cholesterol and MDA levels when compared to the controls. The mean triglyceride and paroxanase levels did not show any statistically significant difference from the controls. The rats on red yeast rice and sunflower oil combination did not show any statistically significant difference in the lipid levels and oxidative stress parameters.

Conclusion: The food combination which had best outcome in preventing the development of hyperlipidemia and oxidative stress in rats fed with hypercholesterolemic diet was red yeast rice and rice bran oil. Combining red yeast rice with coconut oil and sunflower oil gave suboptimal benefits.

INTRODUCTION

Cardiovascular disease is a major cause of mortality and morbidity worldwide. In India, rapid urbanization has led to rising trends in the prevalence of conventional risk factors of cardiovascular diseases [1]. Steadily increasing prevalence of Cardio vascular disease and its risk factors highlight the need to promote primary prevention strategies [1].

Hyperlipidemia is a major risk factor for cardio vascular diseases. A recent study states that prevalence of hypercholesterolemia in India is about 14% and hypertriglyceridemia is about 30% [2]. Though several pharmacological agents are used to lower cholesterol levels such as statins, niacin, resins and fibrates, each has its array of adverse effect [3]. Diet therapy could play a dominant role in the treatment of hyperlipidemia [4]. In addition to being inexpensive, it has the potential to become habitual and augment drug therapy [4]. Most importantly diet therapy can be adopted by the entire family and thus help in primary prevention of acquired hyperlipidemias [4]. Over years many lipid lowering dietary factors have come to light from various cultures across the world [5]. Many of these are being studied for their applicability and effectiveness in different populations [5].

Red yeast rice, a fermented rice product used widely in China and Japan, is known to have lipid lowering effects [6]. Red yeast rice is a promising therapeutic alternative in patients with hypercholesterolemia [5]. Incidentally in regions which traditionally use red yeast rice, rice bran oil is also widely used. Rice bran oil has also been shown to have cholesterol lowering properties [7]. The effect of these two could be additive.

In various regions of India, traditionally people have been using different cooking oils ranging from coconut oil, gingelly oil, mustard oil, to safflower and sunflower oil. The efficacy of the red yeast rice in lowering lipid levels and oxidative stress when combined with these widely used edible oils has not been studied.

AIM

In this present work, we aimed to compare the effects of red yeast rice with different oil (coconut, rice bran and sunflower oil) supplementations on lipid levels and oxidative stress in rats fed on hypercholesterolemic diet.

MATERIALS AND METHODS

A randomized controlled study was carried out in the animal facility of PSG Institute of Medical Sciences and Research (PSG IMSR), Coimbatore, during the period Apr 2014 to Aug 2014. The study was approved by the Institutional Animal Ethics Committee and the experiments were carried out according to the guidelines of Institutional Animal Ethics Committee, PSG IMSR. Twenty eight healthy 2-3-month-old male Sprague Dawley rats, weighing 200-300 gm, were included in the study. Irritable rats and overweight rats were excluded. These were housed in steel cages under controlled temperature (22±2°C) and humidity (55±5%) with a fixed 12 hours light–dark cycle. The rats were randomly divided into 4 groups - control (n=10), Group A (n=6), Group B (n=6) and Group C (n=6).

Hypercholesterolemic diet [8] contained 1% cholesterol, 0.2% bile salts and 5% butter added to the base feed. The base feed used was commercial Laboratory animal feed preparation supplied by Sai Industries, Bangalore. Its composition was Carbohydrates 65%, crude protein 21.5%, crude fat 4.4 %, crude fiber 3.2%, total ash 5.1%, moisture 9.7%, calcium 1.4% and phosphorous 0.4%. In addition to the hypercholesterolemic diet, the test groups were

Keywords
Stroke; Lipid Profile; Atherogenic Indices

Abstract

Background: Stroke makes a significant cause of morbidity and mortality worldwide. Although derangements in the lipid profile have been suggested as a risk factor for the development of stroke, various studies show inconsistent results on the association between lipid profile and stroke. A very few studies have commented on the status of lipid indices in stroke patients.

Methods: After obtaining ethical medical records of the study populations were analyzed, and data collected from patients admitted to the hospital with clinically diagnosed stroke and control group consisted of apparently healthy volunteers selected from the master health checkup department. Baseline characteristics and lipid profile parameters and the number of days of hospital stay for stroke patients were collected. Lipid indices were calculated using following formulae. Atherogenic index of plasma (AIP) = log triglyceride/high-density lipoprotein cholesterol (HDLc), Castelli's Risk Index (CRI-I) = Total cholesterol/HDLc, CRI-II = Low density lipoprotein cholesterol/HDLc, atherogenic coefficient (AC) = (Total cholesterol−HDLc)/HDLc, and non-HDLc (NHC) = Total cholesterol–HDL.

Results: The study included 620 participants of which 290 were stroke patients and 330 healthy volunteers. 61% of stroke patients were hypertensives and 38% were diabetics 28% were both diabetic and hypertensives. In this study, the lipid parameters and the indices were significantly higher in stroke patients than the control group. Three indices, namely, CRI-I, AC, and NHC were found to be contributing to the risk of stroke significantly. There was no statistically significant correlation between the duration of hospital stay and lipid indices or individual parameters of lipid profile.

Conclusion: In this study, the atherogenic lipid indices were significantly higher in stroke patients compared to controls.

Introduction

Stroke is defined as "an acute neurologic dysfunction of vascular origin with sudden (within seconds) or at least rapid (within hours) occurrence of symptoms and signs corresponding to the involvement of focal areas in the brain."[1] It is one of the leading causes of mortality and disability globally.

The prevalence of stroke in India varies in different regions of country, and the estimated prevalence rates increase from 0.3/1000 in < 45 years age group to 12-20/1000 in the 75-84 years age group.[2]

There are several studies in India determining risk factors of stroke. Goldstein et al.[3] described the various non-modifiable and modifiable risk

Comparison of albumin-bilirubin grade with Child-Pugh and Model for End Stage Liver Disease scores in chronic liver disease

Sujatha Rajaragupathy[1], **Jayagowri Karthikeyan**[1], **Lavanya Natarajan**[1]
[1]PSG Institute of Medical Sciences and Research, Coimbatore, Tamilnadu, India

ABSTRACT

Introduction: chronic liver diseases are characterized by injury to hepatocytes, chronic inflammation and progressive substitution of liver parenchyma by scar tissue or fibrosis. Albumin-bilirubin grade (ALBI) includes serum albumin and bilirubin levels, two most commonly performed and cost-effective parameters measured in the Clinical Laboratory. This study aims to establish an association between ALBI grade and Model for End stage Liver Disease (MELD) and Child-Pugh (CP) scores among chronic liver disease patients.
Methods: after ethical approval, information such as age, gender, provisional diagnosis, serum albumin and serum total bilirubin levels, prognostic scores of patients with liver disease were obtained from patient records. Albumin-bilirubin grading system was calculated as following: [$\log_{10}$ bilirubin (µmol/L) × 0.66] + [albumin (g/L) × −0.0852].
Results: this cross-sectional descriptive study recruited 100 patients with chronic liver disease and 100 healthy controls. Alcoholism was the common aetiology among the cases. ALBI was calculated; the mean (SD) grade among cases and controls were -0.94 (0.15) and -3.17 (0.23) respectively with a p-value of <0.001.There was statistically significant difference in ALBI grades between CP scores B and C (p value = 0.001). Pearson's correlation between MELD score and ALBI grade showed a statistically significant correlation (r = 0.723 with significance 0.001).
Discussion: our study demonstrated that there was a significant association between ALBI grade and the most commonly used prognostic scores such as CP and MELD.

INTRODUCTION

Chronic liver diseases are characterized by injury to hepatocytes, chronic inflammation and progressive substitution of liver parenchyma by scar tissue or fibrosis. Chronic liver diseases arise from various causes; the most common being alcoholic and non-alcoholic fatty liver diseases (NAFLD). However, other relevant causes exist: infections, toxins, metabolic and autoimmune causes, malignancy.

The prognosis of chronic liver diseases is being assessed by scores like Child Pugh (CP) and Model for End stage Liver Disease (MELD). CP score calculation requires albumin, bilirubin, International Normalized Ratio, presence of hepatic encephalopathy and ascites. The presence of encephalopathy and ascites require a subjective evaluation; albumin serum concentration and ascites are related to each other leading to variations in grading. MELD score calculation requires serum creatinine, bilirubin and International Normalized Ratio; it is well known that serum creatinine values are influenced by factors like age, gender, muscle mass causing a large variation among individuals. A number of studies have shown that variability in creatinine and International Normalized Ratio determination in different laboratories have led to inconsistency in MELD scores (1,2). As CP and MELD scores show the mentioned limitations, there is an urgent need for other prognostic markers.

One novel indicator is the Albumin-Bilirubin (ALBI) grade utilized by Johnson et al. in 2015 for hepatocellular carcinoma (3). The ALBI grade includes serum albumin and bilirubin levels, the two most commonly performed and cost-effective parameters that are a part of routine liver function tests. Since the first paper, various studies have been carried on to verify its effectiveness and usefulness in hepatocellular cancer. Wang et al. conducted a study to compare ALBI grade with CP score and concluded that ALBI was better than CP in distinguishing patients into different groups based on prognosis of liver cancer; post-operative survival was also better defined in ALBI-classified patients than in CP-classified groups (4). A massive research had been done

Assessment of Palliative Care Awareness among Undergraduate Healthcare Students

RAJARAGUPATHY SUJATHA[1], KARTHIKEYAN JAYAGOWRI[2]

ABSTRACT

Introduction: Palliative care knowledge is being given meager importance in the curriculum of medical and other allied medical sciences. It is vital that all health care practitioners including medical, pharmacy, physiotherapy and nursing are aware and apply the best principles of palliative care.

Aim: To assess the awareness of palliative care among undergraduate students of medical, nursing, pharmacy and physiotherapy.

Materials and Methods: The study population included total of 200 students. Among 200 students, 50 were from each of the colleges of medicine, nursing, pharmacy and physiotherapy. After obtaining informed consent, questionnaire was given. The questionnaire contained the sociodemographic profile and 35 statements under nine groups, for which the respondents were expected to answer one out of the three options (Yes, No, Don't know). The groups of statements deal with palliative care definition, its philosophy, communication issues, non-pain symptoms, medications use and context of application of palliative care.

Results: It was found that less than 20% of nursing students were unaware of palliative care. Among the undergraduates of college of pharmacy, more than 50% had no knowledge of palliative care. More than 80% of physiotherapy, nursing and medical students agree that death should occur without any pain or symptoms. The need of palliative care was well understood by more than 70% of students of physiotherapy, pharmacy, nursing and medical colleges.

Conclusion: Basic knowledge about palliative care was inadequate among the undergraduate students related to healthcare.

Keywords: Knowledge, Questionnaire-based study, Undergraduate medical education

INTRODUCTION

The number of patients with cancer and other life-limiting diseases continue to increase. The last decades have seen a rapid growth in the concern for the severely ill and dying patients. Palliative care is a methodology that improves the quality of life of patients and solves the problems associated with life-threatening illness, faced by the patients and their families. The prevention and relief of suffering can be achieved through early diagnosis, assessment and treatment not restricting to physical pain and other problems but also in other aspects like psychological, social, etc., [1]. Palliative care is not restricted to cancer or terminally ill patients alone. Palliative care also includes diseases that last for many years and other life-threatening conditions. Health professionals function largely within a culture that focuses on cure, and many avoid the patient who is dying inspite of a significant population suffering from end-of-life illnesses.

The significance of palliative care in the undergraduate syllabus of health professionals has been well recognized in the western world. Following this, it was introduced in the St John's National Academy of Health Sciences [2]. Most countries have led to the establishment of palliative care services in a variety of settings with varied staff composition and different quality standards. Palliative care education at medical schools has also increased within the last years [3]. However, undergraduate education in palliative care shows wide variation and there is no standardized core curriculum. There is considerable gap in the knowledge of palliative care among undergraduate students in our country according to Sadhu S et al., [4].

Palliative care is a multidisciplinary approach. A palliative care team may consist of a general physician, specialist, nurses, local pharmacist, medical practice social worker, physiotherapist and many others. In order to provide effective care, the members of the team need to have a common ideal and understanding of the role and contribution each of them have to make an order to achieve successful outcomes.

This study aims to assess the level of adequacy in various aspects of palliative care among undergraduate students of medicine, nursing, pharmacy and physiotherapy. This study may thus pave a way to include palliative care in the syllabus of undergraduate health care students.

MATERIALS AND METHODS

This cross-sectional questionnaire based study was conducted between November 2016 and March 2017. After obtaining approval from the Institutional Human Ethical Committee, questionnaires were given to final and pre-final year students of medicine, nursing, physiotherapy and pharmacy studying in a tertiary care teaching hospital in Southern India. A written informed consent form was given and those who were willing to participate in the study were included in the study and those not willing to participate were excluded. A total of, 200 students, 50 students each from college of nursing, physiotherapy, pharmacy and medicine gave consent to participate in the study.

Sample size calculation was done according to the formula $4pq/d^2$. (p-prevalence of awareness of palliative care from previous studies; q-100 minus prevalence percentage; d-precision which can range from 10%-20%). The prevalence of awareness of palliative care from previous studies was around 60%. The precision was kept around 15% and the calculation provided a sample size of 145.4. We included a few more participants to improve the strength of the study. The questionnaire contained the sociodemographic profile and 35 statements under nine groups for which the respondents were expected to answer one of three options (Yes, No, Don't know). The groups of statements deal with palliative care definition, its philosophy, communication issues, non-pain

Pentraxin-3, alcoholic liver disease, fibrosis, Child Pugh score, MELD score

Abstract

Alcoholic cirrhosis is the end spectrum of alcoholic liver disease, which includes fatty liver, alcoholic hepatitis, fibrosis, cirrhosis and superimposed hepatocellular carcinoma. Fibrosis is central to the pathology of all types of chronic liver disease. Pentraxin-3 is involved in numerous roles like regulation of inflammation and innate resistance to pathogens. It is strongly expressed on collagen bundles and fibrotic areas. After ethical clearance, demographic and laboratory details were collected from medical records. Leftover samples were used for serum pentraxin-3 estimation using an ELISA kit. The study included a total of 40 participants who were males 20 known cases of alcoholic liver disease and the control group included 20 healthy controls. The average value of serum pentraxin-3 in alcoholic liver disease cases was significantly ($p=0.006$) elevated as compared with healthy volunteers (0.51 ± 0.13ng/ml vs 0.27 ± 0.1ng/ml).This study concludes that serum pentraxin-3 could emerge as one of the novel non-invasive biomarkers in predicting the progression of fibrosis in alcoholic liver disease patients.

INTRODUCTION

Alcoholic liver disease (ALD) is a major cause of alcohol-related morbidity and mortality. Its presentation ranges from fatty liver to hepatitis, cirrhosis, and hepatocellular carcinoma. In South India, the prevalence of alcohol use varies between 33% - 50%, with an increased prevalence among the illiterate and the poor [1]. Alcoholic cirrhosis is the end spectrum of alcoholic liver disease, which includes steatosis to steatohepatitis, alcoholic hepatitis, fibrosis, cirrhosis and superimposed hepatocellular carcinoma. Fibrosis that occurs in alcoholic cirrhosis is a wound-healing response that occurs in all types of chronic liver disease. It is characterized by excessive accumulation of collagen and other extracellular matrix proteins [2]. Albeit, steatosis is visualized in all heavy drinkers, however only 10-20% of individuals might develop cirrhosis. Meanwhile, in compensated patients, advanced fibrosis or cirrhosis is the main predictor for long-term survival and clinically it is highly important to diagnose the advanced fibrosis before decompensation to enhance abstinence and survival.

Pentraxin-3is classified under the pentraxin family and is involved in a mélange of roles like regulation of inflammation and innate resistance to pathogens. It is strongly expressed on collagen bundles and fibrotic areas. It is produced by macrophages, endothelial cells, epithelial cells and fibroblasts. It is strongly associated with human and murine fibroblast differentiation [3]. Previous studies show that plasma pentraxin-3 levels are significantly increased in patients diagnosed with acute myocardial infarction, non-alcoholic steatohepatitis and sepsis [4,5]. Pentraxin-3 is highly populated in fibrotic areas and associated with collagen deposition and further aids the differentiation of monocytes to fibroblasts [6]. Narcisso-Schavion et al. showed that the median pentraxin-3 level is significantly higher in cirrhotic patients than control subjects [7]. However, ALD is a common pathological condition encountered among the Indian population. The majority of

Abstract

Team teaching is an innovative method to engage the large group and make lectures more interesting. The aim of the study is to evaluate the impact of team teaching in first year biochemistry lecture classes. After obtaining ethical clearance, 150 first year medical undergraduate students participated in the study on a voluntary basis. Topic identified for team teaching was "Protein biosynthesis" in Biochemistry, which was designed to be carried out in 5 h of lecture by three teachers. At the end of the team teaching module and traditional lectures, a structured anonymous feedback was obtained from the students. At the end of each class, students' understanding of the lecture was assessed by an MCQ test comprising 5–6 items, which mainly tested the recollection and understanding levels of Bloom's taxonomy. This was compared with traditional lectures. The mean MCQ test score was significantly higher for team teaching when compared to traditional teaching. The students had increased attention span and were able to answer questions from later part of the class in team lectures. The students had reported that lectures taught by team were more interesting and informative. They also felt that the team was more receptive to the doubts raised, stimulated discussion on the topic and had a better rapport with the class.

KEYWORDS

medical education, team-teaching, undergraduate

1 | INTRODUCTION

Lecture is still the dominant teaching strategy in Medical schools worldwide.[1] Although lecture has the advantage of organized presentation of concepts to a large body of audience with economical use of time, it has always suffered the disrepute of being boring and unattractively long. Attention span for most of the adult learners is said to be around 20 min.[2] Capturing the attention of the large group and maintaining it through the lecture, encouraging active learning are some of the challenges faced by the lecturer. Many strategies have been explored to make the lectures more interactive and interesting. With an easily distracted audience of 150 (annual intake in most medical colleges in India), taking an effective lecture is a Herculean task.[3]

Collaborative teaching or Co-teaching involves a group of instructors working purposefully, regularly, and cooperatively to help a group of students learn. There are many possible models of Co-teaching—supportive, parallel, alternative, complementary, and team teaching. Team teaching is defined as "well planned, team taught lessons,

Corresponding author: Dr.G.Jeyachandran

Abstract:

Introduction: The TFT results of psychiatric patients are frequently abnormal. Though the inter relation of neural networks & the interference of the drugs are known, our quest is to examine whether any pattern exist in TFT results of psychiatric patients.

Methods: All patients belonging to the Psychiatry department of a tertiary care Hospital in Coimbatore for whom thyroid functions are evaluated during the period for six months period, are included in this study. Ethics clearance was obtained from Institutional Human Ethics Committee. Details of patients including age, gender, ICD10 based diagnosis, TFT results, treatment given and associated co-morbidities were noted from their medical records.

Results:

- Age distribution is mainly between 18 to 70 years.
- Most of the patients (93%) belong to 3 groups – F3 69%, F2 14% & F4 10%.
- Female predominance is seen in F2, F3 & male predominance in F1, F4.
- Dysthyroid status is common in F3(Hypo 14%, Hyper 6%) and F2 (Hypo 15% & Hyper 2%) as shown in Figs: 5,6 & 7.
- Interestingly, only 1 out of 43 patients on Lithium had TSH above 10mIU/Ml.

Conclusion: Form this study , we conclude , in F3 mood disorders both hypothyroidism and hyperthyroidism plays a confounding role. F2 Schizophrenia is associated with hypothyroidism and Lithium doesn't affect thyroid status much.

Keywords: Thyroid hormones, Lithium

Introduction

The TFT results of psychiatric patients are frequently abnormal. Though the inter relation of neural networks & the interference of the drugs are known, our quest is to examine whether any pattern exist in TFT results of psychiatric patients. The psychiatric disturbances which accompany hyperthyroidism and hypothyroidism, the two commonest thyroid disorders, mimic mental illness. People with an overactive thyroid may exhibit marked anxiety and tension, emotional liability, impatience and irritability, distractible over activity, and fluctuating depression with sadness and problems with sleep and the appetite. In extreme cases, they may appear schizophrenic, losing touch with reality and becoming delirious or hallucinating. An underactive thyroid can lead to progressive loss of interest and initiative, slowing of mental processes, poor memory for recent events, fading of the personality's colour and vivacity, general intellectual deterioration, depression with a paranoid flavor, and eventually to dementia and permanent harmful

Abstract

The molecular diagnostic laboratories in developing countries are progressively improving and attaining international accreditation. Hence, understanding and implementing the concept of quality are the needs of the hour. Total quality management system (TQMS) in a diagnostic laboratory is an integrated program involving all laboratory staff aiming for integration, consistency, and increase in efficiency. A comprehensive understanding of such a system is unfortunately only through practice. Our endeavors in establishment of TQMS for laboratory accreditation has helped us gain comprehensive understanding of the process and have compelled us to share the knowledge with the community engaged in such diagnostics. A number of accreditation bodies have put forth guidelines for laboratories seeking accreditation; however, such documents can be overwhelming at times leading to confusion and difficulty in implementation. We aim to present to the reader a lucid script of basic reasoning behind such accreditation guidelines in conjunction with thorough and practical generalized workflows for TQMS implementation. The goal of TQMS is to provide the best possible care for patients; and to achieve top-notch quality, there should be a continuous drive for improvement. The clinical vignettes presented in this paper illustrate the value of applying select ISO 15189:2012 recommendations in a molecular diagnostic laboratory to efficiently ensure quality through TQMS and a basic understanding of nuances for its practical implementation. Implementation of TQMS in a diagnostic setting enables seamless flow of laboratory results and instills confidence in clinicians regarding disease interpretation and treatment.

Keywords Molecular diagnostics · Total quality management system · Next-generation sequencing · Real-time PCR/PCR · ISO15189:2012 · Accreditation

Introduction

At present, globally, healthcare management relies on a battery of molecular diagnostic tests that help clinicians to take highly informed decisions for better prognosis of disease. It is a dynamic area leading to insights in research and treatment that are revolutionizing health care. Molecular diagnostics detect and measure the presence of genetic material or proteins associated with a specific health condition. It helps to uncover the underlying mechanisms of disease and also enables clinicians to individualize therapy, thus facilitating the practice of personalized medicine. These tests cover an array of diseases and contribute to early and precise diagnosis of the disease aiding in preventing disease progression [1••]. Molecular diagnostics gained wide acceptance and attention owing to its quick turnaround time and reliability [2•]. Though there has been a steep increase in the number of laboratories performing such tests on clinical samples for disease diagnosis, the documentation or guidelines for efficient functioning of such laboratories are often tabooed as complicated and incomprehensible for use in regular practice. Nonetheless, it does not diminish the fact that these labs must strictly abide by uniform

Abstract

Background: Critical alert interval is the interval of examination (test) results that indicates an immediate risk to the patient of injury or death. **Materials and Methods:** All consecutive critical data of the month January 2019 are taken from the critical alert register from a tertiary care hospital/DC/BC/Reg/RR/09-Critical. From LIS, we generated the list of data satisfying the critical alert conditions in the same period January 2019. **Results:** The distribution had two peaks. The first peak is the tallest i.e.171 alerts are given within 25minutes. ABG and electrolyte samples processed immediately, contribute to this. This peak is superimposed on a normal distribution with a peak at 50 to 75 minutes interval and a long tail on the right side. **Conclusion:** Critical alert recording is missed in 26.3% of total alerts triggered. After correction, 50% of beta HCG is not recorded in the register. In 171 instances only we have given the alert within 25minutes.
Key Words: Critical alert, Parameters, Samples, Notification and authorized personnel.

INTRODUCTION

Critical alert interval is the interval of examination (test) results that indicates an immediate risk to the patient of injury or death. When examination results fall within established "alert" or "critical" intervals:

-A physician (or other authorized health professional) is notified immediately.

-Records are maintained of actions taken that document date, time, responsible laboratory staff member, person notified and examination results conveyed, and any difficulties encountered in notifications.

This study is about how effectively it is practiced in the laboratory

MATERIALS AND METHODS

Institutional human ethics committee approval was obtained. All consecutive critical data of the month January 2019 are taken from the critical alert register from a tertiary care hospital/DC/BC/Reg/RR/09-Critical. From LIS, we generated the list of data satisfying the critical alert conditions in the same period January 2019.

FOLLOW UP

- We have a LIS based system to trigger, initiate action and record critical alert in 100% instances after this study.
- We have been working to reduce the time taken for issuing alert and efficiency of tracking the authorized personnel to issue the alert.

How to cite this article: J Sowndharya, S Aruna, G Jeyachandran. Study on the biochemistry laboratory performance in notifying critical alerts. *MedPulse International Journal of Biochemistry*. January 2020; 13(1): 01-03. https://www.medpulse.in/Biochemistry/

Abstract

Diabetes Mellitus (DM) is a global pandemic disease with high prevalence as well as increased morbidity. Platelet function plays an important role in the pathogenesis of atherothrombosis in type 2 Diabetes Mellitus. Altered platelet parameters have been reported in patients with Diabetes Mellitus and have been associated with increased risk of vascular complications in these individuals. A hospital-based prospective study was conducted over a period of 12 months from January 2020 to December 2020. The study population was divided into two groups: Cases (n=200) and Controls (n=200). Detailed history, complete clinical evaluation and relevant investigations were obtained, and the results were compared. It was found that Mean Platelet Volume (MPV) and Platelet Distribution Width (PDW) were significantly increased in diabetic patients than in non-diabetic individuals. It was also observed that elevated MPV and PDW were seen in diabetic patients with complications. There was no significant difference in platelet count between the two groups. Hence, MPV and PDW are cost-effective platelet parameters which can be used as markers in predicting the vascular complications in DM.

Introduction

Diabetes mellitus (DM) is perhaps one of the oldest known diseases with diverse terminologies. It is emerging as one of the dominant public health concerns globally with a prevalence increasing in middle and low-income countries. International Diabetes Federation (IDF) indicate that 425 million had DM in 2018 and is expected to further aggravate to 642 million by the year 2040. It is also recognized as one of four priority non-communicable diseases (NCDs). World Health Organization (WHO, 2013) devised targets with a vision of 25% reduction in mortality from NCDs by 2025. The Sustainable Development Goals (SDG) also comprised a target of one-third reduction in the premature deaths caused due to NCDs including diabetes by 2030. Especially in Asian countries like India, the unprecedented economic growth and rapid urbanization led to the transition in health concerns from communicable to NCDs[1]. Among the NCDs, DM and cardiovascular diseases are the leading health problems[1]. An alarming surge in diabetic subjects from 26 million in 1990 to 65 million in 2016 was recorded in India. The prevalence in Indian adults aged 20 years or older escalated from 5.5% in 1990 to 7.7% in 2016. The prevalence in 2016 was highest in Tamil Nadu and Kerala. Untreated type II DM (T2DM) is ultimately leading to macro vascular and micro vascular complications. It is well known that T2DM is known for its expression after 40 years of age.

E-mail: veenaavenkatesh@gmail.com

However, it is now becoming more apparent in young individuals even at the age of ten. Young-onset T2DM prevalence has been reported in many countries with different ethnic and cultural backgrounds with increasing prevalence of the sedentary life style and obesity. It has more aggressive phenotype with adverse impact on quality of life augmenting the possibility of future public heath catastrophe[2].

DM is a growing health problem associated with increased risk of micro vascular and macro vascular complications[3]. Diabetic patients have large platelets that are young, more reactive with increased tendency to aggregate. They contain denser granules, secrete more serotonin, betathromboglobulin and thromboxane A_2 than smaller and less active platelets. This suggests an association between the platelet functions and diabetic vascular complications. Thus, indicating changes in mean platelet volume (MPV) and platelet distribution width (PDW) reflect the state of thrombogenesis[4]. Therefore, MPV and PDW can be considered as predictive markers for vascular complications of Diabetes Mellitus. Identification of such patients can be easily made by simple routine haematological analysis which helps in easy detection of prothrombotic state of the patients. It is a cost-effective tool that could possibly benefit the diabetic patients by preventive actions as a large number suffer from preventable vascular complications. Analysing the platelet parameters can act as an alarm for diagnosing and progression of complications of DM. Hence in view of this, we studied and compared the platelet parameters in diabetic patients and healthy controls.

Materials and methods

A total of 200 subjects who were known diabetic patients and 200 control subjects who had normal blood sugar were taken in this study. The study was conducted in the Department of Pathology, KMCH Institute of Health Science and Research over a period of one year from January 2020 to December 2020 ,after obtaining approval in

institutional ethics commitee.

Inclusion criteria

1. 200 diagnosed cases of type II DM, as per guidelines of American Diabetic Association. (Diabetes is diagnosed if HbA1C is >6.5%, Fasting glucose >126mg/dl, Post Prandial glucose>200 mg/dl)
2. 200 controls with normal blood glucose levels.

Exclusion criteria

1. Male patients with Hemoglobin <12gm and female patients with hemoglobin < l0gm
2. Non diabetic subjects with coronary artery disease.
3. Subjects with any diagnosed malignancy, thrombocytopenia or thrombotic disorders.
4. Patients on anti-platelet drugs such as aspirin and clopidogrel.
5. Pregnant women

This hospital-based study was carried out fulfilling the inclusion and exclusion criteria attending either out-patient or in-patient clinic. They were compared with 200 controls who had normal blood glucose levels.

Detailed history was taken from both cases and control subjects and complete clinical evaluation was done regarding any associated macro or micro vascular complications. Relevant investigations were obtained like blood glucose levels and HbA1C levels and complete blood count analysis was done using Beckman coulter.

Values of platelet indices like Platelet Distribution Width (PDW), Mean Platelet Volume (MPV) and platelet count were noted.

Statistical analysis

Statistical analysis was performed using SPSS version 16.0. Comparison between different groups regarding categorical variables was performed using the student's t-test and Pearson's correlation test (r value as the coefficient) and Probability (p-value).

Results

200 samples of diabetic cases and 200 samples of non-diabetic healthy controls were studied. We studied age distribution and platelet parameters.

Platelet parameters such as MPV, PDW and Platelet count were studied in

a) Diabetic cases and non-diabetic healthy controls
b) Diabetics under glycemic control (Group A) and not under glycemic control (Group B)
c) Diabetics with complications (Group C) and without complications (Group D)

In this study, among the diabetics, 3 patients were less than 40 years, 28 patients were between 41 and 50 years, 45 patients were between 51 and 60 years and 24 cases were above 60 years. Among the control population, 12 individuals were below 40 years, 36 individuals were between 41 and 50 years, 45 individuals were 51 - 60 years and 7 individuals were above 60 years. (Figure 1)

It is observed that the median MPV (mean platelet volume) among the diabetic population was 15fl and it is found to be increased than the median MPV among the control population which was 9fl (Figure 2). 76% of diabetic patients in the study had increased median platelet volume and 24% of diabetic patient had median platelet volume within normal range where as 19% of control population had increased mean platelet volume and 81% of control population had mean platelet volume within normal range. There was a statistically significant difference of between diabetic and non-diabetic population. ($p < 0.001$)

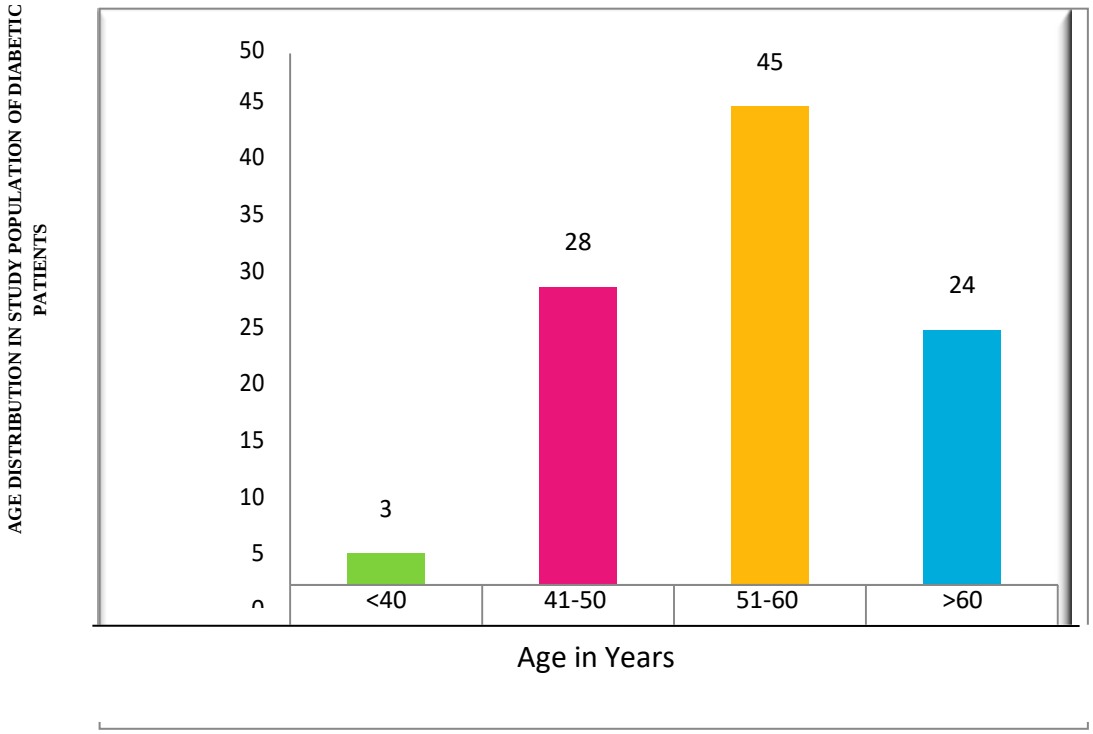

Fig 1:Age distribution in study population of diabetic patients

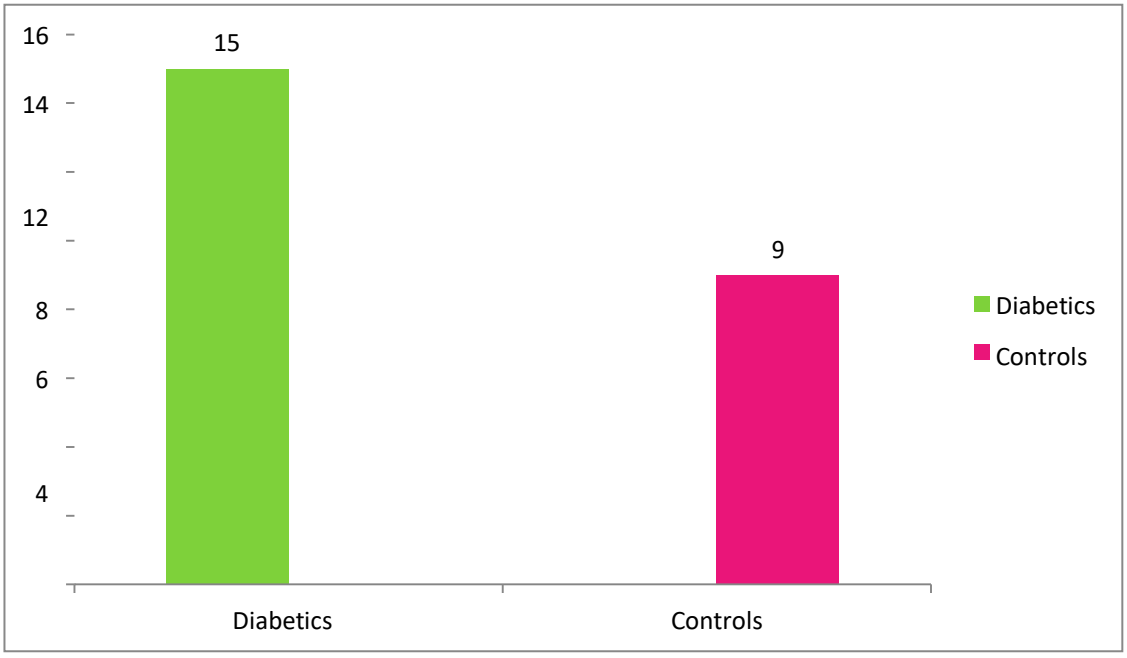

Fig 2:Comparison of median values of MPV between diabetic cases and non-diabetic controls

The median platelet distribution width (PDW) was reported to be higher in diabetic population (21%) when compared to the median platelet distribution width in control population (11%) (Figure 3). The platelet distribution width was found to be increased in diabetic population than non-diabetic and there was a statistically significant difference between them. ($p < 0.001$).

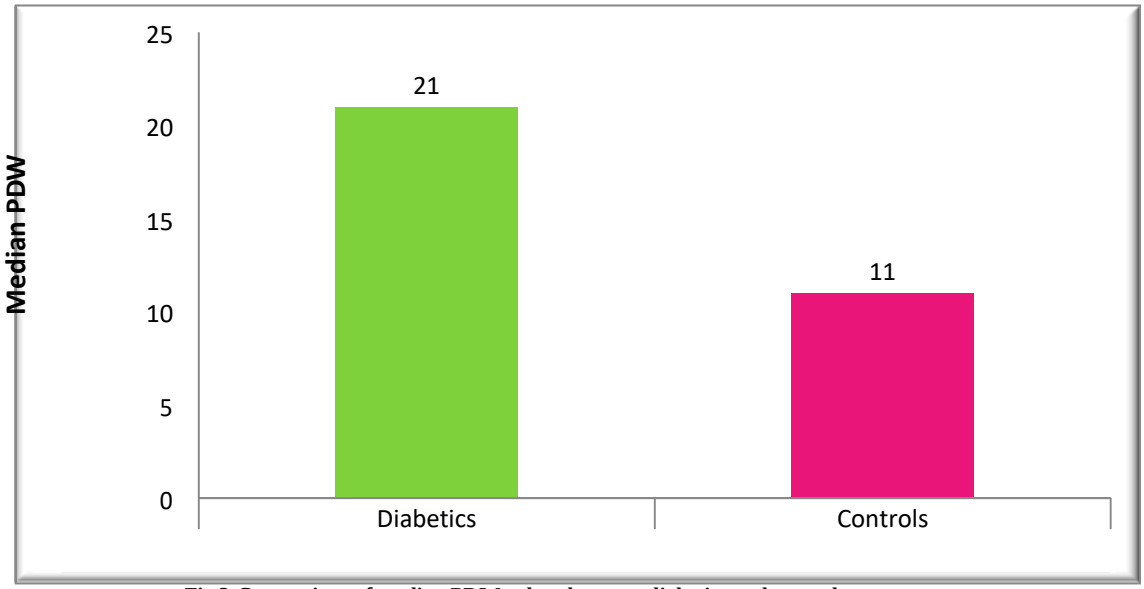

Fig 3:Comparison of median PDW values between diabetics and controls

Median platelet count of diabetic population was $2.66x10^9$/L and that of normal
Among the diabetic population, 7% had decreased platelet count, 90% had normal platelet count and 3% had increased platelet count.
In case of normal healthy individuals, 1% had decreased platelet count, 97% had normal platelet count and 2% had increased platelet count. There was no statistically significant difference of platelet count between diabetics and no diabetic individuals. ($p= 0.207$)
Platelet parameters were compared between diabetics and healthy controls and statistically significant difference of MPV and PDW values were obtained. (Table 1).

Table 1:Comparison of Median values of platelet parameters between diabetic cases and non-diabetic controls

PARAMERTERS	GROUP	NUMBER	MEDIAN	p VALUE
MPV (fl)	Cases	200	15.0	
	Controls	200	9.0	<0.001
PDW (%)	Cases	200	21.0	
	Controls	200	11.0	<0.001
PLATELET COUNT (x10^9/L)	Cases	200	2.77	
	Controls	200	2.60	0.207

Diabetic patients were divided into two groups based on HbA1C levels (glycemic control):
Group A: Diabetics under glycemic control (HbA1C < 6.5) - 33%
Group B: Diabetics not under glycemic control. (HbA1C >= 6.5) - 67%
Patients with complications were categorized as group C and without complications were categorized as group D.
The mean value of mean platelet volume in Group C (14.2) was found to be higher than the mean platelet volume in Group D (9.5fl).
Among group C patients, 96% were found to have increased mean platelet volume and 3% had normal mean platelet volume. Among group D patients, 67% had increased mean platelet volume and 33% had normal mean platelet volume. There was a statistically significant difference between the two-population group C and group D (p< 0.001).
The mean platelet count in Group C patients was 2.45x10^9/L and it was found to be little decreased than the mean platelet counts in Group D (2.66x10^9/L). There was no statistically significant difference of platelet count between Group C and Group D (p= 0.244).
Platelet parameters are compared between Group C and Group D. (Table 2). A statistically significant difference of MPV and PDW values are obtained.

Table 2:Comparison of platelet parameters between diabetics with and without complications

PARAMETERS	COMPLICATIONS	MEDIAN	p VALUE
MPV (fl)	PRESENT (group C)	14.2	<0.0001
	ABSENT (group D)	9.55	
PDW (%)	PRESENT (group C)	18.6	<0.001
	ABSENT (group D)	11.8	
PLATELET COUNT(x10^9/L)	PRESENT (group C)	2.45	0.244
	ABSENT (group D)	2.66	

Discussion

Diabetes Mellitus (DM) refers to a group of common metabolic disorders which share the phenotype of hyperglycemia. The etiology of DM includes reduced insulin secretion and decreased glucose utilization. The metabolic dysregulation associated with DM causes secondary pathophysiologic changes in multiple organ systems which impose a tremendous burden on the individual with DM and on the health care system[5].

The common feature in all the complications of diabetes is vasculopathy both "micro" and "macro", characterized by progressive narrowing of lumen as well as abnormal permeability to proteins[6]. Macro and microvascular diseases are currently the principal causes of morbidity and mortality in patients with type I and type II DM. Loss of the modulatory role of the endothelium may be an initiating and a critical factor in the development of diabetic vascular disease[7].

In our study, platelet parameters such as mean platelet volume (MPV), platelet distribution width (PDW) and platelet count were compared between diabetic population and normal healthy individuals. Platelet volume is a marker of the platelet function and activation. Platelet distribution width (PDW) is an indicator of the distribution of platelet size and also a marker of platelet activation.

In our study, the median platelet volume values were higher in diabetic patients as compared to non-diabetic population and there was a statistically significant difference between diabetic and non-diabetic population. (p < 0.001).Same observations were found in the study conducted by Buchet al[8], Bhattacharjee et al[9], Yilmaz et al[10], Dermitas et al[11], Gupta AV et al[12] which revealed that mean platelet volume was significantly raised in diabetics than non-diabetic healthy individuals.

In our study, median platelet distribution width levels were higher in diabetic population when compared with non-diabetic subjects. There was a statistically significant difference between diabetic population and non-diabetic healthy controls (p <0.001). Observation in our study correlated with study conducted by Alhadaset al[13], Jabeen et al[14], Buch et all[8].

There was no statistically significant difference of platelet count between diabetic and non-diabetic healthy individuals (p=0.207) in this study. Similar results were found in the study done by Buchet al[8], Yilmaz et al[10], Jabeen et al[14] and Kodiattee et al[15].

In our study, there was a statistically significant differences of median platelet volume between diabetics with and without complications. (p <0.001). Similar higher values of mean platelet volume were seen in the study done by Papanas et al[16] and Buch et al[8].

There was also a significant differences of mean platelet distribution width between diabetics with and without complications in our study (p <0.001). Similar results were observed in the study done by Buchet et a1[8].

In case of platelet count there was no significant difference in our study and similar finding was seen in the study conducted by Dermitas et al[11].

Conclusion

Platelet parameters such as Mean Platelet Volume (MPV), Platelet Distribution Width (PDW) and Platelet count were compared between 200 diabetic cases and 200 non diabetic healthy controls. It was found that median Platelet Volume and Platelet Distribution Width were significantly increased in diabetic patients than non-diabetic healthy individuals. Similarly, elevated MPV and PDW were seen in diabetic patients with complications compared to diabetic patients without

complications. Mean Platelet Volume and platelet distribution width are indicators of platelet activity. Increased MPV and PDW are associated with increased risk of thrombogenic events leading to vascular complications of diabetes mellitus. Our study indicates that Mean Platelet Volume (MPV) and Platelet Distribution Width (PDW) are increased in diabetic patients and they can be used as a cost-effective marker in predicting the vascular complications in diabetes mellitus.

Osteoblasts to the Rescue – A Rare Case of Secondary Myelofibrosis

Lawanya Gunaseelan, Eliz Thomas, Prasanna N. Kumar, Sujaya Menon[1]

Abstract:

A 36-year-old female patient presented with joint pain, generalized weakness, and bleeding gums. There was no significant history of other illnesses or intake of drugs. Examination revealed pallor and splenomegaly. Peripheral smear examination showed pancytopenia. A large number of osteoblasts and a few scattered osteoclasts were seen in the bone marrow aspirate. The trephine biopsy revealed marrow fibrosis. A suggestion to investigate for hyperparathyroidism was made. Serum calcium, ionized calcium, and PTH were increased. 99m Tc-Sestamibi scan was done and adenoma was detected in the right inferior parathyroid and subsequently excised. Postsurgery, hematological parameters and bone markers improved. Follow-up bone marrow biopsy revealed hypercellular marrow with marked regression of fibrosis. Splenomegaly was reversed. We concluded that pancytopenia was due to bone marrow fibrosis, resulting from primary hyperparathyroidism. It is important to consider secondary causes of myelofibrosis in the appropriate clinical setting.

Keywords:

Osteoblasts in the marrow, secondary myelofibrosis, marrow fibrosis

Background

Primary myelofibrosis is commonly a disease of the elderly. Secondary myelofibrosis occurs due to various pathological processes that involve the bone marrow such as malignancy, infection, metabolic disorders, radiation, and drugs. Hyperparathyroidism as a precipitating factor for myelofibrosis has rarely been reported. [1,2] It is important to consider secondary causes of myelofibrosis in the appropriate clinical setting. Our patient improved, similar to others after surgery. Diagnosis was confirmed when fibrosis in the bone marrow reversed after surgery.

Case Report

We report a 36-year-old female who presented with joint pain, generalized weakness, and bleeding gums. There was no significant history of other illnesses or intake of any drugs. Examination revealed pallor and massive splenomegaly. Peripheral smear examination showed pancytopenia. Bone marrow aspiration showed a large number of osteoblasts and a few scattered osteoclasts [Figure 1]. The trephine biopsy revealed marrow fibrosis of grade 3 [Figure 2]. On the basis of the presence of abundant osteoblasts and fibrosis, a suggestion to investigate for hyperparathyroidism was made. On further investigation, serum calcium, serum ionized calcium, and PTH were found to be increased [Table1]. 99m Tc-Sestamibi scan was done, and adenoma was detected in the right inferior parathyroid and was subsequently excised [Figure 3].

As early as 6 months postsurgery, hematological parameters and bone markers improved without any intervention. During the follow-up, bone marrow biopsy revealed hypercellular

Table 1: Investigations

Investigations	Initial
Hemoglobin (normal: 12-15 g/dl)	7.4
PCV (normal: 36%-46%)	22.7
WBC (normal: 4-10×10^3 µl)	1.7×10^3
Platelet count (normal: 150-400×10^3)	11×10^3
Bone marrow aspirate	Hypocellular marrow with increase in osteoclasts and osteoblasts
Bone marrow trephine	Grade 3 fibrosis
Ionized PTH (normal: 15-65 pg/ml)	1484
Serum calcium (normal: 8.8-10.2 mg/dl)	15.3
Ionized calcium (normal: 1.1-1.3 mmol/L)	2.224
Serum phosphorus (normal: 2.7-4.5 mg/dl)	2.3

PCV=Packed cell volume; WBC=White blood cell; PTH=Parathyroid hormone

Table 2: Investigations post surgery

Investigations	6 months postsurgery
Hemoglobin (normal: 12-15 g/dl)	11.2
PCV (normal: 36%-46%)	34.2
WBC (normal: 4-10×10^3 µl)	4.9×10^3
Platelet count (normal: 150-400×10^3)	71×10^3
Bone marrow aspirate	Hypercellular marrow with erythroid hyperplasia. Occasional osteoblasts seen
Bone marrow trephine	No evidence of fibrosis
Ionized PTH (normal: 15-65 Pg/Ml)	55
Serum calcium (normal: 8.8-10.2 mg/Dl)	8.0
Ionized calcium (normal: 1.1-1.3 mmol/L)	1.184
Serum phosphorus (normal: 2.7-4.5 mg/dl)	4.0

PCV=Packed cell volume; WBC=White blood cell; PTH=Parathyroid hormone

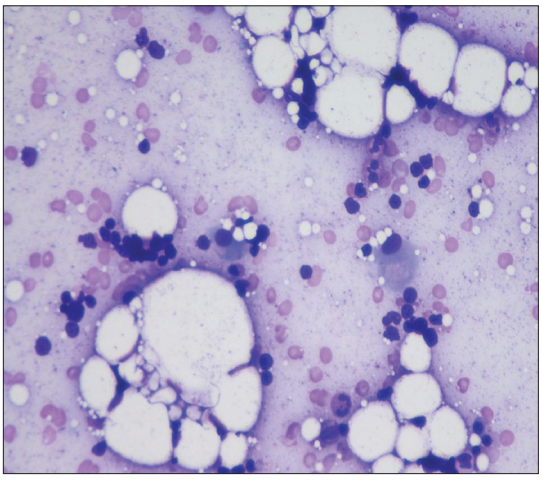

Figure 1: Osteoblasts seen in the bone marrow aspirate

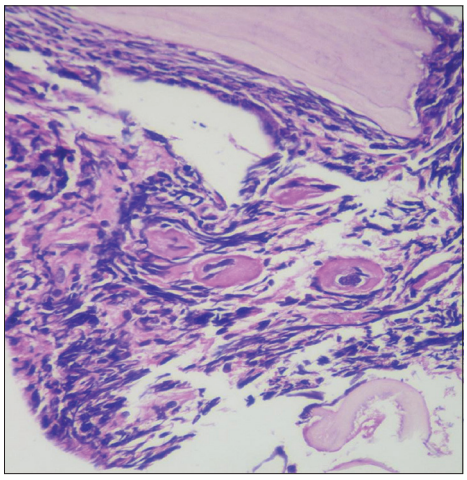

Figure 2: Bone marrow trephine biopsy showing fibrosis

marrow and marked regression of fibrosis. The spleen also gradually decreased in size. We concluded that the pancytopenia was because of bone marrow fibrosis resulting from primary hyperparathyroidism.

Investigations

Differential diagnosis

All the causes for pancytopenia were ruled out one by one. Due to the presence of osteoblasts and osteoclasts in the marrow aspirate, along with fibrosis in the biopsy, a suggestion to investigate for hyperparathyroidism was made.

Treatment

Fluids, diuretics, bisphosphonates, and other supportive measures were administered to treat hypercalcemia. Thalidomide and prednisolone were given in tapering doses.

The parathyroid adenoma was excised and confirmed by histopathology.

Outcome and follow-up

Six months post-surgery, hematological parameters and bone markers improved [Table 2]. Bone marrow biopsy

[Downloaded free from http://www.jahjournal.org on Friday, April 9, 2021, IP: 103.196.31.66]

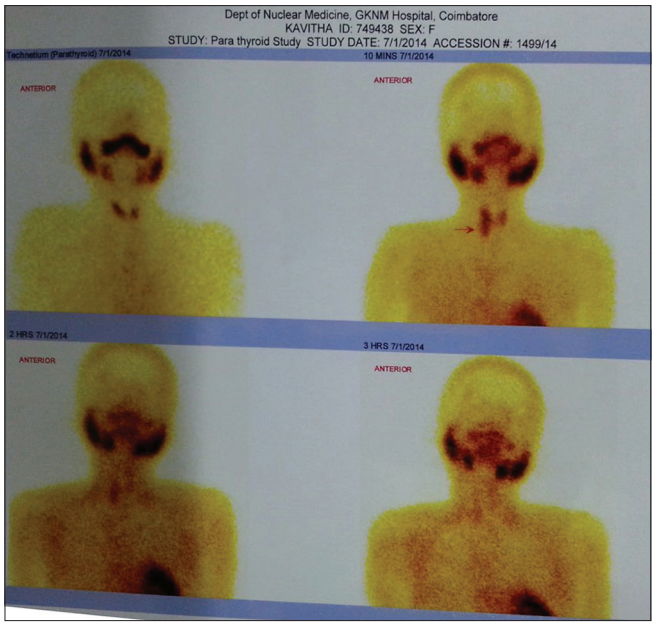

Figure 3: Radioisotope study revealed inferior parathyroid adenoma

revealed hypercellular marrow and marked regression of fibrosis [Figure 4]. The spleen gradually decreased in size.

Discussion and Conclusion

Pancytopenia is a common hematological entity, and the various causes have to be evaluated for. Myelofibrosis is one such cause and primary myelofibrosis is known to occur in the elderly. Secondary myelofibrosis can be due to various etiologies such as drugs, neoplasms, collage diseases, hyperparathyroidism, and renal osteodystrophy. Literature says that asymptomatic primary hyperparathyroidism is rare.[2-5] Our patient had features of advanced hyperparathyroidism such as elevated blood calcium levels, PTH levels, ALP levels and radiological evidence of subperiosteal bone resorption and osteopenia. After the curative parathyroid surgery, improvement in hematological and metabolic parameters is very suggestive of marrow fibrosis due to primary hyperparathyroidism.

Learning points/take home messages

- Evaluation for secondary myelofibrosis in correlation with clinical and biochemical parameters is of paramount significance
- Hyperparathyroidism must be considered with the presence of osteoblasts in the marrow aspirate.

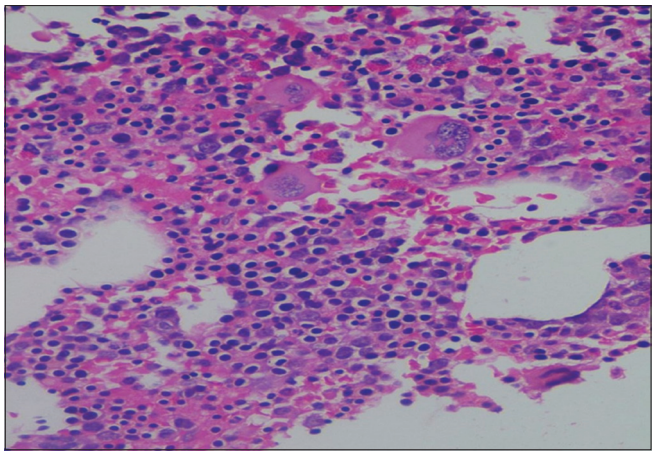

Figure 4: Bone marrow biopsy post surgery shows presence of hematopoietic elements

Profile of Uncommon Primary Adult Hepatic Malignancies at a Tertiary Care Centre

Eliz Thomas* and Amirthavarshini Venkatasubramanian

PSG Institute of Medical Sciences & Research, Off Avanashi Road, Peelamedu, Coimbatore-641 004 Tamil Nadu, India

Abstract

Context: Hepatocellular carcinoma has been the most common primary malignancy of the liver in adults, followed by cholangiocarcinoma. The less common malignancies arise from the vascular endothelial cells, neuroendocrine cells, hematolymphoid tissues, and mesenchymal tissues. Imaging studies alone may pose a diagnostic challenge due to variable appearances. Histological review of the tissue specimen, along with immunohistochemical stains is imperative for diagnosis. However, a multidisciplinary approach is necessary to make an accurate diagnosis and help in management. Out of the 24 liver malignancies encountered, six unusual primary malignancies were seen. Radiologic impression and biochemical parameters helped arrive at a definitive opinion as the lesions were not typical of this location. A high index of suspicion along with the immunohistochemical profile finally facilitated the diagnosis.

Aims: To study unusual adult primary hepatic malignancies in a 2-year study period with clinic-radiological and biochemical correlation and also determine the age and sex distribution.

Methods and Material: This study was performed in 2 years in the Department of Pathology. Ethics approval was obtained. A total of 24 liver malignancies were encountered. Metastatic tumors and tumor-like lesions were excluded. The patient's clinico-radiological findings and laboratory investigations were noted. A total of 6 unusual non-hepatocellular malignancies were seen and identified based on morphology and special stains. Statistical analysis used: SPSS version 23.0.

Results: Out of 6 non-hepatocellular malignancies, 3 were neuroendocrine carcinomas, 2 were leiomyosarcomas and 1 was a hematolymphoid malignancy.

Conclusion: The cases of primary non-hepatocellular malignancies are unexpected. A multidiciplinary approach is mandatory.

Keywords: Hepatopathology; non-hepatocellular liver malignancy; liver cancer; Primary non-hepatocellular malignancies.

Key Messages: Unusual primary non-hepatocellular liver malignancies in adult.

1. Introduction

Primary liver cancers are rare. Because the liver is made up of several different types of cells, several types of tumors can form there.

Hepatocellular carcinoma has been the most common primary malignancy of the liver in adults, followed by cholangiocarcinoma. The less common are those arising from the vascular endothelial cells, neuroendocrine cells, hematolymphoid tissues, and mesenchymal tissues. [1]

Many times, imaging studies alone may pose a diagnostic challenge due to the variable appearances of the tumors. Histological review of the tissue specimen along with immunohistochemical stains is imperative for definitive diagnosis. A multidisciplinary approach is necessary for accurate diagnosis and management.

2. Materials and Methods

2.1 Ethics statement

Approval from the Institutional Human Ethics Committee (IHEC) was obtained (Approval number – 19/137). Consent from patients was not applicable.

2.2 Study design

A retrospective study for a period of 2 years was conducted in a tertiary care center. The study included the collection of data from the patients' record sheets available in the Medical Records Department. Information pertaining to the cases was recorded and tabulated.

All investigated cases of primary non-hepatocellular hepatic malignancies of 2 years were included in the study. Metastatic tumors and tumor-like lesions were excluded.

2.3 Statistical analysis

All the data were analyzed using SPSS version 23.0 (Armonk, NY: IBM Corp.). It is represented as proportions and percentages.

3. Results

We encountered a total of six unusual cases of primary non-hepatocellular hepatic malignancies, which included three neuroendocrine carcinomas, two leiomyosarcomas, and one hematolymphoid malignancy. All were biopsies.

3.1 Age:

The mean age at presentation for the patients was 56 years, the majority of them being males. No cases were reported in childhood or adolescence.

3.2 Symptoms at presentation

There were varied symptoms at presentation, ranging from abdominal pain to asymptomatic presentation. The most common presenting symptoms were abdominal pain and loss of appetite. Other presentations include yellowish discoloration of eyes, tiredness and nausea. Almost all the cases had palpable mass in the right hypochondrium.

3.3 Liver function test

The liver enzymes were deranged in all the cases.

3.4 Imaging Studies

Imaging studies done were ultrasound, computed tomography (CT) scan or both. Diagnosis of malignancy was established for all the cases with most favouring a hepatocellular carcinoma.

3.5 Histopathology

Of the six non-hepatocellular primary hepatic malignancies, three were neuroendocrine carcinomas, two were leiomyosarcomas and one was a hematolymphoid malignancy. Search for primary origin elsewhere was negative, and metastasis was ruled out.

The diagnosis was established with the help of immunohistochemical markers.

Figure 1: Neuroendocrine tumor. The tumor cells show immunopositivity with synaptophysin (C) and chromogranin (D)

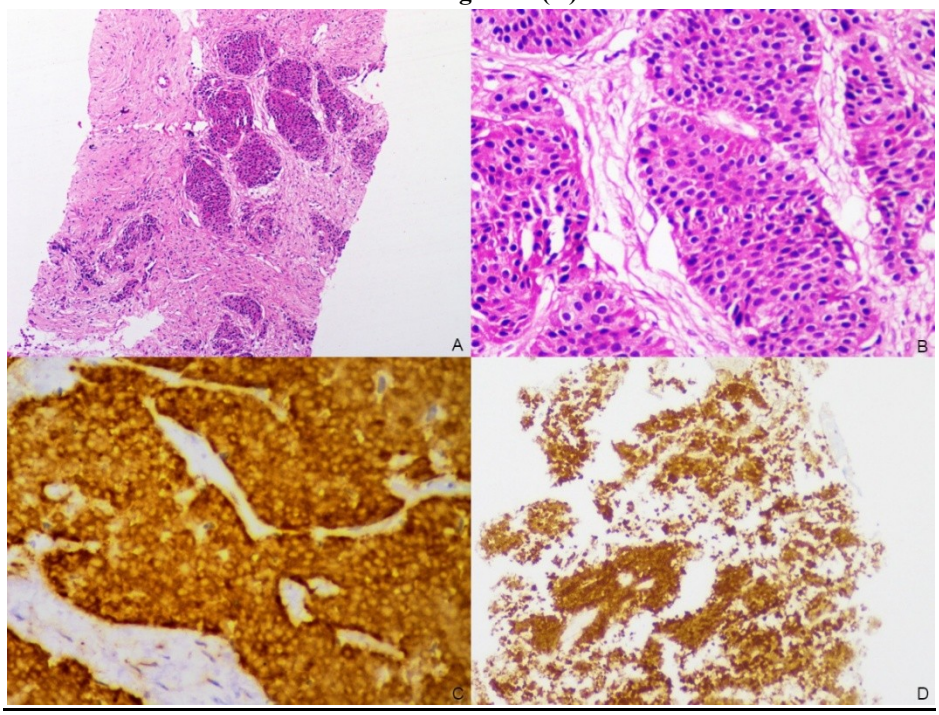

Figure 2: Leiomyosarcoma. The tumor cells show strong immunopositivity with sma (C) and vimentin (D).

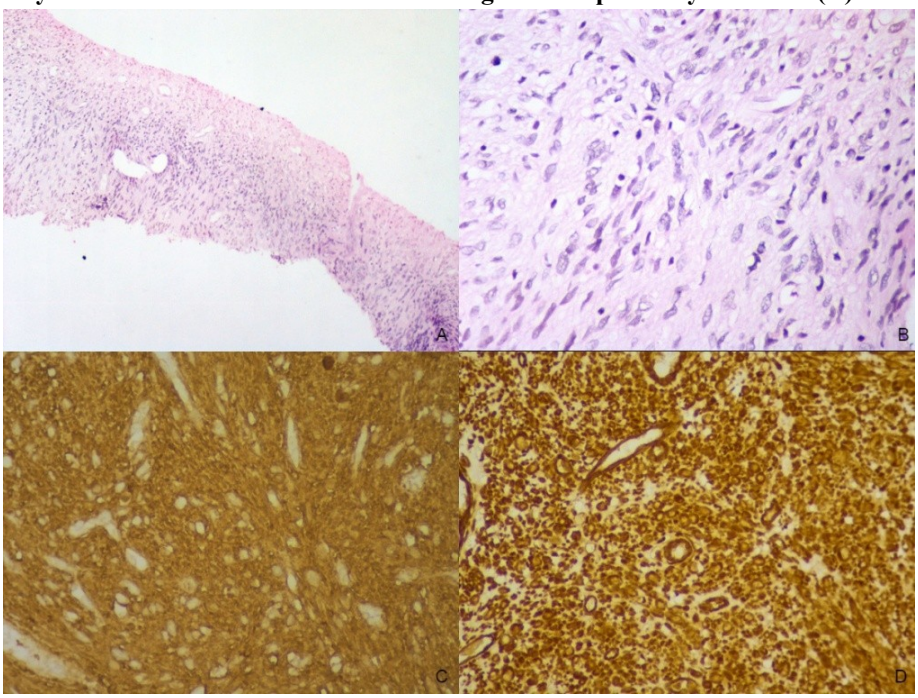

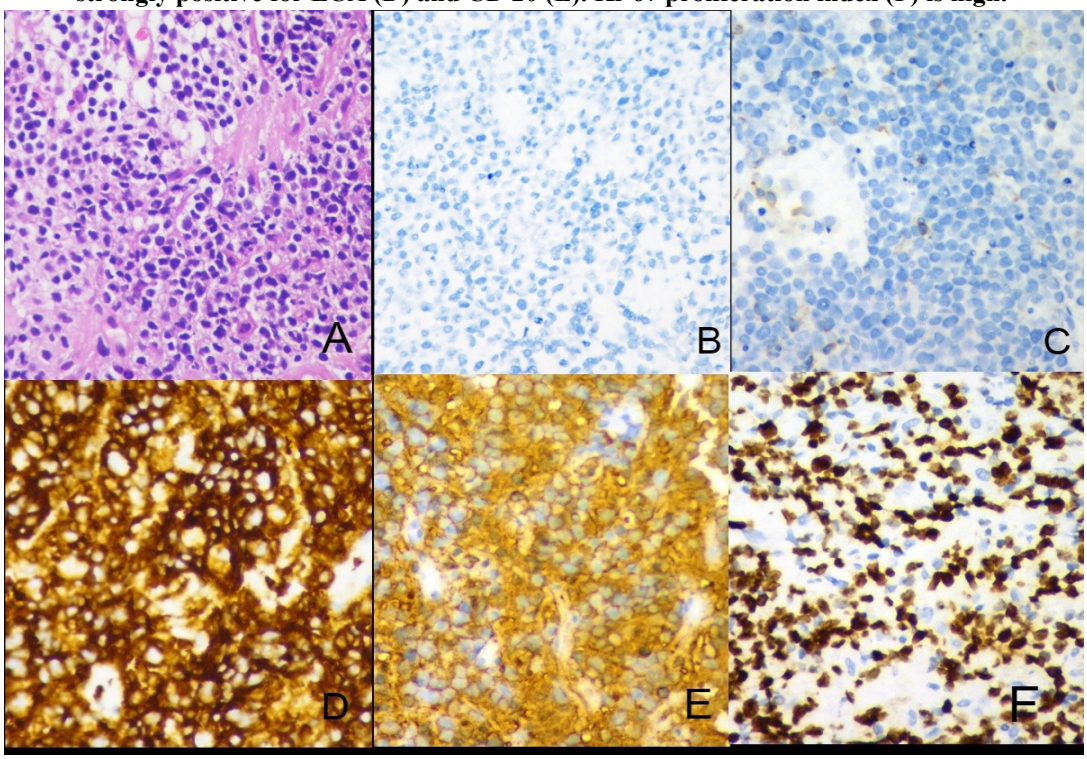

Figure 3: B-cell non-Hodgkin lymphoma. The tumor cells are negative for Heppar-1 (B) and CD 3 (C). They are strongly positive for LCA (D) and CD 20 (E). Ki-67 proliferation index (F) is high.

4. Discussion

A variety of hepatic lesions can present as hepatic masses. Amongst the malignant neoplastic lesions, primary hepatocellular carcinoma and cholangiocarcinoma are the most common. Primary non-hepatocellular hepatic malignancies although rare, are known to occur. [2,3] Prior to pathological examination for primary hepatic malignancies, misdiagnosis is frequent due to similar presentation and imaging findings in both hepatocellular and non-hepatocellular malignancies. [4,5]

Approximately 50- 90% of all neuroendocrine tumors cases are known to arise from the gastrointestinal

tract and the occurrence as primary hepatic location is rare (0.3%) [6].

Definitive diagnosis of primary neuroendocrine carcinoma is possible only after hepatic biopsy and ancillary tools like special stains and immunohistochemistry. Therefore, it can be established that biopsy and pathological examination are the gold standard for diagnosis.[2]

On histopathological examination, neuroendocrine tumors (NET) are composed of uniform round to polygonal cells with pale eosinophilic granulated cytoplasm, monotonous, round, centrally located finely stippled nuclei and small inconspicuous nucleoli. Mitosis and necrosis are infrequent.

The tumor cells show immunoreactivity with synaptophysin and chromogranin and are negative for Heppar-1. This was seen in all our cases reported as NET [Figure 1].

Mesenchymal tumors are also rarely encountered in adults. [7] Amongst the primary malignant mesenchymal tumors, hepatic angiosarcomas are most common. Primary hepatic leiomyosarcoma are again rare tumors and not many cases have been reported in the English literature.[8,9] It is often associated with immunodeficiency or viral infections (HCV, EBV, etc). [10] The cases in our study were not associated with any such underlying condition.

Histomorphology of leiomyosarcoma shows a spindle cell lesion with features of anaplasia which has to be distinguished from other spindle cell lesions of this region.

Our cases were confirmed to be primary, by ruling out metastases from other origin. Immunohistochemical markers helped in confirming the diagnosis [Figure 2].

Hematolymphoid malignancies with hepatic involvement are a relatively common presentation of extranodal disease. Rarely, lymphomas can involve the liver exclusively (primary hepatic lymphomas). As defined by previous studies, primary hepatic lymphoma is to be considered when the patient gives negative history of prior or subsequent lymphoma diagnosis, nil biopsy-proven hematolymphoid neoplasm at a nonhepatic location, and no other reason for clinical concern for hematolymphoid malignancy elsewhere in the body. [11,12] Most common primary hepatic lymphoma reported so far, is diffuse large B-cell lymphoma (DLBCL) which is closely associated with HCV infection and immunocompromised states, including HIV infection. [13,14] Our case was diagnosed as primary non-Hodgkin lymphoma of B-cell type and further typing could not be done as the tissue was insufficient [Figure 3]. The patient was immunocompetent.

5. Conclusion

The correlation of clinical, serological, radiological and histopathological findings is helpful in the early detection, diagnosis, and management of hepatic masses. Imaging studies is a reliable tool to detect hepatic malignancy. However, histological examination with IHC remains gold standard for diagnosis and confirmation of different types of malignancies arising from the liver.

Ethics approval and consent to participate: Ethics approval was obtained and consents to participate was taken from the patient.

Availability of data and materials: The datasets during or analysed during the current study available from the corresponding author on reasonable request.

Competing interests: The authors declare that they have no competing interests**.**

Funding: Nil

Authors' contributions: VA collected all the patient data from the records. TE analyzed and interpreted the patient data regarding the disease & the histolopathological examination of the biopsies. ET was a major contributor in writing the manuscript. All authors read and approved the final manuscript.

ORIGINAL ARTICLE

Type II endometrial cancers: A case series

Flora D. Lobo, Eliz Thomas[1]

Department of Pathology, Kasturba Medical College, Mangalore, Manipal University, Manipal, Karnataka, [1]Department of Pathology, PSG Institute of Medical Sciences and Research, Coimbatore, Tamil Nadu, India

ABSTRACT

Introduction: Endometrial carcinoma ranks 3rd in India among gynecological malignancies. Endometrial cancer (EC) can be classified into two distinct groups – type I and type II, based on histology, which differs in molecular, clinical and histopathological profiles. Type II is nonestrogen dependent, nonendometrioid, more aggressive and carries poor prognosis. Although type II cancers contribute only about 10% of EC incidence, they present at advanced age and cause approximately 50% recurrence and deaths with a low 5-year, overall survival rate. Type II EC are also characterized by genetic alterations in p53, human epidermal growth factor-2/neu, p16 and E-cadherin.
Materials and Methods: Endometrial carcinomas diagnosed from endometrial biopsies and hysterectomy specimens received in the Department of Pathology, Kasturba Medical College, Mangalore, from January 2007 to June 2012 were included in the study. Clinicopathological analysis of the 84 cases of EC was done with emphasis on morphology. p53 immunostaining was performed in two cases of serous carcinoma.
Results: Out of a total of 84 cases of EC, ten cases were of type II (11.9%). Out of which, eight were serous carcinoma (9.5%) and two clear cell (2.4%). p53 immunostain was strongly positive in the serous papillary carcinomas. The age of the patients ranged from 45 to 75 years. Myometrial invasion was more than half. Treatment was hysterectomy followed by aggressive chemotherapy.
Conclusion: Of the type II EC, serous carcinoma is the most common type. Clinical presentation and prognosis differs in comparison to type I EC, thus the recognition of this type of EC is pivotal.

Key Words: Clear cell carcinoma, serous papillary, type II endometrial cancer

INTRODUCTION

Endometrial carcinoma ranks 3rd in India amongst the gynecological malignancies.[1] Endometrial cancer (EC) can be classified into two distinct groups – type I and type II, based on histology, which differs in molecular as well as in clinical and histopathological profiles.[2] Type II is nonestrogen dependent, nonendometrioid, with higher grade histologies, more aggressive and carries an adverse prognosis.[3,4] Although type II cancers contribute only about 10% of EC incidence, they present at advanced age and cause approximately 50% recurrence and deaths with a low 5-year, overall survival rate of 35%.[5,6] Type II cancers typically arise in an atrophic endometrial background, and often have deep myometrial penetration and demonstrate lymph node spread. Type II EC is also characterized by genetic alterations in p53, human epidermal growth factor (HER)-2/neu, p16 and E-cadherin.[7]

MATERIALS AND METHODS

Endometrial carcinomas diagnosed from endometrial biopsies and hysterectomy specimens received in the Department of Pathology, Kasturba Medical College,

Mangalore, from January 2007 to June 2012 were included in the study. All specimens were fixed in 10% neutral buffered formalin and paraffin embedded for histological examination with hematoxylin and eosin staining. The clinicopathological analysis of the cases of EC was done with emphasis on morphology. p53 immunostaining was performed in two cases of serous carcinoma; using mouse monoclonal antibody. p53 immunoreactivity was regarded as positive when brown staining was localized to the tumor cell nuclei.

RESULTS

During the study period, a total of 84 cases of EC were reported. Of these, ten cases were classified as type II EC (11.9%) as per histology. Out of which, eight were serous carcinoma (9.5%) and two clear cell (2.4%). The age of the patients ranged from 45 to 75 years, with mean age being 62 years. Grossly, the type II EC frequently appeared bulky on a background of an atrophic endometrium, with tumor filling almost the entire cavity [Figure 1]. Myometrial invasion was more than half in seven of the cases. p53 immunostain was performed in two of the serous papillary carcinomas which showed strongly positive (>75% of tumor cells nuclei) staining in the nuclei. The tumor, node, metastasis staging and FIGO staging (2008) was done for all the cases, with four cases of stage III disease [Table 1].

Treatment was surgical hysterectomy in all cases, with one case being followed with aggressive chemotherapy due to metastases in the liver.

DISCUSSION

Type II endometrial carcinomas are nonestrogen related, nonendometrioid type. These generally occur in women a decade later than type I carcinoma, and in contrast to type I carcinoma they usually arise in the setting

Figure 1: Endometrial serous carcinoma gross specimen: Uterus with fleshy tumor filling the endometrial cavity with papillary excrescences

of endometrial atrophy. Of the type II EC, serous carcinoma is the most common type. Endometrial serous carcinomas (ESCs) constitute only 10% of ECs but have a substantially higher case-fatality rate than their more common endometrioid counterparts.[8] This is attributable, at least in part, to the advanced stage at which many patients with ESC present.[8]

The patient's age at the time of diagnosis is often a critical factor in determining the prognosis of a patient with endometrial carcinoma.[9] Generally, endometrial carcinoma in younger women, particularly before the menopause, is associated with a 5-year survival approaching 100%. One study found a 5-year survival of 96% for women aged 40–49 years compared with only 53% for women of 70–79 years.[10] Increasing age is associated with a higher grade and stage of endometrioid tumors and the likelihood of a nonendometrioid type tumor, but this accounts for only part of the difference in survival. An additional factor may be that a relative lack of immunocompetence is more prevalent in older patients.[11] In our series too, the mean age was 62 years, and the histomorphological features were of high grade (poorly differentiated).

Out of the 84 cases of EC reported during the study period, eight were serous carcinoma and two were clear cell carcinoma. This showed that serous carcinomas were the most common type of type II ECs. This was in concordance with studies and case reviews done earlier in literature.[4-8] Uterine bleeding in the postmenopausal woman was the presenting feature in all the cases.

ESCs are morphologically characterized by a complex pattern of papillae with cellular budding, cytologic pleomorphism, frequent lymphovascular and/or myometrial invasion, and not infrequently containing psammoma bodies.[12] Histologically, clear, glycogen-filled cells and hobnail cells that project individually into lumens and papillary spaces, and large, highly pleomorphic nuclei characterize the typical clear cell adenocarcinoma.[12]

In our study, ESC showed complex, branching papillae with fibrovascular core [Figure 2]. The papillae are covered by a stratified epithelium with a prominent and characteristic tufting or budding pattern. One case also showed a glandular pattern, lined by polygonal cells. Marked nuclear pleomorphism and large macronucleoli along with occasional bizarre and hyperchromatic giant nuclei was seen. Lymphovascular invasion and deep myometrial invasion was also present. In the clear cell carcinoma, the cells had clear cytoplasm with regular cell outline. The enlarged and pleomorphic nuclei were appearing to protrude into the lumens, presenting a "hobnail" appearance.

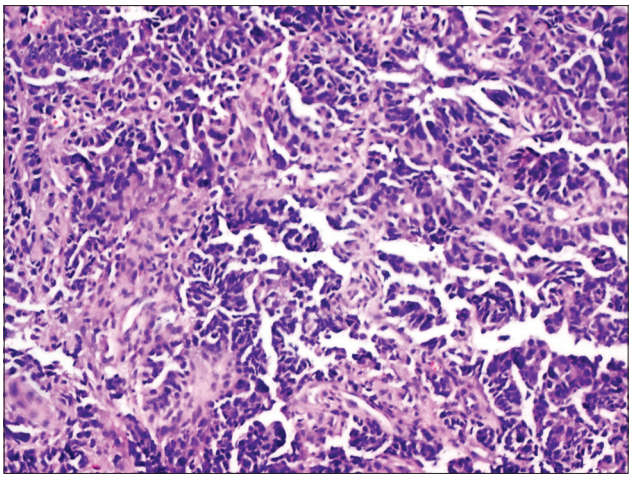

Figure 2: Endometrial serous carcinoma. Complex branching papillae (H and E; ×10)

The precursor of serous carcinoma, endometrial intraepithelial carcinoma, consists of cells identical to those of serous carcinoma but lacks identifiable stromal invasion.[13] Mutations in p53 are found in approximately 75% of these lesions, suggesting that mutation of p53 is an early event in serous endometrial carcinoma.[13] Thus, serous carcinoma presumably begins as a surface epithelial neoplasm that extends into adjacent gland structures and later invades endometrial stroma. Their generally poorer prognosis is thought to be a consequence of a propensity to exfoliate, undergo transtubal spread, and implant on peritoneal surfaces like their ovarian counterparts.

Myoinvasion is described by the presence of a constellation of features, including irregular, jagged contours of the neoplastic glands, single tumor cells or clusters in the myometrium, desmoplastic stroma, haphazard distribution of neoplastic glands in myometrium, etc.[14] Once the presence of myoinvasion is established, the depth of invasion is measured using the deepest undulation of endomyometrial junction. Other authors also advocate this approach.[14] Patients with more than 50% myometrial thickness invasion are at increased risk for extrauterine metastases, including pelvic and para-aortic lymph node metastases. These patients often require more aggressive surgical staging, which may include pelvic and para-aortic lymphadenectomy, as well as postoperative adjunctive therapy.[15] In our findings, seven of the cases (70%) had more than half of myometrial thickness invasion. One of the cases had distant metastases to the liver. For all the cases, Wertheim's hysterectomy was done. Postoperative chemotherapy was given additionally to the case with distant metastases.

The molecular changes of p53 mutation in 80–90% of serous carcinomas is reflected in p53 immunohistochemistry, which typically shows a diffuse and intense nuclear staining

[Downloaded free from http://www.jmidlifehealth.org on Friday, December 17, 2021, IP: 103.196.31.66]

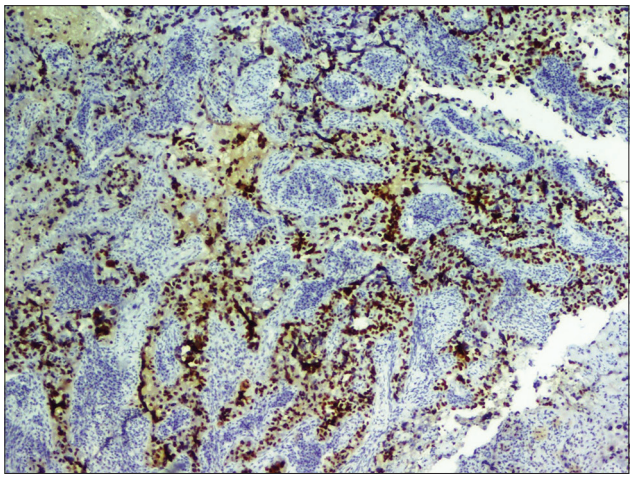

Figure 3: Endometrial serous carcinoma. Immunohistochemistry p53 staining. Diffuse strong positivity seen in the tumor cell nuclei

pattern involving almost all tumor cells.[16] In our study too, intense p53 staining was seen in 2 of the cases diagnosed as ESC and progesterone receptor marker was negative [Figure 3]. Thus, there is a significant association between p53 overexpression and ESC.

CONCLUSION

Our case series shows that the incidence of type II EC is less than that of type I. Among the type II EC, serous carcinomas are higher in number. The aggressiveness and the poorer survival rates of type II EC makes the diagnosis of this type very crucial for the histopathologist and the clinician.

Osteoblasts to the Rescue – A Rare Case of Secondary Myelofibrosis

Lawanya Gunaseelan, Eliz Thomas, Prasanna N. Kumar, Sujaya Menon[1]

Abstract:

A 36-year-old female patient presented with joint pain, generalized weakness, and bleeding gums. There was no significant history of other illnesses or intake of drugs. Examination revealed pallor and splenomegaly. Peripheral smear examination showed pancytopenia. A large number of osteoblasts and a few scattered osteoclasts were seen in the bone marrow aspirate. The trephine biopsy revealed marrow fibrosis. A suggestion to investigate for hyperparathyroidism was made. Serum calcium, ionized calcium, and PTH were increased. 99m Tc-Sestamibi scan was done and adenoma was detected in the right inferior parathyroid and subsequently excised. Postsurgery, hematological parameters and bone markers improved. Follow-up bone marrow biopsy revealed hypercellular marrow with marked regression of fibrosis. Splenomegaly was reversed. We concluded that pancytopenia was due to bone marrow fibrosis, resulting from primary hyperparathyroidism. It is important to consider secondary causes of myelofibrosis in the appropriate clinical setting.

Keywords:

Osteoblasts in the marrow, secondary myelofibrosis, marrow fibrosis

Background

Primary myelofibrosis is commonly a disease of the elderly. Secondary myelofibrosis occurs due to various pathological processes that involve the bone marrow such as malignancy, infection, metabolic disorders, radiation, and drugs. Hyperparathyroidism as a precipitating factor for myelofibrosis has rarely been reported. [1,2] It is important to consider secondary causes of myelofibrosis in the appropriate clinical setting. Our patient improved, similar to others after surgery. Diagnosis was confirmed when fibrosis in the bone marrow reversed after surgery.

Case Report

We report a 36-year-old female who presented with joint pain, generalized weakness, and bleeding gums. There was no significant history of other illnesses or intake of any drugs. Examination revealed pallor and massive splenomegaly. Peripheral smear examination showed pancytopenia. Bone marrow aspiration showed a large number of osteoblasts and a few scattered osteoclasts [Figure 1]. The trephine biopsy revealed marrow fibrosis of grade 3 [Figure 2]. On the basis of the presence of abundant osteoblasts and fibrosis, a suggestion to investigate for hyperparathyroidism was made. On further investigation, serum calcium, serum ionized calcium, and PTH were found to be increased [Table1]. 99m Tc-Sestamibi scan was done, and adenoma was detected in the right inferior parathyroid and was subsequently excised [Figure 3].

As early as 6 months postsurgery, hematological parameters and bone markers improved without any intervention. During the follow-up, bone marrow biopsy revealed hypercellular

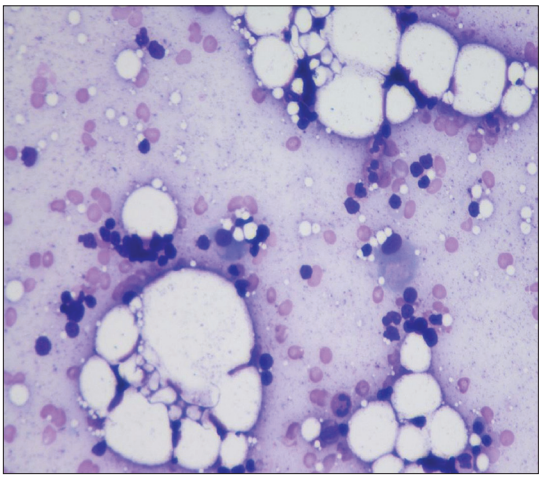

Figure 1: Osteoblasts seen in the bone marrow aspirate

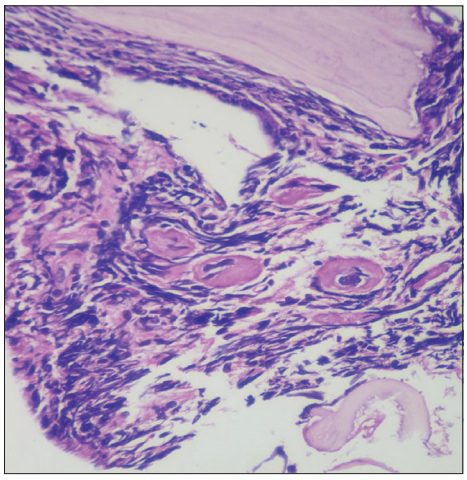

Figure 2: Bone marrow trephine biopsy showing fibrosis

marrow and marked regression of fibrosis. The spleen also gradually decreased in size. We concluded that the pancytopenia was because of bone marrow fibrosis resulting from primary hyperparathyroidism.

Investigations

Differential diagnosis

All the causes for pancytopenia were ruled out one by one. Due to the presence of osteoblasts and osteoclasts in the marrow aspirate, along with fibrosis in the biopsy, a suggestion to investigate for hyperparathyroidism was made.

Treatment

Fluids, diuretics, bisphosphonates, and other supportive measures were administered to treat hypercalcemia. Thalidomide and prednisolone were given in tapering doses.

The parathyroid adenoma was excised and confirmed by histopathology.

Outcome and follow-up

Six months post-surgery, hematological parameters and bone markers improved [Table 2]. Bone marrow biopsy

[Downloaded free from http://www.jahjournal.org on Friday, April 9, 2021, IP: 103.196.31.66]

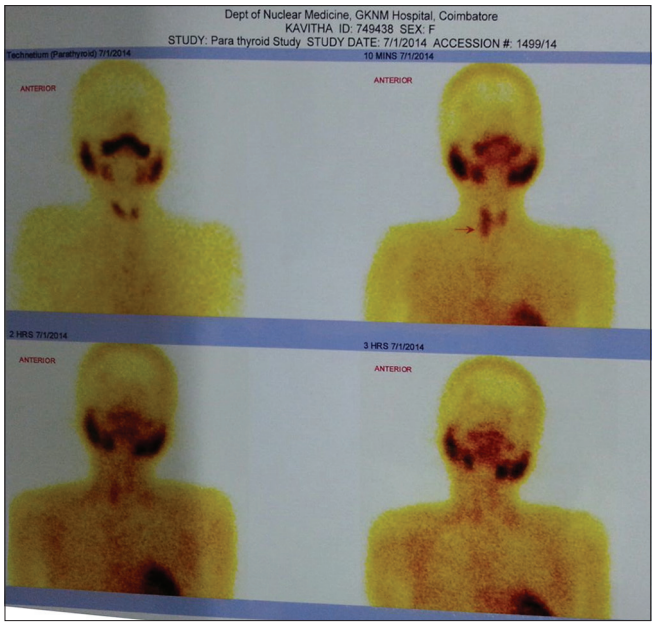

Figure 3: Radioisotope study revealed inferior parathyroid adenoma

revealed hypercellular marrow and marked regression of fibrosis [Figure 4]. The spleen gradually decreased in size.

Discussion and Conclusion

Pancytopenia is a common hematological entity, and the various causes have to be evaluated for. Myelofibrosis is one such cause and primary myelofibrosis is known to occur in the elderly. Secondary myelofibrosis can be due to various etiologies such as drugs, neoplasms, collage diseases, hyperparathyroidism, and renal osteodystrophy. Literature says that asymptomatic primary hyperparathyroidism is rare.[2-5] Our patient had features of advanced hyperparathyroidism such as elevated blood calcium levels, PTH levels, ALP levels and radiological evidence of subperiosteal bone resorption and osteopenia. After the curative parathyroid surgery, improvement in hematological and metabolic parameters is very suggestive of marrow fibrosis due to primary hyperparathyroidism.

Learning points/take home messages

- Evaluation for secondary myelofibrosis in correlation with clinical and biochemical parameters is of paramount significance
- Hyperparathyroidism must be considered with the presence of osteoblasts in the marrow aspirate.

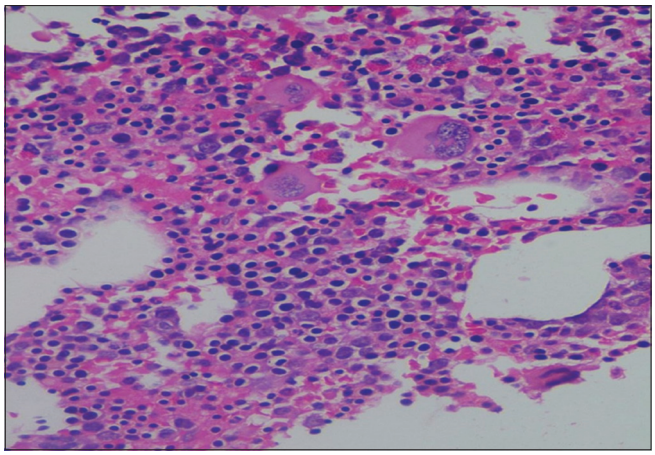

Figure 4: Bone marrow biopsy post surgery shows presence of hematopoietic elements

Ethics approval and consent to participate

Ethics approval was obtained and consent to participate was taken from the patient.

Declaration of patient consent

The authors certify that they have obtained all appropriate patient consent forms. In the form, the patient has given her consent for her images and other clinical information to be reported in the journal. The patient understands that her name and initials will not be published and due efforts will be made to conceal identity, but anonymity cannot be guaranteed.

Sputum, a specialized product of the respiratory tract, is formed as a result of interaction between mucociliary apparatus, immune system of the host and animate, inanimate invaders from the environment. It is not only limited to the diagnosis of tuberculosis and malignancy, but is also equally important in the diagnosis of other diseases. The aim is to study the cellular morphology in the satisfactory sputum samples and to correlate the cytological features with clinical and radiological findings. **M** This study emphasizes the role of sputum cytology in the diagnosis of non-neoplastic lung diseases in correlation with clinical and radiological features. This is a prospective study, undertaken in the Department of Pathology, from July 2016 to December 2018. During this period, 200 sputum samples were collected. In the study period, 200 sputum samples received account for 1.56% of the total cytological samples. Age group ranged from 6 to 84 years with a mean age of 55.41 years. Majority of the patients belonged to the age group of 61-70 years (32%). Male to female ratio was 3.65:1. Among 200 patients, 98 cases were clinically diagnosed to have pulmonary tuberculosis (49%), of which cytological diagnosis was made in 59 cases (60.2%). Of the 32 clinical Bronchial asthma cases, 31 chronic bronchitis, 15 acute bronchitis and 13 pneumonia cases, cytological diagnosis was made in 25, 28, 11 and 10 cases respectively. Three patients each with clinical diagnosis of lung abscess and candida infection had consistent cytological diagnosis. Similarly, one patient each who were diagnosed with Aspergilloma, Actinomycosis, Pulmonary edema, Bronchiectasis, pulmonary eosinophilia clinically, had consistent cytological diagnosis. Sputum cytology is a simple, cheap, non-invasive and free of complications for the early diagnosis of lung diseases. Although fiber optic bronchoscopy and fine needle aspiration provide better diagnostic value, pulmonary cytology provides the primary laboratory means for diagnosing and treating patients with lung diseases.

Clinical correlation, Non neoplastic lung lesions, Sputum cytology

Introduction

Diagnostic cytology is an art and science of interpretation of cells from the human body that either exfoliate (desquamate) from the epithelial surface freely or are removed from tissue sources by various clinical procedures[1]. Diagnostic cytology is based on three sampling techniques i.e. Exfoliative cytology, Abrasive cytology and Aspiration cytology. Rapid urbanization, industrial growth, and increasing pollution have led to dramatic increase in respiratory diseases. On the global basis, ranking of cancer sites in the decreasing order showed lung at the top of the list[2]. There are numerous investigations available, namely sputum cytology, radiological studies, Bronchoalveolar lavage (BAL), Bronchial brushings cytology and fine needle aspiration cytology, etc., to study the morphology of lung diseases. "Sputum cytology" is an example of "Exfoliative cytology" which is based on spontaneous shedding of cells derived from the lining of an organ into a cavity from where they can be removed by a non-abrasive means[1,3,4].Sputum is a specialized product of respiratory tract, produced as a result of interaction between mucociliary apparatus, immune system of the host and animate, inanimate invaders from the environment[5]. Sputum cytology affords a simple, accurate, reliable, cost effective and non-invasive procedure for the assessment of respiratory diseases including pre-invasive and invasive pulmonary malignancies. The cellular and non-cellular components of sputum reflect the pathological

process. Sputum examination plays a vital role in the diagnostic cytopathology. It is not only limited to the diagnosis of tuberculosis and malignancy but also equally important in the diagnosis of other diseases like bacterial, viral, fungal, and parasitic infections of the respiratory tract, necessitating the study of sputum cytology[1].

M□□□□□□□□□□M□□□□□□

This study emphasizes the role of sputum cytology in the diagnosis of non-malignant lung diseases in correlation with clinical and radiological features. This is a prospective study, undertaken in the Department of Pathology from July 2016 to December 2018. All the sputum samples were sent to the Department of Pathology for cytological examination. Inclusion criterion: Non-neoplastic lung diseases. Exclusion criterion: Neoplastic and Unsatisfactory sputum samples. All the patients in this study were examined in detail and routine necessary investigations were done. These patients were given prior instructions about the technique of producing good sputum. They were instructed to brush their teeth, and/or rinse the mouth and gargle with water, upon awakening in the morning. They were then asked to inhale deeply to the full capacity of the lungs and exhale the air with an expulsive cough. This early morning deep sputum samples, were collected in sterile glass bottle (fresh and unfixed sputum) and sent to the laboratory immediately for cytological examination. Radiological investigations were done at the discretion of attending physician. Sterile disposable sticks were used to spread sputum thinly, and the specimen was examined carefully with naked eye and hand lens. The suspicious material, tissue particles and blood stained areas were picked and smeared on the albuminized slides (pick and smear method). Four such smears were prepared for each sputum sample. Among these, two smears were air dried and were stained with Giemsa stain and Ziehl-Neelsen stain (using 20% sulphuric acid) for demonstrating acid fast bacilli. The remaining two were promptly fixed in a fixative containing equal amounts of ether and 95% ethyl alcohol. These two were stained with Papanicolaou's stain and Haematoxylin and Eosin stain.

□□□□□□□

In this study, 200 sputum samples account for 1.56% of the total 12,835 cytological specimens received during the study period. Age group of the patients investigated for sputum cytology ranged from 6 years to 84 years with a mean age of 55.41 years. Majority of the patients belonged to the age group of 61-70 years followed by 51-60 years, 41-50 years, 71-80 years and 31-40 years. (Figure: 1)□

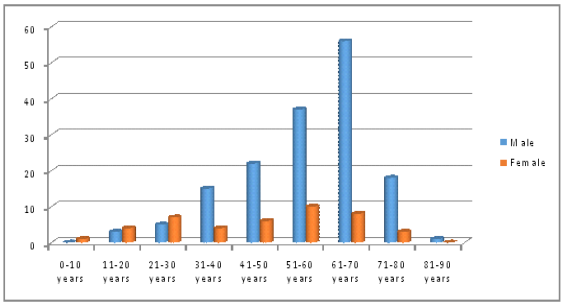

Figure 1: Distribution of Cases According to age And Sex

In this present study, males outnumber females. Male to female ratio was 3.65:1. Among 200 patients, 98 cases were clinically diagnosed to have pulmonary tuberculosis (49%). Rest in the decreasing order, were diagnosed to have bronchial asthma (16%), chronic bronchitis (15.5%), acute bronchitis (7.5%), pneumonia (6.5%), pulmonary candidiasis (1.5%), lung abscess (1.5%), pulmonary edema (0.5%), bronchiectasis (0.5%), aspergilloma (0.5%), actinomycosis (0.5%), and pulmonary eosinophilia (0.5%). (Table No: 1). The cytological diagnosis of pulmonary tuberculosis was made in 59 cases (60.2%), chronic bronchitis in 28 (78.12%), acute bronchitis in 11 (73.3%), pneumonia in 10 (76.92%), lung abscess in 3 (100%), candida infection in 3 (100%), aspergilloma, actinomycosis, pulmonary edema, bronchiectasis and pulmonary eosinophilia were diagnosed in one patient each, which correlated 100% with clinical diagnosis. The above clinico-cytological correlation of various non-neoplastic lung lesions was depicted in Table No: 2. Cytological features of lung lesions are enumerated in Table No: 3.

Table 1: Clinical Diagnoses

Non neoplastic pulmonary diseases	Males	Females	Total	Percentage

□□□□ □ □□□□ □□

In this study, number of sputum samples studied comprises only 1.56% of the total cytological specimens, which indicates that sputum cytology has not gained much popularity among the physicians. However, this procedure has certain advantages over other investigations, in being noninvasive, cheap and repeatability[1,5,6] . Majority of the patients in this study belonged to the age group of 61-70 years (32%). Many of the respiratory diseases are common in this age group, necessitating sputum examination. In this study male patients outnumber female patients with male to female ratio of 3.65:1 and our findings are similar to other studies[7]. Many of the respiratory diseases are common in males[7] and most adult males are habitual smokers in this geographical location, which is in line with Longo *et al* study. In this study clinically diagnosed respiratory diseases in decreasing order are pulmonary tuberculosis (48%), bronchial asthma (16%), chronic bronchitis (15.5%), acute bronchitis (7.5%), pneumonia (6.5%), pulmonary candidiasis (1.5%), lung abscess (1.5%), pulmonary edema (0.5%), bronchiectasis (0.5%), aspergilloma (0.5%), actinomycosis (0.5%)and pulmonary eosinophilia (0.5%). These relative incidences indicate the relative incidence of respiratory diseases in the general population. Pulmonary tuberculosis is the most common respiratory disease in our country[7].Roby *et al* (1988) suggested the adequacy criteria for sputum samples, according to which, sputum samples were regarded as adequate if there were at least 150 macrophages per slide from a nonsmoker or at least 300 macrophages per slide from a smoker. However, quantitative sputum cytology was not done in this study[6]. In the present study, cytological diagnosis was made in 11 cases of acute bronchitis, which revealed predominant neutrophils, a few lymphocytes, ciliated columnar cells, Curschmann spirals and cellular debris. Curschmannspirals□□□□□ **2**□ are considered to be pathognomonic of chronic bronchial disorders such as chronic bronchitis and bronchial asthma. The full significance of Curschmann spirals in the pathology of the respiratory tract has not been fully assessed as yet[1]. Investigations done by Walker and Fullmer (1970) documented that over 90% of asymptomatic cigarette smokers have Curschmann spirals in their sputum. Occurrence of Curschmann spirals in acute bronchitis, seen in this study, is probably related to smoking. Ten cases of pneumonia and three cases of lung abscesses encountered in this study, showed predominant population of neutrophils □□□□□□□ Gram stain and bacterial culture studies were not done in these cases. Gray W *et al* suggested that the overgrowth of the commensals from oropharynx should not be mistaken for an infection. They are unlikely to be significant if mixed with sputum and if found mainly in areas of saliva without accompanying inflammatory cells[6].Cytological diagnosis was made in 59 cases of pulmonary tuberculosis. Epithelioidhistiocytes were observed in 55 cases and Langhans giant cells were observed in 51 cases. The combination of epithelioidhistiocytes and Langhans giant cells (Fig.3) is highly suggestive of tuberculosis but is not pathognomonic since either or both cell types can be seen in other diseases with granulomatous inflammation[6]. Presence of epithelioid cell granuloma and Langhans giant cells in sputum cytology in cases of pulmonary tuberculosis is of very uncommon occurrence. Only a few reports could be found in the English language literature. Presence of epithelioid cell granuloma and Langhans cells, along with demonstration of AFB in routine sputum cytology, is capable of providing a conclusive diagnosis in the appropriate clinical context, obviating the need for additional

investigation[8]. Long, slender acid fast bacilli were demonstrated in eight cases (Grade-II) and five cases (Grade-III). □□□□□□ □□□□□ show AFB positivity in clinically suspected pulmonary tuberculosis patients in comparison with other studies. Dawson *et al* (1981) suggested that the presence of striking pleomorphism and/or cross banding in acid fast bacilli found in smears of sputum is usually indicative of mycobacteria other than mycobacterium tuberculosis[9]. However, atypical strains of mycobacteria causing lung infection can be morphologically similar to mycobacterium tuberculosis and can only be distinguished by culture[6]. In two patients, who were clinically diagnosed with pulmonary tuberculosis, sputum cytology revealed pulmonary candidiasis and Actinomycosis. In these patients, chest x ray showed apical opacities in the lung fields. Therefore concomitant pulmonary tuberculosis could not be ruled out in these cases, though acidfast bacilli were not seen in these sputum samples. Clinical diagnosis of aspergilloma was made in a 70 year old man who was earlier treated for tuberculosis. In this case sputum examination was done, which revealed Aspergillosis. Inhaled air borne spores of aspergillusfumigatus may lodge and germinate in damaged pulmonary tissue, and an aspergilloma (a ball of aspergillus fungus) can form in any area of damaged lung, in which there is a persistent abnormal space. The most common cause of such pulmonary damage is tuberculosis, but an aspergilloma can develop in an abscess cavity, a bronchiectatic space, or even in a cavitatedtumour. Most, but not all are caused by Aspergillusfumigatus[7]. The presence of fungi in sputum specimens raises one of the three possibilities. Firstly, they may be contaminants from the mouth or atmosphere; secondly, there may be saprophytic colonization of an area of pre-existing diseased lung such as a cavity, without any invasion of tissues; or thirdly, there could be an active infection (mycosis), with growth of fungi in the lung parenchyma[6]. Inflammatory debris is usually present when there is invasion of tissues by fungi or if a fungal ball (mycetoma) has formed in cavitatedlung[6] □□□□□□□□In a patient clinically diagnosed with chronic bronchitis, sputum cytology revealed Respiratory Syncytial Virus infection. Patients with viral infection may exfoliate reactive bronchial epithelial cells in tridimensional clusters with prominent nucleoli, mimicking cells derived from a bronchogenic adenocarcinoma. These cells usually disappear within 2 weeks after the recovery of the lung infection[6]. Sputum cytology in a case of clinically diagnosed pulmonary edema revealed superficial squamous epithelial cells, neutrophils, lymphocytes, and carbon laden alveolar macrophages in a mucinous background. Cytological features were non-specific. Cytological diagnosis was made in 28 cases of chronic bronchitis, where sputum samples showed clusters of hyperplastic bronchial epithelial cells in two and Curschmannspirals in nine. Cytological features were non-specific. Gorska *et al* (2008) observed that, neutrophils, macrophages, and lymphocytes are the most significant inflammatory cells found in the airways of patients with COPD[10]. Hyperplastic epithelial cell clusters need to be distinguished from adenocarcinoma and metastatic carcinoma cells. The presence of a few cilia around the border of some of the groups is evident of reactive change. Nuclear features may not be clearly discernible for evaluation of malignancy, but macronucleoli are suspicious of malignancy. Adenocarcinoma cells tend to exfoliate more profusely than benign cells. In this study, clinical diagnosis of bronchiectasis was made in one case, where cytological features were non-specific. Cytological diagnosis was made in 25 out of 32 clinically diagnosed bronchial asthma cases. Curschmann spirals were noted in sixteen patients. Findings such as Charcot–Leyden crystals, Curschmann spirals or Creola bodies have been considered characteristic in patients with asthma[1,5,6]. Pizzichini *et al* (2009) reported that proportion of eosinophils in sputum is a more accurate marker of asthmatic airway inflammation than the proportion of blood eosinophils or serum eosinophilic cationic protein[11]. In one patient, Creola bodies consisting of clusters of ciliated bronchial epithelial cells were seen. They have come to known as Creola bodies after a young girl in whom they were reported, assuming initially that they were adenocarcinoma cells.None of the sputum samples showed Charcot leydencrystals. This is probably related to the absence of clinical evidence that external allergens play a role in the production of late onset asthma (non atopic)[6]. In one case of pulmonary eosinophilia, sputum cytology revealed squamous epithelial cells, a few neutrophils, lymphocytes, erythrocytes and plenty of eosinophils in a mucinous background. Blood peripheral smear of this patient showed increase in eosinophils. Transient pulmonary lesions characterize pulmonary eosinophilia, eosinophilia in the blood, and a benign clinical course. CT scans are often quite striking, with shadows of varying size and shape in any of the lobes suggesting irregular intrapulmonary densities[12].

□□□□□□□□□□

Sputum cytology has been the traditional focus for studying lung diseases for many years. Sputum cytology is a cost effective, non invasive and free of complications for the early diagnosis of lung diseases. However, the emphasis has been altered by the introduction of fiber optic bronchoscopy and fine needle aspiration. Recently,

Copyright © 2019, Medpulse Publishing Corporation, MedPulse International Journal of Pathology, Volume 10, Issue 3 June 2019

automated systems to increase the productivity and accuracy in the cytology laboratory are beginning to appear. As there is no single diagnostic method to exclude the diseases, combinations of various techniques for obtaining material from respiratory tract yield better results. Pulmonary cytology provides the primary laboratory means for diagnosing and treating patients with lung diseases.

Validating Micronucleus Score in Effusion Fluids

Nidhya Ganesan, Manjiri D. Phansalkar, Marie M. Ambroise, Renu G. Varghese

Department of Pathology, PSG Institute of Medical Sciences and Research, Coimbatore, Tamil Nadu, India

Abstract

Background: Identifying malignant cells in effusion fluid is vital in staging and management of cancers. Differentiating reactive mesothelial cells from malignant cells in effusion fluid is a challenging task and there is an ongoing need for simpler and cost effective tool to aid the diagnosis. Micronucleus is an additional smaller nucleus in the cytoplasm, formed by chromosomes or chromosomal fragments formed during cell division. **Aims:** The aim of this study was to assess the significance of micronucleated cell in effusion fluids to distinguish adenocarcinomatous from reactive mesothelial effusions. **Materials and Methods:** Thirty cases of unequivocal malignant effusion fluids and 30 benign cases with reactive mesothelial cells as control were studied. Number of microucleated cells present per1000 well-preserved cells in Leishman-stained smears were counted. **Results:** Mean (±SD) micronucleated score in malignant and benign effusions were 15.77 ± 9.78 and 1.87 ± 1.78, respectively. The median scores were 13 and 2, respectively. Mann–Whitney test showed that this difference was statistically significant ($P < 0.001$). This study revealed that there was a significant difference in micronucleus scoring between benign and malignant effusions. **Conclusions:** Micronucleus score can be used as an additional biomarker in the interpretation of routinely stained cytosmears.

Keywords: Adenocarcinoma, effusion fluid, micronucleus

Introduction

Identifying malignant cells in effusion fluid is of paramount importance in staging and management of cancers. Differentiating reactive from malignant cases in effusion fluid is difficult at many times. We need a simple, inexpensive, and reliable tool to identify them. Micronucleus (MN) test is a simple test which is done on routine staining, thus avoiding the need of expensive methods and the use of immunocytochemistry panels and flow cytometry.[1-5]

MN is an additional smaller nucleus in the cell cytoplasm. Its presence indicates chromosomal damage or breakage and mitotic dysfunction of the cell. MN is round to oval in shape and is separated from the main nucleus. The mean diameter is 1/16th to 1/3rd of the main nucleus and is nonrefractile. Color and texture is the same as that of the main nucleus.[6,7]

Utility of MN scoring have been studied in cervical smears,[8,9] exfoliated buccal and bladder cells,[10] colorectal carcinoma,[11] and lymphocytes[12] to detect chromosomal damage, exposure to carcinogens, and genotoxic agents.

Because limited number of MN studies has been reported on effusion fluids, the present study was undertaken to distinguish malignant cells from reactive mesothelial cells.

The aim of this study was to assess the significance of micronucleated cells in effusion fluids to distinguish malignant cells from reactive mesothelial cells in unequivocal cases. Herein, we found out the utility of micronucleated cell scoring in cytological smears of effusion fluid to distinguish benign and malignant cases.

Materials and Methods

The present study was carried out in our department after obtaining approval from the ethical research committee. A total of 60 cases sent for fluid analysis were considered for the study, 30 were malignant and 30 were benign (reactive).

Relevant clinical details including the age, sex, type of effusion, and site of malignancy were noted from the departmental data base. Additional information regarding radiological findings/tumor markers was collected from hospital records.

All malignant cases included in the study were supported either by histopathology or by radiology. Benign cases included were approved by three cytopathologists independently as benign.

Smears of diagnosed cases of metastatic adenocarcinoma and reactive mesothelial cells stained with Leishman stain were studied for MN scoring. The smears were analyzed by light microscopy under oil immersion (1000×) separately and independently by two scorers and an average score was calculated. Only the noninflammatory cells were considered for scoring. Separately lying cells without overlap were studied. The number of micronucleated cells per 1000 well-preserved cells under oil immersion lens (1000×) was counted. MN [Figure 1] were detected according to the following criteria:[13]

1. Should be within the cytoplasm of the cell
2. Round to oval in shape and nonrefractile
3. Mean diameter less than 1/3 of the main nucleus
4. The shape, color, and texture of MN are similar to those of the original nuclei
5. It should be in the same optical plane as the original nucleus
6. Distinctly separate from the main nucleus with a similar staining intensity.

Degenerated cells, apoptotic cells, cytoplasmic fragments, and overlapping and inflammatory cells were exempted from counting and scoring. Cells with single/multiple MN were counted as one.

Descriptive statistics used was mean (SD) for continuous variables and percentage for categorical and dichotomous variables. Receiver operator characteristic (ROC) analysis was used to determine the sensitivity and specificity. Mann–Whitney test (nonparametric test) was used to detect MN score difference between two groups. MN score in both the groups was expressed as mean ± SD and median (min–max) where appropriate. Area under the curve (AUC) is a measure of the overall performance of a diagnostic test. It was assessed using ROC curve analysis to determine the cut-off point between the two groups. The ROC plots the true positive rate (sensitivity) against the false-positive rate (1-specificity). The closer the AUC is to 1 the better is the overall diagnostic performance of the test, and a test with an AUC value of 1 is one that is perfectly accurate. The practical lower limit for the AUC of a diagnostic test is 0.5. Data processing and analysis were performed using SPSS Statistics for Windows (version 20.0. Armonk , New York: IBM corporation).

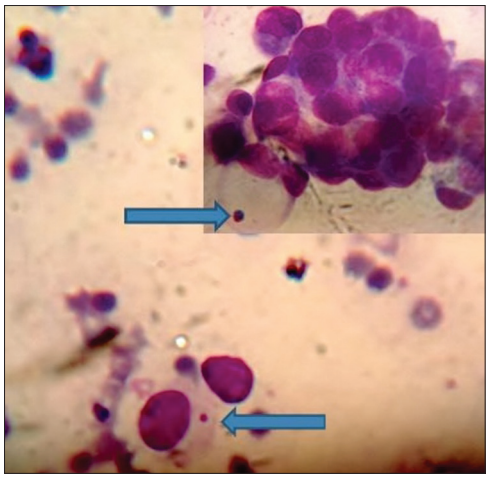

Figure 1: Micronucleus (indicated with an arrow) in a mesothelial cell and (inset) in a signet ring cell, (Leishman stain x1000)

Results

The present retrospective study was done on 60 effusion fluids which included 30 benign (reactive) and 30 malignant cases. Age ranged 33–85 years and females had a higher preponderance than males. The mean ± SD number of MN score in malignant cases was 15 ± 9.78 with a maximum of 50 and a minimum of 6. Median score was 13. Maximum number of MN seen in a cell was 3. The mean ± SD number of MN score in benign cases was 1 ± 1.78 with a maximum of 5 and minimum of 0. Median score was 2 [Table 1]. Mann–Whitney test scoring revealed a statistically significant difference in MN score between the two groups. The results of the ROC analysis showed that MN counts possessed a high degree of sensitivity and specificity. Using the ROC curve method, we found out a cut-off of 5.5 for MN count giving a sensitivity of 100% and a specificity of 100% at this point ($P = 0.000$ and AUC = 1).

Discussion

To the best of our knowledge there are currently only two published studies of MN scoring on effusion fluids, however, these studies have been done on other samples such as exfoliated buccal, vaginal, cervical, and lymphocytes. These studies noticed significant difference in MN scoring between benign and malignant groups. The present study was undertaken to examine the difference in MN score between the two groups (benign and malignant) objectively, and if possible, to evaluate the cut-off point between the two groups by validation of MN score in effusion fluids.

The study conducted by Kaur and Dey on ascitic fluid effusions using MGG stain included 20 and 15 cases of malignant cells and benign mesothelial cells, respectively.[14] In their retrospective study, test group age ranged from 34 to 71 years and females were more than males. They concluded that MN scoring was significantly higher in malignant effusions and their mean MN score in malignant cases was 21 compared to 2.9 in benign cases. Another study done by Tyagi *et al.* on ascitic fluid including 60 benign and 40 malignant fluids showed mean MN score in malignant group to be 13.2 and

Table 1: Result of statistical analysis between two groups

Category	Number of cases	MN score mean ± SD (min-max)	Median
Malignant	30	15.77±9.78 (6-50)	13
Benign	30	1.87±1.78 (0-5)	2

the MN score ranged from 1 to 58. Benign group showed mean a MN score of 0.57 ranging from 0 to 5.[15] Our results correlate with their results [Table 2]. The standard deviation showed wide variation in malignant group and were 9.78 and 1.78 in malignant and benign groups, respectively. A similar finding was noted in many other studies. They suggested that more variation in malignant cases was probably due to type and staging of the primary tumor, carcinogen exposure, and genetic causes. We considered few additional factors to explain this variation in fluid cytology. First factor may be the variable admixture of reactive mesothelial cells with malignant cells in malignant effusions which might lead to extreme differences in MN scoring. It is well-known that malignant effusions also show reactive mesothelial cells. Admixture of more reactive mesothelial cells might have led to low scores. Second, the presence of malignant signet ring cells pose another problem as these cells have peripherally compressed cytoplasm which may obscure the detection of micronucleus, leading to a low score [Figure 1 inset]. These problems were unique to effusions and not noticed in vaginal or oral smears.

Table 2: Comparison of MN scores with previous fluid studies

Study	Sample size	MN Score mean (min-max)	*P**
Kaur *et al*.	T - 20	21 (9-34)	<0.001
	C - 15	2.9 (0-10)	
Tyagi *et al*.	T - 40	13.2 (1-58)	<0.001
	C - 60	0.5 (0-5)	
Present study	T - 20	15.7 (6-50)	<0.001
	C- 20	1.87 (0-5)	

T: Test group, C: Control group

Table 3: Difficulties encountered in detecting MN

Mimickers of MN	Availability of single cells	Other factors
Debris	Cell balls in malignant cases	Signet ring cells
Platelets	Overlapping cells	
Lymphocytes		
Apoptotic cells		
Stain deposits		

Figure 2: Mimickers of micronucleus – nuclear debris (indicated with an arrow), (Leishman stain x1000)

MN scoring can be difficult in situations, as stated in Table 3, where structures mimicking MN such as stain deposits, nuclear debris, overlapping platelets, and lymphocytes were present [Figure 2]. When encountered with such problems, comparing the structures with texture and staining characteristics of original nucleus helps us to isolate the artefacts. Apoptotic cells also mimic MN and can be easily differentiated by noting the absence of original (main) nucleus. The problems of keratohyaline granules mimicking MN were seen only in studies where squamous cells were seen. The present study included only adenocarcinoma and we did not encounter this problem. We did not find any significant difference in MN scoring in relation to age and site of primary cancer. Normal cells during cell division can also rarely give rise to micronucleus, however, this is a less common phenomenon when compared to preneoplastic and neoplastic conditions.

MN scoring is a simple and effective tool to distinguish between benign and malignant effusion in routine cytological analysis. The limitations of our study were smaller sample size and absence of use of specific nuclear stains. Hence, we advocate prospective larger scale studies with adequate sample size and use of specific nuclear stains.

Author Help: Reference checking facility

The manuscript system (www.journalonweb.com) allows the authors to check and verify the accuracy and style of references. The tool checks the references with PubMed as per a predefined style. Authors are encouraged to use this facility, before submitting articles to the journal.

- The style as well as bibliographic elements should be 100% accurate, to help get the references verified from the system. Even a single spelling error or addition of issue number/month of publication will lead to an error when verifying the reference.
- Example of a correct style
  Sheahan P, O'leary G, Lee G, Fitzgibbon J. Cystic cervical metastases: Incidence and diagnosis using fine needle aspiration biopsy. Otolaryngol Head Neck Surg 2002;127:294-8.
- Only the references from journals indexed in PubMed will be checked.
- Enter each reference in new line, without a serial number.
- Add up to a maximum of 15 references at a time.
- If the reference is correct for its bibliographic elements and punctuations, it will be shown as CORRECT and a link to the correct article in PubMed will be given.
- If any of the bibliographic elements are missing, incorrect or extra (such as issue number), it will be shown as INCORRECT and link to possible articles in PubMed will be given.

Clinicopathological Conference

An unusual cause of breathlessness and profuse micronodules

ABSTRACT

We describe a 21-year-old male with a history of smoking and subacute onset of breathlessness with normal cardiorespiratory examination. The presence of "track marks" and digital infarcts prompted evaluation for infective endocarditis and confrontational history taking revealed anorexia, weight loss over 3 months along with intravenous drug abuse of reconstituted tablets of tapentadol. Echocardiography was normal and blood cultures were sterile; computed tomography showed bilateral, diffuse, small centrilobular nodules with "tree-in-bud" appearance. In this clinicopathologic conference, we discuss the clinical and radiological differential diagnosis of centrilobular nodules, lung biopsy findings, and management options for patients with such a presentation.

KEY WORDS: Excipient lung disease, intravascular talcosis, pulmonary foreign body angiogranulomatosis, talc granulomatosis

Address for correspondence: Dr. Srinivas Rajagopala, Department of Pulmonary Medicine, PSG Institute of Medical Sciences and Research, Peelamedu, Coimbatore - 641 004, Tamil Nadu, India. E-mail: visitsrinivasan@gmail.com

PRESENTATION OF THE CASE

A 21-year-old college student presented with breathlessness and left-sided chest pain for a week. Breathlessness was insidious in onset and persisted on walking at own speed at level. Chest pain was left-sided, intermittent, pricking and non-exertional. There was no history of fever, rhinitis, headache, hemoptysis, cough, or joint pains. He did not raise pets but admitted to smoking 7–8 cigarettes/day and consuming whisky (192 g of alcohol weekly). He denied any recent worsening of educational performance. He did not report any significant prior medical illness or pertinent illness in family or occupational dust exposure. He was initially seen in cardiology and evaluation showed normal cardiac and respiratory examination without any pallor, clubbing, or organomegaly. Body mass index was 18.6 kg/m^2. The examination also showed extensive track marks over both arms with evidence of multiple peripheral digital infarcts [Figure 1], raising suspicion for infective endocarditis (IE). On confronting, he disclosed daily intravenous self-injections of three–four powdered and reconstituted 50 mg tablets of Tapentadol (Tydol, Sun Pharma) in sterile distilled water two–three times a day over the last 2 years. He also admitted to using inhaled cannabis twice weekly over the last 2 years. There was associated anorexia and unquantified weight loss over the last 3 months. Three sets of blood cultures were sterile. Electrocardiography showed T-wave inversions in leads V3–V6 and II, III, and aVF. Transthoracic echocardiography (TTE) showed normal valves without any evidence of vegetations or pulmonary hypertension and normal left ventricular function. Serum creatinine

Figure 1: Composite image of the clinical photographs (left) of the right forearm showing "track marks," indicating healed superficial septic thrombophlebitis and (right) both hands showing multiple bilateral distal digital pulp infarcts. Similar findings were also seen in both plantar surfaces (not shown)

was 0.6 mg/dL; urine microscopy was normal without any albuminuria. Hemoglobin was 14.2 g/dL with normal leukocyte and platelet counts. He remained afebrile. Transesophageal echocardiography (TEE) was planned; in the meanwhile, review of his chest radiographs showed diffusely scattered fine nodules bilaterally [Figure 2, left]. Spirometry showed mild restriction with reduced diffusion capacity for carbon monoxide (forced expiratory volumes at 1 s 2.25 L [65%]%, forced vital capacity 2.87 L [71%], DLco 62%). There was desaturation to 92% while walking 6 minutes, with preserved walk distance (545 meters, 89% predicted). Human immunodeficiency virus (HIV), anti-nuclear antibodies, hepatitis B, and hepatitis C antibodies were negative by enzyme-linked immunosorbent assay. Immunoglobulin E levels were 9 IU/mL (normal <100 IU/mL). High-resolution computed tomography (HRCT) of the thorax showed bilateral profuse evenly distributed micronodules with "tree-in-bud" [Figure 2, right]. There was no sputum production on induction with 3% saline. A procedure was planned for diagnosis.

DIFFERENTIAL DIAGNOSIS

Important features of this case

This HIV-negative young adult with significant smoking history, cannabis use, and intravenous drug abuse with reconstituted tablets over 2 years has breathlessness, anorexia, and weight loss with radiological findings of micronodules. There is evidence of distal embolic infarcts, but initial evaluation for endocarditis was negative. The reduced DLco, restriction on spirometry and unexpectedly low walk distance in a young individual with desaturation on walking implies extensive parenchymal and/or pulmonary vascular disease. The differential diagnosis of profuse bilateral micronodules is extensive [Table 1] but can be narrowed by careful history and analysis of HRCT findings in conjunction with the expected pulmonary complications of intravenous drug abuse [Table 2].[1] The first step is to characterize the

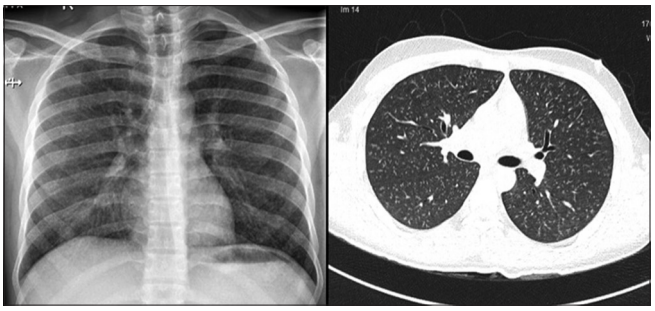

Figure 2: Composite image of the chest radiograph (left) showing small nodular opacities and high-resolution computed tomography of the thorax (right) showed bilateral profuse evenly distributed micronodules with tree-in-budding; pulmonary artery was normal in size, and there were no associated lymphadenopathy. Expiratory computed tomography did not show any air trapping (not shown)

distribution of the micronodules spatially within the lung and also the secondary pulmonary lobule. These nodules were uniform in size and were distributed evenly in a cephalocaudal direction, without any preferential lobar involvement. None of the nodules abut the pleural surface or the fissures [Figure 3]; there is clear evidence of extensive bilateral branching nodules in centrilobular distribution. There is no evidence of bronchiectasis; while no contrast was administered, in conjunction with echocardiography, there is no dilated pulmonary artery or lymphadenopathy. These findings limit the radiological differentials to causes of micronodules in a centrilobular distribution and extensive uniform "tree-in-bud" appearance. "Tree-in-bud" indicates the presence of dilated centrilobular bronchioles with lumen impacted by mucus, fluid, or pus and associated with peribronchiolar inflammation. "Tree-in-bud" indicates small airway disease and is associated with airway infection in the large majority but can also be rarely caused by arteriolar disease.[2] Its presence makes three common causes of centrilobular nodules unlikely: hypersensitivity pneumonitis, follicular bronchiolitis, and respiratory bronchiolitis.

Endobronchial tuberculosis

Mycobacterium tuberculosis is endemic in India, with more than 2.2 million new cases each year. Delayed recognition

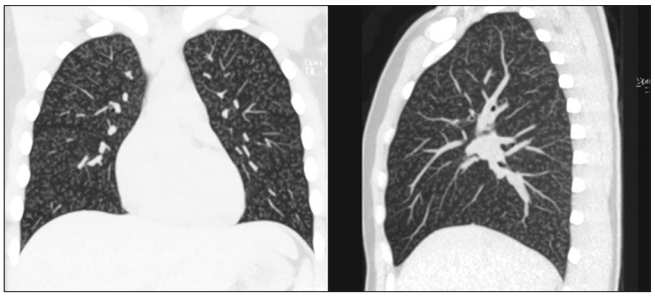

Figure 3: Coronal and sagittal reconstruction of the maximum intensity projection formatting of the high-resolution computed tomography images of the thorax showing diffuse, extensive, bilateral centrilobular nodules with branching and without any lobar predominance

and extensive disease are related to associated substance abuse, poverty, and malnutrition, all of which were present in this patient. Extensive endobronchial spread of tuberculosis can cause extensive tree-in-bud opacities although asymmetry is usually seen.[3] Tuberculosis is also the most common cause of micronodules with a random pattern (miliary). Even though the "pretest probability" of tuberculosis is high in this patient, the marked symmetry and the absence of any cavitation or consolidation is odd; digital infarcts are unusual but could be caused by an associated immune complex phenomenon that can occur with tuberculosis. *Mycobacterium avium*-intracellulare infection can also cause centrilobular nodules with "tree-in-bud," bronchiectasis, and consolidation. While it can be seen in immunocompetent patients, the classic phenotype is a middle-aged woman with slender build and without any constitutional symptoms.

Bronchopneumonia and viral bronchiolitis

Infectious bronchiolitis due to viruses, *Mycoplasma*, and chlamydia is a common cause of profuse and symmetric centrilobular nodules with "tree-in-bud;"[3] however, the prolonged illness and associated embolic phenomenon are unusual.

Allergic bronchopulmonary aspergillosis

Centrilobular nodules with "tree-in-bud" or miliary nodules can be caused by allergic bronchopulmonary aspergillosis but the absence of asthma, central bronchiectasis, and normal IgE levels rule out this diagnosis.[2,4]

Diffuse panbronchiolitis

Diffuse panbronchiolitis (DPB) is a rare disease of unknown cause presenting in males between the second and fifth decade with productive cough, diffuse bilateral centrilobular nodules with "tree-in-bud" and sinusitis. While reported in Indians,[5] it is extremely rare in our population but can explain all the clinical and radiological features.[6] Cold agglutinins are frequent in DPB and pulp infarcts may be due to an associated connective tissue disease. The absence of productive sputum, obstruction on spirometry, sinusitis, and air trapping on expiratory CT are unusual in DPB and necessitate further evaluation with surgical lung biopsy to establish the diagnosis.[6]

[Downloaded free from http://www.lungindia.com on Friday, December 20, 2019, IP: 192.168.30.31]

Excipient lung disease

Centrilobular nodules are usually caused by bronchiolar disease but can rarely be caused by arteriolar disease. Arteriolar causes include pulmonary edema and hemorrhage, excipient lung disease (ELD), granulomatosis with polyangiitis (GPA), plexogenic arteriopathy (PH), veno-occlusive disease (VOD), pulmonary capillary hemangiomatosis (PCH), and metastatic calcification.[2] There was no evidence of heart failure, renal failure or anemia and hemoptysis to suggest alveolar hemorrhage. The absence of pulmonary hypertension makes centrilobular nodules due to PH, VOD, and PCH very unlikely. Nodules due to GPA are larger, fewer, and associated with cavitation. Excipients are insoluble inert particulate filler materials that bind and protect the active drug during production as well as shape and lubricate tablets for easy swallowing. Excipients include talc (hydrated magnesium silicate), microcrystalline cellulose, crospovidone, and starch. Typically, excipients constitute 5% of a tablet's mass. On intravenous injection, excipient particles lodge in pulmonary arterioles and trigger an angiogranulomatous reaction; progressive disease is associated with dyspnea and pulmonary hypertension.[7] However, the presence of finger pulp infarcts, "tree-in-bud" appearance and absence of pulmonary hypertension are unusual in ELD.

CLINICAL DIAGNOSIS

In summary, the differential diagnosis of extensive centrilobular nodules with "tree-in-bud" without bronchiectasis or pulmonary hypertension in this young adult with smoking, cannabis use, and intravenous drug abuse of reconstituted tablets can be narrowed down to extensive endobronchial tuberculosis, diffuse panbronchiolitis, and ELD.

Dr. RM. PL. Ramanthan: With these clinicoradiological possibilities in mind, this patient underwent fundus examination and bronchoscopy with bronchoalveolar lavage (BAL) and transbronchial lung biopsy, with a plan for surgical biopsy if evaluation was inconclusive. Can we now have the findings?

Dr. K. Divya: Dilated fundus examination confirmed refractile particles scattered along both the retinal arteries and retinal veins [Figure 4], confirming systemic embolization of small (<5 μm) talc particles, consistent with intravenous talcosis. Inhalational talc exposure does not cause such marked retinal deposition as the inhaled particles are larger and are restricted by bronchioles and pulmonary circulation.[8,9]

Dr. Nidhya Ganesan: BAL was negative for acid-fast bacilli and for *M. tuberculosis* by Xpert MTB/RIF; occasional needle-shaped crystals were seen on cytology. The transbronchial lung biopsy specimen confirmed perivascular granulomatous reaction to talc particles [Figure 5, left] that appear as birefringent needle-shaped crystals within the granulomas under polarized light [Figure 5, right]. Review of the composition of Tydol confirmed the presence of talc as excipient. Microcrystalline cellulose appears rod like while starch has a maltese cross pattern and crospovidone is nonbirefringent on polarization.[7]

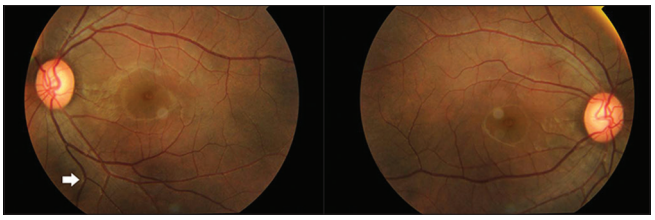

Figure 4: Fundus photograph of both eyes showing refractile particles scattered along both the retinal arteries and retinal veins, confirming the diagnosis of intravenous talcosis

Dr. Srinivas Rajagopala: A diagnosis of ELD (talc granulomatosis) was made. Psychiatry services were involved, and the patient underwent counseling, arrangement for family supervision, and daily-observed methadone replacement. He has successfully discontinued intravenous drug abuse and remains stable at 3 months of follow-up. Serial spirometry, DLco, and radiographs have been advised at 6 monthly intervals. Three unusual findings need an explantation; 1) The presence of "tree-in-bud" in a process that is hematogenous in origin 2)The absence of pulmonary hypertension in ELD and 3)The cause of the bilateral digital infarcts observed.

Dr. B. Devanand: Diseases involving pulmonary arterioles can cause centrilobular nodules as arterioles run in the peribronchovascular interstitium adjacent to bronchioles. Talcosis associated with intravenous abuse is most commonly associated with diffuse fine centrilobular nodules, ground-glass abnormalities or a combination of nodules and lower-lobe emphysema (Ritalin lung with methylphenidate).[9,10] The "tree-in-bud" pattern is unusual for arteriolar disease; it can be caused by intra-arteriolar accumulation of talc with associated adjacent perivascular granulomatous reaction giving the appearance of branching centrilobular nodules and has been described in a few cases of ELD earlier.[11]

Dr. Srinivas Rajagopala: What is the course of ELD? Can the disease progress despite cessation of abuse?

Dr. Kancherla Roopa: Lung fibrosis and pulmonary hypertension are related to the extent of vascular obstruction and granulomatous inflammation and are usually irreversible with talc, cellulose, and crospovidone as these cannot be mobilized; starch can be removed by metabolism and pulmonary hypertension can be reversible to a large degree. Disease progression can occur despite cessation due to ongoing granulomatous foreign-body reaction to the deposited, unmobilizable talc. The initial series of patients described all had progressive symptoms leading to death over 9 months to 5 years.[10,12] The index

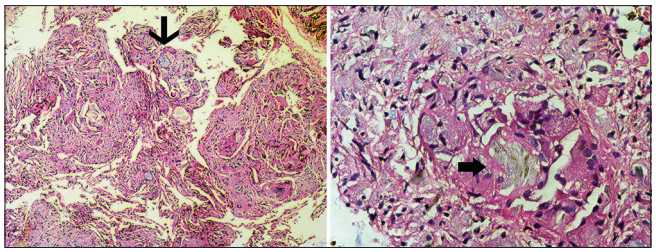

Figure 5: Photomicrographs of the transbronchial lung tissue biopsy specimen (left) demonstrating perivascular foreign body granulomatous reaction to the talc particles (thin arrow, H and E, ×100). Under polarized light, birefringent 20–95 μm needle-shaped crystals were seen in the granuloma, consistent with talc (block arrow, H and E, ×400)

patient has a large load of perivascular disease and is at risk for pulmonary hypertension and disease progression despite cessation of further abuse.

Dr. Srinivas Rajagopala: How common is systemic embolization of talc given that the lung acts as an effective filter?

Dr. K. Divya: The talc that is trapped in the pulmonary arterioles is typically around 10 μm, but smaller particles can escape to the systemic circulation and be detected in the retina, spleen, and virtually every organ on autopsy.[12] Finding excipient crystals in fundoscopy is a rapid noninvasive method to confirm intravenous talcosis.

Dr. Srinivas Rajagopala: Given the presence of digital infarcts, is TEE needed to exclude IE in this patient?

Dr. G. Rajendiran: The first consideration in this patient with possible unsafe needle practices, no murmurs, weight loss, breathlessness, and digital embolic manifestations was subacute native valve IE. TTE has low sensitivity compared to TEE (46% vs. 93%) although both are highly specific (96%).[13] Embolic manifestations are seen in about half of patients with IE.[14] He was not administered any antibiotics, three sets of blood cultures were sterile, and TTE showed all valves clearly without any vegetations. TEE is restricted in our practice to high probability for IE or in whom TTE is rendered less sensitive due to obesity, lung hyperinflation, or prosthetic valves. The index patient met only 2 minor Modified Duke's criteria and was considered low risk for IE after the initial evaluation and TEE deferred.[15] Furthermore, a clear alternative explanation for the observed distal infarcts in the form of talc deposition in the distal microcirculation with thrombosis is available and corroborated by fundoscopy. While this physical finding has not been described in ELD previously, it is consistent with the distal digital embolization and subsequent microthrombosis caused by talc.

Dr. Srinivas Rajagopala: What are the options for those with progressive breathlessness despite cessation of intravenous drug abuse?

Dr. RM. PL. Ramanthan: There are previous small series of lung allografts after a careful selection process in ELD with excellent outcomes.[16] Cadaveric bilateral sequential lung transplantation is a reality in our country today, and he can be listed for the same at our center if he meets criteria and remains free of substance abuse for at least 6 months with adequate psychiatry counseling.

SUMMARY

Clinical examination findings continue to have relevance in this era of investigation-driven medicine. Excipient lung disease can result from intravenous injection of reconstituted tablets and can present with ground glass opacities, small nodules, and emphysema. Pulmonary arteriolar diseases must be considered in the differential diagnosis of centrilobular nodules on CT.

Acknowledgments

The authors would like to thank Jagadeshwari, Research coordinator, and Nissy, Nurse, PSG Institute of Pulmonology, for their help in completing the paperwork for Ethics approval and collating the images for the manuscript.

Declaration of patient consent

The authors certify that they have obtained all appropriate patient consent forms. In the form, the patient has given his consent for his images and other clinical information to be reported in the journal. The patient understands that names, identifying marks, and initials will not be published and due efforts will be made to conceal identity, but anonymity cannot be guaranteed.

© Higher Education Press and Springer-Verlag Berlin Heidelberg 2015

Abstract **Pulmonary alveolar microlithiasis is a rare disease characterized by intra-alveolar presence of microliths. This study reports an interesting case of pulmonary alveolar microlithiasis and provides a systematic review of cases reported from India. A 23-year-old female presented with a history of cough, wheeze, chest pain, and episodic wheeze for five months. Pulmonary function tests demonstrated an obstructive pattern, and chest X-ray showed fine micronodular opacities predominantly involving the middle and lower zones of both lungs. Transbronchial lung biopsy revealed the diagnosis. She responded well to inhaled steroid therapy. A systematic review of literature was performed and identified 73 cases of pulmonary alveolar microlithiasis reported from India. The mean (SD) age of the patients was 28.8 (14.9) years, with an almost equal male:female ratio. Many patients were asymptomatic at presentation. Breathlessness and cough were the most common symptoms, and the disease progressed into respiratory failure associated with cor pulmonale. About one-third of the cases were initially misdiagnosed and treated as pulmonary tuberculosis. Extra-pulmonary manifestations and co-morbidities were also evident in our series. This systematic review helps to determine epidemiological and clinical characteristics of pulmonary alveolar microlithiasis. Further research is needed to elucidate the etiopathogenesis, diagnosis, and therapeutic options, which are beneficial in developing and identifying cost-effective treatment for pulmonary alveolar microlithiasis.**

Keywords pulmonary alveolar microlithiasis; alveolar microlithiasis; microliths; rare diseases

Introduction

Pulmonary alveolar microlithiasis (PAM) is a rare disease characterized by intra-alveolar presence of microliths. It is an autosomal recessive disorder and runs in families. PAM occurs because of mutation in the sodium co-transporter (*SLC34A2*) gene [1]. Affected patients may range from early childhood to elderly and are usually asymptomatic during the early phase of the disease. This disease has a long and progressive course with deterioration of lung function [2].

Malphighi from Italy (1686) was the first to describe the macroscopic features of the disease, and Puhr from Hungary is credited for naming the disease in 1933 [2]. The first PAM case in India was reported by Viswanathan in 1961 [3]. This disease is extremely rare; hence, a systematic review of published cases is helpful in understanding its epidemiology, etiopathogenesis, clinical features, and diagnosis. Two interesting national reviews have already been published from Turkey and Italy [4,5]. In this study, we present an interesting case of PAM and review the literature of 52 case reports (73 cases) from India [3,6–56]. Majority of the case reports have been published in our national journals.

Our case report

A 23-year-old female, born of second-degree consanguineous marriage, presented with cough with expectoration, chest pain, and episodic wheeze for five months. The chest pain was associated with coughing. Sputum production

THE AUTHORS WARRANT THAT THEY WILL NOT POST THE E-OFFPRINT OF THE PAPER ON PUBLIC WEBSITES.

was minimal and not foul smelling or blood tinged. No history of fever, hemoptysis, or loss of weight was present. She did not have any past history of pulmonary tuberculosis, and her personal history was unremarkable. She was not a smoker and had no history of exposure to toxic gases and fumes. Pedal edema, cyanosis, and clubbing were not present. On lung auscultation, vesicular breath sounds were heard bilaterally. Oxygen saturation was 96% on room air. Pulmonary function test revealed an obstructive pattern, with a forced vital capacity of 2.83 L (109% of predicted value), a forced expiratory volume in 1 s of 1.86 L (83% of predicted value), a FEV1/FVC ratio of 65.7 (78% of predicted value), and a PEF of 2.87 L/s (46% of predicted value).

Routine blood investigations were within normal limits, except for a mild eosinophilia. Chest X-ray showed diffuse fine micronodular opacities, predominantly involving the middle and lower zones of both lungs with relative sparing of the apices (Fig. 1). Miliary tuberculosis was initially suspected, but sputum smear and culture were negative for acid-fast bacilli. High resolution computed tomography (HRCT) of chest showed diffuse bilateral micronodules of 1–2 mm size, involving all segments of the lung (Fig. 2).

Fig. 1 Chest X-ray showing fine, diffuse, and symmetric micronodular calcifications.

On bronchoscopy, the respiratory mucosa showed mild congestion without any significant abnormality. BAL was performed, and biopsy specimens were obtained by transbronchial lung biopsy (TBLB) from the right middle lobe. BAL did not reveal respiratory pathogens or any specific pathology. TBLB exhibited dilated alveolar spaces with laminated calcific concretions (Figs. 3 and 4). The calcospherites positively stained with von Kossa stain. Our final diagnosis was pulmonary alveolar microlithiasis with associated bronchial asthma.

Fig. 2 High resolution CT scan showing diffuse bilateral miliary shadows.

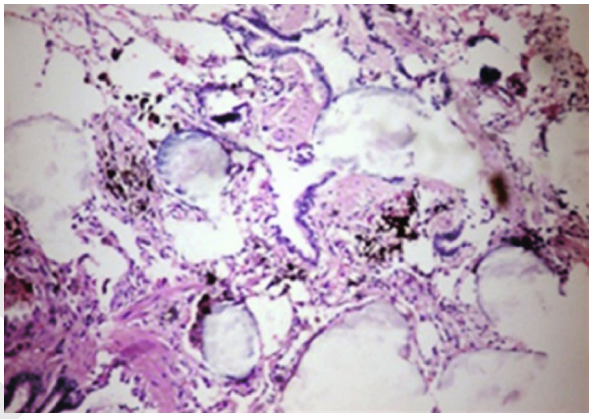

Fig. 3 Calcospherites within the dilated alveolar spaces (H&E stain, 100 ×).

We also assessed the sibling (elder brother) of our patient. He was in good health, and his chest X-ray was unremarkable. The patient was started on inhaled fluticasone propionate/formoterol combination therapy. She improved symptomatically and came regularly for follow-up visits for nine months. A repeat radiograph was performed eight months after her initial presentation, and significant change was not observed (Fig.5). Unfortunately, she was lost to follow-up thereafter.

Methods

Search strategy

A PubMed search was performed with the terms

THE AUTHORS WARRANT THAT THEY WILL NOT POST THE E-OFFPRINT OF THE PAPER ON PUBLIC WEBSITES.
http://journal.hep.com.cn/

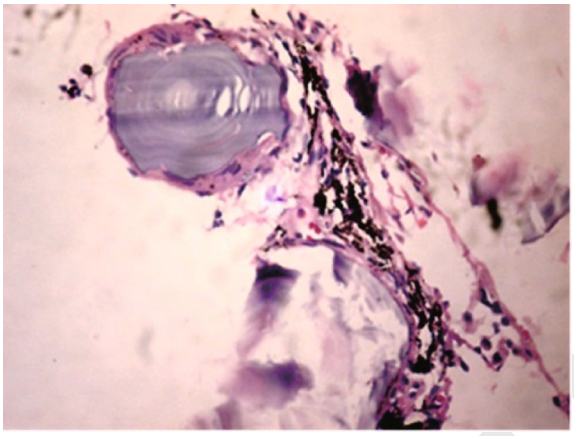

Fig. 4 Concentric calcification (H&E stain, 400 ×).

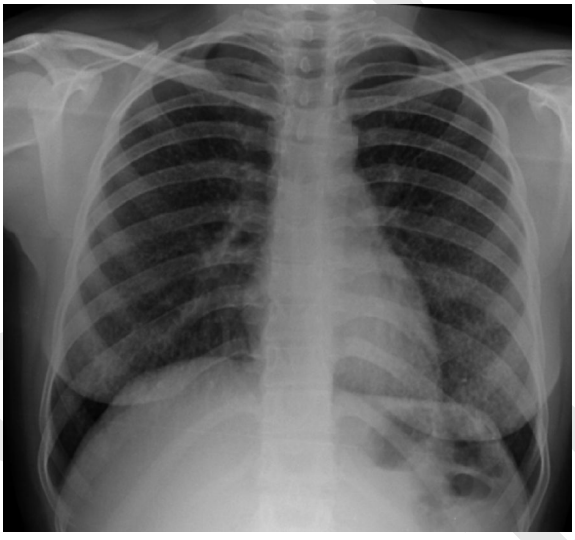

Fig. 5 Repeat chest X-ray also showing diffuse micronodular calcifications.

"pulmonary alveolar microlithiasis" OR "alveolar microlithiasis" OR "microlithiasis alveolaris pulmonale" AND "India." The search was limited to articles published in the English language. Additional publications were also identified from the reference list of the published articles. The websites of national journals of India, such as *Lung India* and *Indian Journal of Pathology and Microbiology* were also searched to identify further citations. Cases published as a case report and subsequently in a case series or as an "interesting image" were not counted separately.

Inclusion criteria

We included only case reports and short case series from India published between 1961 and 2013. All cases diagnosed as PAM from India based on radiological investigations or biopsy were included in our study.

Exclusion criteria

Review studies were excluded. Cases without complete clinical and diagnostic details were also excluded.

Two authors independently screened the title and abstracts of the reports identified in the search. Full text articles were retrieved for relevant citations. The final list of articles was selected by consensus.

Data collection and statistical analysis

Clinical data and basic demographic details of individual cases were extracted and compiled using Microsoft Excel 2010. Categorical data and continuous variables were expressed as percentages and as mean and standard deviation, respectively.

Results

Our analysis included 73 PAM cases (52 case reports/short case series) reported from India between 1961 and 2013 [3,6–56]. The details of familial screening were available in 38 patients. A familial preponderance was evident in 21 cases. All the familial cases were siblings, except for a familial occurrence in a mother and her two daughters. The proband (mother) was married to her maternal uncle who was not affected by the disease.

A total of 37 females and 36 males with a mean ± SD age of 28.8 ± 14.9 years (median age 27.0 years; range 4–60 years) were found. Maximum cases were reported in the age group of 21–30 years (Table 1). The cases were reported from all geographic locations of India. Although occupational history was not mentioned in all the cases, the majority were housewives, students, and farmers. Three cases had history of exposure to respiratory irritants, but the occupational exposure was probably not associated with the development of PAM. A 43-year-old male had worked for four years in a cement retail shop, 15 years before developing PAM [3]. A 25-year-old housewife was employed part time in making biris (local hand-rolled cigarettes) [45]. Both the cases were familial, and their siblings were not exposed to these occupational hazards. Similarly, radiological evidence of the disease was not observed in the coworkers of a 26-year-old machine operator employed in a Calico printing factory [13].

Clinical features

Table 1 shows the frequency of common clinical signs and symptoms in various age groups. Twenty-two cases (30%) were misdiagnosed as pulmonary tuberculosis based on

* For example, 1/8 PAM cases in 0–10 age group (12.5% of cases in 0–10 age group) presented with cough.

radiological features and started on ATT, but only one of them was sputum positive. This particular case was treated for pulmonary tuberculosis twice; the first treatment was based on sputum positivity for acid-fast bacilli, and the second treatment was based on radiological abnormalities. The patients did not improve symptomatically on ATT, and further investigations, such as lung biopsy, revealed PAM. Interestingly, only one case had developed superadded sputum positive pulmonary tuberculosis almost after 12 years of diagnosis.

Six patients aged between 24 and 60 years (mean age of 39.6 ± 14.2 years) had died; five of them died within a week of admission, and one patient died within three months of admission. These patients had symptom duration that ranged from 3 months to 10 years. The 24-year-old patient developed pneumothorax following a bout of coughing and died of respiratory failure. Others died because of respiratory insufficiency associated with cor pulmonale. The 60-year-old female had worsening symptoms for five years and was treated at several centers with antibiotics and anti-tubercular drugs. The patient was finally diagnosed as PAM in a tertiary care center; unfortunately, she died within a week of admission. Two other patients, aged 50 years and 30 years, also had symptoms for 7 and 10 years, respectively; nevertheless, the diagnosis was established only before their death.

Long-term follow-up details were not available for majority of the patients in our series.

Imaging

Chest radiograph was performed in all patients except for one case. The characteristic finding in most of the cases were sand-like calcific micronodules (sandstorm pattern) diffusely involving both middle and lower lobes bilaterally with relative sparing of the apices. The calcific densities were confluent and denser at the bases. Other common roentgen findings included a dark radiolucent strip between the ribs, the markedly radiopaque lung parenchyma (black pleural line or negative pleural sign), and obscuration of the cardiac outline, diaphragm, and hilar vessels (the "drowned heart syndrome"). Twenty-five patients (34%) were evaluated using CT scan/high resolution CT scan. However, about 57% of the cases diagnosed after 1990 were evaluated using CT scan. Technetium-99m bone scan performed in nine patients showed diffuse increase in radiotracer uptake in both lungs.

PAM was associated with nephrolithiasis (one case), appendicitis (one case), and cholelithiasis (two cases). PAM was also associated with infertility (three males and two females).

Pulmonary function tests were performed in 40 patients. Restrictive pattern was evident in 34 patients (85.0%), and obstructive pattern and normal study in one patient (2.5%) and five patients (12.5%) were observed, respectively. Bronchoalveolar lavage was performed in nine patients and revealed the characteristic calcospherites in three cases. Lung biopsy proved to be confirmatory in 37 patients. CT-guided FNAC revealed the characteristic laminated microliths in a patient [26]. Necropsy was carried out in only one case [6].

Majority of the cases were treated conservatively, and none of the cases underwent lung transplantation. The cases in our series were predominantly reported from reputed tertiary care centers and probably represent the tip of the iceberg. A number of PAM cases are possibly undetected and even worse misdiagnosed as miliary tuberculosis in India.

Discussion

PAM has been reported worldwide and has no specific geographic or racial distribution. It is widely prevalent in Turkey, Italy, Japan, India, and USA. Recently, PAM is also being reported frequently from other Asian countries, such as China. PAM has no obvious sex predilection. Although PAM affects all ages, it has been most frequently discovered from birth up to 40 years old [2]. The youngest reported cases were premature twins, who died soon after birth [57]. PAM occurs in families, as well as sporadically [2,4,5,58]. Familial cases account for about half of the reported cases [4]. PAM usually affects siblings and less frequently cousins in a horizontal pattern. Parents and children are rarely affected in a vertical pattern [2]. PAM is a recessively inherited disease with complete penetrance, and no role for non-genetic mechanisms seems to exist [59,60]. Familial PAM is common in our series, and all the familial cases were siblings, except for a rare involvement of a mother and her two daughters [11]. Although the male: female ratio was equal in our series, a female predominance was noted in our familial cases (1:2 ratio). History of significant exposure to specific environmental or occupational risk factors was not observed in almost all our cases.

Recent studies have shown that PAM resulted from the mutation of the *SLC34A2* gene, a type IIb sodium phosphate co-transporter gene involved in phosphate homeostasis in several organs. *SLC34A2* is expressed in the apical membrane of type II alveolar cells in the lungs. These cells synthesize surfactants using phospholipids and are also involved in recycling and degrading the outdated surfactant, thereby releasing phosphates in the process. The clearance of phosphate from the alveolar space is possibly reduced because of SLC34A2 dysfunction, hence leading to the formation of microliths [1,60]. Dogan *et al.* analyzed three siblings with PAM in an inbred family. The genetic analysis revealed homozygous mutation in the *SLC34A2* gene in all three siblings diagnosed with PAM. Both their parents (consanguineous marriage) were carriers, with heterozygous mutation of *SLC34A2* gene. Thus, the impaired activity of the *SLC34A2* gene may be responsible for familial PAM [61].

Autopsy studies revealed that the lungs in PAM are very hard, heavy, and incompressible. The outer surfaces of the lung appear irregular and granular because of microlith protrusion under the visceral pleura. The lungs are gritty on sectioning, and the cut surface has a sandpaper texture. The sandy microliths can be squeezed out [6,62–64]. Bullous emphysematous areas can be found in the anterior margin and at the apex of the lungs [64]. Moreover, the microliths were also found within the bronchial walls in an autopsy case study [65]. Histologically, concentrically laminated calcospherites are observed within dilated alveolar spaces. The pulmonary interstitium shows varying degrees of fibrosis. Recently, morphometric analysis of CD34 immunostained sections in an autopsy case demonstrated a

THE AUTHORS WARRANT THAT THEY WILL NOT POST THE E-OFFPRINT OF THE PAPER ON PUBLIC WEBSITES.
http://journal.hep.com.cn/

significant reduction in the pulmonary capillary beds, which probably leads to pulmonary hypertension [62]. Chemically, the calcospherites are composed of calcium and phosphorus salts. Traces of potassium, iron, copper, and magnesium can also be found [66].

Clinical course

PAM occurs in different age groups, but is frequently diagnosed in the second and third decades. Microliths are probably formed early in childhood, but the manifestations occur much later. The youngest patient in our series was four years old. Many patients were asymptomatic at presentation and were diagnosed incidentally. Breathlessness and cough are the most common symptoms (Tables 1 and 2). Cough probably results from the direct stimulation of the C fibers or other receptors through the microliths [58]. Clubbing is also detected frequently, and wheeze and chest pain are present in less than 10% of our cases. The disease worsens over time and usually progresses into respiratory failure associated with cor pulmonale. Death can also occur because of tension pneumothorax. In our series, the mean age at death is 39.6 years. Mascie-Taylor estimated the mean age at death to be 41.7 years [67]. Mean age at death is not mentioned in the Turkish and Italian series [4,5].

About one-third of the cases from India were misdiagnosed and treated for pulmonary tuberculosis. PAM was also misdiagnosed as miliary tuberculosis in 29% of the Italian cases [5].

Extra pulmonary manifestations

PAM can also be presented with extra-pulmonary manifestations and co-morbidities. Approximately 8% of males in our series were infertile. Semen analysis showed azoospermia in a 40-year-old male [36]. A detailed work up of infertility in a 27-year-old male revealed calcific deposit in the seminal vesicles [28]. Epididymal and periurethral calcifications causing azoospermia and punctate calcification in the seminal vesicles are associated with PAM [68,69]. Calcification of the sympathetic nervous system and possible involvement of the testes in a case of PAM is also reported [70]. Moreover, mutations in SLC34A2 are possibly associated with testicular microlithiasis [60]. These observations make an interesting aspect of PAM, which requires further research.

Co-morbidities, such as mitral stenosis [71], autosomal recessive Waardenburg anophthalmia syndrome [72], lymphocytic interstitial pneumonitis [73], milk-alkali syndrome [74], and diaphyseal aclasia [75], are rarely reported. A case of PAM with concomitant valve calcification, cholelithiasis, and idiopathic medullary nephrocalcinosis is also reported [76]. PAM is rarely associated with pulmonary tuberculosis.

Investigations

Chest X-ray, CT, and high-resolution CT findings are often diagnostic of PAM. Chest radiographs reveal diffuse areas of micronodular calcifications involving both lungs symmetrically. Tomographic evaluation confirms chest X-ray features. Minimal structural changes of the lung parenchyma can also be detected using high resolution CT scans. Most commonly, the CT scan reveals diffuse ground-glass opacities, which are associated with confluent and diffuse calcified nodules [63,77]. Ground-glass attenuation occurs because of small calculi in the alveoli. The calcifications can be observed along the bronchovascular bundles and interlobular septae. The diffuse ground glass attenuation and septal thickening with calcified nodules is referred to as the "crazy-paving" pattern in HRCT scans [77]. Meanwhile, the occurrence of calcification along the interlobular septa is attributed to the accumulation of calcospherites within the peripheral lobular parenchyma adjacent to the septa. HRCT scans can also reveal small sub-pleural cysts and linear subpleural calcifications. The small thin-walled sub-pleural cysts form a peripheral translucent band between the calcified lung parenchyma and the ribs, probably explaining the black pleural sign observed in chest radiographs [77–79]. These small sub-pleural cysts represent dilated alveolar ducts histologically [80]. Apical bullae can also be detected by chest X-ray or CT scans. Multiple calcified pleural plaques [49] and extensive interstitial fibrosis with traction bronchiectasis are observed rarely in our series [45].

The micronodular pattern observed in PAM can mimic diseases, such as miliary tuberculosis. However, PAM involves the middle and lower lobes with relative sparing of the apices, in contrast to pulmonary tuberculosis. The characteristic dissociation between the extensive radiographic alterations and minimal symptoms also helps in diagnosing PAM. Biopsy may be needed to confirm the disease, specifically in regions with a high incidence of pulmonary tuberculosis. In the youngest patient in our series aged four, the lesions were exudative in nature during the earliest phase of the disease [13]. The exudative nodules later got calcified. Discerning these exudative lesions from miliary tuberculosis in young children who presented at an early phase of the disease can be difficult. Small calcifications in children can be difficult to detect on a chest X-ray [73].

Pulmonary function tests usually demonstrate a restrictive pattern, although patients may have a normal lung function initially. An obstructive pattern is rarely observed (Table 2). Our case showed an obstructive pattern probably due to associated bronchial asthma. Brown *et al.* demonstrated that the vital capacity level correctly predicts the development of pulmonary hypertension with exercise in PAM. This relationship suggests the presence of a

http://journal.hep.com.cn/

restricted pulmonary vascular bed [81], as demonstrated recently by morphometric analysis [62].

BAL has proved to be a useful tool in the diagnosis of PAM. In our series, BAL revealed the diagnosis in 3/9 cases and in 4/6 cases in the Turkish series. Occasional cases have been diagnosed by sputum examination [36].

Treatment

Many authors emphasize that lung transplantation is the only effective treatment for PAM. Cases from India have generally been treated supportively. However, our case showed a good clinical response to steroid therapy. The role of steroids or other drugs in the management of PAM is not clear. Literature review clearly reveals that steroid cannot cure PAM. Several cases from India were treated with steroids before the diagnosis, but did not show any improvement. By contrast, a few authors have reported clinical improvement with steroids. A 56-year-old male in our series showed minimal improvement in the follow-up chest X-ray following steroid therapy [55]. Another patient initially showed some improvement of dyspnea and cyanosis, but later deteriorated [7].

A 10-year-old girl who presented with associated lymphocytic interstitial pneumonitis showed a rapid improvement in pulmonary function and exercise tolerance in response to steroid therapy [73]. Improvement was also evident in an eight-month-old infant treated with corticosteroid and hydroxychloroquine [82]. A 45-year-old woman who developed PAM after a varicella zoster virus infection with concomitant antiphospholipid syndrome and discoid lupus erythematosus responded to inhaled steroids (200 μg of budesonide per day) [83]. Pulmonary function tests revealed an obstructive pattern in our patient. Bronchial asthma has probably resulted from the chronic irritation caused by the microliths. PAM can also involve the central airways in addition to the alveoli as previously mentioned. Thus, literature review shows that only few patients have benefited from steroid therapy. Steroids cannot cure PAM, but they have provided symptomatic relief in some cases. Moreover, steroid therapy is unlikely to be effective in the late stages. Further research is needed to identify patients who are likely to benefit from steroids.

Few authors have also described the utility of disodiumetidronate, a bisphosphonate inhibiting the precipitation of hydroxyapatite microcrystals. Ozcelik *et al.* [84] reported clinical and radiological improvement of two patients with PAM who were treated with disodium etidronate for 9 and 11 years, respectively. The patients receiving this drug have to be closely monitored for possible side effects, such as rickets, bone fractures, and hyperphosphatemia. The drug was not effective in an earlier case treated for 18 months [85]. The effectiveness of disodium etidronate for patients who present in the late phase of the disease should be evaluated.

Lung transplantation is the only effective treatment for end-stage pulmonary disease and can be performed safely even in elderly patients. Shigemura *et al.* [86] reported a case of successful double lung transplantation in a 63-year-old recipient with end-stage PAM. Recently, a 64-year-old woman underwent a right-lung transplant and is able to lead an active life without any complications over a 5-year follow-up period [87]. Although complications related to transplantation have occurred in some cases, recurrence has not been reported to date [86–89].

Recent advances

Recent studies, specifically from Turkey, China, and Japan, have helped us better elucidate the genetic basis of PAM [1,60,61,90]. The mutation of *SLC34A2* gene is responsible for PAM, as discussed earlier. Eleven different homozygous mutations of *SLC34A2* gene involving exons 1, 2, 3, 4, 6, 7, 8, 11, 12, and 13 have been identified. The predominant result of these mutations was protein truncation [90]. Interestingly, mutations seem to vary among races. Mutations in Chinese and Japanese are more likely to affect exons 7 and 8 [90]. Yin *et al.* [90] suggested that exon 8 may be the screen target for Chinese patients. No disease-causing mutations or single nucleotide polymorphisms in the *SLC34A2* gene have also been reported [90,91]. Genes other than the *SLC34A2* gene could possibly be involved in the pathogenesis of PAM. Advanced molecular research tools, such as genome-wide single nucleotide polymorphism analysis, will certainly help us gain better insights and devise novel therapeutic strategies.

Takahashi *et al.* [92] showed that surfactant protein-A and surfactant protein-D are potential serum markers to monitor the disease activity and progression of PAM. Dysfunction of *SLC34A2* gene reduces the clearance of phosphate, hence leading to the formation of microliths. Thus, drugs targeting phosphate metabolism rather than calcium metabolism could prove to be beneficial [1].

Conclusions

Physicians should have a high degree of suspicion for this rare disorder in regions with a high incidence of pulmonary tuberculosis. Siblings of a patient with PAM should be screened for PAM even if they are asymptomatic. The clinical manifestations vary with the disease stage. PAM has a prolonged course and can be associated with extra pulmonary manifestations. Long-term follow-up and genetic analysis will help us to better understand the etiopathogenesis. Cost-effective treatment should also be established for PAM in developing nations.

Abstract

Bacterial contamination of transfusion products, especially platelets are the most common cause of transfusion associated morbidity and mortality. Minimizing bacterial contamination in blood products is a priority for safe transfusion practices. A prospective study was done comparing the efficiency of two different disinfectant techniques by studying the flora on donor's arm before and after disinfection. This study was undertaken as there are very few reports on this important transfusion protocol from Southern India. Mean number of colonies in post disinfection swab culture with 2% povidone iodine was found to be greater than that of 2.5% Chlorhexidine in 75% isopropyl alcohol. 2.5% chlorhexidine disinfection offers more effective reduction in bacterial contamination than 2% povidone iodine group.

Keywords: Chlorhexidine, Povidone iodine, Bacteremia.

INTRODUCTION

There are reports to indicate that every year India requires 40 million units of blood but only 4million units are available. Hence the collection and preservation of this precious resource requires utmost care [1]. In India, approximately 57% of transfusion transmitted reactions have been found to be associated with bacterial contamination of donated blood [2, 3].The French Haemovigilance surveillance system cited bacterial transfusion transmission as the most identified cause of transfusion associated deaths [4].In the UK, between 1995 to 2003, bacterial transfusion transmissions accounted for 58% of transfusion reactions [5]. Bacteriological screening tests for platelet units were introduced in the US in 2004 and the study showed that the average prevalence of bacterial contamination in platelets from the whole blood was 33.9/100,000 units, that of platelets from apheresis 51/100,000, while that of red cell concentrates was 2.6/100,000[6].

In India, antisepsis with three-step regimen of spirit-10% povidone iodine-spirit for donor arm is followed currently. The US-FDA has approved use of alcoholic-chlorhexidine as highly effective for donor arm disinfection. However, it is not being used in India. Also, tincture iodine which was used earlier is now discontinued due to its irritant nature [7].

It is observed that Gram positive skin commensals such as coagulase negative Staphylococci and Bacillus cereus are the organisms most often recovered from donated blood which are thought to originate principally through phlebotomy[8]. The introduction of a needle through the skin to collect blood causes the passage of live microbes or the movement of microbes from small skin flaps produced by the needle itself into the collection bags[9].This is found to be effectively reduced by efficient donor arm disinfectants[10].

Approximately 16% of the deaths due to transfusion reactions have been associated with bacterial contamination, which are usually multi-Drug resistant [7]. Hence, it becomes mandatory to analyse the gaps in the process and implement corrective action to prevent them. SHOT(serious hazards of transfusion), BaCON (Bacterial contamination associated with transfusion) and French haemovigilance surveillance system, studies stated that resident skin flora accounted for 90% of platelet concentrates and 70% of red cell concentrates causing transfusion reactions[11,12].

A Blood &Transplant study conducted by NHS revealed reduction in contamination of blood products by 57% using improved disinfection strategies [13].

Review of the literature revealed only a few reports from India on this topic, and since blood safety is a very vital issue, it was thought worthwhile to undertake this study. The aim of this review is to consider the scientific evidence in supporting the efficacy of improved Donor arm disinfection in preventing bacterial contamination of blood.

AIMS & OBJECTIVES

The chief objectives of this study are:

- To assess the rate of bacterial contamination in blood bank setting.
- To compare the results from two different donor arm disinfectant techniques.

METHODOLOGY

This study was a randomised control study using prospective data. 100 subjects were included in the study after calculating the sample size.

The Voluntary donor arrives at the blood bank was tested for eligibility. After obtaining consent form for study, pre-Disinfection sample was collected in sterile swab. Disinfectant was applied for an area of 10cm on cubital fossa in concentric pattern. 2.5% Chlorhexidine in 75% isopropyl alcohol was applied as disinfectant (group 1) and while 70% Alcohol followed by 2% povidone iodine followed by 70%Alcohol was used as disinfectant (group 2). Post-Disinfection sample was collected in sterile swab. Both the swabs were cultured in blood agar and colony count was performed.

Sterile swabs for the project were made on the same day, supplied by the Department of Microbiology. Samples were collected from the cubital fossa of the donor using sterile forceps by gloved hands and immediately plated on 5% Sheep blood agar under bio-safety cabinets with positive pressure and laminar air flow.

All the patients who have received transfusion from the donors of the sample size were followed up for transfusion reactions. Any allergic reactions were to be notified and treated accordingly. To ensure quality periodical controls for swabs and Disinfectant were established. Technical officers were trained on proper method of disinfection techniques. The waste samples were discarded as per hospital's standard waste disposal system.

Data was entered in Microsoft Excel spreadsheet and analysis was done using SPSS software by Microsoft V.22.0. Association between two factors was expressed in form of odds ratio. P<0.005 was considered significant.

OBSERVATION & RESULTS

A total of 98 male and 2 female donors were selected for the study and disinfectant used was randomly assigned to them. Both the pre- and post-disinfection swabs were cultured on blood agar and their efficacy was determined by the number of colonies formed on the blood agar (Table I).

Table-I: Provides the result of swab culture with two disinfectants.

DISINFECTANT USED	n	Colonies-before disinfection	Colonies-after disinfection
Povidone iodine	50	40-210	0-10
Chlorhexidine	50	35-190	0-4

STATISTICAL ANALYSIS

Independent student 't' test was done to compare the colony count of post-disinfection swab culture between 70% Alcohol followed by2% povidone iodine followed by 70% alcohol and 2.5% Chlorhexidine in 75% isopropyl alcohol . Analysis of covariant was done using General linear model on SPSS 24.0 to compare the mean difference in post-disinfection swab culture adjusted to the bacterial load on pre-disinfection swab culture.

Table II presents the mean (SD) of the post-disinfection swab cultures between the two disinfectants and a statistically significant difference was observed. The mean (SD) of the post-disinfection swab culture for 2.5% Chlorhexidine in 75% isopropyl alcohol was 0.2800(0.70102) and 70% Alcohol followed by2% povidone iodine followed by 70% alcohol was 0.9000(1.97174).t=2.095;p<0.05.

Table-II: Comparison of post disinfection swab culture between the two disinfectants

DISINFECTANT USED	MEAN	SD	p
Povidone iodine	0.9000	1.97174	P<0.05
Chlorhexidine	0.2800	0.70102	

Analysis of covariant showed that the mean difference of the post-disinfection swab culture adjusted to the bacterial load on pre-disinfection swab culture was statistically significant F=4.974; p<0.05.

DISCUSSION

The hazards of post transfusion septicaemia became less common when closed plastic bags replaced glass containers for collection of blood. Even though it

has seen a massive decrease, it has not disappeared entirely and there seems to have been a resurgence of interest in it due to modern day increase in genetically improved resistant organisms. It is not always easy to identify the source of bacterial contamination in blood bags. Post transfusion septicaemia can be endogenous which is due to organisms circulating in the blood and in other hand, exogenous post transfusional septicaemia stems from organisms on donors' skin and equipment contamination. Endogenous post transfusional septicaemia is comparatively less than exogenous post transfusional septicaemia due to vigorous donor selection criteria hence extra attention should be given to exogenous post transfusional septicaemia which can be significantly reduced by optimal disinfection of phlebotomy site, since majority of the organisms contaminating the blood products belong to the group of skin commensals[14].

Our skin contains two types of bacterial flora. One is transient flora which can be easily washed away by water and soap. The other is resident flora that requires extensive disinfection with an efficacious disinfectant which we tried to identify in this study.

In our study encompassing 100 donors' disinfection with 2.5% chlorhexidine in 75% isopropyl alcohol was comparatively more efficacious than 70% Alcohol followed by2% povidone iodine followed by 70%alcohol. Mean values of colonies of 70% Alcohol followed by2% povidone iodine followed by 70% alcohol is greater than what was observed in 2.5% Chlorhexidine in 75% isopropyl alcohol in the swab culture of post-disinfection swabs.

We compared our study with similar studies. Lee C K *et al*. reported a relative risk reduction of 3.4% of chlorhexidine over povidone Iodine in disinfection of donors' arm [15].Ramirez Arcos *et al*. also observed that disinfection by70% alcohol followed by chlorhexidine is highly effective having 98.74% of reduction rate in bacterial contamination of blood components than what is seen with isopropyl alcohol and iodine which correlates with the results of our study [16]. Also Benjamin RJ *et al*. proved that the 1.5ml chlorhexidine disinfection method offers more effective reduction in bacterial contamination of apheresis platelets than 70% Alcohol followed by2% povidone iodine followed by 70%alcohol [17]

Chlorhexidine is a broad spectrum agent with cumulative actions, which is recommended in the 'Guidelines on drawing blood' by WHO, Centre For Disease Control (CDC) and Health Care Infection Control Practices Advisory Committee (HIPAC) as an optimal skin disinfectant for variety of uses like phlebotomy, vascular catheterization and pre-op preparation of skin[12].

It is also less irritant and non-staining on skin. We found that both the donors and the staff of the blood bank expressed an increased compliance towards it during the period of this study. On application it disrupts the cell wall and is more effective against gram positive organisms than gram negative organisms. In our study we also detected most of the gram positive organisms are inhibited, but due to the small numbers that were studied, analysis and comparison of data cannot be made at this juncture.

A study done by Lee C K *et al*. detected predominantly Bacillus species and Coagulase-negative staphylococci as the most common pathogens [15]. In this study organisms like Coagulase-negative Staphylococci, Micrococci and Diptheroid were mainly isolated in Pre-disinfection swabs, while only Coagulase-negative staphylococci were identified in post- disinfection swabs. This is explained by the emerging resistance of staphylococci to Chlorhexidine [18]. The use of conventional agar plates and gram-staining to identify the morphology of the organism limits the scope of identifying varied bacterial flora which is more evident on automated culture systems like BACTEC/BacTALERT.

This study prompts us to conclude that there is a decrease in bacterial contamination with 2.5% chlorhexidine in 75% isopropyl alcohol compared to 70% alcohol followed by 2% povidone iodine followed by 70% Alcohol.

Since there is no significant difference in cost between these two methods tested in our study, Chlorhexidine should be affordable in blood banks of resource limited nations as well.

CONCLUSION

- Bacterial contamination of blood components remains a major challenge in the practice of transfusion medicine.
- Optimal skin antisepsis of the phlebotomy site is essential to minimize the risk of contamination of collected blood.
- Every reaction of post transfusional septicaemia must be identified, reported, evaluated and the cause for contamination must be identified in order to prevent future post transfusional septicaemia and maintain safe blood practices.

Compliance with Ethical Standards

Ethical approval

All procedures performed in studies involving human participants were in accordance with the ethical standards of the institutional and/or national research committee

Conflict of Interest

The authors declare that they have no conflict of interest

Informed consent

Informed consent was obtained from all individual participants included in the study

Morphologic Spectrum of Undetermined Causes of Hemoptysis- A Pathologist's Role

Nidhya GANESAN, Umamaheswari GURUSAMY

Department of Pathology, PSG Institute of Medical Sciences and Research, TAMILNADU, INDIA

ABSTRACT

Objective: Hemoptysis is the expectoration of blood or blood-streaked sputum from the tracheobronchial tree. The etiology may derive from nonneoplastic conditions such as infections, chronic pulmonary diseases, and vasculitis or neoplastic causes. Sometimes a definitive cause for hemoptysis cannot be found after ample diagnostic workup. The role of biopsy in such cases is to help the clinician in arriving at the final diagnosis. Diffuse alveolar hemorrhage is the main histopathological finding in hemoptysis and it appears with diffuse chest infiltrates radiologically.

Material and Method: A retrospective study of 2 years duration was conducted to identify the morphological spectrum of diseases presenting with hemoptysis. A total of 243 lung biopsies obtained by various methods were retrieved in this study period and 20 cases with hemoptysis of undetermined etiology were detected.

Results: Based on imaging and histopathology findings, the etiological causes of hemoptysis were divided into hemoptysis with and without capillaritis or due to tumor/tumor-like lesions and due to miscellaneous conditions. The most common etiology was vasculitis followed by infections.

Conclusion: Histopathology helps to detect the etiology, particularly in cases of hemoptysis due to non-immunologic causes. In immunologic cases, histopathological findings may support the diagnosis in correlation with the clinical/imaging features.

Key Words: Hemoptysis, Immunologic, Diffuse alveolar hemorrhage, Capillaritis

INTRODUCTION

Hemoptysis is the expectoration of blood from the pulmonary parenchyma or the tracheobronchial tree below the level of the glottis. The expectoration of blood can vary from a small amount of blood-streaking sputum to massive bleeding with life-threatening consequences. The clinical diagnostic algorithm should aim to differentiate and identify the etiology of hemoptysis, since massive hemoptysis may result in a fatal outcome (1, 2).

The common causes of hemoptysis include pulmonary tuberculosis (TB), malignancy, bronchiectasis, chronic bronchitis, pneumonia, and fungal infections. The other rare causes are vasculitis due to collagen vascular diseases and hereditary hemorrhagic telangiectasia, essential cryoglobulinemia, Behcet's disease, acute lung transplantation rejection, drug-induced (e.g., chemotherapeutic agents, propylthiouracil), idiopathic pulmonary hemosiderosis, and toxin or inhalation injury (3).

About 30% of cases attending respiratory clinics and presenting with hemoptysis pose a problem in clinical diagnosis, and the histopathology plays a vital role in diagnosing these conditions. The condition can be localized or diffuse depending upon the underlying etiology (4). Intra alveolar hemorrhage, fibrin deposition, and hemosiderin-laden macrophages associated with or without capillaritis are the common findings observed in cases of diffuse alveolar hemorrhage (DAH) (5). Radiologically, DAH shows patchy/ diffuse bilateral areas of lung consolidation mainly involving the lower lobes and perihilar regions (6).

A literature search revealed only a few reports on using histopathological interpretation in diagnosing unknown causes of hemoptysis. This is vital to diagnose and treat the condition earlier, as it prevents disease progression, and constituted the reason for conducting the current study. This study aims to identify the various uncommon aetiologies of hemoptysis based on histopathological features and the pathologist's approach in diagnosing this condition.

MATERIAL and METHODS

All lung biopsies, including lobectomy specimens received in the department of pathology, between Jan 2018 to Jan 2020 (2 years duration) were retrospectively reviewed. Of the received 243 specimens, 20 cases had hemoptysis with undetermined causes. The obtained specimens were derived from various procedures and included 117 transbronchial lung biopsies (TBLB), 62 endo bronchial lung biopsies (EBLB), 28 guided (Ultra sonogram /CT) biopsies, 19 thoracoscopic/Video-assisted (VATS) biopsies, and 17 lobectomies. The cases with a history of hemoptysis associated with common causes such as tuberculosis (TB), carcinoma, bronchitis, bronchiectasis, and interstitial lung diseases (ILD) were excluded from the study. The clinical data obtained were age, sex, presenting complaints, clinical diagnosis/differential diagnosis, and significantly associated co-morbidities. Laboratory investigations such as autoimmune workup (ANCA, ANA, etc.), sputum for culture & acid-fast bacilli (AFB), bronchoalveolar lavage (BAL) for culture and cytology, and other relevant information were collected. The findings of imaging (high-resolution computerized tomography - HRCT) and bronchoscopic findings were recorded if available (not always performed).

Ethical approval for this study was obtained from PSG Institute of Medical Sciences & Research (Approval number: 20/117, Date: 27.05.2020).

RESULTS

Out of 243 lung biopsies received, a total of 20 cases with symptoms of hemoptysis due to undetermined etiology were included in our study.

Histopathological Findings

Based on imaging and histopathological findings, the etiology of hemoptysis was divided into localized and diffuse/bilateral pulmonary involvement (Table I). Depending upon the histological findings, the causes of hemoptysis were further divided into

- Hemoptysis with capillaritis (Table II)
- Hemoptysis without capillaritis (Table III)
- Unusual tumors and tumor-like lesions (Table IV)
- Miscellaneous uncommon causes

Miscellaneous uncommon causes are listed below:

Pulmonary Alveolar Microlithiasis (n=1)

HRCT of a 34-year-old male who presented with hemoptysis showed bilateral ground-glass densities with septal calcification -? Interstitial lung disease. TBLB sections showed distended alveoli containing concentric lamellated, calcific material with few hemosiderin-laden macrophages.

Pulmonary Endometriosis (n=1)

A 43-year-old man with a history of cirrhosis secondary to hepatitis 'C' had recurrent episodes of hemoptysis. Bronchoscopy revealed a mucosal white patch in the left lingular segment. The biopsied lesion showed lung tissue intimately admixed with a focus of endometrial glands and stroma. CD 10 immunostaining of the stroma, as well as estrogen and progesterone receptor staining of the glandular component, were both consistent with endometriosis (Figure 1A-D).

Table I: Etiological classification based on imaging & histopathological findings.

Causes of hemoptysis			
Localized	**Number of cases**	**Diffuse /bilateral**	**Number of cases**
Pulmonary hamartoma	1	GPA	3
Aspergillosis	1	Silicosis	3
Myelolipoma	1	EGPA	2
Mucor	1	Invasive aspergillosis	1
Pulmonary endometriosis	1	Invasive mucor+aspergillosis	1
Mucoepidermoid carcinoma	1	Multiple metastases from a leiomyosarcoma	1
Probably benign mesenchymal neoplasm	1	PAM	1
		Pulmonary intravascular hemangioma	1

GPA: Granulomatosis with Polyangiitis / Wegener's, **EGPA:** Eosinophilic granulomatosis with polyangiitis / Churg-Strauss syndrome, **PAM:** Pulmonary alveolar microlithiasis.

Table II: Causes of hemoptysis with capillaritis.

	Granulomatosis with Polyangiitis (GPA)			**Eosinophilic granulomatosis with polyangiitis (EGPA)**	
	Case - 1	**Case-2**	**Case-3**	**Case 1**	**Case 2**
Age, sex	40, M	46, F	51, F	43, M	42, M
Complaints	Cough, hemoptysis, and dyspnoea				
Serology	Anti-CCP, PR3-ANCA&RF: positive	PR3-ANCA positive	PR3-ANCA positive	RF: positive	PR3-ANCA: weakly positive
Imaging studies	Bilateral nodules	Ground glass changes, calcified nodule	Bilateral consolidation with few nodules	Bilateral nodules	Bilateral nodular and cavitating lesions.
Type of biopsy	EBLB	CT guided biopsy	CT guided biopsy	TBLB	VATS lung biopsy
HPE findings: **Vascular changes:**	• Capillaritis, venulitis • Fibrinoid necrosis (Figure 2A)	Vague outlines of thrombosed blood vessels	Vasculitis and Fibrin thrombi (Figure 2C- D)	Eosinophilic infiltration of the vessel wall	• Necrosis of the vessel walls with inflammatory cells infiltration (Figure 3A-C) • Organizing, recanalizing and fibrin thrombi
Parenchymal changes	• Granulomatous inflammation with MNG cells (Figure 2B) • Interstitial inflammation	• Necrosis, karyorrhexis, hematoxyphilic nuclear dust • Neutrophilic micro abscess	• Necrosis, karyorrhectic debris • Granulomatous response with MNG cells • Neutrophilic micro abscess	• Eosinophilic microabscess • Palisading granuloma	• Intraalveolar hemorrhage (Figure 3D) • Eosinophilic microabscess, parenchymal necrosis • Perl's stain highlights the hemosiderin-laden macrophages (Figure 4)

MNG cells: Multinucleate giant cells, **HPE:** Histopathological examination, **EBLB:** Endobronchial lung biopsy, **CT:** Computed tomography, **VATS:** Video-assisted thoracoscopic surgery, **TBLB:** Transbronchial lung biopsy.

Table III: Causes of hemoptysis without capillaritis.

	Silicosis			**Fungal infection**			
	Case -1	**Case-2**	**Case-3**	**Case-1**	**Case-2**	**Case-3**	**Case-4**
Age, sex	61, M	54, M	58, M	28, M	56, M	45, F	15, F
Complaints	Cough, hemoptysis and dyspnoea.			Cough, hemoptysis, and dyspnoea			
Another relevant history	Exposure to silicon dust +			Post Koch's sequelae	DM, CKD	Post TB, DM.	DM, DKA^{+}, Mild PAH
Imaging studies	Bilateral lung nodules&hilar nodes	Calcified nodes	B/L nodules, calcification	NA	Cavitatory consolidation	B/L subpleural nodules	B/L cavitating consolidations
Type of biopsy	TBLB			Right upper lobe segmentectomy	EBLB	Right lower lobectomy	TBLB
HPE Findings	• Nodules of epithelioid and pigment laden histiocytes, predominantly around the vascular channels (Figure 5A,B)			• Dilated bronchi forming a cavity containing the fungal ball • Tissue, angioinvasion & infarct • Fibrosis, chronic granulomatous inflammation • Oxalate crystals (Figure 6A,B)			
Special study	Polarizer: birefringent crystals (Figure 5B inset)			GMS & PAS stains: septate, acute-angled branching hyphae of aspergillus	PAS & GMS stains: broad, aseptate and wide-angle branching hyphae of mucor	PAS & GMS stains: Tangles of fungal elements, consistent with aspergillus and mucor

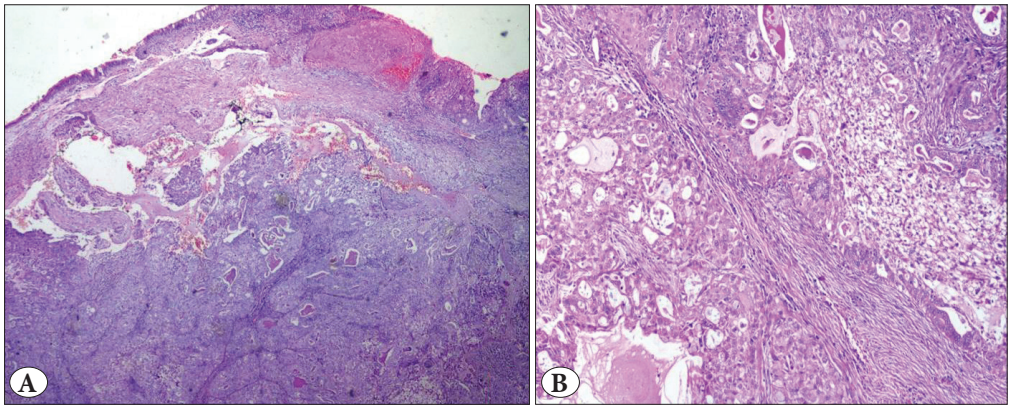

Figure 8: Endobronchial mucoepidermoid carcinoma. **A)** Showing admixture of squamous and glandular elements (H&E; x4). **B)** High power view (H&E; x10).

Pulmonary Intravascular Haemangioma (n=1)

HRCT of an elderly male showed multiple small nodules in both the lungs and a lobulated enhancing soft tissue lesion attached to the anterior wall of the right atrium-? Malignancy. TBLB sections showed lung parenchyma with medium to large-sized vessels containing an intraluminal, adherent lesion of tubular vascular spaces lined by endothelial cells. CD31 & CD34 immunostaining highlighted the endothelial cells. Since the right atrial mass could not be biopsied, the clinical/imaging findings were correlated and the final HPE diagnosis made was intravascular capillary haemangioma/?fragmented from cardiac haemangioma.

DISCUSSION

Haemoptysis is considered to be a serious medical condition and has a broad differential diagnosis. All cases with microscopic evidence of hemorrhage do not present with hemoptysis clinically. Similarly, all patients who presented with hemoptysis will not show alveolar hemorrhage histologically (4).

Haemoptysis with Capillaritis (Granulomatosis with Polyangiitis & Eosinophilic Granulomatosis with Polyangiitis)

Pulmonary vasculitis is characterized by inflammation of the small and medium-sized vessel wall, causing pulmonary hemorrhage. Imaging studies show multiple lung cavitary nodules/masses, which may mimic metastasis. Also in some conditions, the lung infiltrates are transitory making the diagnosis a challenging one (7).

Schnabel et al. stated that histopathological findings may vary depending upon the type of biopsy. They found out that the yield of guided lung biopsy is high when compared to TBLB since gross lesions are easily visible. Similarly, most of our cases had undergone guided biopsies and were adequate (8).

Travis et al. suggested that capillaritis is a morphologic marker of DAH in their study. They concluded that capillaritis and necrotizing granulomatous inflammation with mixed inflammatory cell infiltrate were pathognomonic features of GPA. Parenchymal necrosis, extravasated fibrin, and scattered multinucleate giant cells in a biopsy could suggest the diagnosis of a GPA even in the absence of granuloma. The destruction of the vessel wall can be highlighted by VVG elastic stains. However, correct sampling is essential for the maximum yield (9, 10).

The diagnosis of EGPA can be made if the biopsy shows granulomatous vasculitis with extravasated eosinophils and evidence of eosinophilic pneumonia (11). Correspondingly, three cases in our series showed capillaritis and the remaining two were diagnosed based on relevant clinical and imaging findings.

Haemoptysis without Capillaritis

Fungal Infection: Alveolar hemorrhage resulting from fungal infection is infrequent. The possible pathogenesis of hemoptysis in fungal infection could be 1) due to chronic inflammation as the granulation tissue lining the cavity is rich in capillaries, 2) these new vessels are rather fragile and can rupture easily, and 3) erosion of the blood vessels adjacent to the cavity (12). The presence of calcium oxalate crystals in a patient with a cavitary lesion will raise suspicion of a fungal infection and the pathologist should search for the same in the adjacent area (13). Likewise, our cases also had similar histology which would have led to hemoptysis.

Silicosis: An autopsy case study by Kyeong et al. revealed that unlike silicosis which affects mainly the lung parenchyma, silico - tuberculosis also affects the pulmonary vasculature causing hemoptysis (14). Our cases did not have evidence of tuberculosis. Streak-type hemoptysis seen in our cases could be explained by the destruction of small-sized blood vessels by fibrosis and chronic inflammation (15).

Unusual Tumors and Tumor-Like Lesions of the Lung

Primary Pulmonary Mesenchymal Tumors: Accounts for less than 1% of all lung malignancy. These tumors show lineage differentiation and can be diagnosed in the lung with similar histological and immunological criteria as in other sites (soft tissue) (16). Pulmonary hamartoma is the most common benign mesenchymal tumor of the lung, and is predominantly seen in older males**.** Geramizadeh et al. and Ahmed et al. in their study stated that the occurrence of hemoptysis in hamartoma is very rare and results from giant or endobronchial tumors causing erosion of the vessels (17, 18). In contrast to their findings, our patient was a middle-aged female with a small peripherally located pulmonary hamartoma.

According to Hashimoto et al., it is important to identify and differentiate metastatic mesenchymal tumors correctly, since most mesenchymal tumors presented as occult/unknown primary with pulmonary metastatic foci (19). Identically, one of our cases had metastatic LMS with a known diagnosis of primary LMS of the thigh.

Mucoepidermoid Carcinoma (MEC): MEC is a rare salivary gland type endobronchial tumor with mucous secreting cells, squamous cells, and intermediate cells. A definitive diagnosis requires bronchoscopy and representative biopsy as this tumor exhibits morphological heterogeneity. It can be misdiagnosed as primary non-small cell lung carcinoma if the biopsy is inadequate (20, 21). The diagnosis of this rare neoplasm was possible since ours was a pneumonectomy specimen.

Myelolipoma: Pulmonary myelolipoma is distinctly unusual and rarely presents with hemoptysis. Embolic origin, reticuloendothelial cell metaplasia, and proliferation of hematopoietic stem cells are possible mechanisms of histogenesis. Tumour arising adjacent to the bronchial cartilage may show bony trabeculae and this explains the possible histogenesis of the metaplastic theory (22). Our case also revealed a similar histology.

Miscellaneous Uncommon Causes

Pulmonary Endometriosis: Pulmonary endometriosis is a rare form of extra pelvic endometriosis, occasionally reported in men. Cases of male endometriosis have typically been linked to increased circulating estrogen levels. Peripheral conversion of androstenedione and testosterone to the circulating estrogens was noted in men with cirrhosis of the liver (23). Our patient had a history of cirrhosis, possibly leading to an altered hormonal state that interacted with a reactive/metaplastic process.

Pulmonary Alveolar Microlithiasis (PAM): PAM is a rare autosomal recessive lung disease characterized by the accumulation of concentrically laminated calcospherites within the alveolar spaces. Lauta in his study stated that there is a striking clinico-radiologic disparity in this condition (24). Since our patient did not have other system involvement, the possibility of PAM over secondary calcification was favored by correlating the clinical and imaging features.

Pulmonary Intravascular Haemangioma: The co-existence of cardiac and pulmonary haemangioma is very rare and very few reports of such an association have been described so far. Imaging studies may help in diagnosing cardiac haemangioma while histopathology is essential for confirmation. Complete excision is the treatment of choice in resectable cardiac haemangioma and solitary pulmonary haemangioma (25). Since the general condition of the patient was poor, resection was not possible in our case. Fragmented emboli from a cardiac haemangioma could also be considered as a differential.

In conclusion, in immunologic causes of hemoptysis, histopathological findings may support the diagnosis in correlation with the clinical/imaging features. However, in cases of non-immunologic causes of hemoptysis, a histopathologic examination is mandatory over clinical/imaging studies. The cases presented here are incredibly rare diseases with an uncommon presentation. The diagnosis is often missed or delayed, due to a low index of suspicion. Histopathological examination is imperative in unexplained cases of hemoptysis as it plays a vital role in therapy decisions.

Chediak–Higashi Syndrome in Accelerated Phase

Nidhya Ganesan[1,2] · **Prasanna N. Kumar**[1]

Received: 21 January 2017 / Accepted: 22 March 2017 / Published online: 27 March 2017
© Indian Society of Haematology & Transfusion Medicine 2017

A two-month-old boy, born to consanguineous parents, presented with high grade fever for 5 days. On examination he was febrile, pale with generalized hypo pigmentation of skin and hair, hepatosplenomegaly and cervical lymphadenopathy. He had a past history of recurrent respiratory tract infections. Splenomegaly of 2.5 cm was noted at birth. Complete blood count—total count 3.1 × 10^3/µl, haemoglobin 7.4 g/dl, and platelet count 24 × 10^3/µl. Primary blood and urine cultures were sterile. Peripheral smear showed pancytopenia with large eosinophilic inclusions in the lymphocytes (Fig. 1). Bone marrow revealed large coarse azurophilic granules in the cytoplasm of many of the myeloid precursors and mature granulocytes including eosinophils (Figs. 2, 3).

Erythrophagocytosis was evident in the marrow histiocytes (Fig. 4). Serum iron was 28 µg/dl, ferritin >2000 ng/ml and triglycerides were 325 mg/dl. With the presence of six of the eight diagnostic criteria for HLH being present i.e. fever, splenomegaly, pancytopenia, hypertriglyceridemia, hyperferritenemia and haemophagocytosis in the bone marrow, a diagnosis of Chediak–Higashi syndrome with haemophagocytic lymphohistiocytosis (accelerated phase) was made. The child was treated with IV ceftriaxone and vancomycin. However his condition deteriorated and he expired.

Chediak–Higashi syndrome (CHS) is a rare, autosomal recessive disorder that affects multiple systems of the body mainly the immune system [1]. The clinical manifestations of

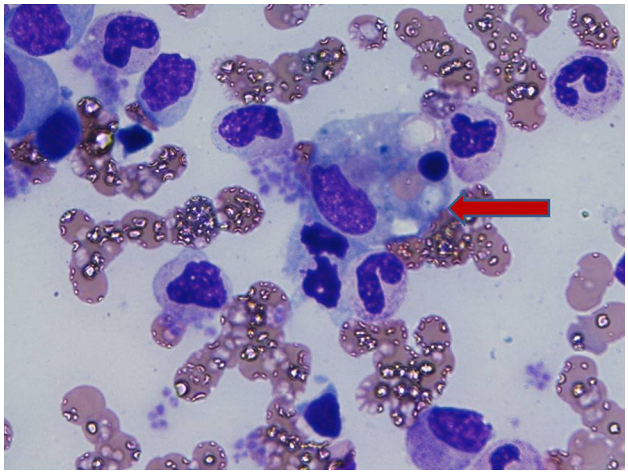

Fig. 4 Erythrophagocytosis (indicated with *red arrow*)

CHS in accelerated phase include high fever, neurological abnormalities, lymphadenopathy, hepatosplenomegaly, pancytopenia, abnormal giant granules in peripheral blood and bone marrow, lymphohistiocytic infiltration in liver, spleen and lymphnodes [2].The only treatment is allogenic haematopoietic stem cell transplantation (HSCT). The prognosis is poor [3].

SHORT COMMENTARY

Enterobius vermicularis Infection of the Uterine Endometrium in an Infertile Female

Hema Rajesh[1] · Balu Kuppusamy[2] · Chaitra Venkataswamy[3] · Nidhya Ganesan[3]

Received: 20 January 2019 / Accepted: 1 July 2019 / Published online: 10 July 2019
© Federation of Obstetric & Gynecological Societies of India 2019

Introduction

Enterobius vermicularis is the most common human helminth infecting the intestine. Due to its low pathogenicity, infection is usually asymptomatic. Extraintestinal infections of *E. vermicularis* are extremely rare. The commonest extraintestinal site of infection is the female genital tract [1]. The male worm dies in the bowel during copulation, and the gravid female worm can migrate from the perianal region to the vagina and can ascend and reach peritoneum through the uterine cavity and fallopian tube. Various reports are available in the literature of the worm in the vagina, myometrium, endometrium, fallopian tube, ovary and pelvic peritoneum as well as an interesting incident of invasion of a human embryo [2–4].

Enterobius vermicularis infection is rarely reported to be associated with infertility. We report the detection of uterine endometrial *E. vermicularis* infestation in a woman who presented with primary infertility and subsequently conceived after treatment for the infection.

Case Report

A 38-year-old woman presented to our fertility clinic for evaluation of primary infertility. She was married for 15 years and had regular menstrual cycles. She had twice attempted intrauterine insemination unsuccessfully elsewhere. A hormonal assay showed normal results (FSH: 3.2 mIU/mL, LH: 5.5 mIU/mL, TSH: 1.6 mIU/mL, PRL: 7.03 ng/Ml and AMH: 1.2 ng/mL). An ultrasound evaluation revealed normal-appearing uterus and ovaries and a small right adnexal cyst. A sonohysterogram showed a normal uterine cavity, and a hysterosalpingogram confirmed the patency of both fallopian tubes. A semen analysis of her husband was also within normal limits.

An informed consent was obtained from the patient. She subsequently underwent hysterolaparoscopy. Laparoscopy revealed normal-appearing uterus and ovaries and a small fimbrial cyst which was excised. Histopathology evaluation suggested a paratubal cyst. On hysteroscopy, the uterine cavity appeared adequate. The endometrium, however, was looking irregular and polypoidal. Endometrial sampling was done and sent for histopathological evaluation which demonstrated the larvae of *Enterobius vermicularis* embedded within the endometrium (Figs. 1, 2). She was treated with a single dose of 400 mg of albendazole which was repeated after 2 weeks. In view of prolonged infertility and advanced age of the female, in vitro fertilization (IVF) was offered which resulted in a successful conception. She is into the sixth month of pregnancy at the moment.

Discussion

Enterobiasis caused by *E. vermicularis* is one of the most common helminthic infestations of the cecum and adjacent gut. Ingestion of eggs present in the contaminated hands or food results in infection by this pinworm [2]. Scratching the perianal skin where the female worm has laid eggs results in hand contamination. The gravid female worm can migrate from the perianal area to the vagina and ascend through the fallopian tube to the peritoneum [3]. The worm can also pass through the intestinal wall and cause pelvic peritoneal granuloma. Such navigation by the larval and adult parasite can result in fallopian tube infiltration, tubo-ovarian abscess, salpingooophoritis or granulomata of the vulva, vagina, uterus, fallopian tubes or ovaries and rarely destruction of the human embryo [4].

Enterobius vermicularis granulomas do not usually cause clinical problems and are incidental findings. They have been reported to cause vulvovaginitis and can masquerade as cervical and endometrial carcinoma. Involvement of the pelvic peritoneum and the fallopian tube resulting in infertility has been reported [5, 6]. Ours is the first instance of uterine endometrial infection with the worm resulting in infertility. Since the patient has never undergone IVF before, the causality of this association cannot be established. The presence of unexplained infertility and its reversal after treatment of worm infestation may suggest causality. The diffuse endometrial inflammation caused by the worm could interfere with implantation and thus cause infertility. The subtle uterine irregularity was visible only on hysteroscopy.

Our case highlights the importance of ectopic enterobiasis in female reproductive ill health, especially in the tropical countries. In addition to the previously reported instances of ectopic enterobiasis-related pelvic inflammatory disease and tubal infection resulting in infertility, uterine endometrial involvement by the worm also seems to be another potential cause for infertility. Co-infection with other bacteria from the intestine and skin is another major concern as they seem to move to these sites along with the pinworm and contribute toward infection and inflammation [7]. We stress on the importance of close observation of the uterine cavity through hysteroscopy in all cases of prolonged unexplained infertility. An endometrial sampling can identify the pinworm infection and allow treatment which might restore fertility.

Disseminated Histoplasmosis in an Immunocompetent Patient Diagnosed on Bone Marrow Aspirate – A Rare Presentation from a Non-Endemic Area

NIDHYA GANESAN[1], REETIKA SHARMA[2], MANJIRI DILIP PHANSALKAR[3], RENUG'BOY VARGHESE[4]

ABSTRACT

Histoplasmosis causing systemic fungal infection is commonly seen in endemic areas. In India, disease prevalence is more in eastern part of the country and there have been very few reports from southern part of India. The occurrence of disseminated histoplasmosis in immunocompetent individual is rare. We report a case of disseminated histoplasmosis in an immunocompetent individual with no underlying risk factors. The disease was not suspected clinically and was diagnosed by bone marrow aspirate incidentally.

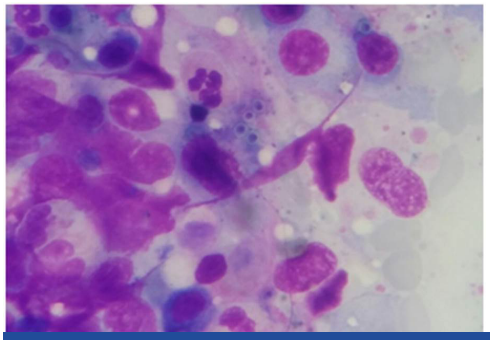
Keywords: Bone marrow aspirate, *Histoplasma capsulatum*, Immunocompetent, Incidental finding

CASE REPORT

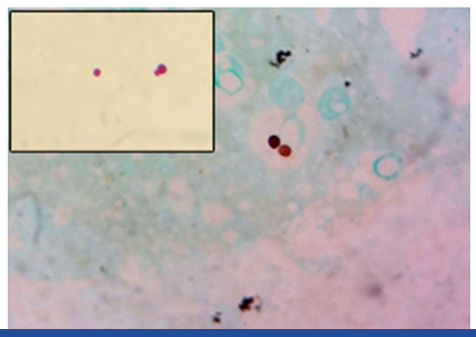
A 55-year-old female patient hailing from Kumbakonam (Tamilnadu) was admitted to our hospital with complaints of abdominal pain and progressive abdominal distention for the last one month. She also gave a history of fever on and off for the last three months. She had undergone aortic valve replacement for calcific aortic valve stenosis three years ago. There was no history of travel to the endemic areas. Her general physical examination revealed pallor and abdominal distention. There was no hepatosplenomegaly. Rest of the general and systemic examination was within normal limits. Her Laboratory results were as follows, Hemoglobin-10.4 gm/dl, Total leukocyte count - 12,500 cells/cumm; Polymorphs - 75%, Lymphocyte - 22%, Eosinophil -2%, Monocyte - 1%. Erythrocyte sedimentation rate - 22. Liver function test, renal function test and serum electrolytes were within normal limits. She was also tested for Malaria and Dengue antigen and was found negative.

Serological tests for Human Immunodeficiency Virus (HIV), Syphilis and Antinuclear Antibody (VDRL and ANA) were negative. Urine routine and culture reports were also normal. Her chest radiograph was within normal limits. Contrast Enhanced Computed Tomography (CECT) abdomen showed massive ascites and no organomegaly.

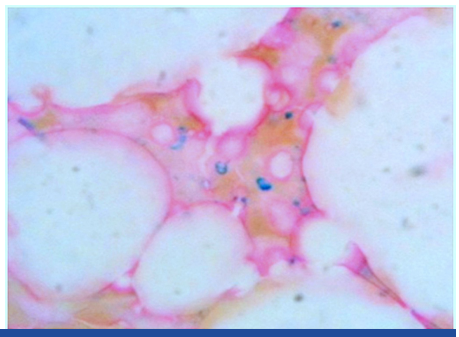
Her blood culture, both aerobic and anaerobic, showed no growth. Sputum for Acid Fast Bacilli (AFB) also tested negative. Stool for occult blood was found to be negative.



She underwent ascitic fluid aspiration twice and the sample was sent for cytology. It showed reactive mesothelial cells with few macrophages and no malignant cells/organisms. Biochemical evaluation of the fluid revealed exudative effusion.



In view of her age and persisting ascites, a high index of suspicion for malignancy was noted and she underwent a bone marrow aspiration (BMA) and biopsy. BMA showed normocellular marrow with myeloid: erythroid ratio being 2:1. Erythroid series showed normoblastic maturation. Myeloid and megakaryocytic series were within normal limits. Plasma cells were increased in number (8%). In addition there were extracellular organisms measuring 3-4 microns in diameter, singly scattered as well as in groups [Table/Fig-1]. Some of them were showing narrow based budding and were surrounded by a clear space resembling *Histoplasma capsulatum*. This was confirmed by special stains (PAS, GMS & Perl's Stain) [Table/Fig-2,3]. Retrospectively we searched for the organisms in buffy coat and it also showed the presence of the organism. Patient was given injection Amphotericin B 0.7 mg for two weeks and tablet Itraconazole 200mg. Patient improved symptomatically and was advised to continue itraconazole for 12 months. Patient did not come for checkup after 6 months possibly due to relief of the symptoms.



DISCUSSION

Histoplasmosis is endemic in the U.S (Ohio and Mississippi valley). It has also been reported worldwide in countries such as Africa, sub –Saharan Africa, South East Asia and India [1].

It is a dimorphic fungus i.e. it can exist as mycelial form (environment) and yeast form (inside the body). The transmission is through aerosols and not through person to person contact [1]. Our patient

[Table/Fig-1]: Bone marrow aspirate showing extracellular 3-4um sized organisms showing halo around these (MGG, 100X) **[Table/Fig-2]:** Encapsulated brown to black coloured structures (GMS, 100X); Inset shows PAS positive structures one of them showing narrow based budding (PAS, 100X) **[Table/Fig-3]:** These organisms showed positivity to perl's stain (Perls stain, 40X) (MGG-May Grunwald Giemsa, GMS- Gomori Methamine Silver, PAS- Periodic Schiff)

was exposed to bird droppings and this might be the probable cause for her to develop the disease. The clinical manifestations vary from asymptomatic to acute or chronic pulmonary histoplasmosis and disseminated histoplasmosis (spread to other organs and bone marrow). The progressive disseminated histoplasmosis usually affects the immunocompromised patients particularly those affected with HIV. It indicates impaired cell mediated immunity [1,2].

In India the first case of disseminated histoplasmosis (DH) was reported by Panja and Sen in 1954. There have been very few reports of disseminated histoplasmosis in immunocompetent individuals from non-endemic areas (South India) [3]. Histoplasmosis in immunocompetent individual is usually asymptomatic and sometimes manifest as minor illness such as cough, fever and chest pain. Chest radiograph shows hilar/mediastinal lymphadenopathy. These changes may mimic tuberculosis and may mislead the clinician [4,5]. Our patient had no pulmonary symptoms and had a normal chest x-ray which rules out pulmonary histoplasmosis. Acute pulmonary histoplasmosis is caused due to intense exposure to spores and can lead to fulminant acute form with shock and increased mortality.

The spores through the aerosol route are inhaled and deposited in the alveoli. The germinated spores are ingested by the pulmonary macrophages and spread to hilar and mediastinal lymph nodes and can spread to other organs via blood stream resulting in disseminated histoplasmosis [5].

The estimated incidence of disseminated histoplasmosis in healthy adults is approximately 1 per 2000 cases [6]. The study of disseminated histoplasmosis from South India was reported by Subramanian et al., in 2005 which included 19 patients in which only 4 patients were immunocompetent and only one was from southern region of India (Tamil nadu). BMA were done in 11 out of 19 patients and positive reports were seen only in 7 patients. In their study they stated that diagnosis of histoplasmosis by histopathology/ culture from bone marrow, adrenal, lymph node is confirmatory [1]. Deodhar et al., (2013) in their study on DH found that 6 patients out of 37 were immunocompetent. This study indicates the rise of presentation of DH in immunocompetent individual [7]. Histoplasmosis may cause ascites [5,8,9] due to peritonitis [8]. This might be the cause for developing ascites in our patient.

The diagnosis of organisms by means of culture testing takes 2 to 6 weeks and may not be an option in acute fulminant form which needs rapid interpretation and treatment and also in cases of self-limited disease demonstration of organism is difficult in culture [4].

Bone marrow examination has a 75% sensitivity in diagnosing fungal stains in HIV patients [3,10]. The differential diagnosis considered are *Leishmania, Candida, Cryptococcus, Blastomycosis and Pneumocystis carnii*. Amastigote form of leishmania may resemble the yeast form of histoplasmosis but can be differentiated by bar shaped kinetoplast and negative fungal stain. *Cryptococcus* and *pneumocystis carnii* are usually larger (2-20 microns) than histoplasmosis and present extracellularly. Blastomycosis has broad based budding when compared to histoplasmosis. The demonstration of histoplasmosis in Perl's Prussian blue iron stain was reported by Caldwell in 1982. *Candida* and *Cryptococcus* usually don't stain with Prussian blue stain [11]. Our case showed positive staining in Prussian blue stain and confirms the diagnosis.

Other diagnostic modalities include histoplasmin skin test which is due to delayed hyper sensitivity reaction, antigen detection from serum or urine and serum antibody assay by complement fixation and immune diffusion [12].

Amphotericin B is the drug of choice for this disease followed by azole groups. Lifelong treatment is required in HIV patients as relapse rates is more in these groups [1,13]. Our patient was given Inj. Amphotericin B 0.7 mg/kg for 2 weeks and she was continued with oral Iatraconazole 200mg thrice daily for 0ne year.

This case warrants discussion due to the nature of presentation i.e. from a non-endemic area (South India) in an immunocompetent individual who on presentation had no or minimal features of histoplasmosis which on contrary is common in most of the presented case series till date [14].

CONCLUSION

Awareness of histoplasmosis is important as this disease is still rare in non-endemic areas of India, has varying clinical course and its features overlap with those of other systemic illnesses including tuberculosis and malignancy. Presence of DH has to be borne in mind while treating spectrum of patients who are immunocompetent and additional testing methods have to be employed (BMA) to rule out histoplasmosis as early diagnosis and treatment is vital in this otherwise fatal condition.

Case Report

Platelet phagocytosis in peripheral blood during acute phase of dengue virus infection

Nidhya Ganesan, Indira Gunasekaran, Somanath Padhi, Anita Ramdas, Manjiri Phansalkar

Department of Pathology, Pondicherry Institute of Medical Sciences, Puducherry, India

Abstract We aimed to describe peripheral blood phagocytosis of platelets as a possible underlying mechanism of thrombocytopenia during the acute phase of dengue virus infection in a young male. Furthermore, enhanced platelet phagocytosis through the apoptotic mechanism is also briefly highlighted.

Key Words: Apoptosis, dengue virus, peripheral blood, phagocytosis, thrombocytopenia

INTRODUCTION

Dengue, a *Flavivirus* and transmitted by *Aedes aegypti* mosquito, is a great public health concern in India. Over the last decade, dengue has reached pan-Indian epidemic proportions leading to significant morbidity and mortality. Four serotypes of dengue virus (DENV) are known to cause the disease such as DENV-1, DENV-2, DENV-3, and DENV-4. A protective immunity against one infecting serotype lasts lifelong, but this is very short lasting (3–4 months) against other serotypes. Therefore, the second infection after the protective period often results in severe disease.[1]

Thrombocytopenia and increased vascular permeability are the two major characteristics of dengue fever (DF).[2] As per 2009 WHO recommendation, dengue cases can be classified into: (i) dengue without warning signs, (ii) dengue with warning signs (abdominal pain/persistent vomiting/mucosal bleed/increase in hematocrit with decrease in platelet count), and (iii) severe dengue (severe plasma leakage, severe bleeding, and severe organ involvement).[3] Thrombocytopenia associated with dengue infection is postulated to have has several underlying mechanisms.[4] In this manuscript, we aimed to describe the occurrence of platelet phagocytosis by peripheral blood monocytes, and highlight apoptosis-phagocytosis as another mechanism of dengue associated thrombocytopenia.

CASE REPORT

A 19-year-old male college student was evaluated for a 3-day history of high-grade fever, generalized myalgia, and the loss of appetite. He had no organomegaly, lymphadenopathy, skin rash, or any bone tenderness. His routine laboratory evaluation, on day 2 postadmission, showed hemoglobin - 130 g/L (reference 120–140 g/L), hematocrit - 43% (37–54%); total leukocyte count - 6 × 10^9/L with differentials of neutrophil - 40%, lymphocytes - 55%, and monocytes - 5%; total platelet

count - 60 × 10^9/L (150–450 × 10^9/L), mean platelet volume - 11 fL (6–11 fL), and platelet distribution width - 23% (11–18%). Leishmann stained peripheral smear evaluation revealed normocytic normochromic red cells, relative lymphocytosis with reactive lymphoid cells, thrombocytopenia with numerous giant platelets, and no blasts. Besides these, there was an evidence of platelet phagocytosis by monocytes [Figure 1, ×400]. His biochemical parameters showed raised liver transaminases (serum glutamic-oxaloacetic transaminase - 105 IU/L, serum glutamic pyruvic transaminase - 115 IU/L, reference < 50 IU/L), and coagulation parameters were within normal reference range. His microbiological workup for HIV, hepatitis B and C viruses, *Salmonella,* scrub typhus, malaria, and leptospira were negative. DENV serology revealed positive nonstructural antigen-1 by ELISA. He was managed symptomatically and finally discharged on 8th-day postadmission with a platelet count of 100 × 10^9/L, and his liver transaminases at the time of discharge were 65 and 59 IU/L, respectively.

DISCUSSION

The proposed mechanisms of DENV associated thrombocytopenia are: (i) DENV induced direct suppression of bone marrow megakaryopoiesis, and (ii) Immune-mediated increased the peripheral destruction.[5] An increased level of platelet associated IgG is frequently observed in patients with chronic idiopathic thrombocytopenic purpura.[6] The previous studies have also found an inverse correlation between the levels of platelet associated antibodies and platelet count during the acute phase of dengue infection. It is hypothesized that increased macrophage clearance of peripheral platelets (coated with immune complexes) through both F_c receptor and complement receptor mechanisms, as well as direct platelet lyses, are the likely causes of thrombocytopenia in these patients.[7]

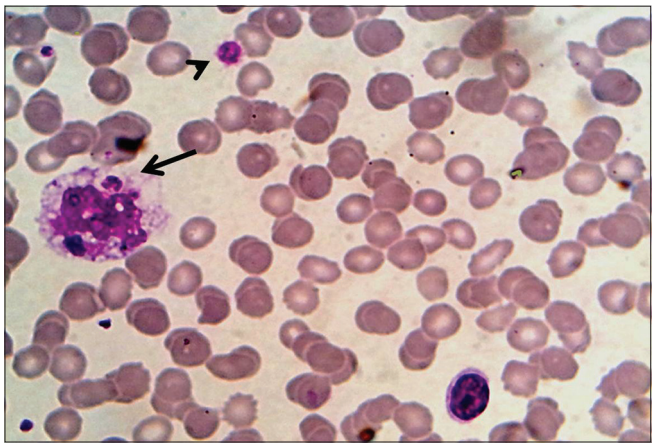

Figure 1: Peripheral blood smear from a young male patient with acute phase dengue virus infection demonstrating platelet phagocytosis by monocytes (black arrow). The platelet count at the time of admission was 60 × 10^9/L. Note the presence of a giant platelet (back arrow head) and a reactive lymphoid cell at the right lower corner of the field (Leishmann, ×400)

Recent *in-vitro* studies on dengue patients have shown that DENV induces increased peripheral platelet clearance by phagocytosis secondary to the apoptotic mechanism, during the acute and early convalescence phases of the infection.[8,9] By using flow cytometry, it was demonstrated that compared to healthy volunteers (n = 38), platelets isolated from dengue patients (57 with DF, 24 with dengue hemorrhagic fever [DHF]) showed significantly higher (P < 0.001) upregulation of proapoptotic markers such as active caspase-3 on their membranes (2.82 ± 1.05% vs. 16.82 ± 11.31%, respectively), increased Annexin V binding (3.27 ± 0.91% vs. 19.67 ± 10.72%, respectively); and thus increased phagocytosis by macrophages (20.29 ± 5.77% vs. 55.46 ± 29.66%, respectively). Furthermore, these findings were significantly (P < 0.05) observed from patients with DHF than those from DF.[8] The outcome of the above study is intriguing because of the very fact that platelet being anucleate particles lacks the machinery to express the apoptotic genes! Hence, the detailed molecular mechanism of DENV induced peripheral phagocytosis of activated platelets remains to be fully understood. As suggested by Honda *et al*., the percentage of phagocytosis should be correlated with platelet associated immunoglobulin titers.[9]

Our observation of peripheral platelet phagocytosis, in the present case, supports the hypothesis that increased peripheral clearance is an important mechanism in DENV associated thrombocytopenia. More prospective studies are required to validate the apoptotic hypothesis as suggested by Alonzo *et al*.[8] However, we do suggest that platelet phagocytosis in peripheral blood should be mentioned, as well as quantified, in clinical pathology reporting in cases with dengue associated thrombocytopenia.

A two-month-old boy, born to consanguineous parents, presented with high grade fever for 5 days. On examination he was febrile, pale with generalized hypo pigmentation of skin and hair, hepatosplenomegaly and cervical lymphadenopathy. He had a past history of recurrent respiratory tract infections. Splenomegaly of 2.5 cm was noted at birth. Complete blood count—total count 3.1 × 10^3/µl, haemoglobin 7.4 g/dl, and platelet count 24 × 10^3/µl. Primary blood and urine cultures were sterile. Peripheral smear showed pancytopenia with large eosinophilic inclusions in the lymphocytes (Fig. 1). Bone marrow revealed large coarse azurophilic granules in the cytoplasm of many of the myeloid precursors and mature granulocytes including eosinophils (Figs. 2, 3).

Erythrophagocytosis was evident in the marrow histiocytes (Fig. 4). Serum iron was 28 µg/dl, ferritin >2000 ng/ml and triglycerides were 325 mg/dl. With the presence of six of the eight diagnostic criteria for HLH being present i.e. fever, splenomegaly, pancytopenia, hypertriglyceridemia, hyperferritenemia and haemophagocytosis in the bone marrow, a diagnosis of Chediak–Higashi syndrome with haemophagocytic lymphohistiocytosis (accelerated phase) was made. The child was treated with IV ceftriaxone and vancomycin. However his condition deteriorated and he expired.

Chediak–Higashi syndrome (CHS) is a rare, autosomal recessive disorder that affects multiple systems of the body mainly the immune system [1]. The clinical manifestations of

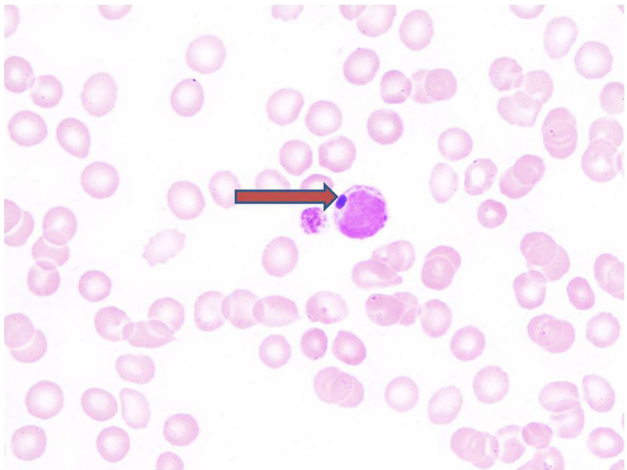

Fig. 1 Lymphocyte inclusion (indicated with *red arrow*)

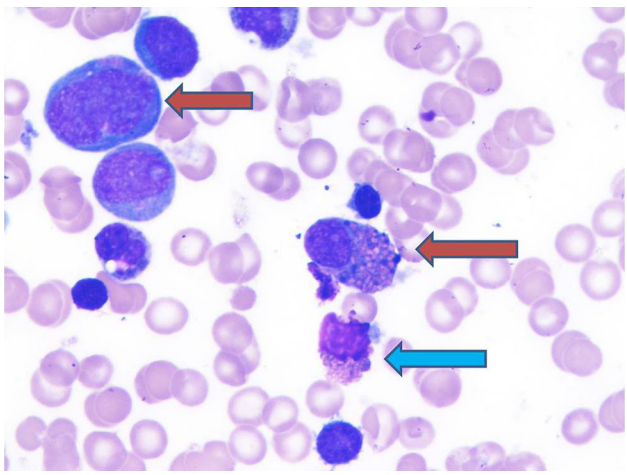

Fig. 2 Large coarse granules are present in the cytoplasm of the myeloid precursor (indicated with *red arrow*) and eosinophils (indicated with *blue arrow*)

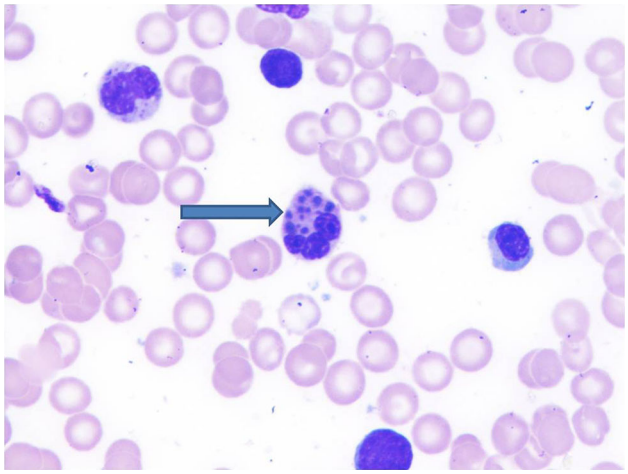

Fig. 3 Giant granules in the cytoplasm of neutrophils (indicated with *blue arrow*)

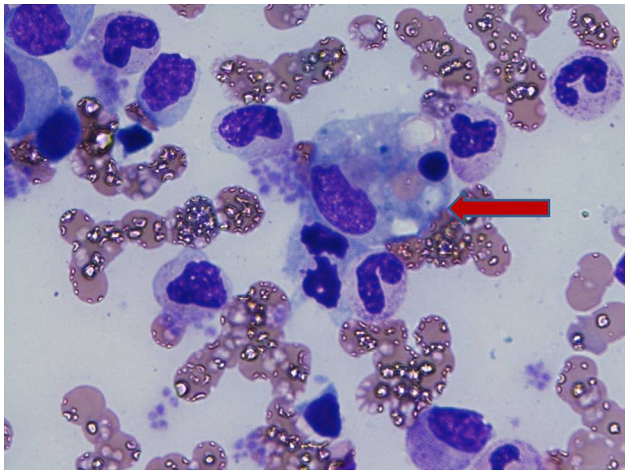

Fig. 4 Erythrophagocytosis (indicated with *red arrow*)

CHS in accelerated phase include high fever, neurological abnormalities, lymphadenopathy, hepatosplenomegaly, pancytopenia, abnormal giant granules in peripheral blood and bone marrow, lymphohistiocytic infiltration in liver, spleen and lymphnodes [2].The only treatment is allogenic haematopoietic stem cell transplantation (HSCT). The prognosis is poor [3].

Laboratory Diagnosis of Renal Disorders: Automated Urine Sediment Analyzer Compared with Manual Methods

Sharanya K[1] and Prasanna N Kumar[2]*

ABSTRACT

Background: Urinalysis is one of the earliest methods used to screen and detect patients with kidney diseases. It also helps to monitor and assess the severity of the disease process in already diagnosed patients. Microscopy plays a vital role in routine urinalysis and gives more information when analyzed together with chemical strip tests. Introduction of automation of the conventional methods of urinalysis has reduced the disadvantages of manual methods in terms of accuracy of results and turnaround time.

Method: Aim of the present study is to evaluate the performance of an automatic urinalysis system – FUS-100 (which in cooperates an automatic urine chemistry analyzer H-800) manufactured by Dirui Industrial Co. Ltd., China in patients with renal diseases and compare the results of microscopy with manual microscopic analysis. In addition, our study aims to find out the possibility of safely reducing the number of manual microscopy analyses by cross-interpretation of the results generated by FUS-100 automated urine particle analyzer with manual methods. The urine sediments of five hundred urine samples were examined by these two methods.

Result: Automation of urine analysis decreases the turnaround time and is less labour intensive leading to better accuracy and precision.

Conclusion: Preanalytical errors related to centrifugation and sediment preparation are prevented in automation. Our study tends to suggest that automation of urine microscopy therefore is a more standardized procedure and makes urine microscopy a more objective investigation.

Keywords: *Automation, Renal Disorders, Manual Methods, Urinalysis, Casts, Crystals, Cells*

Introduction

Urinalysis provides information and clues to many diseases and can also be an indication of the condition of a patient's health. In patients with nonspecific symptoms and severe kidney diseases, urinalysis serves as one of the early laboratory investigations to initiate treatment.[1,2]

Routine urinalysis is mainly done by inspection, chemical testing and microscopic examination of the urinary deposits which can have cells, casts, crystals or microorganisms. Traditionally, microscopy has always been done by manual methods. Manual examination of the urinary sediment, even though considered a time tested and standard method is labour intensive and involves considerable time, leading to delays in reporting. Automation of urinalysis has been introduced to reduce the disadvantages of the manual method.

The present study evaluates the results generated by an automated urine analyzer FUS -100, which incorporates an automatic urine chemistry analyzer H-800(manufactured by M/S. Dirui industrial Co.Ltd., China) in patients with renal diseases and compares the results of microscopy obtained by automation with manual microscopic analysis. Simultaneously, control samples from a population without knowing renal disorders were also studied. It was felt that such a study would be useful, if it is designed to find out the possibility of safely reducing the number of manual microscopy analyses by cross-interpretation of the results of the FUS-100 automated urine particle analyzer with manual methods.[1,2,3]

Materials and Methods

This was a prospective observational study, performed on urine samples received in the Clinical Pathology laboratory, Department of Pathology. Routine urinalysis done during a period of one year was analysed. A total of 500 urine samples collected from both outpatients and inpatients were examined within an hour of receipt. Physical and chemical analysis including tests for detecting glucose, ketones, proteins, blood, urobilinogen, pH, specific gravity, haemoglobinuria, myoglobinuria, hemosiderinuria, bile salts and bile pigments were performed on these samples. All the samples were collected exclusive of preservatives. The study included patients with confirmed renal disorders and those suspected to have renal disorders based on abnormal renal function tests. The clinical details and diagnosis related to all the urine samples were obtained from the test request forms.

This work is licensed under the Creative Commons Attribution 4.0 License. Published by Pacific Group of e-Journals (PaGe)

After receiving the samples, a dipstick chemical strip analyses of the urine samples were performed using the automatic urine chemistry analyzer H-800. Results obtained were used to screen further microscopic urine analysis. An abnormal urine was considered as one in which any of the following parameters tested were out of range - blood, proteins, nitrites, ketones, urobilinogen, bilirubin, WBCs and glucose. The rest of the urine samples were considered as normal controls.

For performing automated microscopic analysis (FUS-100), uncentrifuged urine samples were placed on the sample rack provided with the analyzer. The FUS100 aspirates 0.95 mLof urine and at the end of one minute, the artificial intelligence identification software within the analyzer classifies the particles into twelve categories (Red blood cells, white blood cells, white blood cell clumps, hyaline casts, pathological casts, squamous epithelial cells, non-squamous epithelial cells,bacteria,yeast, crystals,sperm, mucus) present in the given sample by capturing each of their images. Using this classification the software calculates the visible component concentration by taking into account the number of images and the scanned urine volume. All visible component images of a given urine sample are shown on the monitor in separated gridsand presented in the form of numbers/low power or high power field. FUS Focus, FUS positive control, and FUS negative control were run according to the manufacturer's instructions were run every day before testing the urine samples.

The samples apportioned for manual microscopy were gently mixed and centrifuged in a centrifuge test tube at 1500rpm for five minutes and the supernatant was discarded. A drop from the remaining sediment was placed onto a microscope glass slide and covered by means of a cover slip. Microscopic examination of the sediment was done initially under low power (10X) to identify casts and then high power (40X) was used for erythrocytes, leukocytes, crystals, epithelial cells, bacteria, yeast and other significant findings. An average of ten fields was taken and the results were calculated semi-quantitatively and expressed as a range (Table-1).

Among the randomly examined samples with renal function abnormalities, the microscopic sediments quantified from the manual method was compared with that of the automated analyzer.

Results

The following are the results for the various constituents of the urine sediment examined through automation and by manual microscopy.

The area under the curve (AUC) and sensitivity for detecting RBCs by the manual method were 0.8648 and 82%, respectively. By automated method using FUS-100 these values were 0.8763 and 86.5% respectively, which are higher than the values obtained by manual method (Table 2). The changes noticed were seen to be statistically significant, suggesting that FUS-100 analyzer is more efficient than the manual method at detecting RBCs when compared to the manual method. However, the specificity and PPV for detecting RBCs through manual method was found to be higher (Table 2). The AUC for WBCs was registered as 0.6568 by FUS-100 while with manual method was found to be 0.6524 (Table 2). This result reflects that the accuracy of both the methods had comparable results in detecting WBCs, though the result of FUS-100 is marginally higher. The Sensitivity for detecting WBCs was once again marginally increased with the investigations performed by FUS-100 (50.5%), as against the manual method (48%) (Table 2). However, we found a higher specificity for WBCs (80.28%) with the manual method. Finally, the PPV for detecting WBCs by manual method is higher (63%) than with FUS-100 analyzer which is 62%.

In the people without any renal abnormality, nearly 92.7% were detected to have epithelial cells (within a range of 0 to 5) by automated microscopy whereas only 84.7% were detected to have them by manual method. The specificity of manual method in recognizing epithelial cells was 98% and positive predictive value was 70%. However FUS-100 had a better negative predictive value which was 59 % (Table 2).

Among the study population, 482(96.4%) cases detected by FUS-100, 283(94.3%) cases detected positive for bacteria were patients who did not have any renal abnormalities, whereas in the manual method such cases constituted only 265 (88.3%) (Table 3). This shows that automated microscopy is more efficient in detecting bacteria when compared to the manual method whereas,yeasts were detected with equal accuracy by both the methods. However, since simultaneous cultures were not done in any of the cases studied, it is not possible to determine if these bacteria are contaminants or clinically significant entities.

Among the 200 patients with renal abnormalities, the sediments contained a variety of crystals like Ammonium Biurate, Amorphous urates, calcium carbonate, uric acid, etc. Among these, some of the crystals were identified by both the methods, while a few others were identified only by one of the methods. The details of distribution of these deposits are tabulated (Table 4). Additionally, the FUS-100 analyzer classified some of the amorphous urates and calcium carbonates as RBCs, which were reclassified while reviewing the analyzed images.

In addition to the entities mentioned above, FUS-100 identified a total of 74 cases to have hyaline casts out of which only 35 cases truly had the casts. Out of the 35 true positive cases, 3 cases were seen in patients with renal abnormalities in the range of 6-10. However, the manual method was able to detect 29 cases of hyaline casts out of which 26 were in the range of 0 to 5 and the other 3 cases in the range of 6 to 10. Waxy casts, noted in a patient by manual microscopy, was not detected by the automated analysis (Table 4). However, FUS-100 categorizes most of the detected casts and crystals as "unclassified" making it essential for the operator to review the images on the screen before finalizing the reports from the analyzer.

Statistical Analysis: All the diagnostic test evaluation analyses sensitivity, specificity, positive predictive values and negative predictive values for FUS-100 automated urine sediment analyzer and manual microscopic method were done using Medcalc statistical software & STATA statistical software package release 11. Simple calculations like percentages, proportions and mean values were derived. A type I error of 0.05 was considered in all analyses.

Discussion

Urinalysis is one of the earliest methods used to screen and detect patients with kidney diseases. In many laboratories, urinalysis is restricted to chemical strip analysis, which in fact, is a cost-effective and widely accepts screening method. However, microscopy plays a vital role in routine urinalysis and gives more information when analyzed together with chemical strip tests.[4] Better results can be obtained only with the use of standardized techniques for this procedure.

Manual microscopy of the urine may be affected by preanalytical variables such as the speed and time for centrifugation, sediment preparation and interpretation all of which may lead to imprecise and inaccurate results. For a reliable urine microscopy report, the examiner should be skilled to recognize the constituents of the urine sediment correctly and possess knowledge about the clinical importance of detecting substances in urinary sediments. With the introduction of automation in all spheres of clinical laboratory practice, it is no wonder that in the recent past, companies have come out with equipments that automate urine microscopy. [5,6]

A number of instruments offering automated urine analyses are now available. These include the IRIS iQ200, the UF1000i, sediMAX and more recently the DIRUI FUS -100 Series urine sediment analyzer.[7] However, there are only a few studies that have compared the results from automated urine analyzers and microscopic methods in parallel.

This study made use of fresh samples of urine, examined within an hour of collection. However, in reality, when there is a delay in transporting urine samples, they are processed after refrigeration. The reliability of results for such samples derived from the FUS analyzerhas not been studied and is unknown.

Manual examination of urine requires the sample to be centrifuged for five minutes, after which it is examined. It is thus advantageous that the FUS-100 uses urine samples for analysis which are not centrifuged and reduces the turnaround time.

In our study, we found that the sensitivity for RBCs was better in FUS-100 while the specificity for detecting erythrocytes was higher in the manual method. This may be because of the fact that FUS-100 classifies calcium crystals, yeast and sometimes amorphous urates as RBCs. Hence, this will require reclassification. Literature shows similar studies which have made a comparison of FUS-100 with UriSed and manual methods. These studies reveal higher sensitivity for detection and discrimination of RBCs with FUS-100 than with UriSed and manual method.[5,7]

Yuksel et al reported that FUS-100 shows high sensitivity (73%) and high negative predictive value for RBCs (95%) when compared with manual microscopy. Similar to their results, in our study we found that the sensitivity (86.5%) negative predictive value (90%) and also AUC (0.8763) were higher for RBCs with FUS-100 which indicates minimal false negative results even though the possibility of false positive results are more when compared with manual microscopy.[5,7] The automated analyzers iQ200 and UF-100 recognize dysmorphic RBCs in their routine urinalysis and this has been substantiated through studies. [7,8] However this recognition is not possible with the FUS-100.

Leukocytes are routinely noticed in normal urine (upto 5 cells/HPF) and also in interstitial nephritis and proliferative glomerulonephritis.

In our study, we have shown that FUS-100 has a higher sensitivity for RBCsand WBCs in comparison with conventional manual methods. This may be due to the fact that the analyzer recognizes epithelial cells, RBCs and crystals as WBCs. We have been able to detect squamous epithelial cells in the range of 0 to 5 cells/HPF more frequently with FUS-100 (99%) when compared with manual method (95.5%). In the case of the iQ200, David et al in their study state that cell counts for erythrocytes, WBCs and epithelial cells correlate well with manual counts using counting chambers. They also found out that the AUC did not alter even after correcting the captured images for erythrocytes, WBCs and squamous epithelial cells. He concluded that manual review can be greatly reduced when the interpretation of automated analyzer is combined with chemical strip test.

Increased numbers of hyaline casts in urine indicate pathological conditions like acute glomerulonephritis and other renal diseases with proteinuria. We found that the FUS-100 classifies 14.8% (74 cases) of particles as hyaline casts out of which only 7% (35 cases) were true hyaline casts as evidenced by microscopy. The stored images which were captured by the in-built imaging system were also reviewed and the findings were in agreement with what was seen in the manual microscopy.

The falsely elevated hyaline cast count (14.8%) generated by the FUS-100 is due to the inclusion of folded squamous epithelial cells. This was also seen with other analyzers like the sediMAX, iQ200 and UriSed, built imaging system. Granular casts are usually associated with tubulointerstitial disease.[5,7,8] We found that FUS-100 recognized granular casts in patient suspected to have renal abnormalities as did the manual method.

Waxy casts are usually associated with serious renal pathologies like chronic diseases and amyloidosis. [9,10]

Increased uric acid crystals may be associated with hyperuricosuria and acute nephropathy.[7] In our study, we noticed four cases with uric acid crystals in patients with abnormal renal function. All the four cases were recognized by both automated and manual microscopic methods.

This study reveals that even though the FUS-100 was able to recognize and classify RBCs, WBCs, and squamous epithelial cells, all the crystals and casts other than hyaline casts are categorized as “unclassified” by this analyzer. This therefore requires technical assessment of the components of the urine sediment. This observation was also reported in the study done by Yuksel et al. and by Wah DT et al who recommend that a technician review the captured images by the iQ200 analyzer for all casts, WBC clumps and yeasts for confirmation. All the above studies support our observations with the FUS-100. The inability to identify casts in automated urine microscopy is an intrinsic limitation of this technology.

In order to eliminate the false positive results seen in automated urine microscopy a dedicated and well trained technician is required for the urinalysis workstation to visualize and correct the wrongly labeled cells and to classify the images shown as abnormal casts or “unclassified” before finalizing the results. However, the results that were analysed in this study were unedited results from the analyzer. For the correct identification of unknown particles and pathological casts, the manual method is still required for confirmation.

Conclusion

The FUS-100 automated urine particle analyzer performance is better than the manual microscopy for detecting RBCs, WBCs and squamous epithelial cells when compared with the manual method. Though it recognizes some crystals and casts, it fails to classify them. Therefore, manual urine microscopy must supplement the urine examination, especially in patients with abnormal renal function and abnormal urine chemical analysis.

Conventional microscopy is still required for identifying dysmorphic erythrocytes, yeasts, Trichomonas, oval fat bodies, and for the differentiation of various casts and crystals.

Automation of urine analysis decreases the turnaround time and is less labour intensive leading to better accuracy and precision. Automated urine microscopy combined with dipstick results can be used as a screening procedure for large numbers of urine samples in places with a high workload.

Abbreviations

RBC – Red blood cells
WBC –White blood cells
PPV- Positive predictive Value
NPV- Negative predictive Value
AUC-Area under the curve
HPF- High power field

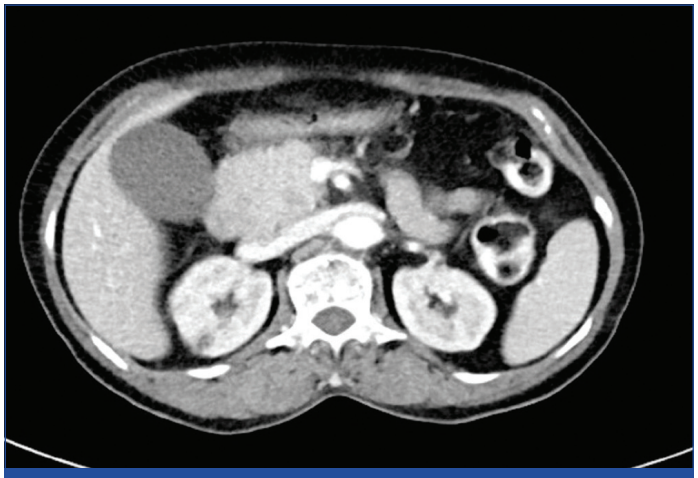
Pancreatic Plasmacytoma Misdiagnosed as Neuroendocrine Tumour: A Pathologist's Dilemma

SAKTHISANKARI SHANMUGASUNDARAM[1], UMAMAHESWARI GURUSAMY[2], PRASANNA N KUMAR[3], BIKU JOSEPH JOHN[4]

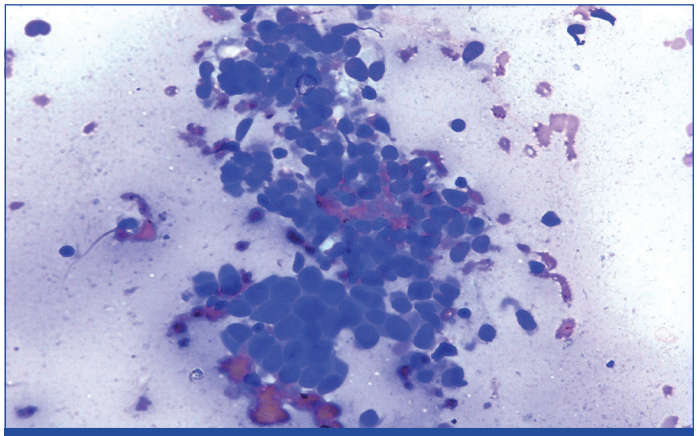
BY-NC-ND

ABSTRACT



Extramedullary plasmacytomas are rare, constituting to about 5% of plasma cell neoplasms. Pancreatic involvement is uncommon constituting to about 2.3%. Localised solitary plasmacytomas has a good response to radiation. When they are associated with pre-existing multiple myeloma, their prognosis is poor. A case of plasmacytoma of pancreas presenting with obstructive jaundice preceding plasma cell leukaemia is presented here. The lesion was misdiagnosed by fine needle aspiration cytology as neuroendocrine neoplasm. The patient did not present with symptoms of myeloma initially. The present case highlights the significance of considering other causes of pancreatic mass than primary carcinomas.

Keywords: Extramedullary plasmacytoma, Pancreatic neoplasm, Plasma cell leukaemia

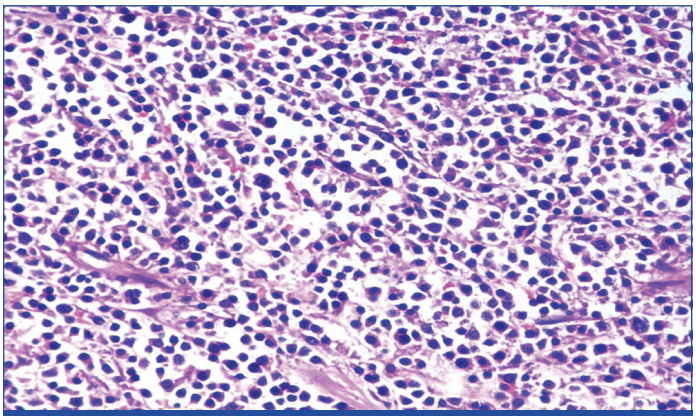


CASE REPORT

A 62-year-old female presented with complaints of fever on and off for 15 days, a vague, non-radiating, intermittent right upper quadrant, paraumbilical pain and vomiting for five days. There was no history of gastrointestinal bleed, loss of weight and loss of appetite. She was a known hypertensive and diabetic for five years and was on treatment with oral hypoglycemics and antihypertensives. Her vitals were within normal limits and there was no organomegaly.

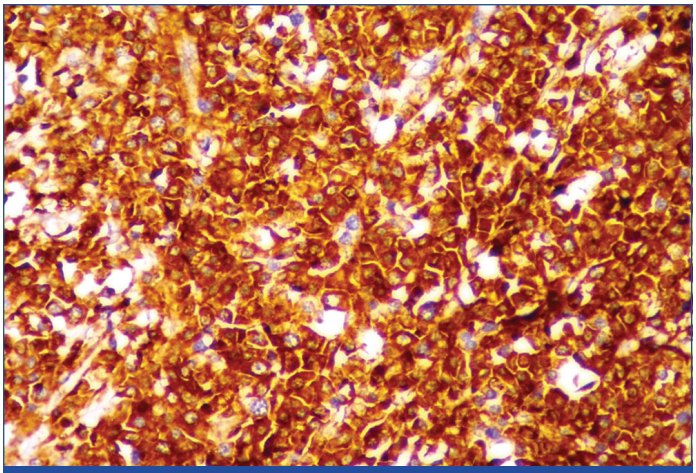
Ultrasound abdomen showed a hypoechoic mass in the pancreatic head dilating the main pancreatic duct. Computed Tomography (CT) revealed an isodense mass lesion with well defined borders in the head of pancreas measuring 4.8×5.5 cm [Table/Fig-1]. Acoustic Radiation Force Impulse (ARFI) elastography showed mean shear velocity of 3.6. The provisional diagnosis included primary pancreatic tumour. Endoscopic Ultrasound Guided Fine Needle Aspiration Cytology (EUS-FNAC) was planned for the evaluation of the pancreatic mass. EUS showed a 3×3.1 cm iso and hypoechoic mass in the head of pancreas with dilated common bile duct measuring 9 mm in the suprapancreatic portion. Dilated main pancreatic duct (6.5 mm) distal to the mass in the pancreas was identified. Visualised tail of pancreas and portal vein appeared normal. Cytological examination of the mass showed sheets and scattered plasmacytoid cells suspicious of a neuroendocrine neoplasm [Table/Fig-2].

[Table/Fig-1]: CT scan showing isodense lesion in head of pancreas.

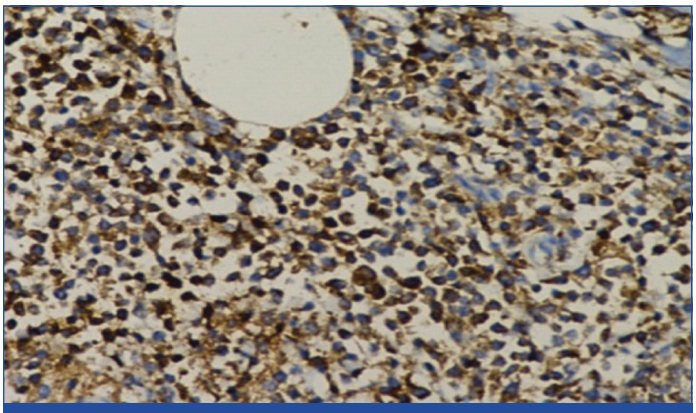


[Table/Fig-2]: Cytology smears showing plasmacytoid cells (40x).

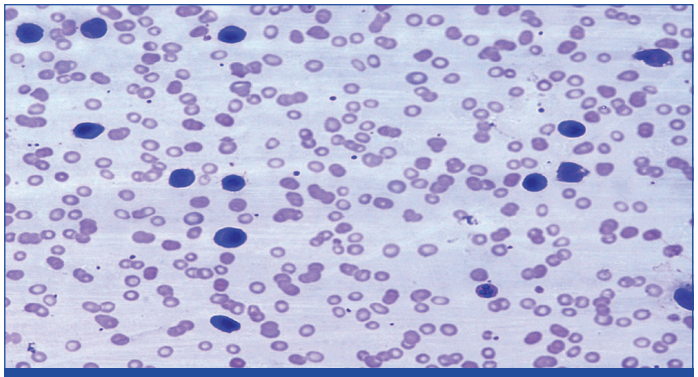
Whipple resection was done with a clinical and cytological diagnosis of a pancreatic neuroendocrine tumour. Pancreas showed an ill-defined mass occupying the head [Table/Fig-3]. Haematoxylin & Eosin (H&E) sections of the mass showed a diffusely infiltrating neoplasm composed of monotonous, plasmacytoid cells infiltrating the acini and ducts [Table/Fig-4]. Few binucleate and multinucleate plasma cells and lymphocytes were present. Morphological differential diagnosis included plasmacytoma and lymphoplasmacytic lymphoma. Immunohistochemical staining was done for confirmation of diagnosis. The tumour cells showed strong membranous positivity for CD138 [Table/Fig-5], CD45 and selective Kappa staining [Table/Fig-6]. They were negative for CD20 and Lambda immunostains. A diagnosis of Plasmacytoma was made and radiological and biochemical workup for multiple myeloma was suggested. Protein electrophoresis was normal. Urine for Bence Jones Protein was negative. Serum calcium and renal parameters were normal. CT spine survey did not reveal any osteolytic lesions. The case was treated as a solitary extramedullary plasmacytoma and suggested follow-up. A month later, the patient developed severe anaemia (Hb-6.8 g/dL). Total count was elevated and peripheral smear showed 40% plasma cells suggestive of plasma cell leukaemia [Table/Fig-7]. Reviewing the patient's peripheral smear and complete haemogram taken a month back, there was normocytic normochromic anaemia and no demonstrable plasma cells in peripheral smear. ESR was elevated (93 mm/hr). Bone marrow aspiration done showed infiltration by sheets of immature



and mature plasma cells. On immunohistochemistry, these cells showed kappa restriction. A diagnosis of plasma cell leukaemia was made. Investigations done at presentation and a month later are tabulated [Table/Fig-8]. The patient was referred to higher centre for further treatment.



[Table/Fig-3]: Whipple's specimen showing ill-defined lesion in pancreas.



[Table/Fig-4]: Diffuse infiltration by plasma cells (H&E, 40x).

[Table/Fig-5]: Strong membranous expression of CD138 by tumour cells (IHC, 40x).

[Table/Fig-6]: Neoplastic cells with kappa expression (IHC, 40x).

[Table/Fig-7]: Peripheral smear with plasma cell leukaemia (40X).

Parameters	At initial presentation	A month later
Serum urea	42 mg/dL	81 mg/dL
Serum creatinine	1.06 mg/dL	3.82 mg/dL
Direct bilirubin	3.3 mg/dL	1.8 mg/dL
Haemoglobin	9.5 g/dl	6.8 g/dL
Total WBC count	4.3×10^3/µL	30.5×10^3/µL
Peripheral smear	Normocytic anaemia	Plasma cell leukaemia
Serum calcium	1.116 mmol/L	1.178 mmol/L

[Table/Fig-1]: Biochemical and haematological investigations.

DISCUSSION

Plasma cell neoplasms include Plasma Cell Myeloma (PCM) which includes smouldering myeloma, non-secretory myeloma, plasma cell leukaemia and plasmacytoma which includes solitary bone and extraosseous plasmacytoma. In majority of the patients with PCM, features of end organ damage in the form of one or more of the following, hypercalcaemia, Renal insufficiency, Anaemia, and Bone lesions (CRAB) are present. The clonal proliferation usually begins in bone marrow. Renal failure occurs due to tubular damage caused by excessive synthesis of monoclonal immunoglobulins [1]. It constitutes 10 to 15% of haematological malignancies. Median age at diagnosis is 66 years [2]. The clinical spectrum varies from asymptomatic to highly aggressive.

Extramedullary Plasmacytomas (EMPs) are localised proliferation of monoclonal plasma cells forming solitary lesions outside the bone marrow. EMPs can be a manifestation of advanced multiple myeloma or can represent a solitary plasmacytoma without involving the bone marrow [3]. EMPs are uncommon and represent 5% of all plasma cell tumours. The most frequent site of involvement being upper respiratory tract followed by gastrointestinal tract and reticuloendothelial system [2].

Primary pancreatic plasmacytoma is rare constituting 2.3% of EMPs. Majority of the reported pancreatic plasmacytoma are secondary [3]. EMPs have the median age of presentation at 55 years (A decade younger than patients with multiple myeloma) and the majority (three-fourths) are males [4].

Most of these lesions are located in the pancreatic head. Diffuse enlargement and presenting as mass in body (4 cases) [5] and tail of the pancreas have also been reported. The typical presenting symptoms include abdominal pain and obstructive jaundice from bile duct compression when there is involvement of head. Diffuse lesions are picked up rather late as they tend to be asymptomatic [6]. The case presented here also had obstructive jaundice raising a concern for primary pancreatic carcinomas [7].

Radiologically plasmacytoma is characterised by a homogenously enhancing multilobular, solid mass on CT, which is non-specific and resemble that of neuroendocrine tumours or carcinoma [6]. The case described presented as an isodense lesion in the pancreatic head. Differentiating plasmacytomas radiologically from other pancreatic tumours is challenging.

Endoscopic Ultrasound (EUS) is a well recognised technique for confirmation of pancreatic masses by histology. EUS- FNAs are reported to have an accuracy of 78-95% in the diagnosis of pancreatic masses. Neuroendocrine tumour presents as a, homogeneous, isoechoic or hypoechoic mass on EUS while plasmacytoma shows heterogenecity with uneven margins. NETs are hypervascular [5,8].

When FNA was done, the lesion was morphologically misdiagnosed as neuroendocrine neoplasm since both share plasmacytoid morphology. In a rare site, one would be more likely to suspect a primary lesion with plasmacytoid features, particularly endocrine neoplasm. Islet cell tumours have been reported to be a great mimic of plasmacytoma with regards to clinical, cytological and radiological appearance [9]. EUS guided core biopsy from the lesion and immunophenotyping with cytokeratin for carcinoma and CD138, kappa and lambda for identifying monoclonality of plasma cells would have helped in arriving at the diagnosis. EUS guided FNA also serves as a platform for obtaining material for flow cytometry.

The patient described here did not present with any symptoms pertaining to myeloma prior to surgery. The patient progressed to plasma cell leukaemia within a short time (one month) which is evident from the investigations [Table/Fig-8]. Plasma cell leukaemias are primary in 60-70% of cases and secondary to multiple myeloma in 30-40 % cases [10,11].

To our knowledge, this is the first case of plasmacytoma of pancreas being the initial manifestation of a plasma cell leukaemia. Two other cases of plasma cell leukaemia have been reported in association with gastric plasmacytoma. One case reported also had a normal WBC and platelet count with normocytic normochromic anaemia three weeks prior to the diagnosis of gastric plasmacytoma. The authors had hypothesised that secondary plasma cell leukaemia would have occurred as a result of rapid transformation of possibly underdiagnosed light chain multiple myeloma. The present case could also represent a similar rapid transformation from a non-secretory myeloma presenting with an extramedullary plasmacytoma [12].

From the previous reports it is clear that in any mass lesion of a solid organ in a patient with multiple myeloma the possibility of secondary plasmacytoma is to be considered [3,4,7]. Present case in addition highlights the fact that plasmacytoma is to be considered when plasmacytoid cells are identified in EUS-FNAs even when previous diagnosis of myeloma or symptoms pertaining to myeloma is not there at presentation. Immunocytochemistry can be used as an ancillary technique to diagnose with certainty in such cases. Presurgical diagnosis is essential as the management varies between primary pancreatic carcinoma and plasmacytoma.

CONCLUSION(S)

This case highlights the importance of considering other causes of pancreatic head mass than a primary carcinoma in a patient with obstructive jaundice. It also emphasises the fact that pathologists must be aware of the existence of pancreatic plasmacytoma as initial manifestation of myeloma despite its rarity, a high index of suspicion being essential.

Abstract

Bacterial contamination of transfusion products, especially platelets are the most common cause of transfusion associated morbidity and mortality. Minimizing bacterial contamination in blood products is a priority for safe transfusion practices. A prospective study was done comparing the efficiency of two different disinfectant techniques by studying the flora on donor's arm before and after disinfection. This study was undertaken as there are very few reports on this important transfusion protocol from Southern India. Mean number of colonies in post disinfection swab culture with 2% povidone iodine was found to be greater than that of 2.5% Chlorhexidine in 75% isopropyl alcohol. 2.5% chlorhexidine disinfection offers more effective reduction in bacterial contamination than 2% povidone iodine group.

INTRODUCTION

There are reports to indicate that every year India requires 40 million units of blood but only 4million units are available. Hence the collection and preservation of this precious resource requires utmost care [1]. In India, approximately 57% of transfusion transmitted reactions have been found to be associated with bacterial contamination of donated blood [2, 3].The French Haemovigilance surveillance system cited bacterial transfusion transmission as the most identified cause of transfusion associated deaths [4].In the UK, between 1995 to 2003, bacterial transfusion transmissions accounted for 58% of transfusion reactions [5]. Bacteriological screening tests for platelet units were introduced in the US in 2004 and the study showed that the average prevalence of bacterial contamination in platelets from the whole blood was 33.9/100,000 units, that of platelets from apheresis 51/100,000, while that of red cell concentrates was 2.6/100,000[6].

In India, antisepsis with three-step regimen of spirit-10% povidone iodine-spirit for donor arm is followed currently. The US-FDA has approved use of alcoholic-chlorhexidine as highly effective for donor arm disinfection. However, it is not being used in India. Also, tincture iodine which was used earlier is now discontinued due to its irritant nature [7].

It is observed that Gram positive skin commensals such as coagulase negative Staphylococci and Bacillus cereus are the organisms most often recovered from donated blood which are thought to originate principally through phlebotomy[8]. The introduction of a needle through the skin to collect blood causes the passage of live microbes or the movement of microbes from small skin flaps produced by the needle itself into the collection bags[9].This is found to be effectively reduced by efficient donor arm disinfectants[10].

Approximately 16% of the deaths due to transfusion reactions have been associated with bacterial contamination, which are usually multi-Drug resistant [7]. Hence, it becomes mandatory to analyse the gaps in the process and implement corrective action to prevent them. SHOT(serious hazards of transfusion), BaCON (Bacterial contamination associated with transfusion) and French haemovigilance surveillance system, studies stated that resident skin flora accounted for 90% of platelet concentrates and 70% of red cell concentrates causing transfusion reactions[11,12].

A Blood &Transplant study conducted by NHS revealed reduction in contamination of blood products by 57% using improved disinfection strategies [13].

Review of the literature revealed only a few reports from India on this topic, and since blood safety is a very vital issue, it was thought worthwhile to undertake this study. The aim of this review is to consider the scientific evidence in supporting the efficacy of improved Donor arm disinfection in preventing bacterial contamination of blood.

AIMS & OBJECTIVES

The chief objectives of this study are:

- To assess the rate of bacterial contamination in blood bank setting.
- To compare the results from two different donor arm disinfectant techniques.

METHODOLOGY

This study was a randomised control study using prospective data. 100 subjects were included in the study after calculating the sample size.

The Voluntary donor arrives at the blood bank was tested for eligibility. After obtaining consent form for study, pre-Disinfection sample was collected in sterile swab. Disinfectant was applied for an area of 10cm on cubital fossa in concentric pattern. 2.5% Chlorhexidine in 75% isopropyl alcohol was applied as disinfectant (group 1) and while 70% Alcohol followed by 2% povidone iodine followed by 70%Alcohol was used as disinfectant (group 2). Post-Disinfection sample was collected in sterile swab. Both the swabs were cultured in blood agar and colony count was performed.

Sterile swabs for the project were made on the same day, supplied by the Department of Microbiology. Samples were collected from the cubital fossa of the donor using sterile forceps by gloved hands and immediately plated on 5% Sheep blood agar under bio-safety cabinets with positive pressure and laminar air flow.

All the patients who have received transfusion from the donors of the sample size were followed up for transfusion reactions. Any allergic reactions were to be notified and treated accordingly. To ensure quality periodical controls for swabs and Disinfectant were established. Technical officers were trained on proper method of disinfection techniques. The waste samples were discarded as per hospital's standard waste disposal system.

Data was entered in Microsoft Excel spreadsheet and analysis was done using SPSS software by Microsoft V.22.0. Association between two factors was expressed in form of odds ratio. P<0.005 was considered significant.

OBSERVATION & RESULTS

A total of 98 male and 2 female donors were selected for the study and disinfectant used was randomly assigned to them. Both the pre- and post-disinfection swabs were cultured on blood agar and their efficacy was determined by the number of colonies formed on the blood agar (Table I).

Table-I: Provides the result of swab culture with two disinfectants.

DISINFECTANT USED	n	Colonies-before disinfection	Colonies-after disinfection
Povidone iodine	50	40-210	0-10
Chlorhexidine	50	35-190	0-4

STATISTICAL ANALYSIS

Independent student 't' test was done to compare the colony count of post-disinfection swab culture between 70% Alcohol followed by2% povidone iodine followed by 70% alcohol and 2.5% Chlorhexidine in 75% isopropyl alcohol . Analysis of covariant was done using General linear model on SPSS 24.0 to compare the mean difference in post-disinfection swab culture adjusted to the bacterial load on pre-disinfection swab culture.

Table II presents the mean (SD) of the post-disinfection swab cultures between the two disinfectants and a statistically significant difference was observed. The mean (SD) of the post-disinfection swab culture for 2.5% Chlorhexidine in 75% isopropyl alcohol was 0.2800(0.70102) and 70% Alcohol followed by2% povidone iodine followed by 70% alcohol was 0.9000(1.97174).t=2.095;p<0.05.

Table-II: Comparison of post disinfection swab culture between the two disinfectants

DISINFECTANT USED	MEAN	SD	p
Povidone iodine	0.9000	1.97174	P<0.05
Chlorhexidine	0.2800	0.70102	

Analysis of covariant showed that the mean difference of the post-disinfection swab culture adjusted to the bacterial load on pre-disinfection swab culture was statistically significant F=4.974; p<0.05.

DISCUSSION

The hazards of post transfusion septicaemia became less common when closed plastic bags replaced glass containers for collection of blood. Even though it

has seen a massive decrease, it has not disappeared entirely and there seems to have been a resurgence of interest in it due to modern day increase in genetically improved resistant organisms. It is not always easy to identify the source of bacterial contamination in blood bags. Post transfusion septicaemia can be endogenous which is due to organisms circulating in the blood and in other hand, exogenous post transfusional septicaemia stems from organisms on donors' skin and equipment contamination. Endogenous post transfusional septicaemia is comparatively less than exogenous post transfusional septicaemia due to vigorous donor selection criteria hence extra attention should be given to exogenous post transfusional septicaemia which can be significantly reduced by optimal disinfection of phlebotomy site, since majority of the organisms contaminating the blood products belong to the group of skin commensals[14].

Our skin contains two types of bacterial flora. One is transient flora which can be easily washed away by water and soap. The other is resident flora that requires extensive disinfection with an efficacious disinfectant which we tried to identify in this study.

In our study encompassing 100 donors' disinfection with 2.5% chlorhexidine in 75% isopropyl alcohol was comparatively more efficacious than 70% Alcohol followed by2% povidone iodine followed by 70%alcohol. Mean values of colonies of 70% Alcohol followed by2% povidone iodine followed by 70% alcohol is greater than what was observed in 2.5% Chlorhexidine in 75% isopropyl alcohol in the swab culture of post-disinfection swabs.

We compared our study with similar studies. Lee C K *et al*. reported a relative risk reduction of 3.4% of chlorhexidine over povidone Iodine in disinfection of donors' arm [15].Ramirez Arcos *et al*. also observed that disinfection by70% alcohol followed by chlorhexidine is highly effective having 98.74% of reduction rate in bacterial contamination of blood components than what is seen with isopropyl alcohol and iodine which correlates with the results of our study [16]. Also Benjamin RJ *et al*. proved that the 1.5ml chlorhexidine disinfection method offers more effective reduction in bacterial contamination of apheresis platelets than 70% Alcohol followed by2% povidone iodine followed by 70%alcohol [17]

Chlorhexidine is a broad spectrum agent with cumulative actions, which is recommended in the 'Guidelines on drawing blood' by WHO, Centre For Disease Control (CDC) and Health Care Infection Control Practices Advisory Committee (HIPAC) as an optimal skin disinfectant for variety of uses like phlebotomy, vascular catheterization and pre-op preparation of skin[12].

It is also less irritant and non-staining on skin. We found that both the donors and the staff of the blood bank expressed an increased compliance towards it during the period of this study. On application it disrupts the cell wall and is more effective against gram positive organisms than gram negative organisms. In our study we also detected most of the gram positive organisms are inhibited, but due to the small numbers that were studied, analysis and comparison of data cannot be made at this juncture.

A study done by Lee C K *et al*. detected predominantly Bacillus species and Coagulase-negative staphylococci as the most common pathogens [15]. In this study organisms like Coagulase-negative Staphylococci, Micrococci and Diptheroid were mainly isolated in Pre-disinfection swabs, while only Coagulase-negative staphylococci were identified in post- disinfection swabs. This is explained by the emerging resistance of staphylococci to Chlorhexidine [18]. The use of conventional agar plates and gram-staining to identify the morphology of the organism limits the scope of identifying varied bacterial flora which is more evident on automated culture systems like BACTEC/BacTALERT.

This study prompts us to conclude that there is a decrease in bacterial contamination with 2.5% chlorhexidine in 75% isopropyl alcohol compared to 70% alcohol followed by 2% povidone iodine followed by 70% Alcohol.

Since there is no significant difference in cost between these two methods tested in our study, Chlorhexidine should be affordable in blood banks of resource limited nations as well.

CONCLUSION

- Bacterial contamination of blood components remains a major challenge in the practice of transfusion medicine.
- Optimal skin antisepsis of the phlebotomy site is essential to minimize the risk of contamination of collected blood.
- Every reaction of post transfusional septicaemia must be identified, reported, evaluated and the cause for contamination must be identified in order to prevent future post transfusional septicaemia and maintain safe blood practices.

Compliance with Ethical Standards

Ethical approval

All procedures performed in studies involving human participants were in accordance with the ethical standards of the institutional and/or national research committee

Conflict of Interest

The authors declare that they have no conflict of interest

Informed consent

Informed consent was obtained from all individual participants included in the study

Guidance for clinical case management of thrombosis with thrombocytopenia syndrome (TTS) following vaccination to prevent coronavirus disease (COVID-19)

Interim guidance

19 July 2021

World Health Organization

WHO continues to monitor the situation closely for any changes that may affect this interim guidance. Should any factors change, WHO will issue a further update. Otherwise, this interim guidance document will expire 2 years after the date of publication.

Key points

Background	Thrombosis with thrombocytopenia syndrome (TTS) has been reported in individuals vaccinated with COVID-19 non-replicant adenovirus vector-based vaccines (AstraZeneca COVID-19 ChAdOx-1 vaccine and Johnson & Johnson (J&J) Janssen COVID-19 Ad26.COV2-S vaccine).
Scope	The present document aims to provide interim guidance on the recognition and management of thrombosis with thrombocytopenia syndrome (TTS) following COVID-19 vaccination.
Case definition	TTS is defined by the presence of a thrombosis/thromboembolism, generally in uncommon locations, such as cerebral venous sinus or splanchnic veins and marked thrombocytopenia (<50 x 10^9/L) following vaccination with a COVID-19 non-replicant adenovirus vector-based vaccine. Cases of thrombosis/thromboembolisms (i.e., pulmonary, deep vein thrombosis, coronary arteries, cerebral arteries) in common location have also been reported following vaccination with a COVID-19 non-replicant adenovirus vector-based vaccine.
Incidence	The cumulative incidence of TTS following vaccination with a non-replicant adenovirus vector-based vaccine ranges from 0.5 to 6.8 cases per 100 000 vaccinees. Incidence rates differ depending on the vaccine, age, sex, geographical distribution and interpretation of the case definition. The observed-to-expected rate is higher following vaccination with the ChAdOx-1 vaccine, in females and in patients aged <60 years. Most TTS cases have been reported within 3 to 30 days following vaccination with a COVID-19 non-replicant adenovirus vector-based vaccine. Information from low- and middle-income countries will be fundamental for understanding the incidence of TTS better, given that the adenovirus vector-based vaccines have been used more extensively in these countries.
Risk factors	The main risk factors for TTS following vaccination with COVID-19 adenovirus vector-based vaccines are the use of non-replicant adenovirus vector-based vaccines and younger age. There is currently no evidence that traditional risk factors for thrombosis/thromboembolisms increase the risk of TTS in this context.
Pathophysiology	TTS has been associated with the presence of anti-platelet factor 4 (anti-PF4) antibodies. There are similarities with autoimmune heparin-induced thrombocytopenia (aHIT). TTS may be caused by the binding of anti-PF4 to platelets, causing platelet activation and aggregation, thrombosis, platelet consumption, and thrombocytopenia. However, the exact mechanisms are still unclear and should be further investigated.
Clinical presentation	TTS should be suspected in patients presenting with severe and unusual headache, abdominal pain with or without vomiting, sudden onset of breathing difficulty, chest pain or limb pains, particularly in those aged under 60 years, within four weeks following vaccination. Patients with suggestive clinical symptoms should promptly undergo investigations to rule out thrombotic events and presence of thrombocytopenia.
Laboratory diagnosis	Individuals who present with thrombosis within four weeks following vaccination should be evaluated for thrombocytopenia, increased D-dimer and positive anti-PF4 antibodies. An enzyme-linked immunosorbent assay (ELISA) should be used to detect anti-PF4 antibodies, as rapid immunoassays are not as sensitive. The presence of anti-PF4 antibodies in a patient with a thrombotic event and thrombocytopenia following COVID-19 vaccination is highly suggestive of TTS. Other biomarkers can be helpful in the laboratory diagnosis of TTS, including D-dimer, fibrinogen, and blood smear to confirm reduced platelets and to rule out platelet clumping. The case definition implies the absence of a better alternative explanation for the condition.

Imaging	Suitable imaging examinations should be performed in patients with suspected TTS as soon as possible, depending on anatomical location, especially in those who present with thrombocytopenia within 30 days post-vaccination.
Clinical case management	Vaccinated individuals should be advised to seek immediate medical attention if they develop symptoms including severe or persistent headache, blurred vision, shortness of breath, chest pain, leg swelling, persistent abdominal pain or unusual skin bruising and/or petechiae (tiny purple, red, or brown spots on the skin) occurring within four weeks after vaccination, although some cases have been reported later than 30 days post-vaccination. These patients should be investigated for thrombosis and thrombocytopenia. Reporting these symptoms must be made easy for the vaccine recipients, and could include helplines and hospital vaccine centre, online reporting systems.
Treatment	WHO advises against the use of heparin in individuals with TTS in the context of COVID-19 vaccination (*conditional recommendation, very low certainty*). WHO recommends against the use of platelet infusion for individuals with TTS in the context of COVID-19 vaccination in all cases other than emergency situations where surgery is strongly indicated, thrombocytopenia is severe (platelets <50 000/μL), and platelet transfusion is required to be able to proceed with emergency surgery *(strong, very low certainty).* WHO recommends the use of intravenous immunoglobulins (IVIG) and/or non-heparin-based anticoagulants for individuals with TTS following COVID-19 vaccination *(strong, very low certainty).* WHO does not provide any recommendation for steroid treatment, but notes the general use of steroids and the likelihood that steroids will usually be given in combination with other treatments.

Background, scope, and rationale

Since March 2021, cases of thromboses associated with thrombocytopenia have been reported in patients vaccinated with the Oxford-AstraZeneca ChAdOx1-S and Johnson & Johnson (J&J) Janssen Ad26.COV2-S COVID-19 vaccines. Evaluation of the cases by national and international bodies concluded that there was a plausible causal link between these two adenovirus vectored vaccines and the events (1-3).

The association was based on the temporal association with vaccination, an increased incidence when compared with expected baseline rates, for cerebral venous sinus thrombosis (CVST), the presence of simultaneous multiple thromboses in some patients, the presence of thrombocytopenia and anti-platelet factor 4 antibodies (anti-PF4), and a higher mortality rate than that reported in the literature (1-30).

The purpose of this document is to provide interim guidance on the recognition and clinical management of this rare adverse event, known as thrombosis with thrombocytopenia syndrome (TTS), following vaccination. This newly reported syndrome has received different names, including vaccine-induced immune thrombotic thrombocytopenia (VIITT), vaccine-induced prothrombotic immune thrombocytopenia (VIPIT), and vaccine-induced thrombotic thrombocytopenia (VITT). **In the present document, the term TTS will used in the context of COVID-19 adenovirus-vector vaccines unless otherwise specified.**

Knowledge about TTS following vaccination with a COVID-19 adenovirus vector-based vaccine is rapidly evolving. This document aims to increase awareness about TTS in the context of COVID-19 vaccination and thereby help healthcare providers in the assessment and management of potential TTS cases. Individuals and healthcare providers must be aware of the symptoms of possible TTS to enable prompt diagnosis and early treatment. Healthcare providers should be aware of the relevant diagnostic tests and know which treatments should be given and which should be avoided. This document reviews the existing information on the epidemiology, risk factors, aetiology, diagnosis and clinical management protocol for TTS with specific considerations for low-and-middle income countries (LMICs). It will be revised as new evidence emerges. Detailed data regarding the methodology used in the guideline development is available in Annex 5: Methods for guideline development. TTS is a very rare adverse event following immunization (AEFI) and the benefits of COVID-19 vaccination clearly outweigh the potential risks.

Case definition

An interim case definition that could be practical to use in clinical settings has been developed with input from a representative of the Brighton Collaboration (BC) group, to ensure the harmonization with the BC definition of TTS (*version 10.16.3-May-23-2021*). The present interim case definition aims to provide an optimal balance between sensitivity and specificity while ensuring applicability across all resource settings. It is based on the existing evidence and as needed, can be updated with the publication of new cases and data (32).

It is important to note that there is a difference between the clinical management of a potential case, and the case definition. The clinical management algorithms (see below) aim to identify all possible cases with the intent of offering the most adequate treatments while continuing to confirm or rule out TTS, and avoid potentially harmful treatments. Since platelet counts can evolve over time and results for some investigations are not available instantly, the classification of cases should ideally be finalized once all available and existing data have been analysed. The investigations must be repeated if symptoms do not resolve.

The definition of TTS is based on the combined presence of a thrombosis and new onset thrombocytopenia (**Table 1**). Three levels of certainty are proposed, based on the anatomical location of the thrombosis, the severity of thrombocytopenia and the outcome of laboratory investigations (**Table 2**). The most common thromboses in the general population are limb vein thrombosis, pulmonary artery/vein thrombosis, cerebral artery thrombosis or myocardial artery thrombosis. However in the case of TTS, the thromboses have been observed mainly in cerebral and splanchnic veins. Multiple-organ thromboses have also been observed, although less commonly. In view of these observations, the term ‘unusual location’ thrombosis is used to describe the thromboses in TTS.

WHO classification of TTS following vaccination with a COVID-19 vaccine is based on the degree of certainty (**Table 2**). It includes three mandatory criteria (A, B and C) with C defining the degree of certainty based on the combination of major and minor criteria presented in **Table 1**:

A. Vaccination against COVID within last 30 days.
B. No alternative explanation for the condition (i.e., no heparin exposure within the previous 100 days).
C. Combination of thrombosis and thrombocytopenia.

Table 1: Major and minor criteria for thrombocytopenia, thrombotic events and laboratory examinations.

Classification	Major criteria	Minor criteria
Thrombosis	**CONFIRMED** diagnosis of thrombosis by imaging study, surgical, or pathology findings consistent with thrombosis/thromboembolism in an **uncommon location**: • cerebral veins OR • splanchnic veins OR • multiple organ	**CONFIRMED** diagnosis of thrombosis by imaging study, surgical, or pathology consistent with thrombosis/thromboembolism in a **common location:** • pulmonary arteries/veins OR • limb veins OR • coronary arteries OR • cerebral arteries OR • other arteries/veins OR **SUGGESTIVE** thrombosis by supporting imaging or laboratory findings **suggestive but not definitive** of thrombosis/thromboembolism in any location OR **SUGGESTIVE** thrombosis by specific **clinical syndromes** consistent with thrombosis or thromboembolism event in any location
Thrombocytopenia	Platelet count: <50 x 10^9/L AND Confirmatory peripheral smear showing reduced platelets AND No evidence of platelet clumping	Platelet count: > 50 x 10^9/L - <150 x 10^9/L OR >50% decrease from baseline platelet count
Laboratory (other than thrombocytopenia)	Positive anti-platelet factor 4 antibodies (with ELISA) or platelet functional assay (i.e., serotonin release assay)	D-dimer > 4000 µg/L fibrinogen equivalent units (FEU)

Table 2. WHO classification of TTS following vaccination with a COVID-19 vaccine is based on the degree of certainty.

Classification	Level 1 (Confirmed case)		Level 2 (Probable case)		Level 3 (Possible case)
Thrombosis	Major / Minor	Major	Minor	Major	Minor
Thrombocytopenia	Major / Minor	Major	Major	Minor	Minor
Laboratory (Other than thrombocytopenia)	Major	Minor	Minor	Minor	Minor / No laboratory

Cases with incomplete investigation or the presence of other possible explanations should be classified as possible cases of TTS until better evidence is available. Detailed information on these diagnostic criteria including imaging modalities, surgical and pathological findings and clinical symptoms for TTS are available in more detail below.

The clinical diagnosis of TTS is summarized in Figure 1.

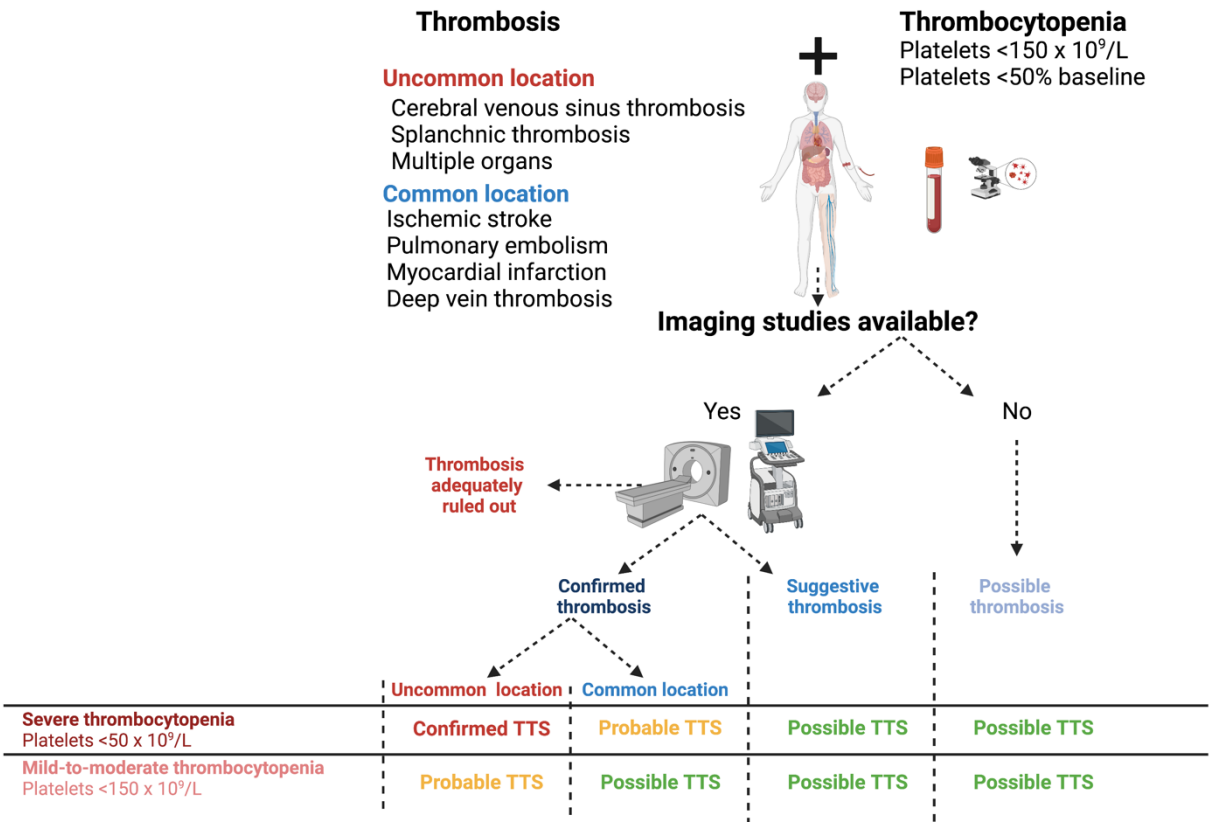

Figure 1: Algorithm for the clinical diagnosis of thrombosis thrombocytopenia syndrome

Figure created with BioRender.com

Incidence

Overview

The epidemiology of TTS is a rapidly evolving field, and its interpretation requires special considerations. The incidence may be influenced by the patient profile in each country and the specific vaccines used. The risk may depend on age, sex or other factors. Public awareness may also influence the clinical outcome as patients who present earlier could receive treatment sooner, resulting in lower morbidity/mortality. In most studies and official reports, the observed case rates are from spontaneous notifications and therefore these are the notification rates rather than with the real case rates, which may be under-estimated due to underreporting. In addition, the epidemiology of uncommon thrombotic events, such as splanchnic thrombosis, is not well established in the general population, so increased risk may be difficult to estimate. In addition, a precise denominator is needed, i.e., the numbers of those vaccinated in different age groups and by gender. A study analysing the background rates of TTS from eight countries reported significant population-level heterogeneity in the rates, suggesting that estimates from one country or region should be interpreted with caution, due to systematic error associated with the databases used to estimate the control rates (33-35).

TTS incidence can be estimated using the crude cumulative incidence per 100 000 persons or the standardized morbidity ratio (SMR), also known as observed-to-expected analysis, that analyses the ratio between the observed number of cases in the population and the number of cases that would be expected according to baseline incidence, with a 95% confidence interval (CI) (1-3).

Incidence of CVST in the general population and in COVID-19 patients

The incidence of CVST in the general population is estimated to be between 1.2 and 2.0 cases/100 000 person/year (36). In a national study done in the United States of America from 2006 to 2016, the incidence varied by sex (more frequent in women), age (more frequent between 18-44 years) and race (more frequent in African American > Caucasian > Asian). The incidence of venous thromboembolism has been reported to be almost 70% less frequent in southeast Asian populations compared to those of European descent (36).

Thrombotic complications are frequent in patients with active or recent severe acute respiratory syndrome coronavirus-2 (SARS-CoV-2) infection (37). Thrombocytopenia (<150 000 platelets/µL) has been reported to occur in about 15% of COVID-19 patients with CVST. The relative risk of having CVST for patients with COVID-19, compared with those without, is estimated to be at least 14 times higher. The incidence of CVST in COVID-19 patients was analysed in a study collecting real-time data from electronic medical records between 24 March 2020, and 1 March 2021. Among the 667 551 COVID-19 patients at risk there were 42 CVST cases and among the 65 796 480 non-COVID patients there were 1022 cases (rate 0.0001 vs. 0.000002, OR: 41.0; 95% CI: 30.1-55.8), with a higher mortality rate in the COVID-19 group (11.9% vs. 2.8%, OR: 4.6; 95% CI: 1.3-13.0) (35). Thrombocytopenia may also be present in patients with COVID-19 infection, including patients with thrombotic complications, however it is generally milder than thrombocytopenia reported in patients with TTS (37). The presence of an active SARS-CoV-2 infection was ruled out in most TTS cases reported to date (1-30).

Incidence of CVST following vaccination with a COVID-19 non-replicant adenovirus-vectored vaccine

Table 1 in Annex 4 summarizes the existing evidence from studies reporting the incidence of TTS after vaccination with a non-replicant adenovirus vector-based COVID 19 vaccine as of 27 May 2021 (18, 39, 41–48). A report from the European Medicines Agency (EMA), published on 8 April 2021, assessed the number of reported cases in the European Economic Area member states and the United Kingdom up to 22 March 2021, using databases from Italy (Agenzia Regionale di Sanità, ARS) and Spain (Foundation for the Promotion of Health and Biomedical Research of Valencia Region, FISABIO) as comparators, reported a global observed-to-expected rate of 7.73 (95% CI: 5.3-10.8) per 100 000 persons over 14 days (7). A population study conducted in Denmark and Norway in patients who received the first dose of ChAdOx-1 vaccine, from 9 February 2021 to 11 March 2021, reported an observed-to-expected incidence of 20.25 (95% CI: 8.14-41.73) cases within 28 days of vaccination, and an excess of 2.5 (95% CI: 0.9-5.2) CVST cases per 100 000 vaccinations over 28 days. The observed-to-expected rate for venous thromboembolic events was 1.97 (95% CI: 1.5-2.54) with 11 (95% CI: 5.6-17.0) excess events per 100 000 doses (38).

The incidence of CVST after vaccination with a non-replicant adenovirus vector-based COVID 19 vaccine is also proportionally higher in women (although this may have been due to vaccination of priority groups that may have included more women) and patients aged <60 years (1, 2). The incidence of cerebrovascular events per 100 000 person-years after ChAdOx1-S vaccination was higher in women (29.4; 95% CI: 19.8-42.0) compared with men (6.2; 95% CI: 1.3-18.0) within one month in a German study (18). The median age was 40 years, with few cases occurring in patients aged >60 years. This study reported a CVST rate of 20.52 (95% CI: 5.59-52.5) per 100 000 person-years in females aged >60 years, but not in males aged >60 yeas (18). The EMA signal assessment report published on 8 April 2021, reported an increased SMR for CVST over 14 days, in patients vaccinated with the ChAdOx1-S COVID-19 vaccine, compared with the background rate, particularly in patients aged 18-60, in patients with and without thrombocytopenia. The association with disseminated intravascular coagulation (DIC) or other embolic and thrombotic events was inconclusive at that time.

Most cases of TTS have been reported after the first dose of ChAdOx-1, but there are still insufficient data to establish whether the risk of TTS differs between the first and second dose because substantially fewer second doses of the ChAdOx-1vaccine have been given. The Ad26.COV2-S vaccine is administered as a single dose. Data about Ad26.COV2-S was initially reported in the United States of America. The Center for Disease Control and Prevention reported 28 confirmed TTS cases among 8 739 657 people vaccinated, as of 12 May 2021, which appears less frequent than for ChAdOx1-S, with the highest rate reported being 12.4 cases per million doses for women aged 30-39 years (39). At the time of publication of this interim guidance, no TTS cases have been reported following vaccination with other adenovirus vector-based COVID-19 vaccines or mRNA COVID-19 vaccines (40). It is also important to acknowledge that although TTS events have been reported following vaccination with the two adenovirus vector-based vaccines, other vaccines using adenovirus as a vector, should also be under careful surveillance since the absence of TTS cases may be due to underreporting, given the absence of well-established pharmacovigilance systems in some countries. Country-level active surveillance could be considered in addition to passive surveillance systems.

Risk factors

The main risk factors for TTS are age (41-48) and the type of non-replicant adenovirus vector-based COVID-19 vaccine, with a higher risk associated with ChAdOx1-s than with Ad26.COV2-S (1-30). To date, there is no evidence that supports an increased risk of vaccine-related TTS or a more severe clinical presentation in patients with pre-existing thrombotic risk factors. The frequency of thrombotic risk factors in TTS (approximately 30%) does not appear to differ from the reported frequency of thrombotic risk factors (37-84%) in patients with thrombotic events unrelated to vaccination (49-58). However, the presence of additional causes for the thromboses must be evaluated according to the local standard of care, to ensure that patients are treated appropriately, whenever necessary, particularly in common location thromboses, such as deep vein thrombosis (DVT) or pulmonary embolism (PE). The list of thrombosis risk factors is available in Annex 1.

Pathophysiology

The aetiology of TTS is thought to be immune-mediated (59). The presence of anti-PF4 antibodies, the temporal association with immunization, the clinical onset of symptoms and the presence of multiple thromboses supports this hypothesis. Since there are several similarities with autoimmune heparin-induced thrombocytopenia (aHIT), it is thought that the pathophysiology of TTS is similar to that of aHIT's. Hence, like for aHIT, TTS may be caused by the binding of PF4 antibodies to an unknown (or yet to be described) polyanion, which then leads to a conformational change in the PF4 antibodies which reveals a new antigen, resulting in IgG antibodies being developed against this neo complex of polyanion-PF4 antibodies (4–6, 10, 59–64). The PF4-polyanion bound to the anti-PF4 antibodies subsequently binds to the Fc-gamma receptors of platelets, thereby crosslinking the platelets which results in platelet activation and aggregation. This leads to platelet consumption and thrombocytopenia as well as microparticle production and thrombin generation that contributes to development of thrombosis (59-69). There are clinical and laboratory similarities between TTS and aHIT, however, the explanation for unusual intracranial or splanchnic vein locations is currently unknown. Some of the cases reported had normal platelet counts but positive anti-PF4 antibodies/abnormal platelet function test or a highly suggestive clinical presentation but were negative for anti-PF4 antibodies (1–30). It is still unclear whether cases without thrombocytopenia are variations of the same syndrome or due to a different cause. The technique and the timing of laboratory tests may partially explain the negative results. (69–74)

Clinical presentation

The most specific elements of TTS are the **delayed onset** after vaccination and **greater severity** (1-30). Most adverse events and symptoms following immunization occur within the first 72 hours and tend to resolve spontaneously, while vaccine-related TTS typically presents after these have resolved. The median time from vaccination to symptom onset is 8 to -9 days with a range of 1 to 37 days. As of 27May 2021 only one of the 21 case series reported cases that occurred within the first 72 hours (18). Onset within the first 72 hours was described for 4 of the 62 cases who had all received the ChAdOx-1 vaccine in that study (18), while the remaining 165 cases reported so far, all occurred within 3 to 25 days, based on the available data, with one case occurring after day 30, reported on day 37 (1-30). Cases could be expected to occur within 30 days, the estimated elimination time of antibodies. Therefore, any case of concurrent thrombosis and thrombocytopenia within 30 days after vaccination with an adenovirus vector-based vaccine must be managed as a potential TTS case, with platelet count monitoring. However, cases occurring between 30-100 days should also be carefully monitored.

TTS is associated with a more severe thrombosis profile, with greater extension of thrombi and a higher frequency of concomitant intracranial haemorrhage in the case of CVST. Mortality rates (20-25%) are two-to-three times higher compared with non-vaccine related thrombotic events, however, there may be a significant reporting bias and the reasons for these findings are still yet to be clarified. In addition, the use of heparin-based anticoagulants could have influenced the clinical outcome of the initial cases that have been reported. Importantly, the clinical symptoms of thromboses in TTS **may be similar** to those of thrombotic events in the general population (75-82).

Table 2 in Annex 4 summarizes the clinical presentation of the most common locations of thrombosis in TTS. Possible symptoms and signs must be recognized, however the clinical evaluation is not sensitive or specific, so a high index of suspicion applies to in patients at risk for TTS. As the clinical symptoms for TTS are non-specific and can be associated with other conditions, physicians should be aware of the possibility of TTS in patients who have received a COVID-19 vaccine.

1. Cerebral venous sinus thrombosis

The most frequently reported vaccine-related TTS location is CVST. The most frequent symptom of CVST is headache (50%), mostly severe, which typically presents with other symptoms or signs (Table 2 in Annex 4, Figure 2). Vaccine-related CVST presents with an increased rate of intracranial haemorrhage (approximately 40% of patients) and a higher mortality rate, compared with non-vaccine related CVST. The mortality rate of CVST in patients with COVID-19 is similar to that in patients with vaccine-related TTS, however, thrombocytopenia is less frequent in COVID-19-related CVST and when present, tends to be less marked (between 100 000 and 150 000 platelets per µL).

2. Splanchnic vein thrombosis

The second most common TTS involves splanchnic vein thrombosis (SVT), including portal, superior mesenteric and/or splenic veins, reported in approximately 30% of cases. The symptoms of SVT are expected to be similar in vaccine-related TTS and TTS related to another aetiology, with the most frequent symptom being abdominal pain.

3. Deep vein thrombosis and pulmonary embolism

DVT and PE have been described in the reported cases of patients with TTS following vaccination with an adenovirus vector-based COVID-19 vaccine. The clinical symptoms of the DVT and PE are non-specific, and these symptoms are as likely to be due to DVT or PE as other alternate diagnoses. Consequently, clinical prediction tools, such as the Wells score for PE and DVT, which takes into consideration the symptoms and signs of DVT/PE, risk factors, and the possibility of an alternate diagnosis, have been derived and validated. Patients who are determined to be 'likely' based on such prediction scores should undergo further investigation with appropriate imaging to confirm or exclude DVT or PE.

4. **Multiple organ thromboses**

Approximately 20-25% of patients with vaccine-related TTS have multiple-organ thromboses, which requires thorough clinical examination and appropriate investigations, as necessary.

Laboratory diagnosis

1. Platelet count

Haemogram (complete blood count) must be done for all patients. Thrombocytopenia is defined as a platelet count <150 000/µL or a 50% decrease from a recent previous platelet count, if available. In most of the reported cases, the platelet nadir was <50 000 platelets/µL, with a median value around 25 000 platelets/µL (83-88).

A few of the reported cases had a normal platelet count but they were positive for anti-PF4 antibodies which was not explained by another cause of thrombosis. If the platelet count is normal, follow-up haemograms must be repeated daily as the patient might be in the early stages of TTS. In inconclusive cases, an increased D-dimer values may be equally suggestive and additional laboratory parameters may be helpful (1-30).

2. Blood smear/film

A peripheral blood smear should be done to rule out a pseudo thrombocytopenia, caused by platelet clumping. The presence of schistocytes (fragmented red blood cells) was reported in one case of TTS (6).

3. D-dimer

A D-dimer value of four times the upper limit of the normal range (i.e., usually >4000 µg/L FEU (fibrinogen equivalent units)) is also highly suggestive, and a value of between 2000 and 4000 µg/L FEU may be suggestive (3-6).

4. Anti-platelet factor 4 antibodies

The presence of anti-PF4 antibodies, in the absence of heparin therapy, is highly specific for TTS (4–6). However, the sensitivity of the assay is influenced by the type of technique used (ideally based on ELISA,

since rapid immunoassays are neither sensitive nor specific and should not be used, if possible) and the timing of the analysis. The anti-PF4 ELISA must be done on a sample taken prior to the administration of intravenous immunoglobulin (IVIG) treatment, as IVIG can interfere with the results.

5. Fibrinogen

Fibrinogen concentrations tend to increase in TTS, but when the blood fibrinogen concentrations decrease or remain low (<1.5 g/L), this should be considered a sign of worsening TTS.

6. Other coagulation parameters: prothrombin time, activated partial thromboplastin time

Prothrombin time (PT) and activated partial thromboplastin time (APTT) should be evaluated whenever possible, as part of a differential diagnosis for other coagulation disorders, such as DIC.

7. SARS-CoV-2 tests

SARS-CoV-2 real-time polymerase chain reaction (PCR) test on a oropharyngeal swab sample should be done for all patients with a suspected TTS and the result provided at the time of the notification. Serum antibody testing should also be considered to evaluate potential past exposure to SARS-CoV-2.

Table 3 in Annex 4 summarizes the laboratory differential diagnosis between TTS, immune thrombocytopenic purpura (ITP), thrombotic thrombocytopenic purpura (TTP) and DIC. Patients with isolated thrombocytopenia and continued absence of thrombosis may have post-vaccination ITP and not TTS. Other entities that should be included in the differential diagnosis of thrombosis/disseminated thrombosis and thrombocytopenia are listed in Table 4 in Annex 4.

Imaging diagnosis

Imaging and clinical workup for thrombosis should be based on the symptoms and location. Table 5 in Annex 4 summarizes the specific diagnostic modalities consistent with a confirmed diagnosis of thrombosis or thromboembolism and the diagnostics modalities that may be supportive but not definitive (89-98).

Table 6 in Annex 4 summarizes the typical and specific radiological signs and the optimal and/or alternative imaging modalities that may be useful for TTS diagnosis. The concept of optimal is based on sensitivity, specificity and availability. In case of suspected CVST, imaging studies should be done promptly, not only for confirming/supporting the diagnosis, but also to rule out the presence of intracranial findings that might increase the risk of complications or may need urgent neurosurgical treatment. This should be considered in patients with altered fundoscopy, decreased level of consciousness, seizures or focal neurological symptoms/signs.

Clinical case management

Patients with suspected TTS within 30 days post-vaccination must be referred urgently to a hospital emergency room/urgent care for evaluation. Management of patients with suspected TTS may benefit from multidisciplinary evaluation, whenever available, including haematology, neurology, neurosurgery, radiology, intensive care, internal medicine and emergency department clinicians. Patients must be hospitalized and whenever possible, transferred to a tertiary-care hospital equipped with all the facilities listed above (83, 84, 99–102).

Clinical evaluation of patients must include the presence of symptoms and signs of thrombosis. CVST may present with headache, visual disturbances, seizures, altered mental status, decreased level of consciousness, focal neurological symptoms and/or vomiting; splanchnic thrombosis may present with abdominal pain, nausea, diarrhoea/constipation, fever, anorexia, back pain or gastrointestinal bleeding; deep vein thrombosis manifesting as limb swelling, pain or tenderness, redness and vein distension; pulmonary embolism may present as dyspnea, chest pain, difficulty to perform physical exercise, haemoptysis, syncope or palpitations; myocardial infarction may present with chest or left arm pain, shortness of breath or cyanosis; and ischemic stroke may present as sudden onset focal neurological symptoms (for further information, please see Table 2 in Annex 4). In settings of high COVID-19 incidence and transmission, patients should be tested for COVID-19, and, whenever possible, fundoscopy carried out to assess for papilledema. Imaging studies should be requested based on the clinical index of suspicion and should not be delayed while waiting for the PCR result or the fundoscopy. The different diagnostic options, including the optimal and alternative tests are described in Table 6 in Annex 4. Patients must be monitored closely, since new-onset thrombosis might occur, and multiple thromboses have been reported in 20-25% of patients.

If a venous or arterial thrombosis is diagnosed or suspected and has a temporal relationship with vaccination with an adenovirus vector-based COVID-19 vaccine, laboratory workup should be requested as outlined above, with at least a **haemogram** (full blood count), and, whenever possible, a D-dimer test. If the index of suspicion for TTS remains high in a patient who presents with a normal platelet count, then **the platelet count must be rechecked at least daily.** Additional laboratory tests that can be done include peripheral blood smear, D-dimer test, fibrinogen concentration, additional coagulation parameters and anti-PF4 antibodies. The differential diagnosis of thrombosis, based on the laboratory results is described in Table 3 in Annex 4.

It is important to consider that patients with high D-dimer and persistently low platelet count, or organ specific laboratory abnormalities (such as increased liver enzymes) may have subtle or paucisymptomatic thrombosis.

Reporting these symptoms must be made easy for the vaccine recipients, and could include helplines and hospital vaccine centre and online reporting systems.

Figures 2 and 3 summarize the clinical workup for patients.

Treatment recommendations

More complete details on the methods used for evidence assessment and formulation of these recommendations can be found in Annex 2 and Annex 3. Consult the Summary of findings and the Evidence tables for full details of the data used to formulate these recommendations.

Recommendation 1: WHO advises against the use of heparin for individuals with TTS following vaccination with a COVID-19 vaccine (*conditional recommendation, very low certainty evidence)*

Recommendation 2: WHO recommends against platelet infusion for individuals with TTS following vaccination with a COVID-19 vaccine in all cases other than emergency situations where surgery is strongly indicated, thrombocytopenia is severe, and platelet transfusion is required to be able to proceed with emergency surgery *(strong, very low certainty).*

WHO recommends the use of IVIG and non-heparin-based anticoagulants (NHAC) for individuals with TTS following vaccination with a COVID-19 vaccine *(strong, very low certainty)*

Full details on the evidence-to-decision process are available in Annex 6.

Table 7 in Annex 4 provides examples of non-heparin anticoagulants based on guidelines and national recommendations for TTS management that are available at present (103 -150). A GRADE evaluation of existing cases was carried out based on available information with these options. A GRADE evaluation of individual treatment options could not be carried out at present because of insufficient number of cases for each option. GRADE evaluation of treatment options will be possible in future versions of this guideline as global experience in TTS case management increases.

The GDG did not provide any judgment on steroid treatment, but noted the general use of steroids and the likelihood that steroids would usually be given in combination with other treatments.

Recommendations addressing vaccination, prevention and lifestyle changes in post-recovery TTS patients and the general population

No studies that provide information about post vaccine-related TTS, prophylaxis and lifestyle were identified. Important considerations include:

1. **Future vaccination**
   Patients with TTS following non-replicant adenovirus-vector-based vaccine should not receive the second dose of this vaccine to avoid repeated exposure to the antigen that caused the syndrome.
2. **Possible prophylactic medication to prevent thrombotic/thrombocytopenic events or other prophylactic measures**
   Although no studies have yet assessed the use of prophylactic medication in patients with post vaccine-related TTS, there are some studies on the long-term use of anti-thrombotic drugs to prevent TTS in patients recovering from COVID-19 disease. There is presently no indication or guideline for prophylactic treatment, including prophylactic anticoagulation or anti-aggregation in patients with other risk factors for thrombosis.
3. **Contraindicated drugs**
   The use of heparin-based anticoagulants is not recommended in patients with suspected TTS. There is insufficient evidence to contraindicate other drugs that have been associated with immune thrombocytopenia syndrome.
4. **Contraindication of adenovirus vector-based COVID-19 vaccines**
   Adenovirus vector-based COVID-19 vaccines and other adenovirus vector-based vaccines must be avoided in patients with a prior history of HIT or major venous and arterial thromboses occurring with thrombocytopenia.

Annexes

Annex 1: Thrombosis risk factors

The main risk factors for venous thromboses in the general population include:

- inherited prothrombotic disorders (Factor V Leiden, prothrombin G2021A mutation, antithrombin deficiency, protein S deficiency, protein C deficiency);
- pregnancy/puerperium;
- hormone therapy or contraceptive treatment;
- obesity;
- cancer;
- myeloproliferative neoplasms;
- immobility;
- dehydration;
- smoking;
- infections;
- inflammatory or immune-mediated conditions (inflammatory bowel disease, Behçet's disease, thyroid disease, systemic lupus erythematosus, antiphospholipid syndrome, nephrotic syndrome, sarcoidosis, paroxysmal nocturnal haemoglobinuria);
- jugular vein catheterization;
- trauma;
- severe anaemia;
- recent neurosurgical procedure;
- post-surgical state.

Chronic liver disease is the main risk factor for splanchnic vein thrombosis, but myeloproliferative neoplasms, cancer, chemotherapy, fatty liver, diabetes and coeliac disease are also known risk factors. Patients with COVID-19 also have a significantly increased risk of thrombotic events, including CVST, however, there were no markers of an active or recent COVID-19 infection in most of the reported cases.

Annex 2: PICO 1: evidence-to-decision formulation

Results of the rapid literature review

The review identified eight studies providing valid data for the outcome of recovery [7 case series and 1 case report] in 127 patients, 45 of who were treated with heparin (5, 6, 10, 11, 14, 15, 18, 39). At the time of publication of the individual studies, 68/127 (53.5%) of patients had recovered. The recovery rate in patients treated with heparin was 7/14 (50%) based on data from 4 studies including 14 patients (5, 6, 10, 11).

Nine studies provided valid data for mortality rates [7 case series and 2 case reports] in 128 patients, 46 of who were treated with heparin (5, 6, 10, 11, 13, 14, 18, 39). The overall mortality rate was 30/128 (23.4%). The mortality rate in patients treated with heparin was 6/32 (18.7%) based on data from 5 studies including 32 patients (5, 10, 11, 14, 15).

Eight studies providing valid data for haemorrhage [6 case series and 2 case reports] including 67 patients, 34 of them treated with heparin (5, 6, 10, 11, 13-15, 39). The overall intracranial haemorrhage rate was 27/67 (40.3%). It was 7/21 (33.3%) in patients treated with heparin, based on data available in 6 studies (5, 6, 10, 11, 13, 14).

Certainty of evidence was very low for recovery, mortality, and haemorrhage.

Certainty of evidence

All studies were observational, either case series or case reports. There were nine valid studies for the mortality outcome and eight for haemorrhage and recovery. There were 127 patients for the recovery outcome, 128 for the mortality outcome and 67 for the haemorrhage outcome. The total number of treated patients was 14 for the recovery outcome, 32 for the mortality outcome and 21 for the haemorrhage outcome. The risk of bias was judged to be very serious, with possible selection bias, as fatal cases were more likely to be quickly published as case reports (within a range of between 5 and 8 days). Not all confounding factors influencing the prognosis were analysed (age, time between symptom onset and treatment, concomitant treatments, presence of multiple organ thrombosis) and follow-up was incomplete in many cases. The degree of inconsistency was judged to be serious, since the dose was not described in many studies, the duration and follow-up protocols varied within the different studies. Imprecision was judged to be very serious, since the number of patients included was less than the number of patients that would be needed for a single adequately powered trial, according to a sample size calculation. There was also a strong suspicion of publication bias.

Balance of benefits versus harms

The evidence was limited and the Guideline Development Group (GDG) agreed with the very low certainty rating. In judging the balance of benefits and harms, the GDG members also discussed that that in heparin induced thrombocytopenia (HIT), which has a similar presentation to TTS, heparin-based anticoagulants could be more harmful than beneficial and that, based on what is known about the pathophysiology of TTS, heparin may also be harmful in TTS. The GDG experts agreed on the need for more and better data, and some stated that heparin could be harmful, and that no benefit had been demonstrated for TTS.

Values and preferences

No data was available to inform how patients judge the value or benefit of heparin. Heparin is the main treatment for most thromboses and thromboembolisms. It is also the most frequently used anticoagulation treatment. Members of the GDG noted that if patients were aware of the uncertainty of the data and aware of the possible harms, some may prefer not to receive it. However, overall, the GDG agreed that there was likely to be major uncertainty and variability in how patients would value heparin for the treatment of TTS.

Resources use

The GDG discussed that not all heparin-based anticoagulants require the same resources. Non-fractioned heparin requires continuous intravenous administration and frequent laboratory monitoring in order to adjust the dose, whereas low-molecular-weight heparin does not need regular monitoring, but its administration requires specific training.

The GDG also noted that not all heparin-based anticoagulation treatments are equally cost-effective, with the cost being associated with not only to the direct cost of the product, but also with laboratory checks and monitoring visits.

Given the lack of specific data available to inform this judgement, the GDG judged that the costs for heparin treatment were likely to be variable and some GDG members reported costs would be large.

Equity and human rights

The GDG discussed that equity was likely to be reduced if other non-heparin treatments were recommended, instead of heparin, as many are not widely available, and choice would therefore be limited. Heparin is available in many LMIC settings, while the other non-heparin treatment options may not be.

Acceptability and feasibility

The GDG members believed that not all non-heparin-based anticoagulants would be equally acceptable to all stakeholders and that not all non-heparin-based therapies are equivalent, and also some of them are not widely available in all settings. The GDG members noted that heparin is the most widely used parenteral anticoagulant, and that many clinicians may not be trained or aware of other non-heparin-based treatments.

Recommendation rationale

The GDG formulated a conditional recommendation *against* heparin use for patients diagnosed with TTS following COVID-19 vaccination because:

1. of the uncertainty of the currently available data on the benefits and harms of heparin in TTS patients;
2. the present recommendations are applicable exclusively for emergency interim use and can be modified or completely changed when evidence becomes available; and
3. heparin may be the only therapeutic drug available in some countries who may not have the resources for treatment with IVIG and non-heparin anticoagulants.

Full details regarding the evidence-to-decision, GRADE tables and the literature review are available in supplementary data: methods for guideline development.

Annex 3: PICO 2: evidence-to-decision formulation

Results of the rapid literature review

Recovery

Six case series, including 110 patients with TTS, provided valid data for recovery rates., 77 who had been treated with NHAC. The global recovery rate was 65/110 (59.1%) (6, 11, 15, 18, 39, 103). Information about recovery in patients treated with non-heparin-based anticoagulants (NHACs) was available in 5 studies including 44 patients. The recovery rate in these patients was 28/44 (63.6%) (11, 6, 15, 39, 103).

Seven studies reported the use of IVIG [2 case reports and 5 case series] in 113 patients, 55 of them had been treated with IVIG (6, 10, 14, 15, 18, 39, 103). The global recovery rate was 64/113 (56.6%). The recovery rate in patients treated with IVIG was 6/9 (66.7%) from 4 studies including 9 patients (6, 10, 14, 103).

Five studies provided valid data about platelet transfusions, [2 case reports and 3 case series], including 48 patients, 16 of them had received platelet transfusion (8, 10, 14, 15, 39). The global recovery rate was 25/48 (52.1%). The recovery rate in patients who had received platelet transfusion was 0/6 (0%) from 3 studies including 6 patients (8, 10, 14).

Four case reports, including nine patients, reported data about steroid treatment seven of them had been treated with steroids (10, 14, 16, 103). The global recovery rate was 4/9 (44.4%). In patients treated with steroids it was 4/7 (57.1%) from four case reports including seven patients (10, 14, 16, 103).

The GDG noted that recovery data indicated some benefit, while noting that the studies were small and heterogenous and many studies were likely to have included combinations of drugs rather than single drugs. The GDG judged benefits as moderate but uncertain. The GDG noted that the data suggested there was no benefit from platelet transfusion although data were only available for 6 patients.

Mortality

Six case series provided data on mortality in 110 patients; 77 had been treated with NHAC (6, 11, 15, 18, 39, 103). The global mortality rate was 17/110 (15.4%). The mortality rate was 1/15 (6.7%) in 4 studies including 15 patients treated with NHAC (6, 11, 15, 103).

Eight studies [3 case reports and 5 case series] reported use of IVIG in 114 patients, 55 had been treated with IVIG (6, 10, 13-15, 18, 39, 103). The global mortality rate was 22/55 (40.0%). The mortality rate in patients treated with IVIG was 4/16 (25.0%) from 5 studies including 16 patients (6, 10, 14, 15, 103).

Five studies provided valid data about platelet transfusions [2 case reports and 3 case series] in 48 patients; 16 had received platelet transfusion (8, 10, 14, 15, 39). The global mortality rate was 12/48 (25.0%). The mortality rate in patients who had received platelet transfusion was 5/6 (83.3%) from three studies including six patients (8, 10, 14).

Six studies provided data about steroids [4 case reports and 2 case series] in 82 patients; 14 of had been treated with steroids (10, 14-16, 18, 103). The global mortality rate was 19/82 (23.2%). The mortality rate in patients treated with steroids was 3/7 (42.9%) from four studies including seven patients (10, 14, 16, 103).

Intracranial haemorrhage

Five case series provided valid data about intracranial haemorrhage in 49 patients; 44 had been treated with NHAC (6, 11, 15, 39, 103). The global intracranial haemorrhage rate was 20/49 (40.8%). The intracranial haemorrhage rate was 7/18 (38.9%) in 18 patients treated with NHAC from 4 studies (6, 11, 15, 103).

Seven studies [3 case reports and 4 case series] described the use of IVIG in 54 patients; 35 had been treated with IVIG (6, 10, 13-15, 39, 103). The global intracranial haemorrhage rate was 25/54 (46.3%). The intracranial haemorrhage rate in patients treated with IVIG was 5/10 (50.0%) from 5 studies including 10 patients (6, 10, 13, 14, 103).

Five studies [2 case reports and 3 case series] provided valid data about platelet transfusions in 48 patients, 16 had received platelet transfusion (8, 10, 14, 15, 39). The global intracranial haemorrhage rate was 23/48 (47.9%). The intracranial haemorrhage rate in patients who had received platelet transfusion was 4/6 (66.7%) from 3 studies including 6 patients (8, 10, 14).

Five studies [4 case reports and 1 case series] providing valid data for steroid treatment in 21 patients; 10 had been treated with steroids (10, 14-16, 103). The global intracranial haemorrhage rate was 12/21 (57.1%). The intracranial haemorrhage rate in patients treated with steroids was 3/7 (42.9%) from four studies including seven patients (10, 14, 16, 103).

The GDG noted that death was reduced in patients treated with NHAC or IVIG compared with the global rates and the intracranial haemorrhage rates were similar. Some GDG members noted that the harms were small and uncertain. The GDG noted a signal that mortality and haemorrhage were markedly increased in patients who had received platelet transfusion. The GDG noted that the events were reported for a small number of patients and acknowledged that platelet transfusion is usually only considered when there are limited alternatives to save the patient or prior to surgery which may introduce bias for the observed events. Uncertainty was also noted in these results., The GDG judged the harms of steroid treatment to be uncertain.

Certainty of evidence was very low for recovery, death and intracranial haemorrhage.

Certainty of evidence

The GDG agreed with the very low certainty rating. All studies were observational, either case series or case reports. The number of valid studies ranged from four to eight, the total number of included patients ranged from 9 to 113 for the recovery outcome, from 48 to -110 patients for the mortality outcome and from 21 to 54 patients for the intracranial haemorrhage outcome. The total number of treated patients ranged from 6 to 44 for the recovery outcome, from 6 to 16 for the mortality outcome and from 6 to 18 for the intracranial haemorrhage outcome. The risk of bias was judged to be very serious, with possible selection bias, as fatal cases were more likely to be quickly published as case reports (within a range of between 5 and 8 days). Not all confounding factors influencing the prognosis were analysed (age, time between symptom onset and treatment, concomitant treatments, presence of multiple organ thrombosis) and follow-up was incomplete in many cases. The degree of inconsistency was judged to be serious, since the dose was not described in many studies, the duration and follow-up protocols varied within the different studies. Imprecision was judged to be very serious, since the total number of patients included was less than the number of patients that would be needed for a single adequately powered trial, according to a sample size calculation. In addition, there was a strong suspicion of publication bias.

Balance of benefits versus harms

The GDG judged the benefits to be probably greater than the harms for NHAC and IVIG treatments. This was informed by the data but also by previous clinical experience and expert opinion, as well as pathophysiology mechanisms. The GDG judged the harms to be greater than the benefits for platelet transfusion. However, the GDG noted that when surgery is considered for thrombosis, there is a role for platelet transfusion. The GDG did not provide any judgment for steroid treatment, but noted the general use of steroids and the likelihood that steroids would usually be given in combination with other treatments.

Values and preferences

The GDG noted that from a patient perspective, given the lack of clear evidence of a single beneficial treatment modality, patients would probably show important variability and uncertainty in their choice of intervention to receive and the value they placed on specific outcomes.

However, some GDG members noted that there was probably no important uncertainty or variability, particularly with respect to not wanting to receive platelet transfusion. Mortality was noted to be the outcome the most highly valued by patients.

Resources use

Most members of the GDG described the current treatments, such as NHAC and IVIG, as expensive and the facilities and human resources required to administer them as costly. However, it was acknowledged that governments may be able to reduce costs of treatments, especially as vaccination is rolled out, in order to ensure appropriate treatment for TTS following COVID-19 vaccination. They noted that this may vary from setting to setting.

Equity and human rights

Equity was likely to be reduced if expensive interventions, such as for NHAC and IVIG that are not widely available, were recommended and this would therefore limit choice. However, it was noted that use of steroids would be unlikely have an impact on equity as these are widely available on the essential drug list.

The GDG noted that if platelet transfusions were not recommended, this would not have an impact on equity.

Acceptability and feasibility

The GDG members said they believed that all treatments were widely accepted by clinicians. The GDG said that despite high cost and requirements for specialist facilities, the treatments are feasible and should be considered as the rollout of adenovirus vector-based vaccines gathers speed in LMICs. Good referral systems and access will be essential (implementation considerations).

Recommendation rationale

The GDG formulated a strong recommendation ***in favour of*** the use of IVIG and NHAC for individuals with TTS following COVID-19 vaccination because:

1. The balance of benefit and harms was deemed to be in favour of their use despite the very low certainty of the evidence; and
2. Both IVIG and NHAC were likely to be widely acceptable to stakeholders and were feasible although costs and availability may continue to be a barrier to use in some settings.

The GDG formulated a strong recommendation ***against*** the use of platelet transfusion in individuals with TTS following COVID-19 vaccination because:

1. The extremely high rate of harms (death and intracranial haemorrhage) reported in the studies using platelet transfusion. Despite the very low certainty of this evidence, the life-threatening nature of the situation warranted a strong recommendation as the potential harms are considered to be catastrophic;
2. There was likely to be minimal variability in how patients value platelet transfusion, and most would not want to receive platelet transfusion, based on current evidence; and
3. The recommendation is strong, with the caveat that it is permissible where surgery is strongly indicated, and thrombocytopenia is severe.

The GDG did not make a specific recommendation on the use of steroids, noting that these were often used in combination with other treatments, and that use was variable and not indicated for all patients.

Full details regarding the evidence-to-decision, GRADE tables and the literature review are available in the Supplementary data: methods for guideline development.

Annex 4: Tables

Table 1. Cumulative incidence of TTS following vaccination with a non-replicant adenovirus vector-based vaccine (27 May 2021)

First author/source	Date of publication	Study period	Country	Vaccine	Dose	Cumulative incidence (95% CI) [cases per 100 000 vaccinees]
Schultz (10)	9/4/21	Unknown-20/03/2021	Norway	ChAdOx-1	First	3.8 (95% CI 1.4-9.3)
Spanish Medicines Agency (41)	11/5/21	01/02/2021-25/04/2021	Spain	ChAdOx-1	First	0.5 [1.3 in patients aged 30-39]
Centers for Disease Control and Prevention (39)	12/5/21	Unknown-07/05/2021	United States of America	BNT162b2, Ad26.COV2S	First	Global: 0.32 [1.2 in female patients aged 30-39]
Schulz (18)	13/5/21	Unknown-14/04/2021	Germany	ChAdOx-1 and BNT162b2	First	6.5 (95% CI 4.4-9.2) overall; 17.9 (95% CI 11.8-26.1) for ChAdOx1
Medicines & Healthcare products Regulatory Agency (48)	27/5/21	09/12/2020-26/05/2021	United Kingdom	ChAdOx-1	First and second	1.4 first dose, 0.13 second dose
Chan (43)	Preprint	Unknown-15/04/2021	Norway, Denmark, The Netherlands, Italy, Canada, United Kingdom, Germany, Australia, France, Spain	ChAdOx-1	First	0.73 (95% CI 0.43-1.23). Age <65 years: 1.60 (95% CI 0.71-3.62), Age 55-64 years: 0.41 (95% CI 0.1-1.65)

Table 2. Clinical syndromes suggestive of thrombosis or thromboembolism

Thrombosis location	Symptoms	Signs

Cerebral venous sinus	• New onset/unexplained headache:
	  • In some cases, may have headache-specific red flags, including resistance to symptomatic treatment and progressive worsening, sudden onset, strict unilaterality in some cases
	  • Headache may present with or without symptoms of increased intracranial pressure, as worsening by decubitus, sudden onset, strict unilaterality, worsening with Valsalva manoeuvres.
	  • Mild headaches immediately after vaccination are common. Headaches associated with TTS typically start or worsen 3-4 days after vaccination and progressively become very severe
	• Visual disturbances: blurred vision, diplopia, ophthalmodynia
	• Seizures
	• Altered mental status/encephalopathy
	• Decreased level of consciousness/coma
	• Focal neurological symptoms: weakness, sensory abnormalities, gait instability, speech disorders, dysarthria
	• Vomiting with or without nausea.
		• Meningeal irritation signs (Kernig sign, Brudzinski sign, Jolt accentuation sign);
		• Papilledema
		• Focal neurological signs (dysphasia, dysarthria, hemiparesis, hemi-hypoesthesia, hemianopia, aphasia, dysarthria, cranial nerve palsies, ophthalmoplegia, ataxia)
		• Cushing triad may suggest increased intracranial pressure: bradycardia, bradypnea (low respiratory rate) and arterial hypertension.

Abdominal veins (portal, superior mesenteric, splenic, hepatic)	• Abdominal pain • Bloating, nausea, vomiting • Diarrhoea/increased frequency of bowel movements • Constipation • Fever, anorexia • Back pain • Gastrointestinal bleeding	• Portal hypertension signs • Abdominal distension/ascites • Hepatomegaly • Jaundice
Deep vein	• Unilateral or bilateral swelling • Painful and tenderness • Limb swelling • Redness, distended veins	• Homan’s sign (discomfort or pain in the calf, or behind the knee, or involuntary flexion of the knee with forced dorsiflexion of the foot) • Asymmetric limb perimeter circumference
Pulmonary veins or arteries	• Dyspnoea, with sudden onset, shortness of breath, cough • Chest pain, with pleuritic characteristics • Difficulty to perform any physical exercises • Haemoptysis • Syncope, palpitations	• Increased respiratory rate • Tachycardia • Arterial hypotension

Thrombosis location	Symptoms	Signs
Myocardial arteries	● Chest pain, often cruising in nature ● Left arm pain ● Shortness of breath, cyanosis ● Sudden death	● Arrythmias, including asystole
Ischemic stroke/cerebral arteries	● Sudden onset focal neurological symptoms ● Weakness, sensory abnormalities, gait instability, speech disorders, dysarthria ● Abnormal gait	● Focal neurological signs (dysphasia, dysarthria, hemiparesis, hemi-hypoesthesia, hemianopia, aphasia, dysarthria, cranial nerve palsies, ophthalmoplegia, ataxia)
Thrombocytopenia	● Easy bruising	● Petechiae (tiny purple, red, or brown spots on the skin)

Table 3. Laboratory tests for the differential diagnosis of TTS

Laboratory test	TTS	ITP	TTP	DIC
Platelet count	Usually 20–50 × 10^9/L	Variable thrombocytopenia	Variable thrombocytopenia	Moderate to severe thrombocytopenia
Haemoglobin	Normal	Reduced if there is bleeding	Normal	Reduced
Peripheral blood smear	Normal/schistocytes	Normal/large platelets	Schistocytes	Normal/Schistocytes
Microangiopathic haemolytic anaemia/haemolysis markers	No	No	Yes	Yes (depending on the cause of DIC, usually non-diagnostic)
Anti-PF4 antibodies	Yes	No	No	No
PT	Normal or slightly prolonged	Normal	Normal	Prolonged
APTT	Normal or slightly prolonged	Normal	Normal	Prolonged
Fibrinogen (Clauss method, if available)	Initially increased, then decreased	Normal	Normal	Decreased
D-dimer	Increased (>4 times ULN)	Normal	Normal to increased	Increased
Other			ADAMST13 <10%	

TTS: thrombosis with thrombocytopenia syndrome; IPT: immune thrombocytopenic purpura; TTP: thrombotic thrombocytopenic purpura; DIC: disseminated intravascular coagulation; PT: prothrombin time; APTT: activated partial thromboplastin time; ULN: upper limit of normality; ADAMST13: *a disintegrin and metalloproteinase with a thrombospondin type 1 motif, member 13, also known as von Willebrand factor-cleaving protease.*

Table 4. Other conditions that should be included in the differential diagnosis of thrombosis/disseminated thrombosis and thrombocytopenia

Conditions	Key elements
Autoimmune heparin-induced thrombocytopenia	Heparin use during the past 4-30 days.
Atypical haemolytic uremic syndrome	Decreased complement factor H, and decreased complement factors 3 and 4 (C3, C4)
Catastrophic phospholipid antibody syndrome	Positive antiphospholipid antibodies, including cardiolipin antibodies, beta 2-glycoprotein I antibodies or lupus anticoagulant
Haemophagocytic syndrome	Decreased fibrinogen, extremely high concentration of ferritins (>10 000 µg/L) and high concentration of lipids
Drug-induced thrombotic microangiopathy	Prior treatment with **quinine**, ticlopidine (currently infrequently used), clopidogrel, trimethoprim-sulfamethoxazole, alendronate, vancomycin, pentostatin, chemotherapy (mitomycin, cyclosporine, tacrolimus, gemcitabine, carmustine, cytarabine, Taxotere), illicit drugs (cocaine, ecstasy)

Table 5. Specific diagnostic methods that provide results that may be consistent or suggestive of thrombosis/thromboembolism

Specific diagnostic methods consistent with confirmed thrombosis/thromboembolism	• Ultrasound – Doppler • CT scan – contrast/angiography • Magnetic resonance venography or arteriography • Echocardiogram • Perfusion V/Q scan • Conventional angiography/digital subtraction angiography
Procedures consistent with the presence of a thrombus	• Surgery • Thrombectomy
Pathologic examination that confirmed the presence of a thrombus	• Biopsy • Autopsy
Specific diagnostic modalities supportive of the presence of thrombosis/thromboembolism	• Chest radiography • Echocardiogram • CT scan without contrast • D-dimer (elevated above upper limit of normal for age)

Table 6: Optimal and alternative investigational tests used in TTS workups and typical diagnostic findings

Suspected thrombosis	Optimal tests	Alternative tests	Investigational findings

Cerebral venous sinus thrombosis	Contrast brain CT with CT venogram
	MRI brain with MR with contrast/MR venogram
		Non-contrast CT
		Brain MRI with T1, T2, SWI, GRE, time-of-flight venogram for those who cannot receive MR gadolinium contrast
		Fundoscopy
			• **CT/MR venogram**: Filling defect in sinus (empty delta sign)
			• **Non- contrast CT**:
			  ○ Hyperdense vein or sinus (cord sign)
			  ○ Venous infarcts: Parenchymal hypodensity in a non-arterial territory, typically in a parasagittal distribution
			  ○ Brain oedema signs: compression, obliteration of the basal cisterns, effacement of cerebral sulci, midline shift, optic nerve tortuosity, flattening of the posterior sclera, intraocular protrusion of the optic nerve hea
			  ○ Intracranial haemorrhage with early oedema in parasagittal locations
			• **Fundoscopy**: papilledema

Splanchnic thrombosis	CT angiography	Doppler ultrasound	• **Doppler ultrasound**: intraluminal echogenic material, absent signal on colour doppler consistent with thrombosis • **Ultrasound**: Hepatic enlargement, hepatic hypo echogenicity • **Contrast-CT**: filling defects • **Non-contrast CT**: Non-enhanced hypo-attenuation suggesting infarct
Deep vein thrombosis	Doppler ultrasound	MRI	• **Doppler ultrasound**: intraluminal echogenic material, absent signal on colour doppler consistent with thrombosis. Increased flow in superficial veins • **Ultrasound**: increased venous diameter, non-compressible venous segment with intraluminal material, loss of phasic flow on Valsalva manoeuvre or with calf squeeze.
Pulmonary thrombosis	CTPA	Echocardiogram Plain chest radiograph ECG V/Q scan	• **CTPA**: filling defects, thrombus surrounding by rim of contrast • **Echocardiogram**: signs of right ventricular dysfunction, thrombus-in-transit, flattening or dyskinesis of the interventricular septum • **Chest radiography**: Enlarged pulmonary artery, peripheral wedge of airspace opacity, regional oligemia, pleural effusions, enlarged right pulmonary artery, dilated right descending pulmonary artery with sudden cut-off • **ECG**: Tachycardia, S1Q3T3 pattern • **V/Q scan**: even distribution of radionuclide through both lungs (normal ventilation) with perfusion defects
Myocardial infarction	ECG, Echocardiogram, Coronary artery angiography		• **ECG:** ST segment elevation or depression, abnormal Q wave, T wave abnormalities • **Echocardiogram:** left ventricle ejection fraction, wall motion abnormalities
Ischemic stroke	Non-contrast head CT	MRI, perfusion CT, angio-CT, doppler ultrasound	• **CT:** loss of grey-white matter differentiation, hypoattenuation of deep nuclei, cortical hypodensity, gyral effacement

CT: computerized tomography; CTPA: computerized tomography pulmonary angiography; GRE: gradient echo sequences; MR: magnetic resonance; MRI: magnetic resonance imaging; SWI: susceptibility-weighted imaging; V/Q scan: ventilation–perfusion scan.

Table 7: Examples of non-heparin anticoagulant treatments for TTS

(based on available guidelines, indirect evidence from autoimmune heparin-induced thrombocytopenia and the first case series that have been published so far (103-150)).

Drug	Dose and mode of administration	Monitoring	Treatment duration
Argatroban IV	0.5-2 µg/kg/min (continuous IV infusion)	APTT monitoring (therapeutic range: 1.5-3) Argatroban should ideally be monitored by a direct thrombin inhibitor assay, if available, e.g., HEMOCLOT™ as APTT correlates poorly with the Argatroban effect due to the high concentrations of factor VIII	≤14 days
Bivalirudin IV	0.75 mg/kg bolus and continuous IV infusion 1.75 mg/kg/h	APTT monitoring (therapeutic range: 1.5-3)	Up to 3 months or until switch to oral anticoagulation
Fondaparinux SC	5mg/24h (<50kg) 7.5mg/24h (51-99kg) 10 mg/24 h (SC) >100kg	50% dose in case of platelet count <30 000/µL Reduce dosing with severe renal impairment	Up to 3 months or until switch to oral anticoagulation
Danaparoid SC or IV	500 IU/kg /12h 1x2 (<50 kg) or 750 IU/kg / 12h (SC) IV bolus < 60 kg 1500IU 60-75 kg 2250 IU 75-90 kg 3000 IU >90 kg 3750 IU. Infuse: 400 IU/h for 4h->300 IU/h for 4h-maintenance dose 200 IU/h, if GFR (<50ml/min) 150 IU/h and anti-FXa activity target (0.3-0.5 IU/ml, or trough with SC dosing), SC: 750-1250 IU/8-12 h Prophylactic dose: 750 IU / 12h (SC)	Measure anti-FXa activity, if available.	Up to 3 months or until switch to oral anticoagulation
Rivaroxaban PO	15 mg/12 h	To be considered in less severe patients, with no active bleeding and platelet count >50 000/µL	From day 22: 20 mg/24 h once daily Adjust the dose in case of renal impairment
Apixaban PO	10 mg/12 h	To be considered in less severe patients, with no active bleeding and platelet count >50 000/µL	From day 8: 5 mg/12 h Adjust the dose in case of renal impairment
Dabigatran PO	110 mg/12 h or 150 mg/12 h	CSVT or DVT or PE	According to GFR and patient's weight

APTT: activated partial thromboplastin time; GFR: glomerulus filtration rate; IV: intravenous; PO: per os (oral); SC: subcutaneous

Annex 5: Methods for guideline development

Summary

The present guideline has been developed by a group of multidisciplinary experts and members of the WHO secretariat representing different departments. The scientific approach has been based on PICO questions and the existing literature has been systematically searched, reviewed and summarized. The treatment recommendations have been derived through GRADE methodology.

Methodology

On 13April 2021 the COVID-19 subcommittee of the Global Advisory Committee on Vaccine Safety (GACVS) of the World Health Organization (WHO) recommended the creation of an expert group for advice and guidance on the clinical diagnosis and case management of thrombosis with thrombocytopenia syndrome (TTS) following vaccination with a COVID-19 non-replicant adenovirus vector-based vaccine. A Guideline Development group (GDG) comprising 18 expert specialists in internal medicine, epidemiology, haematology, immunology, neurology, neurosurgery and pharmacology, was established, ensuring gender, age and geographic balance, and LMIC representation. Experts and a subject matter expert contracted by WHO had to sign a confidentiality agreement as well as undergo conflict of interest assessment. Experts with conflicts were excluded from the GDG. The WHO secretariat included staff from different departments: Immunizations, Vaccines and Biologicals (IVB), Quality Norms and Standards (QNS), Regulation and Prequalification (RPQ), Mental Health and Substance use (MSD), Noncommunicable Diseases (NCDs) and WHO Health Emergencies Programme (WHE). Key questions were formulated, a literature search was performed and identified studies were reviewed, and distributed to the GDG members, to provide comments and feedback. These were collated in a zero draft by the subject matter expert. The work of the group was coordinated by the Vice Chairperson of the GACVS. The treatment guidelines section was overseen by a Guideline Methodologist. The guideline was developed between Tuesday 27 April and Friday 4 June 2021.

Guideline development

Based on the expertise of members, four subgroups (coordinated by a secretariat focal person) were established to develop four main sections of the document that were merged and handed over to the subject matter expert (SME) (David Garcia Azorin –Hospital Clínico Universitario de Valladolid, Valladolid, Spain) for harmonization of the different sections and presented to the GDG as a single document. The subgroups were:

- Subgroup 1: Epidemiology, risk factors and pathophysiology (Kim Mulholland (GDG), Huyun Tran (GDG), David Garcia Azorin (SME), Adwoa Bentsi-Enchill (Secretariat focal point)
- Subgroup 2: Manifestation of TTS after COVID19 vaccination (Georgy Genov (GDG), Prasanna Kumar (GDG), Viola Macolic Sarinic (GDG), Huyun Tran (GDG), Nicoline Schiess, (Secretariat focal point)
- Subgroup 3: Case definition, clinical features and laboratory diagnosis. (Dale Nordenberg (GDG), Doris Oberle (GDG), Prasanna Kumar (GDG), Riitta Lissala (GDG), Tom Solomon (GDG), Kameshwar Prasad (GDG), Annick Janin (Secretariat focal point)
- Subgroup 4: Clinical case management, including review of drug treatment and other therapeutics Kameshwar Prasad (GDG), D.S Akram (GDG), Imo J. Akpan (GDG), Kiran Thakur (GDG), Ayeesha Kamal (GDG), Ushma Mehta (GDG), Julio Resendiz (GDG), NK Arora (GDG), Claudia Patricia Vaca Gonzalez (GDG), Madhava Rao Balakrishnan (Secretariat focal point)

Full affiliations of all members are provided in the Acknowledgements section.

A timeline for the work and the process were discussed and developed as described below. Then each subsection was developed independently by the respective subgroups, coordinated by a secretariat focal person, and then merged. The merged document was harmonized by the subject matter expert (SME) before being posted on a dedicated SharePoint for review by all the GDG members.

Stage	Milestone
Week 0	Identification of experts, contact and clearance
Week 0	Subgroups defined
Week 1	Literature review to identify published studies by WHO Rapid Review Group Team Members* from WHO's COVID-19 database, PubMed and Global Index Medicus (GIM) (search terms and the flowchart of the identified, screened and included studies are available in Search strategies for bibliographic databases: PubMed, WHO COVID-19 Database and Global Index Medicus). The selected studies were categorized as ***A. Studies on patients vaccinated with a COVID-19 vaccine (40 citations)*** • studies describing clinical characteristics; • studies describing health services; • studies describing physiopathology of TTS; • studies describing other aspects of TTS, e.g., diagnosis, prognosis; • studies describing epidemiology of TTS. ***B. Studies on patients with COVID-19 without vaccination (107 citations)***
Week 2	Research questions developed and focus areas clearly defined by each subgroup
Week 3	First zero draft for each of the four subsections developed
Week 4	Updated literature review by the WHO Rapid Review Group Team Members using a new search strategy based on the comments/ and recommendations from the clinical experts Only studies that included patients having received ≥1 dose of a COVID-19 vaccine and that met the eligibility criteria were included. • studies describing clinical characteristics (12 records) • studies describing treatment (3 records) • studies describing diagnosis of TTS (4 records) • studies describing epidemiology of TTS (5 records) • studies describing prognosis of patients with TTS (2 records) • studies describing physiopathology of TTS (1 record) • studies describing health services (1 record)
Week 4	All subgroups submit a zero draft with feedback from the meeting on 17 May
Week 5	Zero draft harmonized and posted on SharePoint for feedback from all GDG members
Week 6	Expert discussion

*WHO Science Division

A rapid review of the literature, based on the key questions, was performed on 6 May 2021 and updated on 22 May 2021 to identify existing publications on TTS in patients with COVID-19 and those who had been vaccinated with a COVID-19 vaccine. The search strategies were developed by members of the WHO secretariat. (The search terms are available in Search strategies for bibliographic databases: PubMed, WHO COVID-19 Database and Global Index Medicus). Three electronic databases were searched, WHO's COVID-19 database, PubMed and the Global Index Medicus (GIM) database. Screening of these results to select potential studies was performed by two reviewers, members of the WHO secretariat.

The first strategy, which included COVID-19 populations with and without vaccination, retrieved 404 citations. A total of 257 were excluded by screening the titles and abstracts. After the second screen of the full text, 40 studies in COVID-19-vaccinated populations and 107 studies in non-vaccinated COVID-19 populations.

The second search strategy, which only included COVID-19-vaccinated populations, retrieved 381 citations. A total of 353 were excluded after screening the titles and abstracts. After the second screen of the full text, 28 were included.

In total, 785 citations were retrieved. References from the included studies were also reviewed and the 'similar articles' function in PubMed was used to identify additional records, leading to a total of 804 citations retrieved that were screened by the subject matter expert, who reviewed and extracted the information and summarized the evidence. The documents created by the experts were collated, and all the comments and changes were tracked.

Treatment guidelines

Rapid review for treatment

For the treatment guidelines, two PICO questions were formulated:

1) Should heparin-based anticoagulants (I) versus no heparin or other anticoagulants (C) be administered to individuals diagnosed with TTS following COVID-19 vaccination (P)?
2) Should specific drugs or procedures (intravenous immunoglobulin (IVIG), steroids, anticoagulants excluding heparin-based anticoagulants, blood products transfusion) (I) versus none or other drugs or procedures (C) be administered to individuals who present with TTS following COVID-19 vaccination (P)?

The outcomes of interests were: recovery, death and intracranial haemorrhage.

The risk of bias in the treatment guidelines was assessed for each study included using the GRADE Handbook1. Biases specific to observational studies were analysed, including failure to develop and apply appropriate eligibility criteria, presence of control populations, flawed measurement of both exposure and outcome, failure to adequately control confounding and incomplete follow-up. The data from the included studies were analysed descriptively and the certainty of evidence, which included assessment of the limitations of study design or execution, inconsistency of results, indirectness of evidence, imprecision and publication bias, was evaluated using GRADEPro2.

Three outcomes were considered to be critical; according to the GRADE approach (i.e., most important to the patient who will be affected by the recommendations):

1) recovery, defined as the explicit mention of discharge of the patient in a recovered status;
2) mortality, including all-cause mortality and not just treatment-specific mortality; and
3) intracranial haemorrhage.

Patients with uncertain outcomes were not classified as recovery or death. Studies and patients in the studies with valid information for each of the different outcomes were analysed. The outcome rates were calculated for all patients in the individual studies regardless of treatment received and only for patients who had received the treatment of interest. The outcome rates for all patients were calculated by dividing the total number of patients with the outcome by the total number of patients included in each study. The outcome rates for each specific treatment were calculated by dividing the total of patients who received the treatment with outcome of interest by the total number of patients in the studies that provided valid data for the treatment. Only the data available in the publications were analysed, and no attempt to find missing information was made. Summary of findings (SoF) are presented in GRADE Evidence Profile Tables (Evidence tables)

Recommendation formulation

Two virtual meetings were held via Zoom on 7 and 8 June 2021. The meetings were chaired by a member of the GDG approved by the group in advance of the first meeting. An experienced guidelines methodologist facilitated the evidence-to-decision-making (EtD) process as described in the WHO Handbook for Guideline Development.3 Although the original aim was to base all decisions on a consensus, at the beginning of the meeting the GDG members agreed that if any decisions required a vote, the vote would need to be carried by a 60% majority.

The GDG reviewed the evidence contained in the systematic reviews and in the GRADE EtD tables, and discussed the topics under consideration, facilitated by the guideline methodologist. The GRADE EtD communicate the GDG's judgements about several factors as well as their judgements on the benefits and harms and their certainty. These factors include:

- the values and preferences of end-users;
- resource use, including costs and cost-effectiveness;
- potential impact on human rights and equity; and
- acceptability and feasibility.

1 GRADE Handbook, available from https://gdt.gradepro.org/app/handbook/handbook.html#h.ged5uqebmir9. Accessed 30 May 2021.

2 GRADEpro GDT, available from https://gradepro.org/. Accessed 28 June 2021.

3 World Health Organization. WHO handbook for guideline development – 2nd ed, available from https://www.who.int/publications/i/item/9789241548960. Accessed 28 June 2021.

During the virtual meets, care was taken to ensure that all members of the GDG gave their responses through regular unofficial votes and use of the chat function to gain an initial hint about the GDG members' views on the direction of each recommendation (i.e., for or against an intervention), and on the strength of each recommendation (strong or conditional). The methodologist also asked participants to raise their hands to show support for each separate option. Although there was no formal vote system, this approached enabled the methodologist and the chair to assess the distribution of opinions and to prompt further discussion with the aim of reaching consensus.

The strength of the recommendation was established by considering both the certainty of the evidence and the availability and feasibility of the interventions. A recommendation **for** an intervention indicates that it should be implemented and a recommendation **against** an intervention indicates that it should not be implemented. The strength of a recommendation, which was either 'strong' or 'conditional', reflects the degree of confidence the GDG had that the desirable effects of the recommendation outweighed the undesirable effects for a positive recommendation, or the reverse (that the undesirable effects outweigh the desirable effects) for a negative recommendation.

The final wording of each recommendation, including an indication of its direction and strength, was confirmed by consensus between all GDG members and each member of the GDG was asked to express their decision verbally. The judgements made by the GDG related to each recommendation are summarized in the section Evidence to decision tables framework.

As new data continues to emerge, these observations and recommendations may change. Therefore, these guidelines have a shelf-life of 3-6 months and clinicians should be aware of this.

External review

Seven external reviewers (from Argentina, China, Ghana, Iraq, Morocco, Myanmar and Russia), were invited to review the pre-final version of the guidelines to ensure readability and geographic relevance. All experts signed a confidentiality agreement and were assessed for any conflict of interest.

Limitations

The main limitations of the present guidelines are related to the quality and quantity of the existing evidence., often based on single cases or case series. The degree of certainty was affected by the presence of biases that should be better managed in future studies. In addition, the number of patients represented in the analysis of the different treatment modalities was not balanced and in some cases was significantly low. Evidence regarding some treatment options for LMIC settings was also limited and should be properly evaluated, ideally with well-designed observational studies or with randomized-controlled trials.

The GDG did not include patient representatives, which should be addressed in future updates.

Annex 6: Supplementary information on literature review methods and results

Thrombosis with thrombocytopenia syndrome (TTS) in the context of post-COVID-19 vaccination

Rapid Review Group Team Members: Mónica Ballesteros, Jesús López Alcalde, Kavita Kothari.
Last Date of Search: 22 May 2021
Date of Report: 23 May 2021

1. Objective:

To update the evidence available on TTS in the context of post-COVID-19 vaccination.

2. PICOs:

The unique component of PICO structure included was population because the clinical questions require a comprehensive literature search strategy.

Population (in the context of post COVID-19 vaccination): Adult population who have received a COVID-19 vaccine with clinical signs and symptoms of thrombosis and associated novel thrombocytopenia within 4 to 28 days of vaccination. In this updated version, we have included the following terms without being associated with a new episode of thrombocytopenia: cerebral venous sinus thrombosis (CVST), Splanchnic vein thrombosis (intra-abdominal), deep vein thrombosis (DVT), disseminated intravascular coagulation (DIC), pulmonary embolism (PE), stroke and myocardial infarction.

3. Methods

3.1 Search methods for study identification

This updated search strategy was developed by a WHO librarian taking into account comments and recommendations from clinical experts. More details can be found in the section Search strategies for bibliographic databases: PubMed, WHO COVID-19 Database and Global Index Medicus.

3.2 Electronic databases:

- WHO COVID-19 database
- PubMed
- Global Index Medicus

3.3 Methods for screening search results

The screening was performed by two reviewers (MB, JLA), who classified the results according to the type of data present in the publication (Table S1).

Table S1. Classification of studies by data type

Data type	Definition
Epidemiology	Study describes burden of disease or describes the distribution of disease
Mechanism	The study describes the possible underlying causes of TTS or its physiopathology
Clinical characteristics	Study describes clinical characteristics of inpatients or outpatients
Diagnosis	Study describes clinical signs and symptoms, laboratory tests, imaging examinations, or any other test to establish the diagnosis of TTS
Prognosis	The study provides data on the predicted prognosis of an outcome of interest
Treatment	The study describes the assessment of a treatment or management intervention for TTS (e.g., treatment, maximize comfort, alleviate symptoms or side effects).
Health services	The study describes the assessment of the delivery, processes, management, organization, or financing of healthcare.

Selected PICO questions used in the rapid review of evidence

Selected PICO questions used in the rapid review of evidence on TTS indications and treatment in the context of post-COVID-19 vaccination: a rapid review of evidence. Search Strategy Development.

05 May 2021

- What is the global aetiology, baseline epidemiology of TTS in adults post-COVID-19 vaccination?

- What is the clinical presentation of TTS in patients post-COVID-19 vaccination?

- Is an internationally agreed case definition for patients presenting with TTS post vaccination emerging in the literature? What definitions are currently available, including clinical features and laboratory diagnosis?

- **What algorithm is most suitable for triaging and case management of patients with Covid-19 vaccine-related TTS and thrombosis/thromboembolism after vaccination with an adenovirus vector-based COVID-19 vaccine?**

- The main component of the PICO question was population, because the clinical questions required a comprehensive literature search strategy.

- The second search strategy included the following terms: Cerebral Venous Sinus Thrombosis (CVST), splanchnic vein thrombosis (intra-abdominal), deep vein thrombosis (DVT), disseminated intravascular coagulation (DIC), pulmonary embolism (PE), stroke and myocardial infarction.

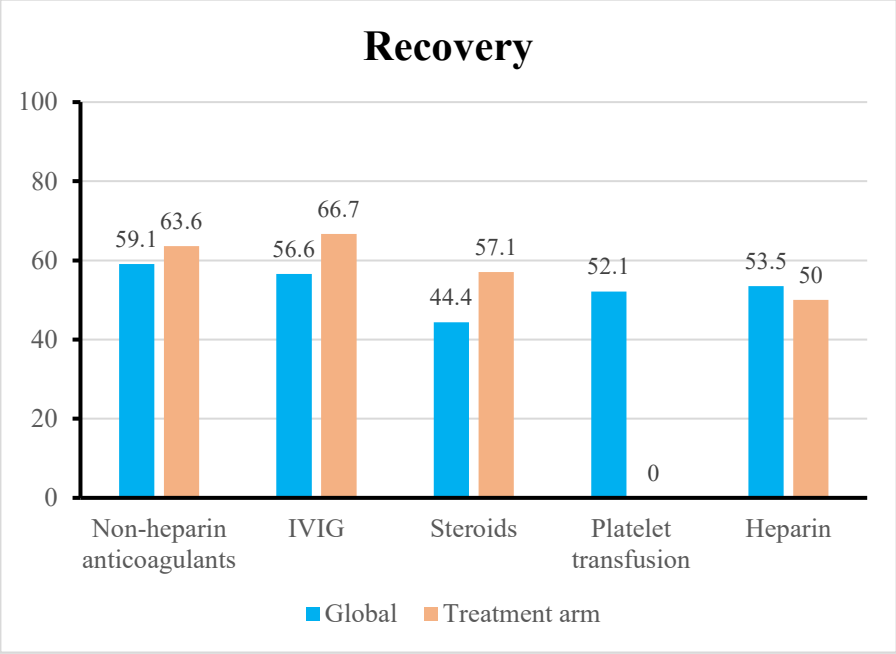
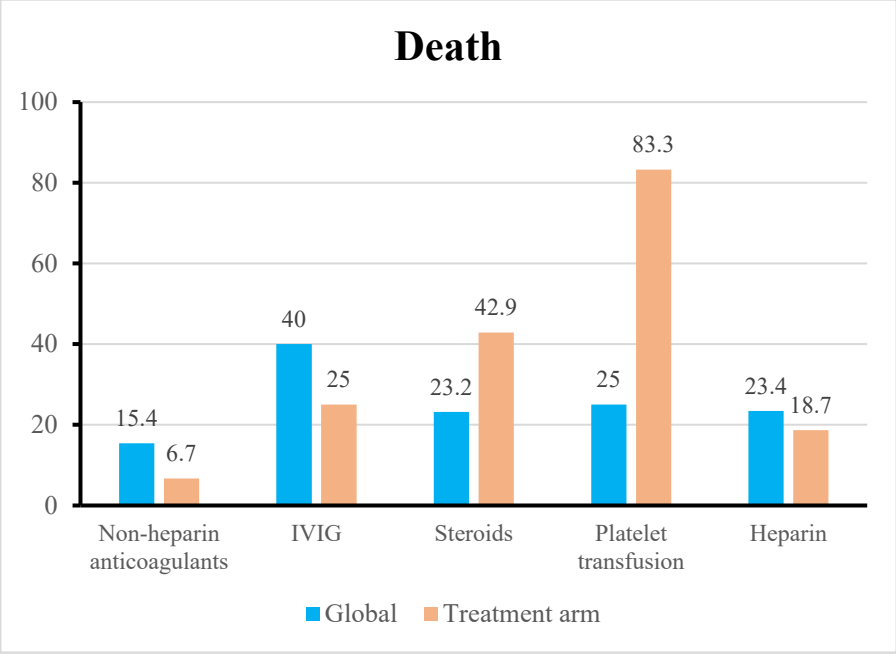
Flowchart of the identified, screened and included studies.



Evidence to decision tables framework[4]



Question	Judgement
1. Is the problem a priority?	No, Yes, Varies, Uncertain
2. How substantial are the Benefits?	Large, Moderate, Small, Trivial, Varies, Uncertain
3. How substantial are the Harms?	Large, Moderate, Small, Trivial, Varies, Uncertain
4. What is the overall certainty of the evidence?	High, Moderate, Low, Very Low
5. What is the balance between benefits and harms?	Favours intervention, Against intervention
6. How do people value treatment for TTS?	Degree of Variability or Uncertainty
7. How large are the resource requirements (costs)?	Large, Moderate, Negligible costs or savings
8. What is the certainty of the evidence for the costs?	High, Moderate, Low, Very Low
9. Are treatments for TTS cost-effective?	Favours intervention, Against intervention
10. What would the impact be on health equity?	Reduced, Increased, Varies, Uncertain
11. Are treatments for TTS acceptable to all stakeholders?	No, Yes, Varies, Uncertain
12. Are treatments for TTS feasible to implement?	No, Yes, Varies, Uncertain

Summary of findings

Drug	Number of studies	Global rate	Number of studies with valid data	Treated rate
Non-heparin anticoagulants	6	65/110	5	28/44
IVIG	7	64/113	4	6/9
Steroids	4	4/9	4	4/7
Platelet transfusion	5	25/48	3	0/6
Heparin	8	68/127	4	7/14

Drug	Number of studies	Global rate	Number of studies with valid data	Treated rate
Non-heparin anticoagulants	6	17/110	4	1/15
IVIG	8	22/55	5	4/16
Steroids	6	19/82	4	3/7
Platelet transfusion	5	12/48	3	5/6
Heparin	9	30/128	5	6/32

Drug	Number of studies	Global rate	Number of studies with valid data	Treated rate
Non-heparin anticoagulants	5	20/49	4	7/18
IVIG	7	25/54	5	5/10
Steroids	5	12/21	4	3/7
Platelet transfusion	5	23/48	3	4/6
Heparin	8	27/67	6	7/21

Possible research gaps for future prophylactic management:

- Should hydroxychloroquine be used in patients having TTS?
- Genetic markers for 'at risk' patients.
- Risk factors for TTS and the role of other thrombotic risk factors.
- Role of point-of-care devices and diagnostics like the thromboelastography (TEG), that gives an indication of fibrinogen levels, or point-of-care ultrasound (POCUS) which would enable frequent testing of coagulation/bleeding profiles.
- Duration and persistence of anti-PF4 antibodies in COVID-19 vaccine-related TTS. In patients with HIT, the median time to antibody clearance is 50 days for platelet activation assays and 85 to 90 days by immunoassays. Immunoassays may remain positive in ~35% of patients for up to 1 year, with levels decreasing over time. Hence patients may be at risk for thrombosis because of circulating anti-PF4/heparin antibodies.
- Duration of immunosuppressive treatments.
- Management of treatment-resistant cases.
- Possibility of organ donation in TTS-deceased patients.
- Consider rapid literature search to identify the most common cause of hypercoagulability.
- Research on increase in hypercoagulopathy in patients with a previous of COVID-19 infection, given any COVID-19 vaccine.
- Randomized controlled trials (RCTs) to determine the safety of proposed anticoagulation, alternate anticoagulants and the role for anti-platelets, such as Ticagrelor, in patient management.
- RCTs to evaluate the efficacy of using new oral anticoagulants (NOACS) as prophylaxis in patients recovering from TTS after COVID-19 vaccine? (If anti-PF 4 antibodies are present).

Evidence tables

Question: **Heparin compared with no heparin or other anticoagulants for patients diagnosed with TTS following COVID-19 vaccination Outcome: death (all-cause)**

Certainty assessment							Impact	Certainty	Importance
№ of studies	Study design	Risk of bias	Inconsistency	Indirectness	Imprecision	Other considerations			
Death (All-cause)									
9	observational studies	very serious [a]	serious [b]	not serious	very serious [c]	publication bias strongly suspected [d]	There were 9 studies providing valid data [7 case series and 2 case reports], including 128 patients, 46 of them treated with heparin. Global death rate was 30/128 (23.4%). Information about death in patients treated with heparin was available in 5 studies including 32 patients. Death rate in patients treated with heparin was 6/32 (18.7%).	⨁◯◯◯ VERY LOW	CRITICAL

Explanations

a. Selection bias: Fatal cases were more likely to be quickly published as case reports (range 5-8 days) than large case series. Not all confounding factors influencing the prognosis were analyzed (age, time between symptom onset and treatment, other treatments, presence of multiple organ thrombosis), incomplete follow-up in most cases

b. The dose was not described in studies. Duration of follow-up was different. There is heterogeneity clinically (different treatment paradigms, location and severity of thromboses) and methodologically between studies, and there is limited certainty regarding that the differences explain the observed differences in effects.

c. The total number of patients included is less than the number of patients that should be included according to a sample size calculation for a single adequately powered trial

d. Outcome was not available at the moment of publication in many cases.

Question: **Heparin compared with no heparin or other anticoagulants for patients diagnosed with TTS following COVID-19 vaccination** **Outcome: intracranial haemorrhage**

Certainty assessment							Impact	Certainty	Importance
№ of studies	Study design	Risk of bias	Inconsistency	Indirectness	Imprecision	Other considerations			
Intracranial haemorrhage									
8	observational studies	very serious [a]	serious [b]	not serious	very serious [c]	publication bias strongly suspected [d]	There were 8 studies providing valid data [6 case series and 2 case reports], including 67 patients, 34 of them treated with heparin. Global intracranial hemorrhage rate was 27/67 (40.3%). Information about intracranial hemorrhage rate in patients treated with heparin was available in 6 studies, and was 7/21 (33.3%).	⨁◯◯◯ VERY LOW	CRITICAL

Explanations

a. Selection bias: Fatal cases were more likely to be quickly published as case reports (range 5-8 days) than large case series. Not all confounding factors influencing the prognosis were analyzed (age, time between symptom onset and treatment, other treatments, presence of multiple organ thrombosis), incomplete follow-up in most cases

b. The dose was not described in studies. Duration of follow-up was different. There is heterogeneity clinically (different treatment paradigms, location and severity of thromboses) and methodologically between studies, and there is limited certainty regarding that the differences explain the observed differences in effects.

c. The total number of patients included is less than the number of patients that should be included according to a sample size calculation for a single adequately powered trial

d. Outcome was not available at the moment of publication in many cases.

Question: **IVIG compared with no treatment or other drugs or procedures for patients diagnosed with TTS following COVID-19 vaccination – Outcome: intracranial haemorrhage**

Certainty assessment							Impact	Certainty	Importance
№ of studies	Study design	Risk of bias	Inconsistency	Indirectness	Imprecision	Other considerations			
Intracranial haemorrhage									
7	observational studies	very serious [a]	serious [b]	not serious	very serious [c]	publication bias strongly suspected [d]	There were 7 studies reporting use of IVIG, [3 case reports and 4 case series], including 54 patients, 35 of them treated with IVIG. Global haemorrhage rate was 25/54 (46.3%). Information about haemorrhage in patients treated with IVIG was available in 5 studies including 10 patients. Haemorrhage rate in patients treated with IVIG was 5/10 (50.0%).	⨁◯◯◯ VERY LOW	CRITICAL

Xeroderma Pigmentosum and Bone Marrow Aplasia: A Rare Association

Abstract

Xeroderma pigmentosum (XP) is a rare autosomal recessive disorder characterized by hypersensitivity to ultraviolet rays and predisposition to cutaneous malignancies. Hematological disorders associated with XP include myelodysplastic syndrome and acute leukemia. We report a 7-year-old child with XP along with squamous cell carcinoma and bone marrow aplasia.

Keywords: *Aplastic anemia, pancytopenia, squamous cell carcinoma, xeroderma pigmentosum*

Introduction

Xeroderma pigmentosum (XP) is a rare inherited autosomal recessive disorder characterized by extreme hypersensitivity to ultraviolet rays predisposing to early cutaneous malignancies. Other abnormalities include neurological and ocular diseases.[1,2]

The incidence of XP varies across geographic areas, one in one hundred thousand in Europe and the US to one in 22,000 in Japan. The incidence in India has not been studied so far but is believed to be less when compared to the Western countries.[2,3]

There is no sex predilection. Pathophysiology of this inherited disorder is the defect in the nucleotide excision repair mechanism, and hence, the DNA damage caused by ultraviolet (UV) rays is unrepaired resulting in genomic instability which leads to predisposition to oculo-cutaneous malignancies as well as other internal malignancies. The other manifestations of XP include hyperpigmentation, premature aging, and neurological dysfunction. Photosensitivity and burning sensation after exposure to the sun precede the dryness (xeroderma) and pigmentation of skin and ocular manifestations such as photophobia and keratitis.[4,5]

Hematological abnormalities reported include myelodysplastic syndrome, which is characterized by refractory anemia with excess blast cells and leukemias.[6] A single case of XP in association with bone marrow failure has also been reported.[7]

Bone marrow aplasia in XP is very rare when compared to its presence in other DNA repair mechanism defects such as Fanconi anemia, Bloom syndrome, and ataxia telangiectasia.

We present here an interesting case of XP associated with bone marrow aplasia.

Case Report

A 7-year-old male child, a known case of XP, presented with a swelling in the right infraorbital region of short duration associated with pain and discharge from the lesion.

The diagnosis of XP was made based on the clinical findings in the previous admission when the child presented with dermatological symptoms, photosensitivity, itching over the face, and hyperpigmentation. Pigmentation progressed with age. Erythematous scaly plaques with pigmented macules were seen over the areas exposed to the sun. The child was born of a nonconsanguinous marriage and attained normal developmental milestones. There were no neurological manifestations.

In the current admission, complete hemogram showed pancytopenia (white blood cell count - 3.5 × 10^3/μl, red blood cell count - 1.01 × 10^6/μl, and platelet count - 21 × 10^3/μl). Peripheral smear revealed a macrocytic blood picture. There were no atypical cells in the smear [Figure 1].

Bone marrow aspiration was done. The smears were paucicellular with adipocyte fragments and scant hematopoietic elements. There were no features of dyspoiesis in any lineage [Figure 2].

Bone marrow trephine was markedly hypocellular with fatty marrow and minimal hematopoietic tissue. There was no evidence of an infiltrative disease [Figure 3].

Wide-local excision of the infraorbital swelling showed a moderately differentiated squamous cell carcinoma [Figure 4].

Discussion

XP is a rare genodermatosis caused by defects in the normal repair of DNA damaged by exposure to sunlight. There are eight complementation groups of XP (XP-A to G) caused by defective nucleotide excision repair, corresponding to mutations in the genes encoding XPA, XPB, XPC, XPD, XPE, XPF, XPG, and XP dominant. The incidence and the age at presentation vary, ranging from early infancy to adulthood. XP has been reported to be common with consanguineous marriages.[8]

There are a 1000-fold increased risk of development of cutaneous malignancies, especially in those diagnosed under the age of 2 years and a 10-20-fold increased risk of developing noncutaneous malignancies.[9]

The commonly reported cutaneous malignancies include squamous cell carcinoma followed by melanoma and basal cell carcinoma.

Our patient had squamous cell carcinoma of the face.

In addition, the patient had pancytopenia which suggested the possibility of an infiltrative disorder of bone marrow. Bone marrow metastasis of malignant melanoma presenting as pancytopenia has already been reported in cases with XP.[10] In our patient, bone marrow aspirate and trephine were consistent with aplastic anemia.

Review of the literature revealed that the common hematological disorders associated with XP are myelodysplastic syndrome and acute myeloid leukemia.[6]

Marrow aplasia in XP is very rare and has been reported so far in only a single case of XP.[7] However, marrow

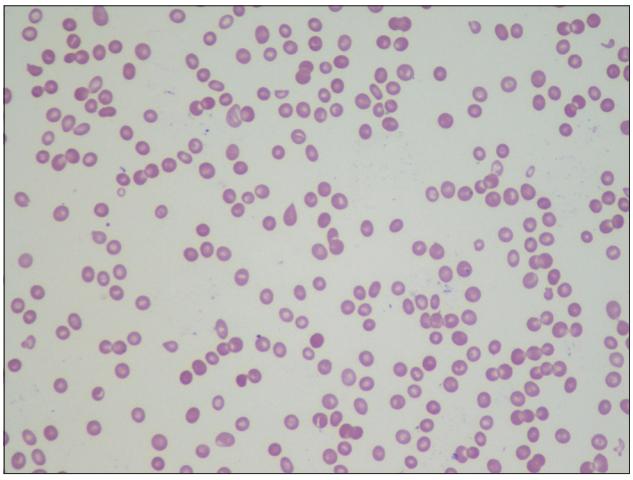

Figure 1: Peripheral smear showing pancytopenia (×40)

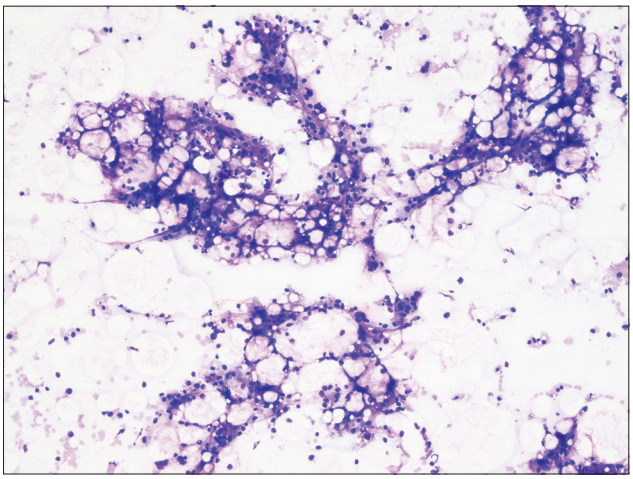

Figure 2: Bone marrow aspirate showing hypocellular marrow particles (×10)

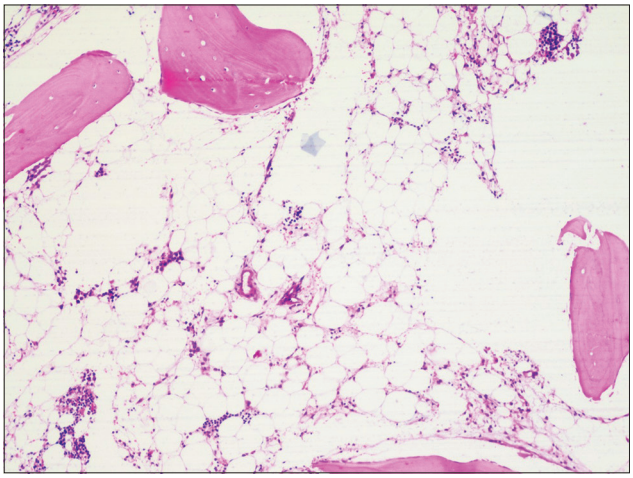

Figure 3: Bone marrow trephine showing fatty marrow (×10)

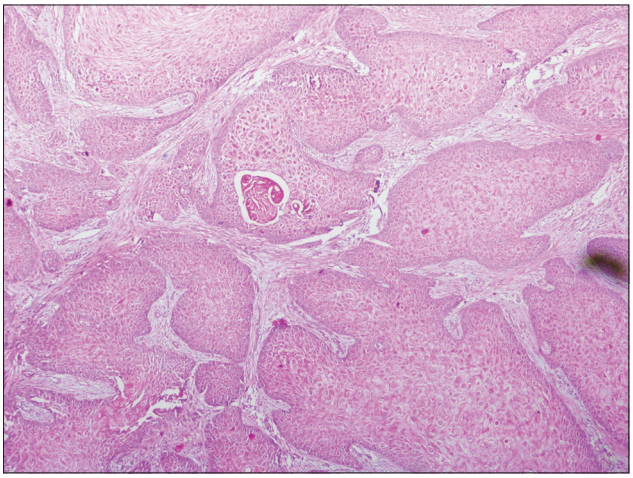

Figure 4: Biopsy showing squamous cell carcinoma (×10)

aplasia is quite common in other inherited DNA damage repair diseases such as Fanconi anemia. The patient did not have any features of Fanconi anemia. Even though skin hyperpigmentation has been reported in Fanconi anemia, it is not restricted to sun-exposed areas unlike in XP.

Aplastic anemia in children is generally attributed to drugs and viral infections. However, 90% of these cases are idiopathic in nature.[7]

The association of XP with leukemias and other internal malignancies shows that DNA damage repair mechanism is essential in repairing non-UV-mediated mutagenesis as well.

The association of aplastic anemia and XP as a new variant of this disease has not yet been proven.[7] The clonal evolution of aplastic anemia to leukemia has been reported.[7] Considering the foregoing discussion, it is tempting to suggest that this patient under reference can be considered to be at the increased risk of developing leukemia.

Background: Human resources are essential to the sustainability and scalability of health interventions. A barrier to global cancer efforts has been the scarcity of trained pediatric hematology/oncology (PHO) professionals in low- and middle-income countries (LMIC). Studies highlight this inequity and the need to develop a global PHO workforce through allocation of financial resources, strengthening of healthcare infrastructure, and development of innovative training programs. Ethiopia is the second most populous country in Africa. Because of recent reduction in infant mortality and improved treatment of Malaria and HIV in Ethiopia, non-communicable diseases contribute an increasing proportion of childhood mortality.

The annual incidence of pediatric cancer in Ethiopia is estimated to be 6000-8000 cases. Prior to 2013, no dedicated PHO programs existed in Ethiopia, and there was no formal process for training local physicians in PHO. The following intervention aimed to increase local capacity for treating childhood cancer through the creation of a formal two-year PHO fellowship.

Strategy: The PHO fellowship program was created by The Aslan Project, a US non-profit led by a group of experts in PHO, pediatric oncology nursing, and pathology with experience practicing in LMIC, in collaboration with Addis Ababa University (AAU). The goal was to provide a robust educational experience for fellows within the existing resource-constrained clinical environment. Tikur Anbessa Specialized Hospital (TASH) was the initial clinical site (in 2013) for the training program with a second at Jimma University Medical Center (JUMC) in 2016. An Aslan clinical director was present throughout the first year at each location. Visiting faculty from the US and Canada provided clinical supervision, on-site didactics, and professional mentorship. The second year of training included a six-month rotation at a high-functioning cancer institution in India. Fellows were expected to complete a scholarly activity, pass a certification exam, and serve as pediatric hematologist-oncologists in Ethiopia for a minimum of two years following training.

Outcomes: Since 2013, four physicians completed PHO fellowship based in Ethiopia, with extensive support of local healthcare leadership and visiting faculty. One additional fellow left training prior to completion and one fellow currently is in training. Twenty-three faculty members from 18 Universities made 51 trips to Ethiopia for onsite training of fellows from 2013-2019. Each fellow completed a rotation in India in his/her second year (Tata Memorial Hospital, Mumbai, or TMC Kolkata). Fellowship projects included a comprehensive pediatric cancer unit assessment, safe chemotherapy practices, and the role of diagnostic pathology. The four subspecialty-trained physicians have remained local, two at TASH, one at JUMC, and one returned to Gertrude's Children's Hospital in Nairobi, Kenya. JUMC now supports a 22 bed PHO unit running at 90% capacity with over 300 new diagnoses since August 2016. TASH supports a 26 bed inpatient unit and 16 additional inpatient beds at a nearby oncology center, treating over 600 new patients annually. The fellowship structure has succeeded in training subspecialty physicians to establish PHO care in Ethiopia.

Discussion: Developing specialized care in LMIC requires a multifaceted approach, including nursing training, social support, health system buy-in, diagnostic expertise and facility, pharmacy services, and subspecialty physicians. Focusing on physician training for PHO in Ethiopia, we designed a training structure and curriculum to 1) teach resource appropriate medical care, 2) provide sustained clinical mentorship, 3) develop health system leadership skills, and 4) retain physicians to support local pediatric oncology units. Onsite training by visiting faculty was augmented by sending fellows to a mature, middle-income country program and the support of full-time clinical faculty/mentorship for a large portion of the

program. Challenges included fellow recruitment, pathologic accuracy, chemotherapy access, nutritional support, and treatment retention. Formal subspecialty PHO training can be implemented in LMIC without established subspecialty physicians, but requires ongoing commitment of administrators, visiting faculty, local universities, and a multidisciplinary team of health professionals.

Abstract

Purpose: To study the impact of an early clinical exposure program designed to provide a wide variety (cognitive, affective and psychomotor) of learning experiences for the preclinical year students.
Method: One hundred and fifty preclinical students were posted in small groups to selected departments – Transfusion medicine, Catheterization lab, Simulation lab, Radiology, Neurology, Nephrology, Respiratory medicine and General surgery. Each student had atleast ten hours of clinical exposure under this program. The program was evaluated through a series of pre and post-test questionnaires, which were designed based on the learning objectives of each session. Students who wished to participate in the program evaluation gave informed consent, took up the pre / post test and were also asked to give their written open comments about the program.
Results: There was a significant increase in the post-test scores (ranging from 9.14 ± 2.67 to 36.65 ± 6.62) when compared to the pre-test scores (ranging from 7.94 ± 2.31 to 28.69 ± 6.11) for all the sessions (p value < 0.001, $n = 144$). Analysis of the open feedback showed that the program had significant impact on the cognitive, psychomotor and affective domains. "Application of basic sciences in clinical practice", "motivation to learn", "got familiar with various specialties", "insight about what the patient undergoes" were the themes identified from the open comments.

Conclusion: The innovative use of early clinical exposure program to teach/learn clinical skills like phlebotomy and Basic Life Support had been well appreciated by the students. The present design involving a variety of learning experiences has been successful in introducing the various dimensions of medical profession like scientific, ethical, interpersonal, professional and social to the new entrants in addition to enhancing their motivation to learn.

Keywords: Attitude; Learning; Simulation lab; Medical education; Curriculum

1. Introduction

In India, students enter medical schools at an early age with little priming towards the profession. Entry of students in most of the medical colleges is entirely based on their academic performance with no weighting for humanistic attitude and communication skills.[1,2] Due to lack of adequate exposure, most students do not realize what to expect in the medical profession. A few enter the medical college purely due to parental pressure.[3] Large classes, intense competition, exploding vocabulary and voluminous content delivered over a short time are some of the challenges faced by the first year MBBS students.[3,4] Insufficient level of guidance and problems pertaining to transition from school to college life can also be included to this list of problems faced by the students during this period. Some students find the abrupt shift of medium of instruction from vernacular language to English difficult to cope. All these, along with the traditional curriculum, where the students are engaged in long hours of classroom and laboratory teaching with no exposure to the clinical setup, plays a major role in dousing the enthusiasm of the upcoming doctor. Under these circumstances, students often find their preclinical year to be tough, dreary and most importantly, they fail to understand the relevance of basic sciences in the clinical setting.

There has been an urgent call for curricular reforms with emphasis towards vertical and horizontal integration and competency based training.[5] Many parts of the world have responded to these needs by shifting away from discipline-based curriculum. In line with these changes, Medical Council of India (MCI) developed the 'Vision 2015' document. MCI vision 2015 aims to produce a new generation of medical graduates of global standards through curricular reforms. "The roles of this new age doctor are recognized as clinician, communicator, life-long learner, team leader and professional".[6] Required curricular changes begin early in the form of a foundation course; early clinical exposure; properly designed integrated teaching and programs to develop the correct attitude and communication skills (ATCOM module).[6]

Early clinical exposure (ECE) needs to be a coordinated effort by the preclinical, paraclinical and clinical faculty. If implemented effectively, it has the potential to improve motivation for learning and promote deep learning, better understanding and longer retention of the knowledge. It can facilitate the students to understand the application of basic sciences in clinical practice and aid in effective learning of clinical skills. It could also serve as a platform for students to improve their communication skills and get initiated into inculcating professionalism at a very early and impressionable stage of their medical education.[7] Above all, it provides an opportunity for them to see the illness from the patient's perspective. All this can foster the development of a holistic doctor who will be competent, communicative, humanistic and empathetic towards the patients.

To offer this experience, 'Clinical observership' program was started in PSG Institute of Medical Sciences and Research (PSGIMSR) in the year 2000. In this program, the first year MBBS students had the opportunity to spend half a day in the following selected specialties in small groups: Cardiology, Gastroenterology, Radiology, Nephrology and Transfusion medicine. This initiative was highly appreciated by the students.[8] This program has now been modified and expanded to include more departments and implemented readily to suit the mandates from MCI as early clinical exposure. The aim of this study was to evaluate the impact of an organized program of early clinical exposure for the preclinical students in enhancing their motivation to learn basic science in relevance to clinical medicine.

2. Methods

2.1. Participants

One hundred and fifty first year MBBS students participated in early clinical exposure program conducted in the year 2015–16. Students were divided into

three batches (A, B, C) based on their roll numbers. Each batch was further divided into five small teams comprising of ten students. Each team spent an hour (from 4 pm to 5 pm) in the clinical departments every day of the week in turns, ensuring that there were no more than ten students in an ECE session. Last hour of the working day was selected for this program without interfering the conventional teaching sessions. Keeping the program at the end of the day also gave an opportunity to extend the session beyond the allotted hour when required.

Though attendance for the ECE program was compulsory as per MCI and University guidelines, participating in the program evaluation and giving feedback was strictly on voluntary basis. Informed consent was obtained from the participants. The study was approved by the Institutional Human Ethics committee.

2.2. Materials

The program was implemented in two cycles of three weeks duration. Five clinical departments were covered in each cycle. The first cycle of ECE sessions were conducted in the months of Nov-Dec 2015 and included rotations in Clinical simulation laboratory (for phlebotomy training), blood bank, and departments of neurology, radiology and surgery. During the second rotation of the program, which was conducted in March 2016, the students were posted once again in the Clinical simulation laboratory (for Basic Life Support training) and Radiology in addition to the Departments of Nephrology, Respiratory medicine and Cardiology (Catheterization laboratory).

Selection of departments was done with an intention to expose the students to a variety of learning experiences involving all the three domains of learning- cognitive, psychomotor and affective. The program also included super specialty departments like Cardiology, Nephrology and Neurology for which the students would not have the opportunity to be exposed in their regular curriculum. The departments to which the students were posted in each rotation were selected based on the subject matter covered in basic sciences until the time of the program. For example, the first rotation concurred with the completion of lower limb in Anatomy, hence visiting the Surgery department to see a case of varicose veins/ peripheral vascular disease was more pertinent than visiting Catheterization lab. Catheterization lab was reserved for the second rotation, which was scheduled when the students were learning or just finished learning thorax and abdomen in Anatomy.

Table 1
Comparison of pretest and posttest scores of ECE sessions.

ECE Session (Maximum score)	Pretest score ($n=144$)	Post test score ($n=144$)	P value
Radiology (50)	28.69 ± 6.11	36.65 ± 6.62	< 0.001
Neurology (50)	21.44 ± 5.77	30.14 ± 7.55	< 0.001
Surgery (50)	22.57 ± 5.93	34.31 ± 7.76	< 0.001
Simulation Lab (Phlebotomy) (30)	15.54 ± 4.75	24.06 ± 4.60	< 0.001
Blood Bank (15)	7.94 ± 2.31	9.14 ± 2.67	< 0.001
Nephrology (40)	16.33 ± 2.84	28.51 ± 5.11	< 0.001
Respiratory Medicine (35)	15.3 ± 12.59	23.27 ± 4.74	< 0.001
Simulation lab (Basic Life Support) (40)	16.11 ± 5.87	29.19 ± 5.93	< 0.001
Cardiology (40)	18.08 ± 5.44	29 ± 5.33	< 0.001

2.3. Process

An orientation session for the students was conducted by the program coordinator prior to starting the rotations, wherein the objectives of the program, clear directives regarding the conduct of the sessions and the expected goals of this innovative venture were highlighted. Clinical

Table 2
Summary of open written comments.

General	'Knew about various departments/ specialties in the hospital, their functioning & infrastructure'
	'Made us familiar with various fields'
Knowledge	'Learnt a lot, better way of learning'
	'Able to correlate theory with practical work'
	'Learnt the importance of basic science and its application in clinical medicine'
Psychomotor domain	'CPR - empowered us'
	'Learnt and taught CPR to my family members'
	'Observed live procedures, saw instruments, drugs'
Affective domain	'Insight about what patient undergoes'
	'Learnt about the duties of a doctor'
	'Learnt the importance of human life'
	'Learnt how to handle a patient'
	'Learnt to behave kindly towards patients'
Motivating	'Interesting motivating inspiring useful worthy awesome'
	'Invoked self interest'
	'Made us feel proud to be a doctor'
	'My dream to walk into the hospital as doctor made true'
Suggestions	'Program timing can be increased'
	'One more cycle'
	'Timing can be shifted to morning hours'
	'Can include all departments in hospital especially cardiothoracic surgery, oncology, gynecology, clinical lab and opportunity to interact with patients and staff'

department postings were coordinated by a faculty in each department. The designate faculty drew out the learning objectives for this session based on the student's prior knowledge and availability of clinical materials. This arrangement was kept uniform for the entire class.

The learning objectives for each session were chosen carefully in view of student's prior knowledge, the availability of clinical material and relevance. In departments like Nephrology, Radiology, Simulation lab, Blood bank the content was fixed and all students were uniformly exposed. For example in nephrology, the students witnessed a patient undergoing dialysis. The principle of dialysis, biochemical alterations in the blood before and after dialysis was discussed. In other departments like Respiratory medicine, Surgery, Neurology the experience was more impromptu, based on the availability of cases. In Cardiology, the objective was to give the students an experience of observing coronary angiogram followed by a discussion on the relevant anatomical aspects. If there were no patients scheduled for angiogram at the time of ECE session they were allowed to view the recorded procedure.

Based on the learning objectives, questionnaires were formulated for all the sessions and used as pre-test and post-test for the students. Students who wished to participate in the program evaluation gave informed consent, took part in the pre-test and post-test and were also encouraged to give their written open comments anonymously.

2.4. Data collection and analysis

The questionnaires were designed in a five point Likert scale with 6–10 items to assess the effectiveness of ECE sessions. The scores used were 1 = not aware, 2 = not sure, 3 = know vaguely, 4 = know with reasonable clarity and 5 = know confidently. The questionnaire was meant to assess the impact of the program on the students. This was achieved by comparing the scores obtained by the students in pre- and post-tests. The scores were expressed as mean ± standard deviation and were compared by paired't' test using IBM SPSS software version 19.

The open comments regarding the program were analyzed through inductive approach. [9] Specific themes were identified and the comments were assigned to the appropriate theme.

3. Results

Among the one hundred and fifty participants, one hundred and forty four participants submitted their filled in pre and post test questionnaires. There was a significant increase in the post-test scores when compared to the pretest scores for all ECE sessions (Table 1).

One hundred and eight students had given their written open comments anonymously. The review of the open comments has been tabulated in Table 2.

4. Discussion

Regulatory bodies of the medical education have spelled out clearly that the medical education needs to be geared to train professionals capable of providing holistic care to patients with compassion.[6] Early clinical exposure, if implemented effectively could very well initiate the changes in the medical education system in the right direction to achieve the stipulated goal. There have been no clear directives to implement this program in terms of content, duration and mode of delivery. This has left the challenging responsibility of designing ECE entirely to the individual institutions, and the resultant programs would certainly depend upon the resources and initiatives available. Reports on the details of the conduct of ECE are scanty.[11–13] Interactive lectures, case scenarios, case based learning and occasional hospital visits have been implemented by a few of the institutions, as part of ECE.[11–13] In PSG Institute of Medical Sciences and Research (PSGIMSR), this program has been implemented as postings to selected departments of not less than an hour's duration per session. Each student gets an exposure of at least ten hours of this experience. The posting involves a variety of experiences like observing an interventional or investigative procedure, seeing a patient in ward or observing the doctor-patient interaction in the outpatient clinics, observing the demonstration of clinical signs, learning and practicing skills like phlebotomy or Basic Life Support (BLS) on manikins in the Clinical simulation laboratory.

Most students appreciated the ECE experience as 'inspiring', 'motivating', 'interesting' 'awesome', 'useful', 'good way of learning', 'evoked self interest'. They felt it helped them see the relevance of basic science in clinical practice. Interested students also contacted the clinicians in the specialty of their choice later and pursued their interest in the subject. For students who entered the medical profession without prior exposure, this program provided a bird's eye view of the opportunities that lay ahead of them as evidenced from their comments like 'Knew about various departments/ specialties in the hospital, their functioning & infrastructure' 'Made us familiar with various fields'.

In the Clinical simulation laboratory students had instructions in Phlebotomy in the first rotation and hands-on training in BLS in the second rotation. BLS enables a person to recognize and support people in life threatening emergencies until full medical care can be provided. Any trained person can perform this if the need arises. Introducing BLS training as early as possible is considered essential and may help to increase their eagerness to learn and passion for the profession.[10,14] ECE could be the ideal platform to introduce BLS training to the medical students. Students in their feedback expressed that learning BLS empowered them and made them feel more confident.

The program seemed to have helped students to develop a humanistic attitude towards the patients as evidenced by their comments like –'developed an insight about what the patient undergoes', 'learnt how to behave kindly with patients', 'learnt the importance of human life'. They also commented that they gained an insight about the various roles/duties of a doctor. Students were of the opinion that more departments need to be incorporated in the program and the duration of the program should be increased. Authors fully endorse these views and feel that time factor could probably be a major restriction for expanding this program as per the students' wishes.

5. Conclusion

ECE can serve as a platform for providing the preclinical year students a cosmic variety of experiences involving all the three domains of learning. It can also be adapted as the teaching strategy to introduce the various dimensions of medical profession like scientific, ethical, interpersonal, professional and social. This program if implemented effectively has the potential to be the ideal first step in the making of a holistic doctor.

Abstract

Purpose: A considerable barrier to global pediatric oncology efforts has been the scarcity and even absence of trained professionals in many low- and middle-income countries, where the majority of children with cancer reside. In 2013, no dedicated pediatric hematology-oncology (PHO) programs existed in Ethiopia despite the estimated annual incidence of 6000-12000 cases. The Aslan Project initiative was established to fill this gap in order to improve pediatric cancer care in Ethiopia. A major objective was to increase subspecialty PHO-trained physicians who were committed to practicing locally and empowered to lead programmatic development.

Methods: We designed and implemented a PHO training curriculum to provide a robust educational and clinical experience within the existing resource-constrained

The Aslan Project

environment in Ethiopia. Education relied on visiting PHO faculty, a training attachment abroad, and extraordinary initiative from trainees.

Results: Four physicians have completed comprehensive PHO subspecialty training based primarily in Ethiopia, and all have remained local. Former fellows are now leading two PHO centers in Ethiopia with a combined capacity of 64 inpatient beds and over 800 new diagnoses per year; an additional former fellow is developing a pediatric cancer program in Nairobi, Kenya. Two fellows currently are in training. Program leadership, teaching, and advocacy are being transitioned to these physicians.

Conclusions: Despite myriad challenges, a subspecialty PHO training program was successfully implemented in a low-income country. PHO training in Ethiopia is approaching sustainability through human resource development, and is accelerating the growth of dedicated PHO services where none existed 7 years ago.

1 | INTRODUCTION

Human resources for health care are one of the core building blocks of health systems, and are essential to the sustainability and scalability of health interventions.[1] A considerable barrier to global pediatric hematology-oncology (PHO) efforts has been the scarcity and even absence of trained professionals in many low- and middle-income countries (LMIC), where the majority of children with cancer reside. Studies highlight this inequity[2] and the need to develop a global oncology workforce through allocation of financial resources, strengthening of health care infrastructure, and development of innovative training programs.[3] The 2015 United Nations Sustainable Development Goal 3, "Ensure healthy lives and promote well-being for all at all ages," includes a call to reduce by one-third premature mortality from noncommunicable diseases through prevention and treatment, which provides financial and policy support for cancer control programs in LMIC. Even with this international support, competing priorities for child health, including neonatal care, nutrition, and infection control, have raised concerns about the practicality of focusing efforts on PHO in LMIC. However, the potential for success of PHO clinical care in LMIC has been established for decades,[4] and recent efforts have demonstrated both the cost-effectiveness[5,6] and the international momentum for such programs.[7] The World Health Organization Global Initiative for Childhood Cancer was established in 2018 to help coordinate program development for childhood cancer in LMIC.

Ethiopia is the second most populous country in Africa with a population exceeding 110 million persons spanning 426 400 square miles. As noted in the 2019 UN Human Development Index, more than 83% of Ethiopia's population lives in multidimensional poverty, unable to withstand additional health care expenditures associated with cancer care,[8] with a skilled labor force of 6.8% and a gross national income per capita of $1782. Nearly 80% of the population lives in rural areas, far from urban settings, which can influence access to health care and challenge assessment of disease burden.[9] Current health expenditures constitute 4% of the country's GDP, and the childhood mortality rate (less than 5 years old) is 58.5 per 1000 live births.[10]

Because of the improved treatment of malaria and HIVand other infectious disease in Ethiopia, noncommunicable diseases contribute an increasing proportion of childhood mortality. The annual incidence of pediatric cancers in Ethiopia has been estimated between 6000 and 12 000 cases in children aged 0-14 years,[11,12] who as of 2019 constitute 40% of the population,[13] more than twice the percentage of the population of 0-14 years living in the United States. Prior to 2013, no dedicated PHO programs existed in Ethiopia, and there was no formal process for local PHO subspecialty physician training. To address this gap, we established an organization with the objective to develop sustainable local capacity in Ethiopia to treat pediatric blood disorders and cancers through creation of a formal 2-year PHO fellowship program in tandem with the development of specialized allied health and supportive care services. In 2015, the Ethiopian Federal Ministry of Health (FMOH) developed the first National Cancer Control Plan.[14] While the plan does not specifically address PHO care, support services and palliative care for children are mentioned in the plan. The implementation of the National Cancer Control Plan thus demonstrated a national commitment to cancer care, and provided momentum to our efforts to develop local PHO capacity. Herein, we describe our approach, successes, and challenges to PHO fellowship training in Ethiopia.

2 | METHODS

2.1 | Strategy

The PHO fellowship program has been led by The Aslan Project, a US nonprofit organization consisting of experts in PHO, pediatric

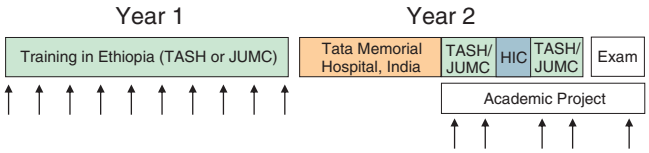

FIGURE 1 Schedule of training through 2 years of subspecialty fellowship. Abbreviations: ↑, visiting faculty - lectures, clinical teaching, clinical consultation, fellow evaluation; TASH, Tikur Anbessa Specialized Hospital; JUMC, Jimma University Medical Center; HIC, high-income country

oncology nursing, and pathology with experience in LMIC.[12] While most faculty are affiliated with academic institutions, this PHO training effort was not a direct collaboration with a specific high-income country (HIC) academic center. Sited initially in 2013 at Tikur Anbessa Specialized Hospital (TASH)—the location of the first comprehensive Ethiopian pediatric cancer program that Aslan developed in collaboration with the FMOH and Addis Ababa University (AAU)—the goal of the fellowship program was to increase subspecialty PHO-trained physicians committed to practicing locally and empowered to lead programmatic development throughout the country. To that end, we sought to provide a robust educational and clinical experience for fellows within the existing resource-constrained environment, and to equip them with the tools to become strong leaders, administrators, and advocates with ownership of the direction of PHO in Ethiopia. To expand capacity to major national hospitals serving other significant catchment areas in the country, we established a second pediatric oncology unit and PHO fellowship program at Jimma University Medical Center (JUMC) in southwestern Ethiopia in 2016. In March 2019, at the direction of the FMOH, we relocated the fellowship program back to TASH to consolidate training programs for PHO at a single center.

2.2 | Curriculum

In developing the fellowship program, we considered a variety of training models, including training abroad, installation of a full-time external PHO specialist, and short focused coursework to share PHO skills with interested pediatricians. To optimize available organizational and local resources, we chose a hybrid model in which the majority of training occurred in Ethiopia with consistent teaching and clinical training from external experts in PHO through onsite faculty visits (Figure 1). Because neither TASH nor JUMC had specialized PHO physicians, one of two Aslan-supported clinical directors—practicing pediatric hematologist-oncologists with significant clinical experience in LMIC—was present throughout the first year at each location.

The fellowship curriculum was based on international standards to cover medical expertise, scholarship, professionalism, communication, management, and health advocacy (Figure 2). Experiential training blocks included 18 months of PHO service in Ethiopia with inpatient, outpatient, and consultation responsibilities. To augment onsite training by visiting faculty, we sponsored fellows for a 6-month attachment at a high-functioning cancer institution in a middle-income country and, as noted, the support of full-time onsite clinical faculty/mentorship for the early stages of the TASH and JUMC programs.[15–17] We initially attempted to supplement onsite training through a tele-lecture series, but use of that tool was not feasible due to poor internet access. Fellows were expected to complete a scholarly activity. Fellows were cosponsored by their home institution and The Aslan Project. Prior to starting fellowship, fellows signed an agreement to serve as PHOs in Ethiopia or their home country in Africa for a minimum of 2 years following training. AAU and Jimma University (JU) approved the PHO fellowship curriculum for TASH and JUMC, respectively.

2.3 | Evaluations and subspecialty certification

Fellows were evaluated on a continuous basis. Following each onsite training visit, the visiting faculty member completed a written evaluation assessing the fellow(s) based on performance, skill level, attendance, and other measurements approved by the academic institution (AAU or JU). Written evaluations were submitted to the academic institution. Additional means of evaluation included the fellow's personal portfolios, case logs, or mini-clinical encounters.

An interim multiple-choice examination was administered at the completion of the fellow's first year of training solely for purposes of assessing skills. At the end of the 2-year program, fellows demonstrating excellent performance were approved to sit for a final qualifying examination, developed by the Aslan Medical Advisory Board, with practical, written, hematopathologic, and clinical skill components. Fellows who fulfilled the above requirements and obtained an aggregate score of 75% in the final qualifying examination were awarded a "Subspecialty Certificate in Clinical Pediatric Hematology/Oncology" by the academic institution, and subsequently endorsed by governing bodies in Ethiopia and Kenya.

2.4 | Partnership development

From the outset, we enlisted and relied upon strong governmental, institutional, and nongovernmental organization (NGO) partnerships in building Ethiopia's pediatric cancer health system. Both the pediatric oncology unit and the PHO fellowship programs at TASH were developed pursuant to agreements with TASH, AAU, and the FMOH, and both JU and JUMC have been key partners in the development of pediatric oncology unit and fellowship program there. Moreover, as the vast majority of pediatric cancer patients in Ethiopia come from extreme poverty, a critical component of our work at TASH and JUMC has been the establishment of and funding support for a local NGO, Tesfa Addis Parents Childhood Cancer Organization (TAPCCO), to provide psychological, social, accommodation, nutritional, and other health and financial support to the pediatric cancer patients and their families. TAPCCO has directly contributed to fellowship training through supporting longitudinal patient care experiences, and teaching fellows the critical components of patient care that exist outside health care

Teaching Blocks

- Block 1: Emergency pediatric hematology/oncology (7 LH)
- Block 2: General aspects of hematology and immunology (2 LH)
- Block 3: Basic principles of chemotherapy (4 LH)
- Block 4: Disorders of hemostasis and management (4 LH)
- Block 5: Anticoagulants and their effects on hemostasis (1 LH)
- Block 6: Supportive care needs in pediatric hematology/oncology (4 LH)
- Block 7: Life course perspectives in pediatric hematology/oncology (2 LH)
- Block 8: Consultative hematology (2 LH)
- Block 9: Transfusion medicine (3 LH)
- Block 10: Redblood cell disorders (6 LH)
- Block 11: Leukocytes, lymph nodes and spleen (2 LH)
- Block 12: Approach to pediatric oncology (4 LH)
- Block 13: Acuteleukemia (4 LH)
- Block 14: Myeloproliferative neoplasms (3 LH)
- Block 15: Malignant lymphomas (4 LH)
- Block 16: Solidtumors (6 LH)
- Block 17: CNS tumors and retinoblastoma (4 LH)
- Block 18: Histiocytic disorders (2 LH)
- Block 19: Infectious diseases and pediatric hematology/oncology (3 LH)
- Block 20: Laboratory technology (4 LH)
- Block 21: Scholarly development (Research and Teaching) (7 LH)
- Block 22: Quality assurance and management practices (4 LH)

Teaching Schedule

Month	PHO Faculty	Education Goals and Programs to be Developed	Other Faculty
1	Hematologic Malignancies	Acute leukemias Emergencies/supportive care	Pharmacy faculty
2	Hematologic Malignancies	Acute leukemias Supportive/Palliative care	Infectious disease faculty
3	Hematologic Malignancies	Lymphomas CML, Supportive/Palliative care	
4	Hematologic Malignancies	Lymphomas Histiocytic disorders Supportive/Palliative care	
5	Solid Malignancies	Bone and soft tissue sarcomas Imaging, Path., Radiation, Surgery	Surgery faculty
6	Solid Malignancies	Bone and soft tissue sarcomas Imaging, Path., Radiation, Surgery	
7	Solid Malignancies	Retinoblastoma, Neuroblastoma Wilms tumor Imaging, Path., Radiation, Surgery	Pathology faculty
8	Solid Malignancies	Brain tumors Imaging, Path., Radiation, Surgery	Radiation oncology faculty
9	Hematology	Red blood cell disorders Hemopathology, Lab medicine	
10	Hematology	Red blood cell disorders Hemopathology, Lab medicine	Pathology/Lab medicine faculty
11	Hematology	Coagulation and hemostasis Hemopathology, Lab medicine	
12	Hematology	Other hematologic disorders Hemopathology, Lab medicine	

FIGURE 2 Curriculum block and samples training schedule throughout the first year of fellowship. The specific schedule was adjusted based upon available traveling faculty, but we required every teaching block to be covered. Abbreviation: LH, lecture hours

settings. Additional program development components required to support fellowship training included establishment of dedicated PHO units, supportive care and cancer treatment guidelines, training for pharmacy, nursing, infection control, and data collection, and partnership creation with blood banks, subspecialty physicians, radiologists, and pathologists.

3 | RESULTS

3.1 | Process

Committed visiting faculty with significant experience in low-resource settings led onsite training to cover the blocks of the approved curriculum. Twenty-five faculty members from 21 universities made 53 trips to Ethiopia between 2013 and 2019. Faculty included PHO clinicians, infectious disease clinicians, pathologists, pediatric oncology nurses, and oncology pharmacists based in Cameroon, Canada, Egypt, England, India, Israel, Pakistan, South Africa, Switzerland, and the United States. Faculty members provided didactic lectures, clinical teaching, professional mentoring, and advocacy during their 1-4-week site visits. In the second fellowship year, fellows completed a 6-month specialized training rotation in India at either Tata Memorial Hospital, Mumbai or Tata Medical Center, Kolkata. In Mumbai and Kolkata, fellows actively performed inpatient and outpatient clinical care alongside world-renowned specialists in PHO, infectious diseases, and pathology. Through this experience, they gained not only the skills and knowledge that came from intensive training, but also the experience of working in comprehensive cancer care centers with access to a full complement of diagnostic technology, therapeutic opportunities, and supportive care resources as well as a patient population similar to children with cancer in Ethiopia.

3.2 | Capacity development

Four physicians have completed PHO fellowship training in Ethiopia, with extensive support of local health care leadership and visiting faculty. An additional fellow left training prior to completion and two fellows currently are in training. The four subspecialty-trained physicians have remained local, two at TASH, one at JUMC, and one returned to her home hospital, Gertrude's Children's Hospital in Nairobi, Kenya, where she has established a PHO unit as the second Kenyan medical board-recognized PHO specialist.

The fellowship structure has succeeded in training subspecialty physicians to establish PHO care in Ethiopia. TASH supports a 26-bed inpatient unit and 16 additional inpatient beds at a nearby oncology center, treating over 650 new patients annually. JUMC likewise supports a 22-bed PHO unit running at 90% capacity with over 340 new diagnoses from August 2016 to November 2019. Moreover, each fellowship graduate is actively leading education and training along with clinical, research, and administrative leadership responsibilities, exponentially expanding the capacity of PHO services at their institutions. In addition to the four fellowship graduates, one additional PHO consultant at TASH, one PHO consultant at Ayder Comprehensive Specialized Hospital (ACSH) in Mekele, one PHO consultant at St Paul's Hospital, and one PHO consultant at the University of Gondar Hospital (UGH) in Gondar were recently trained through other international initiatives. With the development of a cadre of trained PHO clinicians and increased capacity for supporting children with cancer, the Ethiopian

FMOH has recently adopted its first ever National Control Plan for Pediatric Cancer.

3.3 | Challenges

Success of this training effort was not guaranteed. A primary unexpected challenge was fellow recruitment in Ethiopia. The PHO subspecialty was and remains relatively unknown in the country, and thus was not a popular choice for graduating pediatrics residents. As a result, most fellows transitioned from full-time work as practicing pediatricians, leading to a significant pay decrease during fellowship. While subspecialty-credentialing leads to small increase in reimbursement, pay-related challenges continue for the PHO consultants at public hospitals where the PHO units are located, in comparison to salary for pediatricians in the private sector. In addition, the multitude of services required to develop a PHO unit and critical to trainee experiences were sometimes lacking. Key pharmaceutical deficiencies early in the program were chemotherapy and antimicrobial acquisition, supply chain logistics, drug preparation, and safe administration. Additional medical services—diagnostic pathology tools, imaging capabilities, ophthalmology, radiation oncology, surgical availability, infection prevention, and blood product support—were inconsistent or incomplete at times, further complicating efforts to train PHO physicians. Moreover, despite sustained efforts to train pediatric oncology nurses at TASH and JUMC, the frequency of staffing rotations made it difficult to establish and retain a skilled pediatric oncology nursing workforce. Treatment abandonment is also a substantial challenge, which as noted we are addressing through development of an array of social services through TAPCCO.

3.4 | Transition

PHO services in Ethiopia are now in operation with varying levels of capacity at TASH, JUMC, ACSH, and UGH, with a unit opening soon at St Paul's Hospital Millennium Medical College in Addis Ababa (Figure 3). Leadership from each center is actively collaborating on initiatives designed to further the development of Ethiopia's pediatric cancer health system. The PHO unit leaders, the FMOH, and visiting Aslan partners consistently advocate for capacity building beyond fellowship training, including continued pediatric oncology pharmacy and nursing specialization, treatment guideline and registry development, quality improvement monitoring, patient psychosocial support services, and comprehensive social services for families.

4 | DISCUSSION

Models of subspecialty training in low-resource settings have expanded in the past decade alongside the increased development of global health workforce capacity.[18] Initial efforts appropriately focused on infectious disease care; in recent years, workforce development has followed the epidemiologic shift from communicable to noncommunicable diseases (including cancer) and injury as increasingly significant causes of morbidity and mortality.[19]

FIGURE 3 Map of Ethiopia with locations of the four established pediatric oncology units. Blue stars represent the locations of sites that have been used for training. Red stars represent the additional active pediatric hematology-oncology (PHO) units, each supported by a single PHO-trained physician

Early models of subspecialty training existed primarily in the broad categories of training abroad,[20] short-term training,[21] or full time relocation of international health care providers from a HIC to a LMIC setting.[22] However, each of these approaches has significant limitations. Fellowship training abroad presents potential negative consequences as these efforts remove talented physicians for multiple years and can increase the permanent emigration from LMIC.[23–26] Additionally, many of the skills learned in HIC may not be immediately applicable to LMIC settings. Short-term skillset-based observerships or brief coursework can be beneficial for procedural services and increasing funds of knowledge, but these approaches do not provide comprehensive subspecialty development. Subspecialty training can occur through attaching international experts from HIC on a full-time basis to LMIC institutions for extended periods to set up clinical services, administrative structures, and an educational curriculum for complete in-country subspecialty training.[22] While this model has been successful, it has the potential to interfere with the development of local leadership and is not a scalable solution. More recently, researchers have emphasized hybrid approaches focused on local education and physician retention without sacrificing comprehensive training knowledge and skill-based training, including at a program similar to ours in Ethiopia.[27,28] We successfully developed such a hybrid model with limited attachment of full-time physicians from HIC and monthly external faculty visits to anchor the training in Ethiopia, while also supporting meaningful clinical training in a middle-income country setting.

Subspecialty oncology training programs in LMIC remain a recent development[17] and specific attempts at PHO training are just beginning.[29,30] Modern pediatric oncology care requires myriad robust systems to be in place. Because health care infrastructures in LMIC can be fragile or in early stages of strengthening, access to consistent services and specialized support is essential in the following areas: diagnostic pathology, chemotherapy, specialized nursing support, imaging capabilities, ophthalmology, general surgery, neurosurgery, radiotherapy, infection prevention programs, pediatric oncology pharmacists, blood banks, and psychosocial and palliative care support services. This is what makes caring for children and adolescents with cancer so challenging. However, as these health systems improve, other patients also benefit.

Pediatric oncology is a highly demanding subspecialty, and managing immunosuppressed patients in low-resource health care settings is particularly difficult. Through the establishment of two POUs, the implementation of fellowship, pathology, pediatric oncology nursing, and pharmacy trainings, and the partnership with TAPCCO over the past 7 years, we have reached several fundamental conclusions. *First*, it is critical that the newly specialized pediatric oncology workforce in Ethiopia is protected from burnout and work-related compassion fatigue. These pioneer physicians are managing large patient populations while simultaneously training pediatric residents and future fellows. Their daunting workload requires continuing remote and in-person support from visiting faculty. As the number of Ethiopian pediatric hematologist-oncologists increases and their professional organization matures and partners with the MOH, it is foreseeable that external support will no longer be required. At that time, Ethiopia will have a strong network of collaborating pediatric oncology programs capable of addressing the growing burden of childhood cancer going forward.

Second, we have become acutely aware of the interdependence of each service that impacts pediatric cancer care. Without diagnostic pathology, treatment cannot be accurately prescribed; without chemotherapy access or preparation, no hope can be given; without blood bank support, chemotherapy is too toxic; without housing services, patients and families will abandon. Wherever a PHO training program is considered, detailed needs assessment must be performed to assess capacity of ancillary services and to address parallel development needs. Thus, in addition to fellowship training, over the past 7 years we have provided opportunities for international training and conference attendance for TASH and JUMC health professionals who partner in PHO care, including nurses, pharmacists, ophthalmologists, and pathologists. In express recognition of both this interdependence and continuing resource limitations, we were directed in 2018 by the FMOH to centralize PHO fellowship training in Ethiopia at TASH. As the primary teaching and referral hospital in the country, TASH handles the largest patient volume, has access to broad supportive care services, and has the most PHO subspecialty-trained faculty working full-time. TASH currently has two fellows in training, with the capacity to add an additional two-three fellows each year. Together with the three attending PHO consultants, fellows handle a significant patient load, upwards of 7000 inpatient and outpatient visits a year.

Third, in spite of the success in developing PHO services at TASH, JUMC, ACSH, UGH, and soon St Paul's, an estimated 80% of children with cancer in Ethiopia are still not being diagnosed or referred to a PHO treatment center. Accordingly, our experience dictates that PHO workforce training must remain a priority of capacity development in Ethiopia, not just at TASH but at the additional centers as well. Communication technology advances alongside improved internet access in in Ethiopia may facilitate the scaling up of fellowship programs to institutions beyond TASH, particularly the use of interactive remote learning interfaces to conduct much of the required didactic teaching. Our increased use of virtual platforms to continue our fellowship lecture series during the recent SARS-CoV-2 pandemic, for example, highlights how such training can expand in scope to include active participation, not just by physicians in our fellowship program but also trained through other domestic and international initiatives. Moreover, with the further development of reliable remote learning and the PHO workforce capacity now in place in Ethiopia, we anticipate a steady transition of leadership for training, administrative support, and advocacy away from external Aslan staff and faculty and into the hands of PHO-trained Ethiopian physicians.

Development of oncology clinical care and training required an unbalanced amount of our effort. However, we have consistently committed one-third of the didactic curriculum to nonmalignant hematology and offered hematology-focused rotations in HIC. Fellows performed mentored consults and provided direct patient care in Ethiopia for patients with thrombosis, bleeding disorders, red blood cell disorders, bone marrow failure syndromes, and inflammatory conditions. We expect that the growing workforce of PHO subspecialty-trained physicians in Ethiopia will increasingly support critical research and comprehensive clinical care for nonmalignant hematologic conditions.

In summary, developing specialized PHO care in LMIC requires governmental and institutional buy-in and a multifaceted approach, including PHO workforce training and retention, social support, diagnostic expertise and facility, pharmacy services, and subspecialty physician support. Focusing on physician training for PHO in Ethiopia, we designed a training structure and curriculum to: (a) teach resource-appropriate medical care, (b) provide sustained clinical mentorship, (c) develop health system leadership skills, and (d) retain physicians to staff local pediatric oncology units. Challenges included fellow recruitment, chemotherapy access, diagnostic accuracy, retention of pediatric oncology nurses and oncology pharmacists following their training, infection control, blood product availability, and treatment abandonment. Locally sustainable subspecialty PHO training can be implemented in LMIC without previously established subspecialty care, but requires the relentless commitment of government officials, local and international NGOs, local academic and health institutions and faculty, external faculty, trainees, and a multidisciplinary team of health professionals.

ACKNOWLEDGMENTS

This work has been a combined effort of The Aslan Project, the Ethiopian Federal Ministry of Health, Addis Ababa University, Jimma University, Tikur Anbessa Specialized Hospital, and Jimma University

Medical Center. We are thankful for the dedication of faculty members, the commitment of the fellows, the support of governmental and institutional leaders, and, most importantly, the patients and their families.

Anaplastic Multiple Myeloma- a Morphological Challenge – A Case Series

Abstract

Anaplastic multiple myeloma (AMM) is a rare and aggressive variant of plasma cell neoplasm. It is relatively treatment resistant when compared to conventional myeloma. It can arise *de novo* or transform from a preexisting plasma cell myeloma. Morphologically, AMM is recognized by the presence of immature plasma cells and pleomorphic, multilobated cells. Here, we present three cases of AMM.

Keywords: *Anaplastic myeloma, anaplastic variant of multiple myeloma, bizarre plasma cells, multilobated plasma cells*

Introduction

Anaplastic multiple myeloma (AMM) is a very rare morphological variant of multiple myeloma. It has an aggressive clinical course and poor prognosis. It is relatively more treatment resistant when compared to conventional myeloma. It can arise *de novo* or transform from a preexisting plasma cell myeloma.[1,2]

Morphologically, AMM is recognized by the presence of immature plasma cells and pleomorphic, multilobated cells. These cells can be mistaken for carcinoma or lymphoma cells or even at times megakaryocytes. Here, we present three cases of AMM.[3]

Case Reports

Case 1

An 85-year-old male who was diagnosed to have chronic kidney disease presented with the symptoms of anemia and back pain. Laboratory investigations showed anemia (hemoglobin [Hb]: 6.6 g/dl), erythrocyte sedimentation rate (ESR) of 120 mm, and elevated renal parameters (blood urea – 87 mg/dl and serum creatinine – 4.38 mg/dl). Serum albumin was 3.1 g/dl and globulin was 4.8 g/dl. Peripheral smear showed normocytic anemia with exaggerated rouleaux formation [Figure 1].

Bone marrow aspiration showed hypercellular marrow with significant plasmacytosis (plasma cells −72%). Also seen were many large cells with eccentrically placed hyperchromatic nuclei exhibiting marked nuclear lobulations and indentations. Subsequently, serum protein electrophoresis was done which demonstrated a discrete M band.

Case 2

A 61-year-old male, a diagnosed case of chronic kidney disease, presented with severe fatigue and bony tenderness. Blood investigations showed elevated renal parameters (blood urea – 95 mg/dl and serum creatinine – 7.42 mg/dl). There were significant albumin–globulin ratio reversal (serum albumin – 2.1 g/dl and globulin – 12.3 g/dl) and markedly elevated ESR (109 mm/h). Peripheral smear showed normocytic anemia (Hb – 4.4 g/dl), thrombocytopenia (87,000/mm^3), white blood cell count of 4400/mm^3, increased rouleaux formation, and presence of 4% atypical cells [Figure 2].

Serum protein electrophoresis showed a significant fall in albumin level and a steep increase in the gamma globulin region suggestive of "M band." Bone marrow aspiration showed hypercellular marrow particles with pleomorphic plasmacytoid cells with lobated nuclei along with a few mature, binucleate and multinucleate plasma cells. Hypercellular marrow spaces with sheets and singly scattered pleomorphic cells were observed on trephine biopsy. Plasmacytoid morphology was focally discernible [Figure 3]. The differentials

Quick Response Code:

included lymphoma versus myeloma. Immunohistochemical markers were done. The cells expressed CD138 and were negative for CD20 immunostain [Figures 4 and 5].

Case 3

A 70-year-old male presented with severe fatigue, loss of appetite, and weight loss. He was a known case of multiple myeloma diagnosed 6 years back. He was in remission following treatment. Peripheral smear showed pancytopenia with increased rouleaux formation and presence of plasma cells. Bone marrow studies were done to rule out recurrence. Bone marrow aspirate showed bizarre plasma cells [Figures 6 and 7]. The marrow spaces showed diffuse infiltration by plasmacytoid cells and bizarre cells with multilobated nuclei. The cells expressed membranous staining for CD138. The bone marrow features were consistent with the anaplastic transformation of a myeloma.

Discussion

Multiple myeloma is a common hematological malignancy of the middle aged and elderly. AMM was originally used to describe high-grade transformation occurring as a terminal event in the malignant plasma cell clones having pleomorphic morphology and immature plasma cells.[3,4] It has been referred by various names such as plasma cell sarcoma, aggressive-phase myeloma, and dysplastic myeloma. It is more commonly reported in younger adults, with the median age being 53 years, associated with predisposition to extramedullary sites and immunoglobulin A isotype.[2] Cases of anaplastic myeloma with poorly differentiated cells having extensive involvement of intra-abdominal and retroperitoneal sites have been reported in literature. AMM has morphological and flow cytometry features which are distinct from those of the conventional myeloma.[4]

Historically, this disease has been very resistant to chemotherapy. It has been suggested that this aggressive phase could result from a clonal evolution of the original malignant cell and not considered as the development of an independent new neoplasia.

All the three cases reported were seen in adults. None of them had any evidence of extramedullary disease. Two

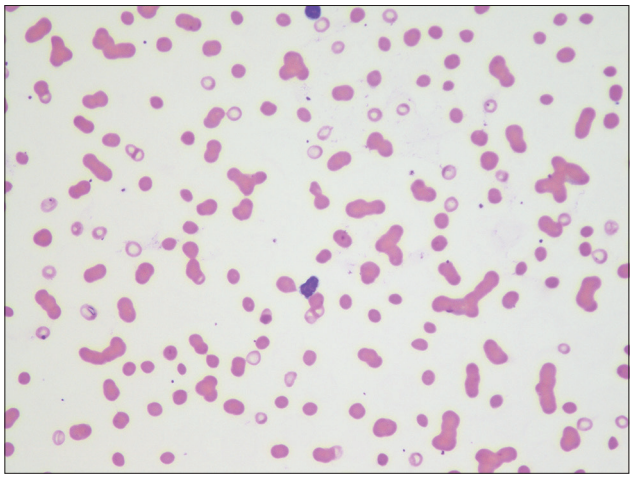

Figure 1: Case 1: Peripheral smear with exaggerated rouleaux formation (×40)

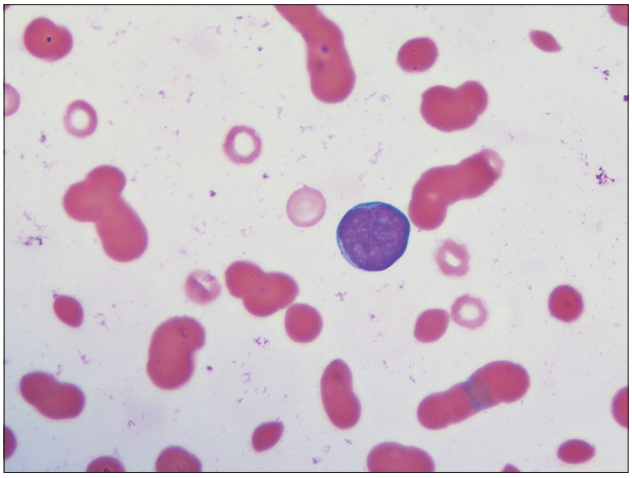

Figure 2: Case 2: Peripheral smear with a blast cell (×100)

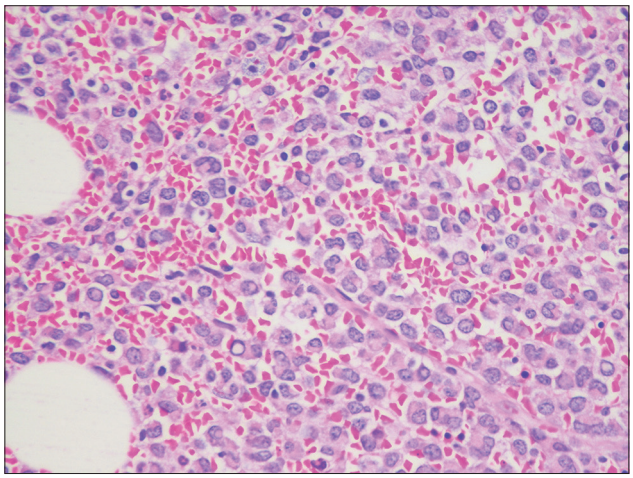

Figure 3: Case 2: Bone marrow trephine showing sheets of plasma cells, anaplastic cells, and Dutcher bodies (H and E, ×40)

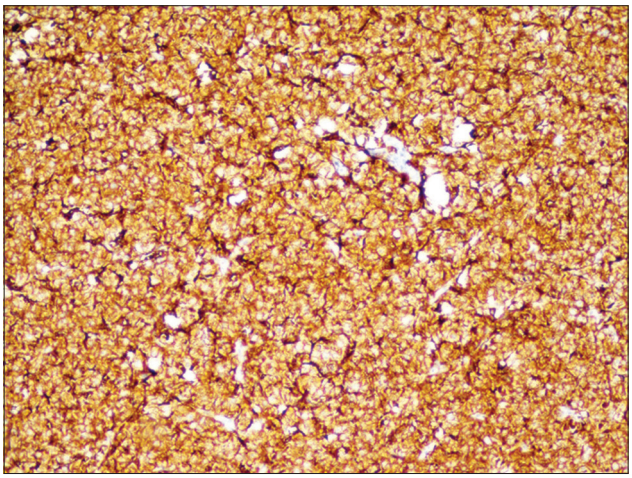

Figure 4: Case 2: Bone marrow trephine with cells expressing membranous CD138 (immunohistochemistry × 40)

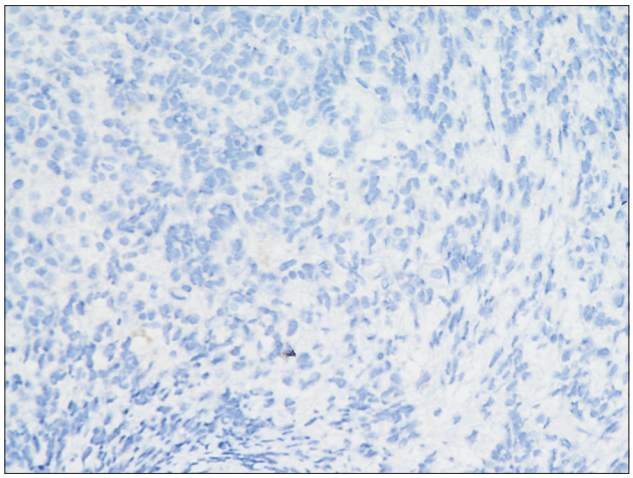

Figure 5: Case 2: Bone marrow trephine showing the neoplastic cells negative for CD20 (immunohistochemistry ×40)

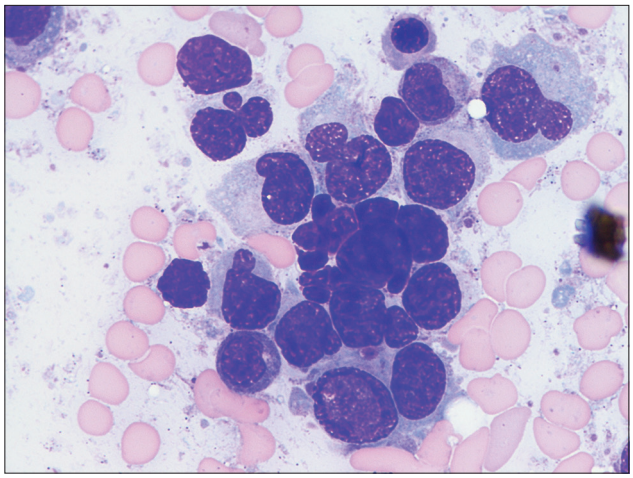

Figure 6: Case 3: Bone marrow aspirate with bizarre plasma cells (×100)

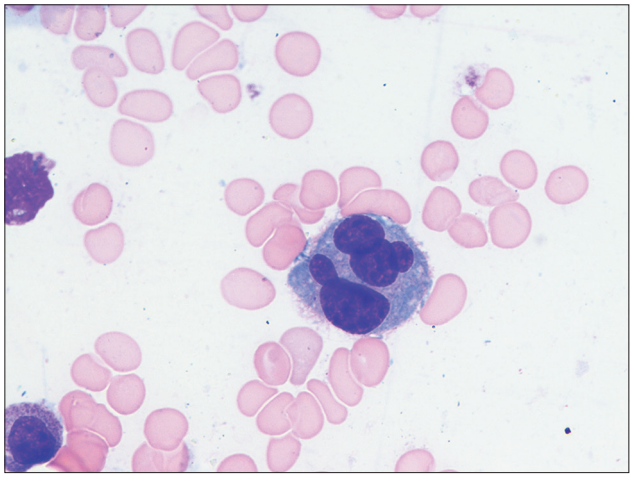

Figure 7: Case 3: Bone marrow aspirate with a plasma cell showing abnormal nuclear lobulation (×100)

cases presented *de novo*, whereas the other was anaplastic transformation seen in a patient in remission after treatment.

Multiple myeloma exhibits a broad morphological variation ranging from mature plasmacytic to highly anaplastic variants. The anaplastic variant poses a morphological diagnostic challenge as it mimics carcinoma and lymphomas, especially when presenting *de novo*. The presence of large cells with nuclear budding may mimic a megakaryocyte in bone marrow samples.[5,6]

Case 2 reported here had a very anaplastic morphology, and the diagnosis was made with the aid of immunohistochemical staining with CD138.

Diagnosing a case as anaplastic myeloma without ancillary techniques is difficult, especially when the histology shows primitive cells. One of our cases had an undifferentiated morphology.

Bone marrow findings varied among the three cases.

Case 1 showed 72% plasma cells with the presence of few anaplastic cells. Whereas, case 2 showed predominantly large cells with pleomorphic morphology and scattered plasma cells.

Case 3 showed plasmacytoid cells with anaplastic morphology and occurred as a recurrence.

AMM, irrespective of presenting *de novo* or as progression, has been reported to have poor response to chemotherapy.[4]

Conclusion

Here, we present a series of three cases of anaplastic myeloma for the rarity of this entity and also for the fact that these cases were considerably different from the previously reported cases in having no evidence of extramedullary disease and presenting at an older age. Anaplastic myeloma needs to be considered in bone marrow aspirates with pleomorphic morphology in a patient with other supportive evidence of plasma cell dyscrasia.

Declaration of patient consent

The authors certify that they have obtained all appropriate patient consent forms. In the form the patient(s) has/have given his/her/their consent for his/her/their images and other clinical information to be reported in the journal. The patients understand that their names and initials will not be published and due efforts will be made to conceal their identity, but anonymity cannot be guaranteed.

Immunohistochemical Profile and Distribution of Non-Hodgkin and Hodgkin Lymphoma – An Experience in a Medical College Hospital in Tamil Nadu

Sakthisankari Shanmugasundaram[1], Krishnagiri Balan[2], Dhanalakshmi Arumugam[2]

[1]Department of Pathology, PSG Institute of Medical Sciences and Research, Coimbatore, Tamil Nadu, India, [2]Department of Pathology, Coimbatore Medical College, Coimbatore, Tamil Nadu, India

Abstract

Context: The subtype distribution of non-Hodgkin lymphoma (NHL) and Hodgkin lymphoma (HL) shows distinct pattern across geographic regions. This study analyzes the subtype distribution of lymphomas based on the WHO 2017 Classification using immunohistochemistry (IHC) and also investigates the IHC profile of various lymphomas. **Subjects and Methods:** Fifty consecutive cases of lymphoma diagnosed in the department of pathology in a medical college hospital were included in the study. The cases were subcategorized using panels of IHC based on the light microscopic findings. **Results:** The ratio of NHL to HL was 4.5:1. B-NHL formed 78.5% (n = 32), while T-cell NHL formed 21.5% (n = 9). Among the B-NHL cases, small lymphocytic lymphoma/chronic lymphocytic leukemia (SLL/CLL) (34.4%) was the most common, followed by diffuse large B-cell lymphoma, NOS (DLBCL NOS) (31.2%), follicular lymphoma (FL) (25%), and then by Burkitt's lymphoma (BL) constituting 9.4%. Peripheral T-cell lymphoma, NOS (PTCL NOS) (14.1%) (n = 6) was the most common T-cell NHL, followed by angioimmunoblastic T-cell lymphoma (4.8%), and then by lymphoblastic lymphoma (T-LL) (2.4%). Among Hodgkin lymphomas, mixed cellularity (MC) accounted for 55.6% (n = 5), lymphocyte depleted type (LD) being 22.2%, while nodular lymphocyte predominant and lymphocyte rich type each constituted 11.1%. **Conclusion:** SLL/CLL was the most common lymphoma reported in the study followed by DLBCL which is different from the other Indian studies where DLBCL was most common. CD5 expression was noted in 21% of FLs. PTCL-NOS constituted the most common T-cell lymphoma and MC, the most frequent subtype of classical HL. Further replication studies including larger sample size will be needed to understand the difference in subtype distribution in our population.

Keywords: *CD5, Hodgkin lymphoma, immunohistochemistry, Lennert's lymphoma, non-Hodgkin lymphoma, small lymphocytic lymphoma*

Introduction

There has been a rising incidence of malignant lymphoma. The incidence varies among the different countries as well as within various regions of a country.[1,2] Age-adjusted incidence of non-Hodgkin lymphoma (NHL) in India is 5 / 100,000.[1] NHL accounts for 5.1% of all malignancies and Hodgkin lymphoma (HL) constitutes 9.5% of cancers in men and 5.5% in women.[3,4]

With the advent of changes in lymphoma therapy, the accurate diagnosis of lymphoma and prognostication wherever possible becomes critical. Similarly, the classification of lymphomas has evolved with the incorporation of various novel immunohistochemical markers in the diagnosis and prognostication.[5-7]

Immunohistochemistry (IHC) has become an integral part in the lymphoma diagnosis, histology being the gold standard. The utility of IHC has led to a better understanding of pathogenesis. The panel of IHC markers was chosen based on the morphological findings in light microscopy. The markers include CD45, CD20, and CD3 to differentiate T- and B-cell lymphomas and CD15 and CD30 for HLs. Other markers used for subtyping were CD10, CD5, CD23, BCL2, Cyclin D1, TdT, ALK, and proliferation marker KI67. There are many studies from the various states of the country reporting on the frequency and distribution of malignant lymphomas. Majority of them are from tertiary referral centers.[8-13]

Literature search reveals that the subtype distribution of malignant lymphomas varies

among countries and also across the geographic regions within the countries, the reason for which remains largely unknown. Mondal *et al*. had reported the frequency of follicular and mantle cell lymphoma to be lower when compared to the Western population.[8] Among HLs, mixed cellularity (MC) was the most common subtype reported by them.[8] DLBCL was the most common B-NHL in most of the Indian studies.[8-13] Arora *et al*. had found the frequency of peripheral T-cell/NK-cell lymphoma to be higher than Western countries but less than that of the other Asian countries.[9] They had reported peripheral T-cell lymphoma, NOS (PTCL NOS) as the most common T-NHL in contrast to other Indian studies,[10] while Devi *et al*. had reported lymphoblastic lymphoma (LL) as the most common subtype of T-NHL.[12] Sandhu *et al*.[11] and Sharma *et al*.[12] had found that the incidence of follicular and mantle cell lymphoma was lower in India than the USA and Europe. T-cell LL and anaplastic large T/null cell lymphomas are more prevalent in India according to the study by Naresh *et al*.[13]

The study was undertaken with the aim of analyzing the subtype distribution of lymphomas in our population using IHC according to the World Health Organization (WHO) 2017 Classification in the patients visiting the medical college hospital. As a secondary aim, this study also analyzed the immunohistochemical profile of various lymphomas.

Subjects and Methods

Between August 2011 and August 2013, 50 consecutive cases diagnosed as lymphoma in the histopathology department in a medical college hospital were included in the study. The study was approved by the Institutional Human Ethics committee. Patients of all ages and either gender with both primary and extranodal lymphomas (treatment naive) were included in the study. For histopathological and immunohistochemical studies, the tumor samples were fixed in 10% neutral buffered formalin, and after tissue processing, they were embedded in a paraffin block. The diagnosis was made by histopathological examination using hematoxylin and eosin. For immunohistochemical studies, 4-μm thick sections were taken in specially coated slides using chrome alum and gelatin. Antigen retrieval was done by microwaving. Various panels of markers were chosen based on histological diagnosis. They include CD20, CD3, CD45, CD15, CD30 CD5, CD10, CD23, BCL2, CYCLIN D1, KI67, TDT, and ALK. These antigens are bound with mouse monoclonal antibody (BioGenex) and then detected by the addition of secondary antibody conjugated with horseradish peroxidase polymer and diaminobenzidine substrate. The slides were counterstained with hematoxylin and mounted.

NHL was further categorized morphologically as small-, medium-, or large-cell lymphomas. Accordingly, the panel of markers was chosen as follows.

For HL – CD45, CD20, CD15, CD30, and CD 3.

For NHL small cell type – CD20, CD5, CD23, CD10, CYCLIN D1, and BCL2.

For NHL medium cell type – CD20, CD3, CD5, CD23, CD10, CYCLIN D1, TDT, KI67, and BCL2.

For NHL large cell type – CD20, CD3, CD5, CD23, CD10, CYCLIN D1, TDT, KI67, CD30, ALK, and BCL2.

All the cases were interpreted by experienced pathologists in the field of lymphoma diagnosis.

Results

During the study period, there were 50 cases of lymphomas which met the inclusion and exclusion criteria. Two cases in which there was no material for IHC workup were excluded from the study. Forty-one cases (82%) were diagnosed with NHL and 9 cases (18%) were diagnosed with HL.

Of the 41 cases of NHL, 61% (n = 25) were male and 39% (n = 16) were female. Of the nine cases of HL, 55.6% (n = 5) were male and 44.4% (n = 4) were female. In both the groups, males outnumbered females (male-to-female ratio being 1.5:1). About 44% (n = 22) cases were in the age group of 41–60 years, 32% (n = 16) were >60 years, and 24% (n = 12) were <40 years.

Nodal lymphomas (88%, n = 44) were more common than extranodal lymphomas (12%, n = 6). The extranodal sites included the gastrointestinal tract (n = 2), pleura, pericardium, skin, and breast (one each). Cervical lymphadenopathy (n = 26, 59.2%) was the common presentation among the nodal group [Table 1].

B-NHL formed 78.5% (32 cases), while T-cell NHL formed 21.5% (9 cases).

Based on the pattern and cellular composition of lymphoma, the lymphomas are classified into small-cell, medium–cell, and large cell type and various panels of immunohistochemical markers were used. The expression of various immunohistochemical markers is tabulated in Table 2.

Small lymphocytic lymphoma/chronic lymphocytic leukemia (SLL/CLL) (n = 11,34.4%) was the most common B-NHL followed by diffuse large B-cell lymphoma (DLBCL NOS) (31.5%, n = 10), follicular lymphoma (FL) (25%, n = 8), and Burkitt's lymphoma (BL) constituting 9.4% (n = 3).

Among the 11 cases of SLL/CLL, peripheral smear findings and bone marrow aspiration studies were available in eight cases. Five cases of SLL/CLL showed bone marrow infiltration, three of which had diffuse infiltration and the remaining two had nodular infiltration. Only three of them showed features of CLL.

Peripheral T cell lymphoma, NOS	6	5 nodal and 1 extranodal (skin)	-
Angioimmunoblastic T cell lymphoma	2	Nodal	-

NHL: Non-Hodgkin lymphoma, NOS: Not otherwise specified, FL: Follicular lymphoma, SLL: Small lymphocytic lymphoma, DLBCL: Diffuse large B-cell lymphoma, BL: Burkitt's lymphoma

Table 2: Immunohistochemical profile of B non-Hodgkin lymphoma

Subtype of NHL	Positive markers	Negative markers	Other findings
SLL	CD5, CD23	CD3, CD10, Cyclin D1, Bcl2	Weak membranous expression of CD20
FL	CD10, CD20, BCL2, Ki67 variable	CD3, Cyclin D1 and CD5	5 were CD5 positive. 2 cases of Grade III FL showed decreased BCL2 expression
DLBCL	CD 20, CD79a, CD10	BCL2, CD3, ALK	
Burkitt lymphoma	CD20, CD10, KI67 95-100%	CD3, BCL2, TdT	

SLL: Small lymphocytic lymphoma, DLBCL: Diffuse large B-cell lymphoma, FL: Follicular lymphoma, ALK: Anaplastic lymphoma kinase, NHL: Non-Hodgkin lymphoma

Of the nine cases of FL, one was Grade III. The case showed a predominant follicular pattern (85%–90%), with a diffuse area (10%–15%) that was centrocyte rich. There were no sheets of centroblasts in the diffuse areas, and hence, the case was diagnosed as FL Grade III A. Six cases were of Grade II morphology, while the other belonged to Grade I category. Bone marrow involvement was seen in three cases of FL (two were Grade II and the other was Grade III A).

Of the ten cases of DLBCL NOS, nine cases presented with cervical lymphadenopathy, while one case presented as an intestinal mass. Morphological variants included seven cases of centroblastic type, two cases of anaplastic, and one case of immunoblastic category. None of them showed bone marrow involvement at diagnosis.

All the three cases of BL were extranodal lymphomas, of which one case presented with intussusception in a 3-year old child. There was also a rare case of BL presented with breast mass.

PTCL-NOS (14.1%, n = 6) was the most frequent T-cell NHL, followed by angioimmunoblastic T-cell lymphoma (AITL) (4.8%, n = 2), T-LL constituting 2.4% (n = 1). All except one case of PTCL NOS presented with nodal enlargement. LL presented with a pericardial mass.

Among HLs, MC formed 55.6% (n = 5), lymphocyte-depleted type (LD) formed 22.2% (n = 2), and nodular lymphocyte predominant HL (NLPHL) and lymphocyte rich (LR) type each constituted 11.1% (n = 1). The age of the patients ranged from 19 to 78 years. All the nine patients were seronegative for HIV. Both the cases of HL, LD, occurred in elderly males.

Immunohistochemical analysis

All the 11 cases of SLL/CLL were CD5 and CD23 positive with weak expression of CD20 [Figure 1].

Of the 10 cases of DLBCL, CD10 positivity was noted in 5(50%) cases [Figure 2]. All the cases showed diffuse expression of CD20 and CD79a. Ki67 index varied from 76 to 90%.

All the cases of FL expressed CD10, BCL2, and CD20. Grade III FL showed less intense CD10 expression. Three of the nine cases of FL showed positivity for CD5.

All the cases of T-NHL expressed CD3. Ki67 was a variable ranging from 20% to 90%.

Eight cases of classic HL expressed CD30, of which five cases also expressed CD15 [Figure 3].

One case of NLPHL was positive for CD20 and negative for both CD15 and CD30.The background polymorphous cells showed a variable expression of CD3 and CD20.

Discussion

Geographic variations in the incidence as well as distribution of histological subtypes of lymphoma are

(c) Large cells expressing CD10 (Immunohistochemistry, ×10). (d) High proliferation index with Ki67 staining (Immunohistochemistry, ×10)

well-documented. A higher rate of nasal T-cell lymphomas has been reported in China. BL occurs in endemic form in Africa. Gastric lymphomas and adult T-cell leukemias are reported to be more frequent in Italy and Japan, respectively.[1] The incidence rates for NHL in India are quite high in urban cities when compared to rural centers.[1] The incidence rate is one-quarter of what is reported in America and Europe.[1]

The male-to-female ratio is 1.6 in Asia compared to 1.2 and 1.1 in North America and Europe, respectively. The present study also reports a male preponderance. The median age was 50 years which is higher when compared to Eastern India in which the median age was 39.4 years.[8]

The ratio of NHL to HL was 4.5:1 which is higher when compared to another South Indian study which had reported the ratio of NHL to HL to be 3.6:1.[9]

In line with most other studies in India, the most common mode of presentation in the present study was lymphadenopathy constituting to 86%.[8-11] The most commonly involved lymph node groups were cervical (n = 22,59.5%) followed by inguinal (18.2%, n = 8) and axillary (11.3%, n = 5), Which is similar to that reported by Devi *et al*.[11] Extranodal presentation was seen in 14% of cases in the present study, the frequency of which was much lower than that reported in Northern and Eastern India (44.2 and 27.7%, respectively).[10,11] This could be attributed to the smaller sample size of the present study.

The extranodal lymphomas in the present study were exclusively Non-Hodgkin's lymphomas. The predominant subtype was BL which constituted for about 50%, which is in contrast to the other regions of India and other Asian countries where DLBCL was the most frequent subtype.[11-13] The gastrointestinal tract was the most common site for extranodal lymphomas which is consistent with other Indian studies.[12-14] [Table 3].

Bone marrow involvement was seen in 22% (n = 9) of NHL. The reported percentage varied from 20 to 40% in various western studies and 30.3%–63% in Indian studies.[8-10] Bone marrow biopsy studies were available only in 28 cases.

B-cell non-Hodgkin lymphoma

The ratio between B-cell and T-cell NHL was 3.5:1. SLL formed the major proportion of B-cell NHL constituting 34.4% in contrast to most other studies where DLBCL NOS was the most frequent lymphoma.[15-17] This could be possibly due to higher number of elderly patients found in our study. Extensive literature search did not find any Indian study reporting SLL/CLL to be more frequent.[11-17] Currently, available studies on the distribution of lymphomas are from tertiary referral centers where aggressive lymphomas are likely to be referred. Our study population being the patients attending a teaching hospital, they can show a distribution much different from those studies. However, one cancer registry-based European study done by Marcos *et al*., which had analyzed 5-year survival rate in patients with lymphoid neoplasms, had observed a greater number of SLL/CLL cases during their study period of 7 years.[18] All the 11 cases of SLL showed weak expression of CD20 similar to that observed by Veronika *et al*. in which it was shown that of all mature B-cell neoplasms, SLL/CLL has the dim expression of CD20.[17]

SLL/CLL was followed in frequency by DLBCL constituting to 28%, which is in contrast to majority of other Indian studies reporting the incidence to be between 30% and 58%.[10-14,17] However, Roy *et al*. and Kalyan

NHL: Non-Hodgkin lymphoma, AITL: Angioimmunoblastic T-cell lymphoma, PTCL: Peripheral T-cell lymphoma, BL: Burkitt's lymphoma, DLBCL: Diffuse large B-cell lymphoma, FL: Follicular lymphoma, SLL: Small lymphocytic lymphoma, T-ALL: T-cell acute lymphoblastic leukemia

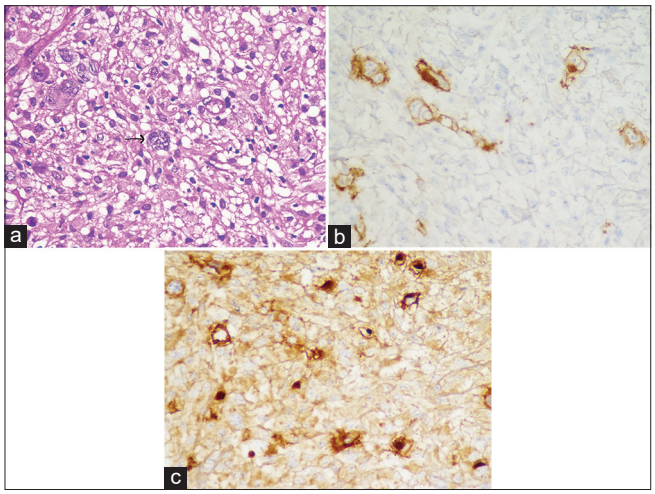

Figure 3: (a) Pleomorphic Reed–Sternberg cells (H and E, ×40). (b) RS cells expressing CD30 (Immunohistochemistry, ×10). (c) RS cells expressing CD15 (Immunohistochemistry, ×10)

et al. had reported the incidence to be 29.3% and 26%, respectively,[19,20] which were not much different from the present study.

DLBCL NOS was the most common of aggressive NHL observed in the current study. The most common mode of presentation was cervical lymphadenopathy except one which presented with an intestinal lymphoma. None of them showed any bone marrow involvement at diagnosis. In contrast, bone marrow involvement had been reported to be varying from 4 to 20% in the Indian population.[21] CD10 positivity was noted in 5 (50%) cases which is similar to that reported by Diwivedi *et al*.[22]

Among the nine cases of FLs, we observed five of them to express CD5 constituting to 21% of CD5-positive lymphomas in our study which was similar to the observation made by Dong *et al*., in which FL accounted for 24% of cases positive for both CD5 and CD10.[23] The case of Grade III FL showed decreased expression of BCL2 which is similar to the other studies.[24,25]

All the three cases of BL were extranodal lymphomas, of which one case presented with intussusception in a 3-year-old child. The presentation was similar to other studies which had shown abdomen, particularly the ileocecal region as the most common site of involvement.[14] We also found an unusual presentation of BL with breast lump in a 25-year-old female. Histology showed that the typical morphology of BL and Ki67 proliferation index was 97%. Primary BL of the breast is much less common than the other types of lymphoma. Primary breast lymphomas are extremely rare, and the most common histologic type is DLBCL.[26]

T-cell non-Hodgkin lymphoma

T-NHL constituted for 24% (*n* = 9) which is similar to other Indian studies.[11-17,27] The frequency of T-NHL is higher in India when compared to Western countries but less than what is reported in other East Asian countries. PTCL NOS was the most common subtype of T-NHL in the present study similar to that reported by Arora *et al*. and Nair *et al*.[9,28] Sharma *et al*. had reported T-LL to be more common followed by anaplastic large cell lymphoma (ALCL) and AITL accounting for 6.4, 2.1, and 2.1% of all NHL, respectively.[27] Naresh *et al*. had reported the incidence of T-LL and ALCL to be 6% and 4.3%, respectively.[13] Although ALCL was the most common PTCL in Eastern India, it was not identified in our study, the reason for which is unknown.

We also found a rare variant of PTCL, Lennert's lymphoma in a patient who presented with bilateral cervical lymphadenopathy. Morphologically, it showed microgranulomas typical of the lymphoepithelioid lymphoma. All the neoplastic cells expressed CD3.

[Downloaded free from http://www.ijmpo.org on Tuesday, November 17, 2020, IP: 103.224.34.2]

Hodgkin lymphoma

HL included eight cases of classic HL and one case of NLPHL HL. The mean age of presentation in HL was 34 years which is almost similar to studies in South and Eastern India where the mean age reported was 33 and 31.3 years, respectively.[8,9] All the cases of HL presented with peripheral lymphadenopathy. Extranodal presentation and bone marrow involvement were not seen in any of these cases. The other studies in India too have not reported any extranodal presentation. In contrast, bone marrow involvement was reported to be 14.3% in HL.[8,9]

The most common subtype found in the study was MC (n = 5, 55.6%), followed by LD. Reed–Sternberg cells in LD HL showed strong expression of both CD15 and CD30 [Figure 2]. Other Indian studies had also reported MC to be the most common subtype of HL, followed by nodular sclerosis subtype, which is in contrast to Western countries where NS is much more frequent than other subtypes.[29,30] LD subtype was found in elderly adults.

One case each of LR and NLPHL HL were identified in this study. CD15 expression was seen in 5 (62.1%) of eight cases of classic HL. This is slightly higher than reported in a study which has reported that 49.11% of the cases expressed CD15.[29]

Limitations

One of the limitations of the study is a smaller sample size, yet there was a significant difference in subtype distribution. Follow-up data were not available to assess the value of prognostic markers used in the IHC panel.

Conclusion

The distribution of lymphoma subtypes differs from other regions of India. SLL/CLL was the most common NHL reported in our study, followed by DLBCL which differs from other studies. About 21% of FL expressed CD5 and CD10. PTCL NOS was the most common T-NHL in the study. MC was the most frequent HL. CD15 expression was more frequent in HL. IHC is an essential diagnostic aid in categorization. Further replication studies including larger samples are essential to understand the difference in subtype distribution in our population.

Histomorphological Spectrum of Mediastinal Masses with Special Emphasis on Rare Lesions

SAKTHISANKARI SHANMUGA SUNDARAM[1], S VIDHYALAKSHMI[2]

(cc) BY-NC-ND

ABSTRACT

Introduction: Mediastinal lesions are not frequently observed in routine clinical practice. A wide variety of disease process can occur within the mediastinum. Tissue from needle biopsies forms the major diagnostic material. There is need for detailed studies to make pathologists aware of the wide histological spectrum and to know the unusual lesions that can be encountered during diagnosis.

Aim: To describe the histomorphological spectrum of various mediastinal lesions and to highlight the rare lesions that posed a diagnostic challenge.

Materials and Methods: This was a retrospective study done on all mediastinal masses over a period of two years from January 2016 to December 2018. The clinical data and imaging findings were collected from the test request forms and patients' files for all the cases. Haematoxylin and eosin stained slides of all cases and immunohistochemistry markers and cytochemical stains wherever done were reviewed and analysed. Mean, median and percentage were used for statistical analysis.

Results: Thirty-four cases of mediastinal lesions were included in the study. Of these, 28 cases (82.4%) presented as anterior mediastinal masses, three cases (8.8%) each in the middle and posterior mediastinum. Thymoma (n=15) followed by lymphoma (n=4) were the most frequent neoplasms reported. There were five lesions which were rare in the mediastinum with unusual presentation that posed diagnostic difficulties. These lesions included Primitive neuroectodermal tumour in an adult, Primary Mediastinal B Cell Lymphoma (PMBCL), Malignant Peripheral Nerve Sheath Tumour (MPNST) with nodal metastasis, Seminoma deposits in mediastinal node occurring as late relapse and dedifferentiation of thyroid carcinoma in mediastinal node metastasis without an obvious primary.

Conclusion: Primary mediastinal tumours were more frequent than metastasis. Although thymomas and lymphomas are dealt extensively in literature, this article highlights the fact that pathologists must be aware of those lesions that don't display the classical histological and/or clinical features as observed in our study.

Keywords: Malignant peripheral nerve sheath tumour, Mediastinum, Mediastinal B cell lymphoma, Morphological spectrum, Primitive neuroectodermal tumour

INTRODUCTION

Primary mediastinal tumours are rare. Anterior mediastinal masses constitute >50% of mediastinal lesions and majority of them involve thymus. Middle mediastinal lesions include congenital cyst, (pericardial and bronchogenic cyst) while neurogenic tumours form the majority of posterior mediastinal masses [1-3]. Lymphomas can arise in any of these three compartments [4]. Aggarwal R et al., in their study of mediastinal lesions have reported 70% of lesions confined to anterior mediastinum, of which thymic lesions were the most frequent, constituting to 45.7% [1]. Posterior, superior and middle mediastinal lesions were reported to be 19, 6 and 4%, respectively. Lymphomas were the second most common tumour (11.2%) after thymoma. Sarcoma was seen in 6.9% cases and showed random compartment localisation. In their study, primary lesions were more common when compared to secondary deposits.

Dixit R et al., in their evaluation of 144 cases of mediastinal lesions have reported metastasis to be the most common, contributing to 37.4% of malignant lesions followed by lymphoma [5]. The clinical findings with radiological findings can narrow the differential diagnosis. However, advent of new techniques has made it easier to obtain tissue material from this site [5,6]. Hence, it is important for a pathologist to be familiar with the wide variety of lesions in the mediastinum since an accurate early tissue diagnosis directs therapy. There are variations in the existing literature regarding the frequency of individual lesions encountered in mediastinum. Hence the study was undertaken to analyse the histopathological spectrum of mediastinal lesions in our population and to highlight the rare lesions.

MATERIALS AND METHODS

This was a retrospective study done on all mediastinal masses over a period of two years from January 2016 to December 2018. The data was retrieved from the archives of Pathology department of PSG Institute of Medical Sciences and Research. Institutional Human ethics committee clearance was obtained before conducting the study (vide letter 20/108).

Needle biopsies and surgical resections were included in the study. A total of 36 cases were received during the study period. Of these cases, two cases showed only necrosis and hence were excluded from the study. The remaining 34 cases were included.

Relevant demographic and clinical data including the presenting symptoms, past history relevant to the lesions and examination findings was collected from patient files in all the cases. Laboratory investigations such as serum markers like carcinoembryonic antigen, CA125, alpha fetoprotein wherever available were obtained from test request forms and hospital information system. Computed Tomography findings including the location, size and solid or cystic nature of the lesion were recorded. Haematoxylin and eosin stained slides of all cases and Immunohistochemistry (IHC) markers and cytochemical stains like periodic acid, Ziehl Neelsen wherever done were reviewed and analysed. Immunohistochemical markers included cytokeratin (Mouse, polyclonal, AE1/AE3), CD99 (Mouse, 12E7) S100 (rabbit, polyclonal, 504),Thyroid transcription factor (Mouse, 056), napsin (EP205), CD45 (Mouse, EP273), CD3 (rabbit, polyclonal, 503), CD20 (Mouse, L26), CD15 (Mouse, 273), CD30 (Mouse, BER-H2), CD117 (IB 077) and PLAP (mouse, 376). IHC was done on paraffin embedded tissue sections using heat induced antigen

retrieval. Diaminobenzidene was the chromogen used. The cases which posed diagnostic challenge or had an unusual presentation were extensively studied. Mean, median and percentage were used for statistical analysis. The analysis was done using SPSS software version 20.0.

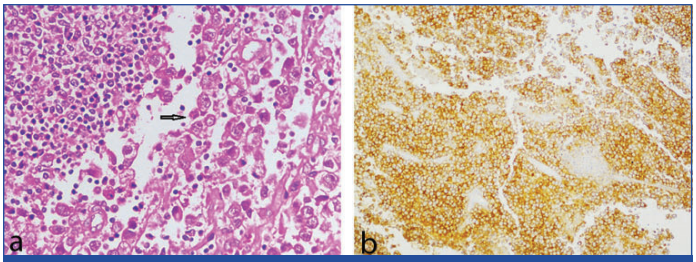
RESULTS

Thirty four cases of mediastinal lesions were included in the study. Age of the patients ranged from 14 to 75 years. Majority of the lesions were in females with male to female ratio being 1:1.5. The presenting symptoms included chest pain, cough and breathlessness in 26 cases. A total of 24 cases were the Primary mediastinal tumours while metastatic lesions were two in number. About Twenty eight (82.4%) cases presented as anterior mediastinal masses, and three cases each in the middle and posterior mediastinum. The majority of lesions were involving the thymus (n=21) constituting to 67.8% [Table/Fig-1]. The frequency of malignancy was higher in females (6 cases).

S. No.	Diagnostic category	Anterior 82.4% (n=28)	Middle 8.8% (n=3)	Posterior 8.8% (n=3)	Total % (n)
1	Non-neoplastic				
	Retrosternal goitre	1		1	23.5 (8)
	Sarcoidosis	1	1		
	Thymic cyst	2			
	Thymolipoma	2			
2	Neoplastic, Benign				
	Thymoma	15			47 (16)
	Teratoma		1		
3	Neoplastic, Malignant				
	Thymic carcinoma	2			
	Lymphoma	3	1		23.5 (8)
	Primitive neuroectodermal tumour			1	
	Malignant peripheral nerve sheath tumour			1	
4	Neoplastic, metastatic	2			6 (2)

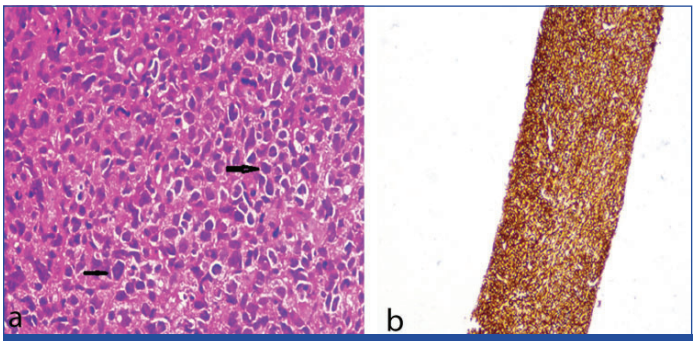
[Table/Fig-1]: Distribution of mediastinal lesions.

The variants of thymoma included four cases each of type A, B1 and B2 and three cases of type AB thymoma. Both the cases of thymic carcinoma occurred in females, one of which occurred in a young female (age 28 years).



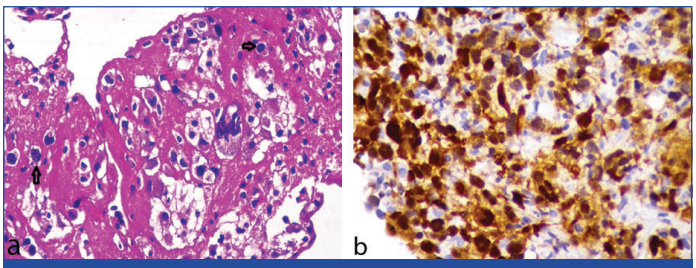
The two cases of Non-Hodgkin Lymphoma (NHL) reported were precursor T-lymphoblastic lymphoma in adolescent patients. The other NHL was Primary Mediastinal B Cell Lymphoma (PMBCL). The two cases of Hodgkin Lymphoma (HL) included one case each of Nodular Sclerosis and Mixed cellularity HL.

Of the 34 cases, 13 (38.2%) were diagnosed on guided biopsies and 21 (61.8%) on excision biopsies. In all the guided biopsies, a confirmatory diagnosis was made only after immunohistochemistry.

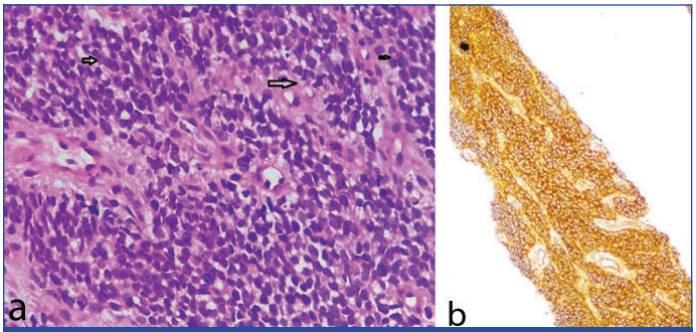


The rare tumours encountered are described below [Table/Fig-2]. Case 1 presented with multiple lymph nodes involvement suggesting the possibility of lymphoma. Seminoma relapse was not initially considered for this case. The diagnosis of seminoma metastasizing to lymph node was made only with the help of immunohistochemistry [Table/Fig-3]. Case 2 (PMBCL) was a rare lesion occurring in a young male, but had the typical presentation. Differential diagnosis entertained in this case were PNET and thymoma based on the morphology [Table/Fig-4]. Case 3 (MPNST) occurred in a patient with Neurofibromatosis. Cytology of pleural fluid also showed atypical cells. Based on the morphology, a provisional diagnosis of high-grade sarcoma was made. The diagnosis of MPNST with nodal metastasis was made with immunohistochemistry (S100 positive and Ki67 90%) [Table/Fig-5]. Case 4 (PNET/Ewing's sarcoma) occurred in an adult female (65 years) which is rare [Table/Fig-6]. Case 5 (dedifferentiated thyroid carcinoma in mediastinal nodes) occurred in an adult female who did not have any history of thyroidectomy. Histopathological examination showed an anaplastic tumour suggesting the possibility of sarcoma/carcinoma. Extensive sampling revealed tiny foci of conventional papillary thyroid carcinoma which was supported by IHC markers (Thyroid transcription factor positive, Napsin negative, Cytokeratin positive in anaplastic areas). Lung carcinoma was ruled out by napsin negativity [Table/Fig-7]. Normal thyroid parenchyma was not identified in the tissue and thus the possibility of aberrant

Case No.	Clinical details	Imaging findings (CT Scan)	Histology and IHC	Diagnosis and unusual finding
1	48/M, operated for testicular seminoma 5 years back and had defaulted surveillance	Hypodense, soft tissue mass of size 5.5×2.9 cm in anterior mediastinum. Mediastinal lymphadenopathy +. Beta HCG-420 mIU/mL LDH-1820IU/L	Lymph node with sheets of large cells having pleomorphic vesicular nuclei and prominent nucleoli separated by fibrous septa rich in lymphocytes. There was no other germ cell tumour elements. CD117 and PLAP positive.	Seminoma metastasing to mediastinal lymph nodes. Late relapse presenting with generalised lymphadenopathy
2.	21/M, anorexia, night sweats, significant loss of weight for two months. No organomegaly or superficial lymphadenopathy	large anterior mediastinal mass of size 6×7 cm invading superior vena cava.	Monomorphous population of blue round cells separated by thick fibrous septa. CD20 and CD45 positive Neuron Specific enolase, Cytokeratin negative	Primary Mediastinal B Cell Lymphoma (PMBCL). Rare lesion (incidence-2 to 3% of NHL) [1]
3.	35/M, known case of Neurofibromatosis presented with a complaint of dry cough associated with breathlessness	Multiple nodules in both lungs and pleura. Multiple enlarged mediastinal, para-aortic, celiac lymph nodes suggesting metastasis	Oval to spindle neoplastic cells exhibiting marked pleomorphism arranged in sheets. Vimentin, S100 positive. Ki67 index-90% Desmin and CD34 negative	MPNST with nodal metastasis. Rare presentation
4	65/F, chest pain, breathlessness and fever	intrathoracic mass measuring 15×12 cm extending into posterior mediastinum, encasing and lifting aorta, inferior vena cava and causing diaphragmatic inversion.	Small round cells with scant cytoplasm, uniform hyperchromatic nuclei with perivascular accentuation and surrounded by fibrous septa. Differential diagnoses entertained were lymphoma, Ewing's sarcoma and rhabdomyosarcoma. CD99 positive, CD45, Tdt and Myogenin negative	PNET/Extraskeletal Ewing's sarcoma in adult. (incidence -1.8%) [27]
5	69/F, chest pain, breathlessness and intermittent fever and inspiratory stridor	Large heterogeneously enhancing mass measuring 5×4×5 cm in the right upper posterior mediastinum encasing the esophagus in the left lateral aspect. Few small nodules in the right lung suggestive of metastasis were seen. A small nodule was noted in the thyroid. Thyroidectomy could not be done in this patient.	An anaplastic tumour composed of multinucleated giant cells and highly pleomorphic cells with extensive areas of coagulative necrosis. Tiny foci of conventional papillary thyroid carcinoma. No normal thyroid tissue identified. (strong nuclear expression of TTF1 in conventional papillary thyroid carcinoma. The anaplastic component was positive for Cytokeratin and lacked TTF 1 expression. Napsin-negative (rules out lung carcinoma)	Dedifferentiated thyroid carcinoma metastasis with no obvious lesion in thyroid.



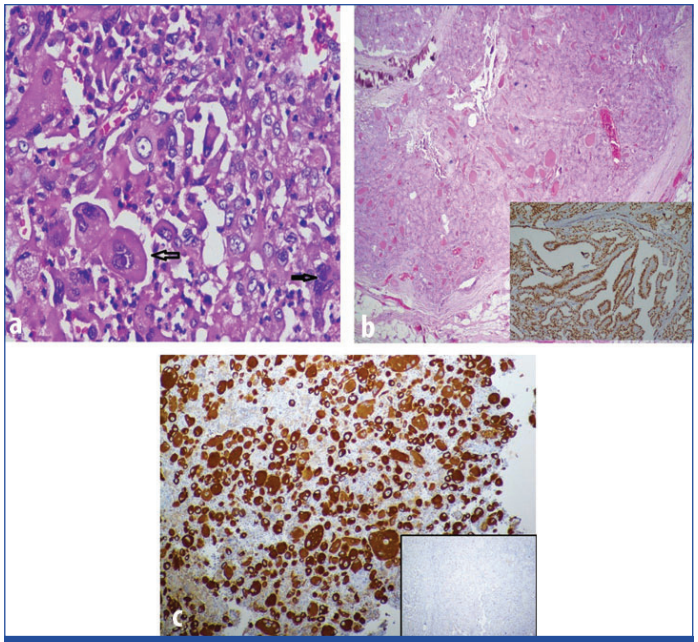
[Table/Fig-2]: Unusual features of the reported rare cases.
MPNST: Malignant peripheral nerve sheath tumour; PNET: Primitive neuroectodermal tumour



[Table/Fig-3]: a) Large neoplastic cells separated by fibrous septa rich in lymphocytes, Seminoma (H&E,40X). b) Neoplastic cells with strong membranous expression of PLAP (IHC-40X).

[Table/Fig-4]: a) Discohesive pleomorphic large round cells (arrow), PMBCL (H&E, 40X).b) Neoplastic cells with strong membranous CD20 expression (IHC, 10X).

[Table/Fig-5]: a) Pleomorphic tumour cells, MPNST (H&E, 40X). b) Tumour cells expressing S100 (IHC 40X).



[Table/Fig-6]: a) Small round cell tumour, PNET (H&E, 10X). b) Tumour cells expressing membranous staining for CD99 (IHC 10X).

thyroid and retrosternal extension were ruled out. Small nodule identified in thyroid by Computed Tomography of neck could not be evaluated since thyroidectomy could not be done on this patient.

DISCUSSION

In the present study, the majority of the tumours were primary in origin (88.2%) except for two cases. Literature review also showed that primary mediastinal lesions are more common than metastatic malignancies [3,4,6-9]. There was a female predominance in the current study which contrasts with the previous studies [5-9].

In keeping with other studies [3-10], most of the lesions were in the anterior compartment (82.4%) and benign lesions (47%) were more frequent than malignant tumours (23.5%). However, there are studies reporting malignant lesions to be more commoner constituting about 60% of lesions [11,12].

[Table/Fig-7]: a) Sheets of pleomorphic cells with multinuleation and hyperchromatic nuclei (H&E- 40X).b) Conventional papillary carcinoma component. (IHC-10X). Inset TTF1 expression (IHC 10X). c) Anaplastic carcinoma with CK expression (IHC-40X). Inset TTF 1 negative (IHC 10X).

Thymoma was the most frequent neoplasm in the present study which is similar to other studies [3-9]. However, Vaziri M et al., in their study had reported lymphomas to be more common than thymoma in a series of 105 cases [11]. In the current study, thymic lesions constituted 61.7% of anterior mediastinal masses which is higher when compared to the studies by Aggarwal R et al., and Dasgupta S et al., [1,3].

Thymic carcinomas are reported to be rare malignancies occurring in the age group of 30 to 60 years. Suster S, in his study have reported a slight male predilection (1.5:1) [13]. In the present study both the cases of thymic carcinoma occurred in females.

Retrosternal goitres are usually located anteriorly, in the superior or anterior mediastinum. Posterior mediastinum is rarely involved. Their incidence in the general population is about 1:5000 [14]. The case described in the study also occurred in posterior mediastinum. In the present study, there were five cases which were either rare or had unusual presentations that posed diagnostic difficulties [Table/Fig-2].

Primary mediastinal Seminomas originating from extragonadal germ cells are rare [15]. In general, the relapse occurs within 2 to 3 years. It has been reported in inguinal lymph nodes, contralateral testis, retroperitoneum, mediastinum and lung [16-18]. The case described here presented with seminoma deposits in mediastinal lymph nodes along with multiple abdominal lymphadenopathy 5 years after orchidectomy. Hence, the possibility of any mediastinal germ cell tumour representing a metastasis from testicular primary should always be investigated. Considering the above facts, this case is unusual since it presented as a late relapse.

PMBCL is a subtype of Diffuse Large B Cell Lymphoma (DLBCL) of thymic B cell origin affecting adolescents and young adults and having a slight female preponderance. Of the cases reported, 75% present with bulky anterior mediastinal mass greater than 10 cm that grows rapidly and nearly always present with superior vena cava obstruction [19]. Bone marrow involvement is reported to be extremely rare. It shares the biological and clinical characteristics with Nodular Sclerosis type of Hodgkin Lymphoma (NSHL) [19]. The characteristic histologic findings include clearing of cytoplasm of cells and alveolar fibrosis. Because of the presence of compartmentalisation of

cells divided by fibrous septa, it mimics thymoma, NSHL and germ cell tumours. Hence, immunohistochemistry becomes an essential aid in diagnosis. All the cases of PMBCL express CD20 and a proportion of cases express CD30. PMBCL has been reported to have better prognosis when compared to DLBCL with secondary mediastinal lymph node involvement [19,20]. The case presented here had the typical presentation of PMBCL with superior vena cava obstruction and absence of superficial lymphadenopathy and organomegaly but its occurrence in a young male is rare.

Intrathoracic presentation of MPNST is rare. There are nearly 20 such cases reported in literature, majority of them in the posterior mediastinum [21]. A 20 -30% of MPNST occur in the setting of Neurofibromatosis. Those cases show an increased recurrence and risk of distant metastasis [22,23]. Lung, bone and pleura are the most common sites of metastasis. Metastasis to lymph nodes is reported in less than 10% of patients and is usually seen as a part of widespread metastasis. In the case presented here, there was mediastinal lymph node metastasis from MPNST. Since these tumours show a weak expression of S100 in majority of cases, it becomes difficult in cases of unusual presentation like nodal metastasis, especially in small biopsies to diagnose [24]. The challenge faced in this case was that the presence of neurofibromatosis in this patient was not available at the time of diagnosis.

PNET is a rare and aggressive tumour of neuroectodermal origin most frequently occurring in children and young adults. There are only a few published series of PNET in adults [25]. Primary mediastinal PNET is very rare constituting 1.8% of mediastinal tumours. In a study by Applebaum MA et al., it was found that Extraskeletal Ewing sarcoma had a higher mean age when compared to those with skeletal tumours [26,27]. Metastasis was frequent in the cases with extraskelatal Ewings sarcoma/ PNET [25,28]. The case presented here also occurred in an adult female (65 years).

PTCs are known for anaplastic transformation at the metastatic sites [29] and have been reported in retroperitoneum, liver and lungs. This has been proven even with papillary microcarcinoma [29,30]. The cases reported previously were postsurgery for papillary carcinoma which occurred as a recurrence, many years after treatment for papillary carcinoma [29]. The case presented here did not have any history of proven PTC nor did the patient present with thyroid mass. This could probably represent an occult papillary microcarcinoma in thyroid with mediastinal metastasis of papillary thyroid carcinoma that has undergone dedifferentiation. The diagnosis of dedifferentiated thyroid carcinoma was not made on the initial sections. This case re-emphasises the need for extensive sampling in a case of anaplastic tumour to look for a well differentiated tumour to accurately diagnose even a remote possibility.

Limitation(s)

The smaller sample size in this study precludes generalisation of study results considering the frequency and distribution of mediastinal tumours. Further studies including larger sample size and studies aiming at analysing correlation with clinical and radiological findings are needed to estimate the subtype distribution of mediastinal lesions.

CONCLUSION(S)

To summarise, benign tumours were more common than malignant ones. Primary mediastinal tumours were more frequent than metastasis. Although thymomas and lymphomas are dealt extensively in literature, this article highlights the fact that pathologists must be aware of those lesions that don't display the classical histological and/or clinical features as observed in our study.

Miliary Sarcoidosis: does it exist? A case series and systematic review of literature

Srinivas Rajagopala[1], Sakthi Sankari[2], Roopa Kancherla[1], Ramanathan Palaniappan Ramanathan[1], Devanand Balalakshmoji[3]

Abstract. *Background and Objectives:* Sarcoidosis typically presents with peribronchovascular and perilymphatic nodules on high-resolution computed tomography (HRCT); a miliary pattern is reported but not well described. *Design, setting:* We describe four patients with miliary sarcoidosis and results of a systematic review of all previously reported cases from 1985 onwards. *Results:* We identified only 27 cases of "miliary" sarcoidosis in the HRCT era. These patients were older (85.2% older than 40 years), had more co-morbidities (72.7%) and were symptomatic compared to "typical" sarcoidosis. Respiratory symptoms were present in 61.9% at diagnosis. Hypercalcemia was seen in 28.5%. On review of HRCT images, only 34.6% (9/26) had a "true miliary" pattern without fissural nodules. In our series, prominent perivascular granulomas were seen on histopathology in all. 44.4% (12/27) had tuberculosis preceding or concurrent to miliary sarcoidosis. Of the eight true associations, tuberculosis preceded sarcoidosis by 52 (median, IQR 36) weeks in six and occurred concurrently in another two. The diagnosis of tuberculosis was clinical in all with concurrent diagnosis of tuberculosis and sarcoidosis. Treatment with steroids had 100% response and 14.2% relapse. *Conclusions:* A true miliary pattern in the HRCT era is very rare in sarcoidosis and subtle perilymphatic pattern is nearly always seen; this should be labeled "pseudo-miliary". Prominent perivascular granulomas are associated with true miliary pattern. Miliary sarcoidosis patients are older and symptomatic, needing treatment at diagnosis. "Miliary" sarcoidosis may follow treatment for tuberculosis; concurrent cases possibly indicate the difficulty in differentiating both or a "tuberculo-sarcoid" presentation. *(Sarcoidosis Vasc Diffuse Lung Dis 2020; 37 (1): 53-65)*

Key words: sarcoidosis, miliary, micronodules, miliary tuberculosis

Introduction

Miliary sarcoidosis has been described as a rare presentation of sarcoidosis and was reported in <1% of all cases in the pre-computed tomography (CT) era on chest radiography (1). With the advent of high-resolution-CT (HRCT), peribronchovascular and perilymphatic nodules in relation to the secondary pulmonary lobule are recognized as classic of sarcoidosis (2). However, random micronodules (miliary pattern) have been described and sarcoidosis is included in the differential diagnosis of a "miliary" pattern on HRCT (3, 4). There are no well-described series or systematic reviews of "miliary" sarcoidosis in the high-resolution CT (HRCT) era. On the other hand, tuberculosis continues to be a global pandemic with an estimated 10 million cases worldwide in 2016 (5). Miliary tuberculosis accounts for 1-2%

of all cases of new cases of tuberculosis and 8% of all extra-pulmonary tuberculosis (6). The relationship between tuberculosis and sarcoidosis continues to be enigmatic; tuberculosis can precede, follow or present concurrently with sarcoidosis (7). In patients with miliary tuberculosis, the clinical symptoms of night sweats, weight loss and fatigue are non-specific and overlap markedly with sarcoidosis. Respiratory symptoms are often minimal in either forms of miliary disease and microbiological evidence of *M.tuberculosis* is only present in 20-30% of miliary tuberculosis (8). Sarcoidosis has a characteristic perilymphatic pattern on histopathology and radiology (2); the co-relation of random nodules seen on radiology with pathology in "miliary" sarcoidosis is unclear. We describe a series of patients with miliary sarcoidosis and the results of our systematic review on miliary sarcoidosis in the HRCT era.

Materials and methods

We describe four patients with miliary nodules and proven sarcoidosis that was managed in the authors' institution over three years and performed a systematic search of literature for miliary sarcoidosis.

Systematic search of literature

Two of the authors (R.S and R.K) conducted a systematic search of literature in PUBMED independently using the MeSH term "miliary" *AND* "sarcoidosis" limited to title/abstract and restricted the search from the year 1985 onwards (9). The choice of the year was defined by the first description of the current HRCT protocols and detailed description. This was further supplemented by search of IndMed using the same terms, the references of retrieved articles, our personal records and the Internet search engine GOOGLE. These articles were screened without blinding, by title and abstract review to identify relevant studies. Any discrepancy was resolved by consensus. Full texts or abstracts were then retrieved to identify the type of lung involvement in reported cases with miliary sarcoidosis. Only those articles that included patients with HRCT according to established protocols (9), included representative images or detailed descriptions and had a histological diagnosis compatible with sarcoidosis (10) were included for analysis. For the purpose of this systematic review, we included all descriptions that were accepted as "miliary" in published cases but reanalyzed the images independently. The diagnosis of sarcoidosis was according to previous published guidelines (10).

Data extraction

Data was abstracted from selected cases in a predefined data extraction form (Supplementary Table).

Statistical analysis

Continuous data are presented as mean (standard deviation (SD), median [range or Interquartile Range (IQR)] and categorical data as percentages and proportions. All statistical analysis was done using the Statistical software SPSS Version 14.

Ethics

The Human Ethics Committee of PSG IMS&R, Coimbatore, approved the study. All data was anonymized to maintain patient confidentiality.

Case reports

Case 1

A 65-year-old lady presented with cough, night sweats and exertional breathlessness of two months' duration. There was no history of weight loss or fever. Her past history was significant for hypertension and non-productive cough two years before that was evaluated at another center. CT had shown right paratracheal and bilateral hilar lymphadenopathy along with upper lobe-predominant micronodules. Tuberculin skin testing was negative and endobronchial ultrasound-guided needle aspiration (EBUS-FNA) and transbronchial lung biopsy (TBLB) were performed. EBUS-FNA showed few non-caseating granulomas and TBLB was non-contributory. A presumptive diagnosis of tuberculosis was made and four-drug anti-tuberculosis treatment (ATT) was administered for six months with improvement in cough. Examination was unremarkable during current evaluation. There was no exposure to pets, drugs

or occupational dusts. Chest radiography was normal. Spirometry was normal and diffusion capacity showed mild reduction. HRCT showed profuse random micronodules without lymphadenopathy and an upper-lobe and peripheral predominance that was visualized better with maximum intensity projection (MIP, Figure 1). Renal function tests, serum calcium and angiotensin-converting enzyme (ACE) levels were normal. Fibreoptic bronchoscopy (FOB) was done with bronchoalveolar lavage (BAL) and TBLB; BAL Fluid was negative for acid-fast bacilli and Xpert MTB/RIF and TBLB showed interstitial inflammation only. Surgical lung biopsy was performed and showed extensive perivascular non-caseating granulomas (Figure 2). BAL mycobacterial cultures were subsequently reported as negative. She was started on steroids with resolution in cough and breathlessness by second month of treatment. She remains asymptomatic and off steroids after one year of treatment.

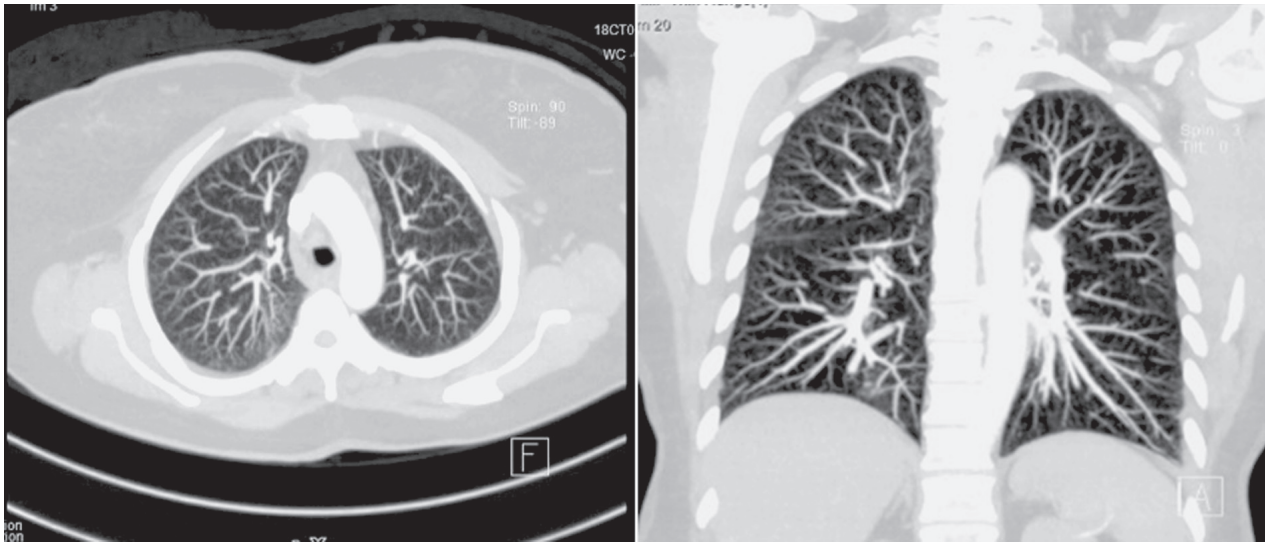

Fig. 1. Composite image of Maximal Intensity Projection images of high-resolution computed tomography (HRCT) of the thorax from patient 1 showing upper-lobe and peripheral-predominant miliary micronodules

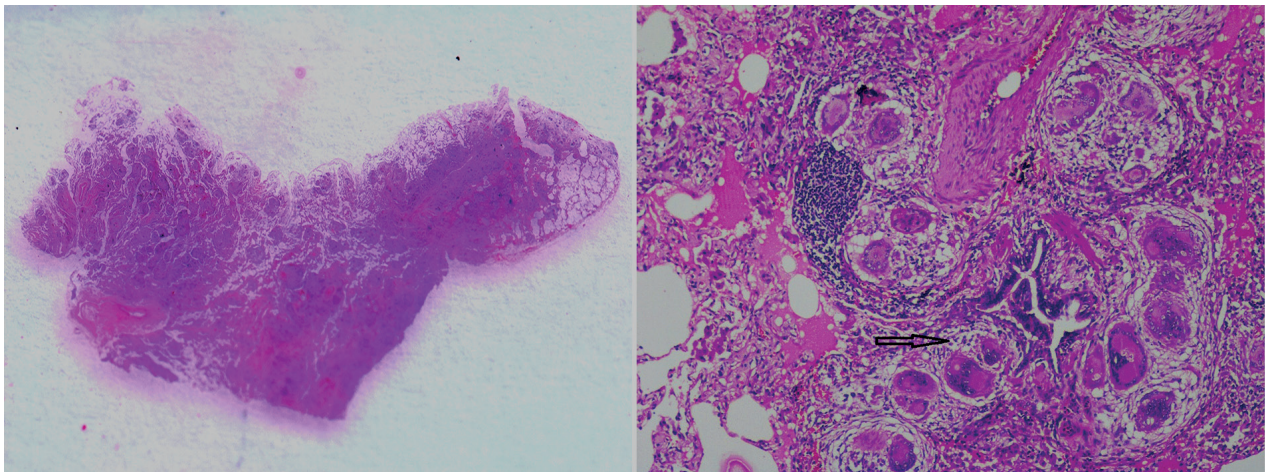

Fig. 2. Composite image of photomicrographs of surgical lung biopsy specimen of Patient 1 with left [Gross Pathological specimen, transverse plane] showing subpleural sparing and (right, Hematoxylin and Eosin stain (H & E), x 4) showing peribronchial and perivascular granulomas (arrow)

Case 2

A 40-year old gentleman presented with polyuria, fatigue and nausea of 20 days duration. There was also history of unquantified weight loss and exertional dyspnea. He did not smoke and did not raise pets, abuse drugs or have exposure to occupational dusts. Physical examination showed raised papulonodular skin lesions over hands and legs. Renal function tests showed serum creatinine of 2.65 mg/dL (normal <0.8 mg/dL); Urine microscopy showed 2+ albumin with bland sediments. Hemoglobin was 10.9 g/dL with normal leukocyte and platelet counts. Ultrasound showed normal kidney size with preserved corticomedullary distinction. Chest radiographs showed miliary nodules. Serum ionized calcium was 1.8 mg/dL (normal 1.1-1.3 mg/dL) with suppressed parathyroid hormone (1.9 pg/mL, normal 15-65) and normal vitamin D levels (23.6 ng/mL). ACE levels were elevated (98 U/mL, normal 8-53). Tuberculin skin testing was negative. CT-Chest showed random micronodules without zonal preponderance and bilateral hilar lymphadenopathy (Figure 3, left). FOB was done with BAL and TBLB; BAL was negative for acid-fast bacilli and Xpert MTB/RIF. TBLB showed perivascular non-caseating granulomas with Schaumann and asteroid bodies (Figure 4). Punch biopsy of the skin also showed non-caseating granulomas in the dermis**.** He was started on steroids with resolution of hypercalcemia and normalization of renal function. His subsequent course was complicated by steroid-aggravated diabetes presenting with hyperosmolar coma; methotrexate was added and steroids were tapered. He remained asymptomatic with near-complete radiologic clearing (Figure 3, right) after one year of stopping methotrexate but relapsed by 18 months and remains on methotrexate.

Case 3

A 55-year old gentleman with moderately controlled diabetes mellitus presented with exertional breathlessness, cough, right-sided shoulder pain and weight loss of one month's duration. There was no anorexia or expectoration. He was a farmer by occupation and did not have exposure to poultry or occupational dusts and chemicals. Physical examination showed fine bilateral crepitations without clubbing. Renal function tests, serum calcium, urine microscopy, ACE levels and hemogram were normal. Chest radiographs showed miliary nodules (Figure 5, left). Human Immunodeficiency virus was negative by enzyme-linked sorbent assay. Tuberculin skin testing was strongly positive (18 mm, 1 TU). CT-Chest showed random micronodules without lymphadenopathy (Figure 6, left). FOB was done with BAL

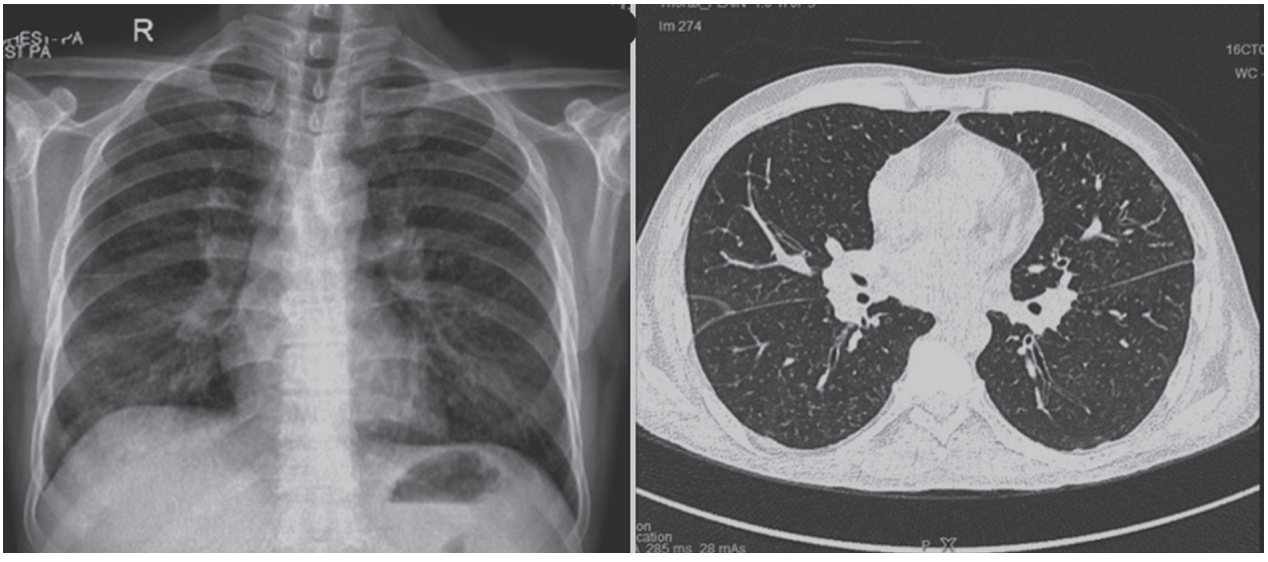

Fig. 3. Composite images of chest radiography of patient 2 showing miliary nodules (left) and HRCT images (major fissure level) showing upper lobe-predominant random nodules. No involvement of the fissure or "beading" of the fissure is seen

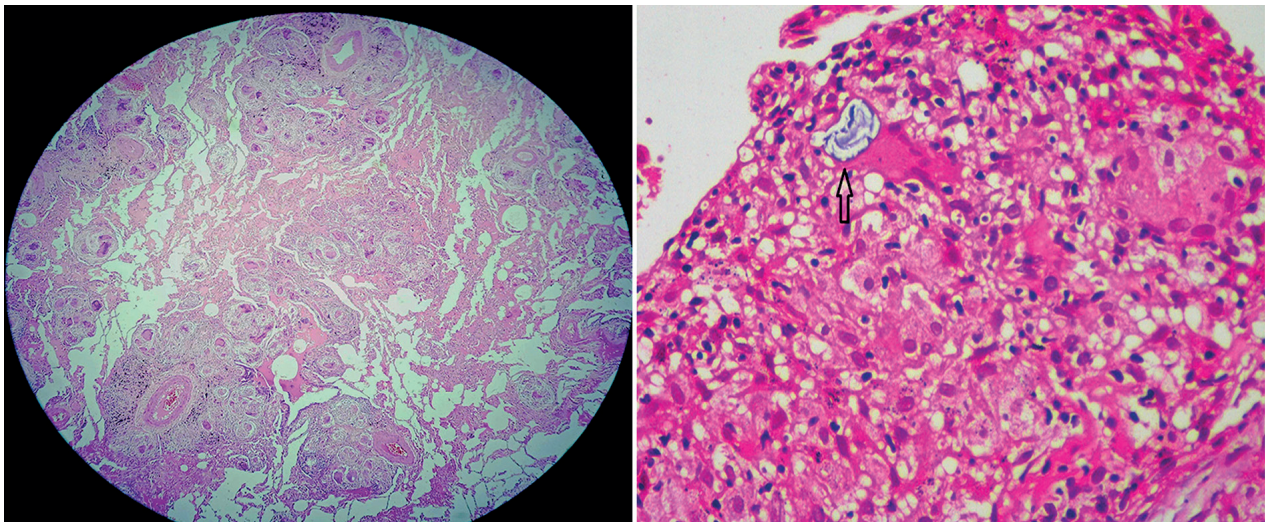

Fig. 4. Composite image of Photomicrographs of lung biopsy sample of Patient 2 with left, [Hematoxylin and Eosin stain (H & E), x scanner power] showing multiple non-necrotizing perivascular granulomas, and right, [H & E stain, x 40) showing a Schaumann body within a giant cell (arrow)

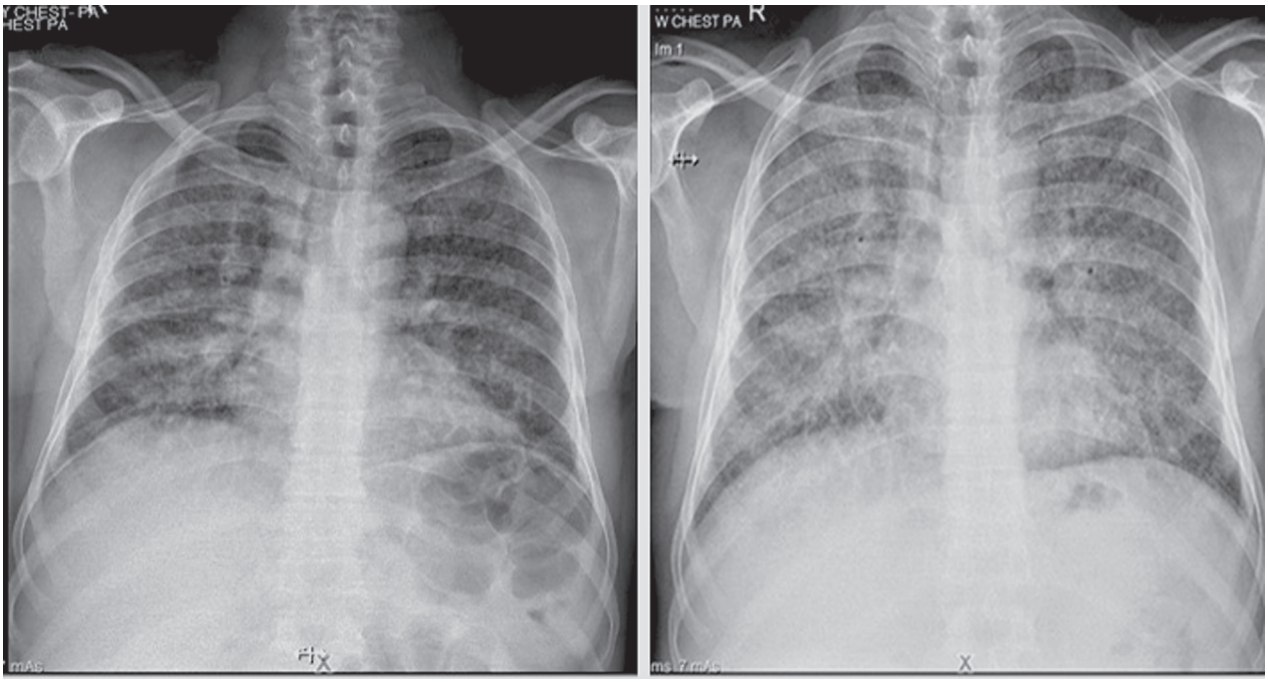

Fig. 5. Composite image of the Chest Radiographs of Patient 3 at initial evaluation (left) showing extensive miliary nodules. Subsequent Chest radiograph (right) after six weeks of anti-tuberculosis treatment alone show profusion of nodules with diffuse ground-glass opacification. Worsening hypoxemia was clinically noted

and TBLB; BAL was negative for acid-fast bacilli and Xpert MTB/RIF. TBLB showed well-formed perivascular granulomas with Langhans' giant cells, occasional fibrinoid necrosis and lymphocytes rimming (Figure 6, right). A diagnosis of miliary tuberculosis was made and four-drug weight-based ATT was started. However, his symptoms continued to worsen with worsening nodules and development

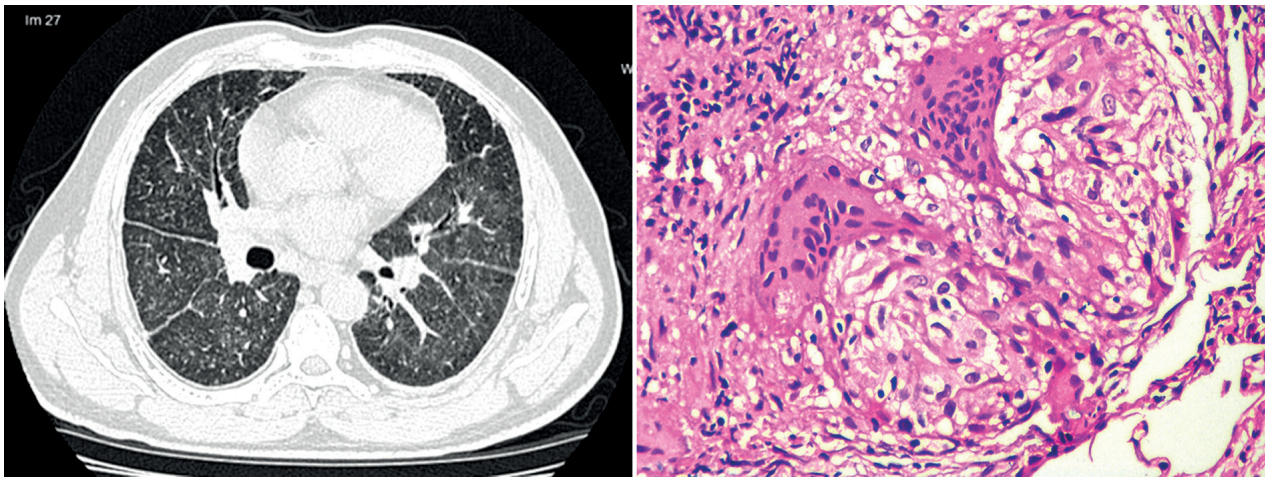

Fig. 6. Composite image of the HRCT image of Patient 3 at the level of major fissure during worsening hypoxemia corresponding to right-side of Figure 5 (left), showing random nodules with fissural prominence, with beading in both oblique fissures; some interlobular septal thickening and diffuse ground glass opacity can be seen and right, (Hematoxylin and Eosin stain, x 40) showing a non-necrotizing granuloma with peripheral lymphocyte cuffing

of hypoxemia needing oxygen at four weeks (Figure 5, right). BAL mycobacterial cultures were negative in the meantime. Steroids were added with a presumptive diagnosis of immune reconstitution syndrome, with resolution of hypoxemia and symptoms. Symptoms recurred after stopping steroids at four weeks; right-sided vision loss due to uveitis occurred. After a clinico-pathological review, a possibility of concurrent miliary tuberculosis with sarcoidosis was considered. ATT was continued and low-dose tapering steroids and methotrexate (in view of poorly controlled diabetes) were added, with complete resolution of symptoms by eight weeks. He remains asymptomatic after two years of cessation of ATT and methotrexate.

Case 4

A 48-year-old gentleman presented with fatigue for two weeks. There was no history of night sweats, weight loss or fever. He did not smoke, did not raise pets, abuse alcohol or drugs and did not report exposure to occupational dusts. Physical examination was normal. Renal function tests, urine microscopy and hemogram were normal. Serum calcium was elevated (1.43 mg/dL, normal 1.1-1.3). Chest radiographs showed miliary nodules (Figure 7, left). ACE levels were elevated (76 U/mL, normal 8-53). Tuberculin skin testing was negative. CT-Chest showed upper lobe predominant random micronodules and lower-lobe interlobular septal thickening (Figure 8, left & right). FOB was done with BAL and TBLB; BAL was negative for mycobacterial cultures and Xpert MTB/RIF. TBLB showed prominent perivascular non-necrotizing epitheloid granulomas with asteroid bodies (Figure 7, right). A diagnosis of miliary sarcoidosis was made and steroids were initiated. His symptoms and hypercalcemia resolved by four weeks and steroids were tapered over the next nine months. He remains asymptomatic on follow-up.

Results of the systematic search

Our systematic search identified 27 reports of miliary sarcoidosis in 21 reports (3, 11-30); this included 16 men and 9 women (Table 1, supplementary Table). This cohort of "miliary sarcoidosis" was older, was mostly symptomatic and had high co-morbidity burden. The mean age of the included patients was 47.5±13.2 years; 85.2% were older than 40 years. 72.7% reported at least one associated co-morbidity (11, 12, 16, 18, 21, 27, 30).

The median time to presentation was 8 (IQR 12) weeks. The majority had symptoms at the time of presentation (90.9%, 20/22); only two patients recognized by surveillance transbronchial lung biopsies post-lung transplantation were asymptomatic

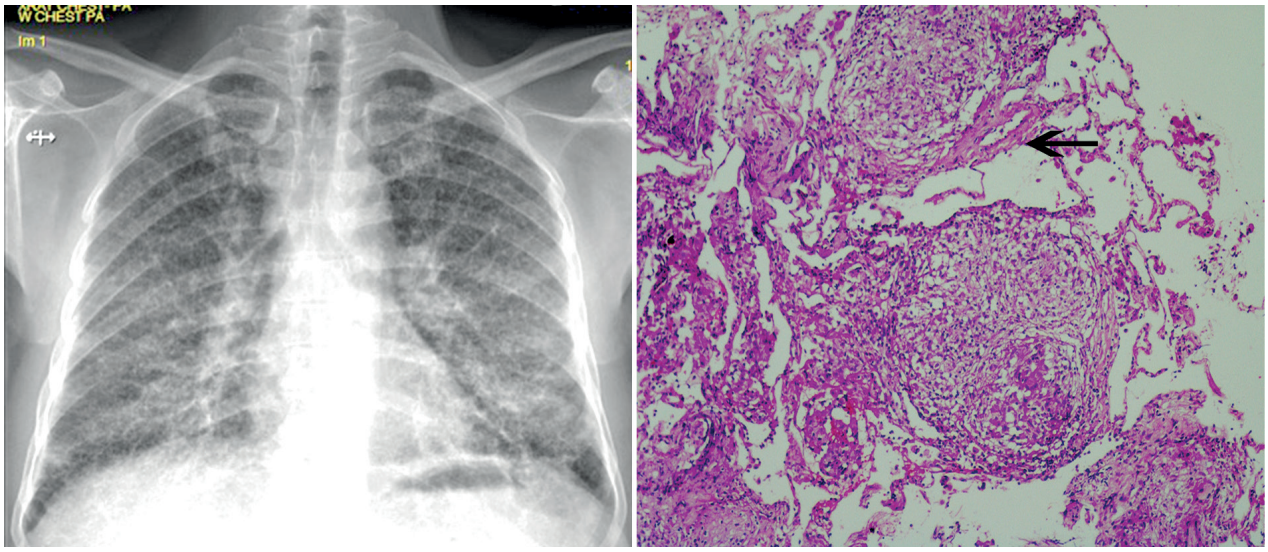

Fig. 7. Composite image of chest radiography images (left) of Patient 4 showing miliary nodules at diagnosis and photomicrographs of the lung biopsy specimen [right, Hematoxylin and Eosin stain (H & E) x 4] showing multiple perivascular granulomas (arrow)

Fig. 8. Composite image of the HRCT image of Patient 4 showing (left, upper lobes) random nodules with perilymphatic predominance, beading of the right oblique fissure and perivascular nodules and (right, lower lobes) marked interlobular septal thickening in the lower lobes associated with random nodules

at diagnosis (11, 12). Respiratory symptoms, however, were present in 63.6% only at diagnosis (13, 14, 16, 20, 21, 23-25, 28-30). In those with respiratory symptoms, breathlessness and cough were present in less than 50% (45.4%). Fever (27.3%) (13, 21-23, 29), night sweats (11.1%) (22, 27) and weight loss (22.7%)(18, 22, 27) were all seen in a significant percentage at diagnosis.

Symptomatic multi-systemic disease in association with miliary sarcoidosis was seen in 36.4%.(17, 19, 20, 23, 30) Hypercalcemia was seen in 27.3% (19, 20, 23, 27) and acute kidney injury was seen in 9.1% (19) at diagnosis. None needed dialysis but chronic kidney disease occurred in association with nephrocalcinosis (19). Ocular (13.6%, 3/22) involvement (25), bone (4.5%, 1/22) disease (17), sicca syndrome

Table 1. Summary of clinical features of all reported cases of thoracic sarcoidosis with miliary nodules on High-resolution Computed Tomography (N=27) [$]

Characteristic	Description
Age, Mean ± S.D, N=24	47.5±13.2 years; Age >40 years 85.2%
Gender (Male: Female), N=25	16:9
	In those >40 years, Male: Females O.R 0.26, p=1.00 (61.9% vs 75%)
Country of description	India (10/26), United States (7/26), Greece (5/26), Japan (3/26), Germany (1/26)
Symptoms at presentation	
Any symptoms, N=22	None, asymptomatic (9.1%, 2/22)
Symptom duration prior to presentation, Median, IQR N=19	8, (12) weeks
Symptoms	Any respiratory symptom (63.6%, 14/22)
	Dyspnea (45.4%, 10/22), cough (45.4%, 10/22)
	Fatigue (30.4%, 7/23), fever (27.3%, 6/22), weight loss (22.7%, 5/22), night sweats (11.1%, 3/22)
Acute kidney injury	9.1%, 2/22
Hypercalcemia	27.3%, 6/22
Co-morbidities, N=22	Any 72.7% (16/22)
	Smoking (18.2%, 4/22), diabetes (13.6%, 3/22), hypertension (18.2%, 4/22), lung transplantation (9.1%, 2/22), dust exposure (13.6%, 3/22)
Symptomatic disseminated sarcoidosis	8/22 (36.4%)
Other site involvement	Ocular (13.6%, 3/22), pleural effusion (9.1%, 2/22), bone (4.5%, 1/22), sicca syndrome (4.5%, 1/22), pancreas (4.5%, 1/22)
Radiological findings (N=26)	
True miliary pattern on HRCT	17/26 (65.4%) only
Perilymphatic nodules on HRCT in miliary CT	8/17 (47.1%); Truly random nodules total 9/26 (34.6%)
Zonal predominance seen	Upper & middle (7/26, 26.9%), central (7.7%, 2/26), peripheral (19.2%, 5/26)
Fissural nodules	65.4% (17/26)
Peripheral subpleural predominance	69.2% (18/26)
Interlobular septal thickening	23.1% (6/26)
Intralobular septal thickening	11.5% (3/26)
Ground glass opacity	11.5% (3/26)
Mediastinal adenopathy	Yes (50%, 13/26); Right paratracheal (23.1%, 6/23), bilateral hilar (23.1%, 9/23), others (8.7%, 2/23)
Generalized lymphadenopathy	8.7% (2/23)
Steroid treatment	Yes 21/22 (95.2%), Response 100% (21/21)
Relapse	14.2% (3/21)
Tuberculosis and miliary sarcoidosis	
Both tuberculosis and sarcoidosis	Both tuberculosis and sarcoidosis 44.4% (12/27)
	Definite or probable tuberculosis followed by sarcoidosis 29.7% (8/27)
	Probable misdiagnosis of tuberculosis 33.3%, (4/12)
	Microbiologically proven 37.5% (3/8) of all cases only
	Sequential (87.5%, 7/8), concurrent (25%, 2/8)[@@]

(continued on next page)

Characteristic	Description
Time to sequential miliary sarcoidosis in those with tuberculosis preceding sarcoidosis, (Median, IQR) N=7	52 (36) weeks
Site of tuberculosis	Pulmonary 87.5% (7/8), spinal 12.5% (1/8)
Yield of TBLB, N=21	85.7% (18/21)
Miliary tuberculosis preceding or concurrent with miliary sarcoidosis	5/8 (62.5%), 2/5 with miliary TB preceding miliary sarcoidosis
ATT-induced hepatitis	2/8 (25%)

Abbreviations: S.D standard deviation, IQR Inter-quartile range, HRCT High-resolution Computed Tomography, TBLB transbronchial lung biopsy, ATT Anti-tuberculosis treatment
[@@]One patient had both sequential and concurrent diagnosis of tuberculosis and sarcoidosis

(4.5%, 1/22) (20) and pancreatic mass (4.5%, 1/22) (28) were the other manifestations seen. Pleural effusion was seen in association in 9.1% (2/22) (24, 28).

On review of the HRCT images, a "true miliary" pattern was seen in 65.4% (17/26) of the reported cases only. In these cases, fissural nodules and prominence could still be seen in 47.1% (8/17); only 34.6% (9/26) of reported cases could be classified as random micronodules on radiologic review (12-14, 17, 18, 24, 26, 28, 30). An upper and middle lobe distribution of nodules (11-13, 15, 16, 25-27) was seen in 26.9% (7/26) and a peripheral distribution was seen in 69.2% (11, 12, 15, 24, 28). Perilymphatic clustering of nodules (3, 11-18, 22, 24-26, 28) or a perivascular dominance (3, 13, 15, 19, 22, 26-28) of nodules was seen in 65.4% and 42.3% respectively. Interlobular septal thickening, often lower-lobe in distribution, was seen in 23.1% (Table 1) (12, 14, 15, 18). Mediastinal adenopathy was observed in 50% in association with micronodules and generalized systemic lymphadenopathy was seen in 8.7% of patients (19, 20).

44.4% (12/26) of the reported patients had tuberculosis preceding or concurrent to the diagnosis of miliary sarcoidosis (13-17, 20-22, 29). In four of these patients, this was likely a misdiagnosis (13, 14, 30). In eight patients, tuberculosis occurred preceding (15-17, 21, 22) sarcoidosis in six (62.5%), concurrently in one (37.5%) (29) and both in one (23). In those with tuberculosis preceding sarcoidosis, a microbiological confirmation was made in 42.9% (15-17, 22); Others were diagnosed based on pathology and clinical response (21). In patients with concurrent diagnosis of tuberculosis and sarcoidosis, the diagnosis of tuberculosis was clinical in all; in all these patients, clinical and pathological findings, including caseous necrosis, were consistent with tuberculosis but clinical resolution occurred on initiation of steroids only (23, 29). The time to subsequent diagnosis of miliary sarcoidosis after treatment for tuberculosis was a median of 52 (IQR, 36) weeks. Miliary tuberculosis followed or concurrent with miliary sarcoidosis was reported in four patients (Table 2) (15, 16, 23, 29).

TBLB was the most common modality used for diagnosis and was reported as diagnostic in 85.7%. As most patients were symptomatic, treatment with steroids was offered in 95.2%, with 100% response. Methotrexate was administered in two patients for steroid-related severe adverse effects, with good response in both. Three patients (14.2%) relapsed after steroid taper; prompt response was noted on re-institution without further relapse.(21)

Discussion

The description of "miliary" refers to small, well-defined, 1 to 3 mm nodules on chest radiography and is derived from Latin miliarius, meaning millet seed (8). This pattern implies hematogenous dissemination of disease and is classically associated with hematogenous spread of tuberculosis, fungal infections and malignancy (31). However, more than 40 diseases have been associated with this pattern on chest radiography (Table 2). The importance of quickly establishing the diagnosis, especially in high prevalence areas of tuberculosis, is that miliary tuberculo-

Table 2. Reported causes of miliary nodules on High-resolution Computed Tomography

Classification	Cause of miliary Nodules	Site of micronodules in SPL
Infectious	Mycobacterium tuberculosis	Random
	Disseminated Bacillus-Calmette-Guerin infection	Random
	Bacterial: Mycoplasma pneumoniae, Hemophilus influenzae	Centrilobular
	Fungal: Histoplasmosis, Coccidioidomycosis, hematogenous Candida infection	Random
	Viral: Varicella-zoster, cytomegalovirus	Centrilobular
	Parasitic: Tropical pulmonary eosinophilia	Centrilobular
Immunologic	Pneumoconiosis: Silicosis	Perilymphatic
	Pneumoconiosis: Coal worker's pneumoconiosis	Perilymphatic
	Hypersensitivity pneumonitis	Centrilobular
	Sarcoidosis	Perilymphatic
	Idiopathic pulmonary hemosiderosis	Centrilobular
	Pulmonary alveolar microlithiasis	Centrilobular
	Diffuse panbronchiolitis	Centrilobular
	Allergic bronchopulmonary aspergillosis	Centrilobular
Malignancy	Secondaries from bronchogenic carcinoma	Perilymphatic
	Others: melanoma, papillary thyroid carcinoma, renal, breast, Trophoblastic tumor, osteosarcoma	Random
	Pulmonary Langerhans' cell histiocytosis	Random
	Metastasizing leimyoma	Random
	Lymphoma	Perilymphatic
Substance abuse	Excipient lung disease	Centrilobular

Abbreviations: SPL secondary pulmonary lobule

Table 3. High-resolution computed tomography findings in Thoracic Sarcoidosis (Modified from Criado et al)

Typical features	
Lymphadenopathy	Site (hilar, right paratracheal), bilateral, symmetrical, well defined. May show "cluster of black pearls" sign. If calcified, patchy or egg-shell
Nodules	Micronodules 2-4 mm, bilateral, well-defined, upper and middle zone and peri-hilar predominant. Peri-bronchovascular, subpleural, interlobular septal (peri-lymphangitic pattern)
Fibrotic changes	Interlobular septal thickening, Reticular opacities, architectural distortion, traction bronchiectasis
Atypical features	
Lymphadenopathy	Unilateral, isolated, anterior or posterior mediastinal
Nodules	Miliary
	Lower-lobe predominant, unilateral, "Halo" sign or "Atoll" sign
Consolidation	Mass-like opacities, conglomerate masses, solitary pulmonary nodules, confluent alveolar opacities and ground-glass opacities
Linear opacities	Intra-lobular septal thickening
Airway	Mosaic attenuation, trachea-bronchial abnormalities, atelectasis
Pleural	Effusion, chylothorax, pneumothorax, pleural thickening, calcification, plaque-like lesions

sis is the most common cause, has 25-30% mortality in adults and is invariably fatal if untreated (8).

The finding of a miliary pattern on chest radiographs was noted in early roentgenologic series of thoracic sarcoidosis; 1.3% (2/150) had "miliary" disease (1). Thoracic sarcoidosis has been reported to have several typical and atypical findings on HRCT; miliary is classified as an atypical finding (Table 3) (3). The description of micronodules by their distribution in relation to the "secondary pulmonary lobule" on HRCT along with the clarity of margins and attenuation further helps in narrowing the differential diagnosis of diffuse pulmonary micronodules. Micronodules can be accurately classified as having a centrilobular, perilymphatic or random distribution with their characteristic disease associations (Table 2) (4). Miliary nodules have a random distribution and can be seen in relation to pleural surfaces, small vessels and interlobular septa but do not have a consistent or predominant relationship to any of these (31). Given the reported prevalence of sarcoidosis varies from 4.5-36 per 100,000, the very small number of cases of "miliary" sarcoidosis reported in literature in the HRCT era (Table 1) suggests that this is a very rare occurrence. Most series of computed tomographic findings in sarcoidosis and a review on atypical findings in thoracic sarcoidosis did not report "miliary" sarcoidosis (32, 33).

Our systematic review suggests that this small reported number is an overestimate as a true miliary pattern was seen only in 34.6% (9/26) of the published cases of "miliary" sarcoidosis; and subtle perilymphatic pattern is nearly always seen and the term "pseudo-miliary" may be more appropriate. Distinct perilymphatic clustering of nodules or a perivascular dominance of nodules was seen in 65.4% and 42.3%; fissural nodules leading to the "beaded fissure sign" was prominent and seen in 65.4% of cases. Further, unlike true miliary nodules that lack any zonal predominance, an upper lobe and peripheral clustering was seen in 30.8% and 19.2% respectively. In all our patients with random micronodules, we observed a prominent perivascular distribution of micronodules on histopathology (Figures 2, 4, 6 and 8); two of these had associated "beaded fissure sign" on HRCT. Pathologically, sarcoidosis causes perilymphatic clustering of granulomas; hematogenous or airway spread has not been postulated (34). Profuse clustering of micronodules along the centrilobular and perilymphatic compartments gives rise to an appearance of random nodules in the majority with a "pseudo-miliary" appearance. In the few patients with a true random pattern, prominent perivascular granulomas or drainage into the pulmonary lymphatics and subsequent dissemination by hematogenous route could be postulated.

The link between mycobacteria and sarcoidosis continues to be an enigma (7, 35). In the original descriptions, about 5% of sarcoidosis had tuberculosis preceding them. Polymerase chain reaction analyses of lung biopsies of sarcoidosis have shown mycobacterial DNA in 26.4%.(35) Tuberculosis may present concurrently and confound the diagnosis and management of these patients (23, 36, 37). It has been hypothesized that the immunological responses in sarcoidosis are analogous to "tuberculoid" or "pauci-bacillary" leprosy (38); persisting immunological responses to mycobacterial antigen can explain the extraordinarily high rates of tuberculosis preceding the diagnosis of pseudo-miliary sarcoidosis in the present systematic review.

The diagnosis of sarcoidosis rests on a constellation of clinical, radiological, histopathological and laboratory findings (39). Constitutional features including significant weight loss can occur in up to 25% of patients (Table 2). Fibrinoid necrosis and rarely, caseation can occur in sarcoidosis on histopathology (40, 41). Caseation may sometimes be absent in tuberculosis (41). Radiology can help in the differentiation of sarcoidosis from tuberculosis (26). The presence of hypercalcemia, skin involvement, negative tuberculin skin-testing, upper and middle-lobe distribution of nodules, a peripheral distribution of nodules when present and interlobular septal thickening all point to the diagnosis of "pseudo-miliary" sarcoidosis alone (42). However, sarcoidosis can precede, occur concurrent with or follow tuberculosis and differentiating tuberculosis from sarcoidosis remains a major challenge, especially in high prevalence areas of tuberculosis (43, 44). When the constellation of findings are non-conclusive, a trial of anti-tuberculosis treatment is appropriate in high prevalence areas given the very small number of true miliary sarcoidosis reported in literature. Steroids could be added when there is no clear response at 4-6 weeks (39, 43).

Conclusion

A true miliary pattern in the HRCT era is very rare in sarcoidosis and subtle perilymphatic pattern is nearly always seen; this pattern should be labeled "pseudo-miliary". Prominent perivascular granulomas are associated with true miliary pattern. Miliary sarcoidosis patients are older and symptomatic and mostly need treatment at diagnosis. "Miliary" sarcoidosis may follow treatment for tuberculosis; concurrent cases possibly indicate difficulty in diagnosis or a "tuberculo-sarcoid" presentation. Transbronchial lung biopsy had a good yield for diagnosis. Most patients were symptomatic and treated with steroids, with 100% response and 14.4% relapse.

Acknowledgements

Dr. R.S, Dr. RM.PL and Dr. R.K were responsible for patient care and initiated the manuscript preparation and performed the systematic review. Dr. S.S reported the histopathologic findings of these patients and provided valuable inputs to the manuscript. Dr.B.D reviewed all the radiology images and the images retrieved from the systematic review for re-reporting.

Drs. R.S and Dr. S.S take responsibility for the content of the manuscript, including the data and analysis

The authors would like to thank Senior Librarian, PSGIMS&R, for his help in procuring manuscripts for the systematic review. No funding was utilized for this manuscript

ABSTRACT

Objectives Simple and radical nephrectomies are done for benign and malignant lesions of the kidney respectively. This study was conducted to find out the histopathological spectrum of diseases that were encountered in those received nephrectomy specimens and compare it with other studies.

Methods Nephrectomy specimens both simple and radical that were received during our study period were included. Age, sex and gross measurements of the tumor were retrieved from the records. The slides were reevaluated by a panel of pathologists, classified, graded and staged and detailed discussion of those cases was done.

Results Nephrectomy specimens constituted around 0.5% of all the specimens. Mean age at which nephrectomy was done was 28.7 years with a female preponderance. As our center is a tertiary referral center of south Tamilnadu, this value has a demographic significance. The mean age at which benign lesions were seen was 32 years with M: F: 1:9. Chronic pyelonephritis was the most common benign lesion seen in our study followed by benign cystic lesions. The mean age in the malignant tumor category was 25 years with M: F: 0.8:1. Wilm's tumor in pediatric age group and renal cell carcinoma in the adult age group were commonly seen in the malignant category.

Conclusion Histopathological spectrum seen among the nephrectomy specimens correlated with those available in the literature. Mucinous cystadenoma of the pelvis and clear cell papillary carcinoma – two rare tumors were diagnosed during our study period. Chronic pyelonephritis incidence had some regional variance.

KEYWORDS chronic pyelonephritis, cysts, malignant tumors

INTRODUCTION

Nephrectomy is done for both benign and malignant lesions of the kidney. Simple nephrectomy is done for benign lesions and radical nephrectomy is done for malignant lesions. Under the benign category, nonfunctioning kidney is the most common reason for which nephrectomy is done followed by hydronephrosis. Under malignant tumors, renal cell carcinoma in adults and Wilms tumor in children are most commonly encountered in the nephrectomy specimens[1]. Spontaneous regression, primary tumor harboring metastasis from other tumors and paraneoplastic syndromes are unique features observed among renal tumors[2,3].

This study was conducted to evaluate the benign and malignant lesions encountered in nephrectomy specimens that were received in our department for one year period.

MATERIALS AND METHODS

This study was conducted during one year period from August 2015 to September 2016. Nephrectomy specimens both simple and radical were included in our study. Age, sex and gross measurements of the tumor were retrieved from the records. These parameters were compared with those available in the literatures. The slides were reevaluated by a panel of pathologists. Histopathological examination was done and the specimens were categorized into benign and malignant. Malignant tumors were graded using Furhams nuclear grading and WHO staging was used to stage adultrenal tumors. North American National Wilms' tumor study group staging system for renal tumors was followed to stage Wilms' tumor. Detailed discussion of the histopathology, molecular markers and immunohistochemical markers were analyzed with reference to the global literatures.

RESULTS

Out of 3790 histopathological specimens, nineteen nephrectomy specimens were received during our study period.

Received: 02 September 2016 Accepted: 27 November 2016 Published Online: 20 December 2016

Nephrectomy specimens constituted around 0.5% of all the specimens. Out of that, 52.6% were benign lesions. The rest were malignant tumors. Mean age at which nephrectomy was done was 28.7 years. M: F was 1:2.8 (Table 1). As our hospital is a tertiary referral center for south Tamilnadu, these parameters can be taken as a representative of their respective incidences in our area.

Benign lesions were distributed along all age groups. The mean age at which benign lesions were seen was 32 years with M: F: 1:9. Chronic pyelonephritis was the commonest lesion seen among the benign category. The mean age in the malignant tumor category was 25 years with M: F: 0.8:1. A malignant tumor was seen more in the pediatric age group in our study. Wilms' tumor was the commonest tumor seen in our study with the mean age of 2.7 years with M: F: 0.7:1. One case was associated with WAGR syndrome- Wilms' tumors, bilateral undescended testis, mitral regurgitation and aniridia. Among the adults, renal cell carcinoma was most commonly encountered (Table 2). Mean age among adults with malignant renal tumor was 51.75 years with M: F: 1:1

When stage wise stratification was done, Wilms' tumor was seen in the advanced stage in our study (Table 3). Fuhrman nuclear grading was followed only in clear cell renal cell carcinoma and papillary renal cell carcinoma (Table 4).

TABLE 1 Demographic details associated with nephrectomy specimens.

Age	1–10 years	11–20 years	21–30 years	31–40 years	41–50 years	51–60 years	61–70 years
No. of persons	6	2	2	2	3	3	1
Male	2	–	–	–	1	2	–
Female	4	2	2	2	2	1	1
Benign	1	2	2	1	2	2	–
Malignant	5	–	–	1	1	1	1

DISCUSSION

Kidney can be affected by both neoplastic and neoplastic conditions that require nephrectomy. According to Ghalayini's study, the mean age at which nephrectomy was done for benign condition was 38.4 years and for malignant tumor it was 46.7 years[4]. It was 32 years and 25 years for benign and malignant lesions respectively in our study group which was in correlation with their study. When the sex incidence of nephrectomy from our study group was compared with that of Aiman et al., M: F was 1:2.8 in our study group and was found to be similar with their study group [M: F: 1:1.05] and with Rafque M's study group[5,6]. In our study majority of the cases detected in the nephrectomy specimens [52.6%] were benign lesions in accordance with Aiman et al. and Ghalayini study[4,5]. Benign and malignant lesions which were encountered in our study are discussed below.

TABLE 3 Stage wise stratification of the renal tumor cases encountered in our study.

Stage	T1a	T1b	T2a	T2b	T3a	T3b	T3c	T4
Wilm's Tumor	–	2	2	–	1	–	–	–
Clear cell papillary renal cell carcinoma	–	1	1	–	–	–	–	–
Clear cell renal cell carcinoma	–	–	1	–	–	–	–	–
Papillary carcinoma	–	–	–	1	–	–	–	–

TABLE 4 Fuhrman grading of the renal tumor cases encountered in our study.

Grade	Grade I	Grade II	Grade III	Grade IV
Clear cell papillary renal cell carcinoma	–	2	–	–
Clear cell renal cell carcinoma	1	–	–	–
Papillary carcinoma	1	–	–	–

TABLE 2 Age and sex wise stratification of various tumors encountered in our study.

HPE findings	Benign			Malignant				
	Simple cyst	Multi cystic renal dysplasia	Mucinous cystadenoma of the pelvis	Chronic pyelonephritis	Wilm's tumor	Clear cell papillary renal cell carcinoma	Clear cell renal cell carcinoma	Papillary renal cell carcinoma
Numbers	1	2	1	6	5	2	1	1
Male	–	–	–	1	2	1	–	1
Female	1	2	1	5	3	1	1	–
Age								
1–10 years	–	1	–	–	5	–	–	–
11–20 years	–	1	–	1	–	–	–	–
21–30 years	–	–	–	2	–	–	–	–
31–40 years	–	–	1	1	–	–	1	–
41–50 years	1	–	–	–	–	1	–	–
51–60 years	–	–	–	2	–	–	–	1
61–70 years	–	–	–	–	–	1	–	–

Chronic pyelonephritis [CPN] was the commonest benign lesion seen in our study which correlated with Popat et al. and Adamson et al.[7,8] There was a bimodal age related peaks in our study group, 20–30 years and 50–60 years respectively. This was in accordance with Popat et al.[7] CPN may be due to non-obstructive pathology secondary to vesicoureteral reflux or due to obstructive pathology[9]. Gross picture varies according to the etiology. In CPN due to reflux there will polar scars as compound papillae are involved in reflux. This result in blunting and loss of pyramids in the polar regions. Conversely, in obstructive CPN there will diffuse involvement of pyramids. Microscopically in both obstructive and non-obstructive CPN, there is interstitial inflammatory cell infiltrates, tubular atrophy, thyroidization of the tubules, peri-glomerular fibrosis, global glomerular sclerosis and interstitial fibrosis (Fig. 1).

The incidence of nephrectomies for benign conditions such as chronic pyelonephritis is decreasing and nephrectomies for malignant lesions are increasing in the developed countries[10,11]. The reason for this change in trend being early detection and better treatment modalities that prevent the need for surgeries are available for inflammatory lesions of the kidney in the developed countries compared with developing nations.

Cystic lesions of the kidney were classified into four types by potter[12]. Type I- Autosomal recessive polycystic kidney disease. Type IIa -Multicystic renal dysplasia. Type IIb -Aplastic renal dysplasia. Type III -Autosomal dominant polycystic kidney disease, focal renal dysplasia, dysplasia in hereditary syndromes and autosomal recessive polycystic kidney disease. Type IV- Dysplasia associated with lower tract obstruction. The incidence of cystic lesions was 40% in our study which included multicystic renal dysplasia, simple cyst and mucinous cystadenoma of the renal pelvis. Cystic lesions were seen in 12.5% of the cases in Salma et al. which was lower than our study group[13].

In our study group, among the cystic lesions multicystic renal dysplasia was the predominant etiology for which nephrectomy was done. Multicystic renal dysplasia present with varied histological findings. Primitive or dysplastic ducts lined by columnar epithelium and surrounded by the collars of spindle cell and fetal or immature-appearing cartilage derived from the blastema and aberrantly formed glomeruli are the histopathological features commonly seen in multi cystic dysplasia (Fig. 2)[14].

Presence of immature cartilage is diagnostic of multi cystic renal dysplasia according to Rosdon RA[15]. In our study multi cystic dysplasia cases were seen in 20% of the cases with female preponderance. In Amina et al., the incidence of multi cystic renal dysplasia was 10% with a female preponderance which is in correlation with our study[16]. In contrast to our study group [mean age incidence 9.25 years] the age incidence in their study was less than 5 years[16].

Simple cyst is the commonest cystic lesion encountered in the kidney. Microscopically, the cysts are lined by cuboidal epithelium (Fig. 3). A fifty year old female patient had a simple cyst in our study which was in agreement with Marumo K. et al's study[17]. The incidence of simple cyst increase as the age advances according to Kissane and Smith[18], which was also noticed in our study group.

Primary adenocarcinoma of the renal pelvis accounts for <1% of the renal pelvic tumors. The histogenesis of this tumor is metaplastic transformation of multipotent transitional epithelium of the renal pelvis secondary to chronic irritation from the calculi, hydronephrosis and pyelonephritis[19]. Few cases of its benign counterpart were reported in the literature especially in India. Ross and

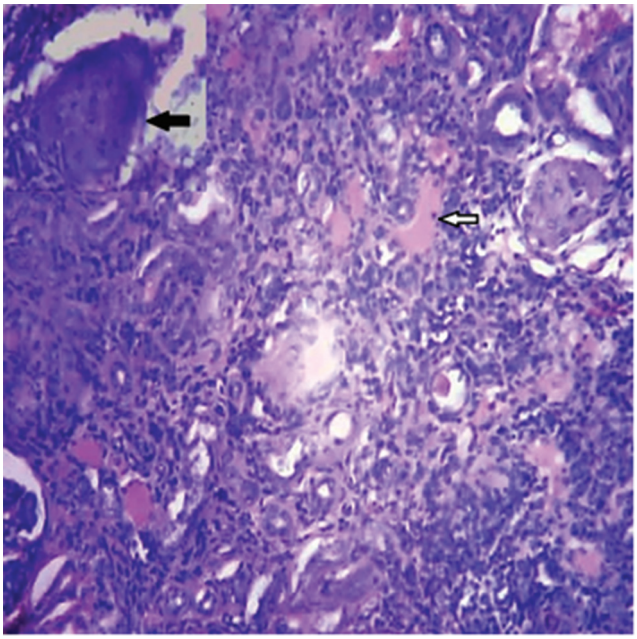

Fig. 1 Shows thyroidization of the tubules [White arrow] with interstitial inflammatory cell infiltrates. Inset shows global glomerulosclerosis [Black arrow] – Chronic pyelonephritis [H&E, 40x].

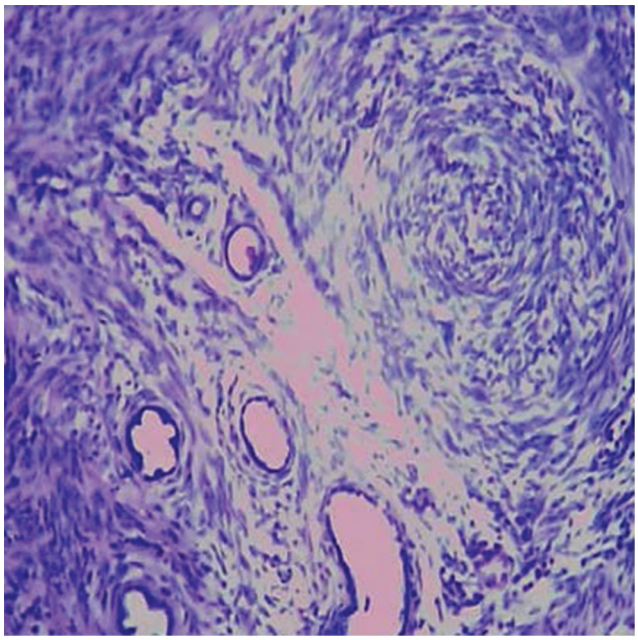

Fig. 2 Shows collars of spindle cell surrounding a primitive tubule- Multi cystic renal dysplasia [H&E, 40x].

D'Amato had reported papillary mucinous cystadenoma in a horseshoe kidney and had suggested the same criteria that were used to categorize ovarian mucinous tumors apply to renal mucinous tumor as well[20]. Mucinous cystadenoma of the pelvis, a rare tumor was seen during our study period. It was diagnosed in a forty year old female. It was radiologically diagnosed as a hydatid cyst attached to the renal pelvis. Histopathologically, the cyst was lined by mucin secreting single layer of columnar epithelium replacing the ureter and pelvis. There were no atypia or pleomorphism or invasion seen (Fig. 4). Tumors with borderline malignant potential and malignant transformation have been reported[21,22]. Its malignant counterpart has a poor prognosis. As borderline and in situ changes cannot be assessed radiologically, radical nephrectomy with total ureterectomy is the treatment of choice. Intra operative frozen section diagnoses invasive and in situ changes thus can help in the treatment planning.

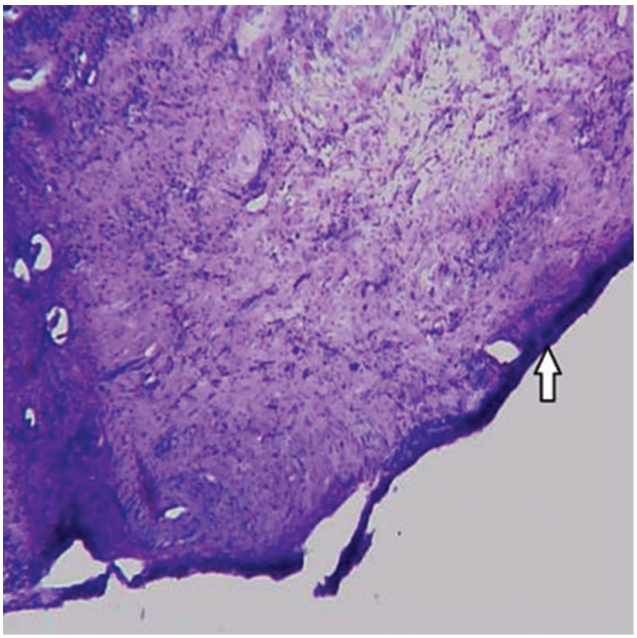

Fig. 3 Shows a cyst lined by flattened cuboidal epithelium [Arrow]- Simple cyst [H&E,10x].

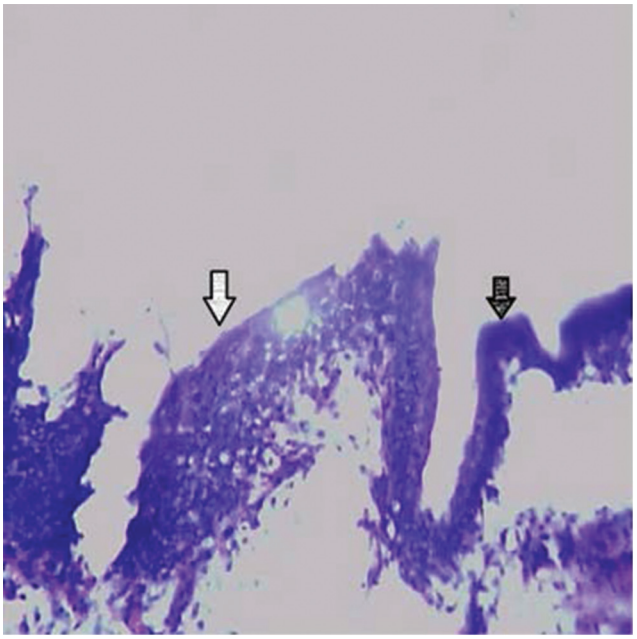

Fig. 4 Shows transitional epithelium [White arrow] replaced by benign mucinous epithelium [Black arrow] – Mucinous cystadenoma of the pelvis [H&E,10x].

Among the malignant tumors, Wilms' tumor was the most reported tumor in our study. It is the most common childhood malignant renal tumors with an incidence of 85%[23]. The incidence of Wilms' tumor in Salma et al. was 18.19%, in Amina et al. was 28.2%, whereas it was 55.56% in our study group[13,16]. The mean age at which it occurred was 3 years in Lemerle et al. and 3.5 years in Amina et al. which were in correlation with our study [2.7 years mean][16,24]. Female predominance seen in our study was in concordance with Abdulkareem et al.[25] Histologically, the tumor is composed of three elements blastema, epithelium and stroma in varying proportions (Figs. 5 and 6). No anaplasia was noted in our study group. Biphasic and monophasic Wilms' have also been reported. Triphasic Wilms' predominated in our study [60%] which was in concordance with Amina et al.[16] The WT1 gene located in chromosome11p13 is altered by germline deletions in the WAGR syndrome[26]. One such case was reported during our study period. This tumor responds to chemotherapy. Immuno histochemically, this tumor show nuclear positivity for WT1. Diffuse anaplasia and secondary carcinoma or sarcoma arising within nephroblastoma is associated with resistance to chemotherapy.

Renal cell carcinoma [RCC] is the most commonly reported malignant tumor among the adults. The incidence of renal cell carcinoma was 44.44% in our study.

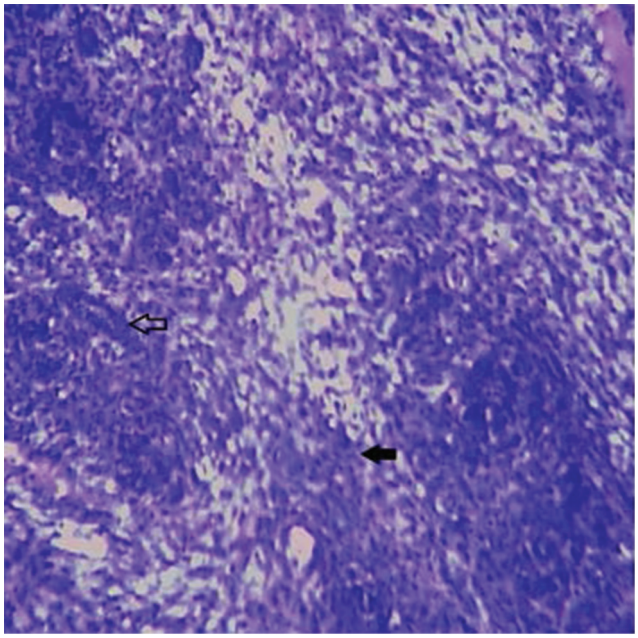

Fig. 5 Shows malignant epithelial cells [Empty black arrow] and mesenchymal component [Dark black arrow] – Wilms' tumor [H&E, 40x].

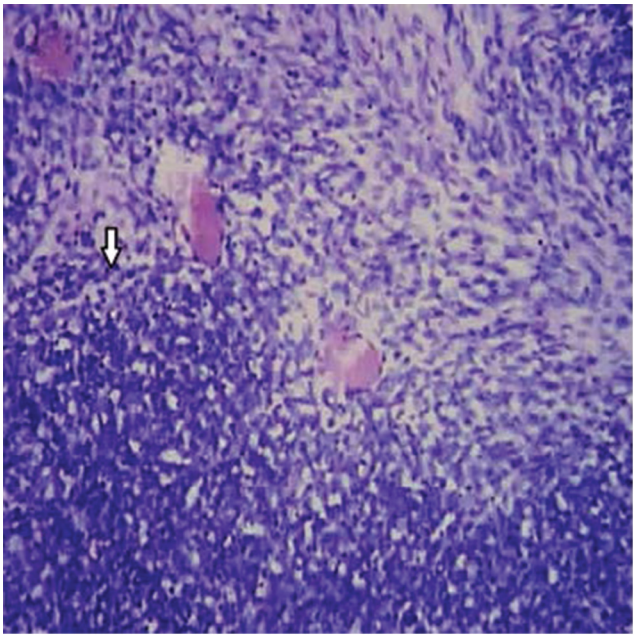

Fig. 6 Shows blastemal component- Wilms' tumor [H&E, 40x].

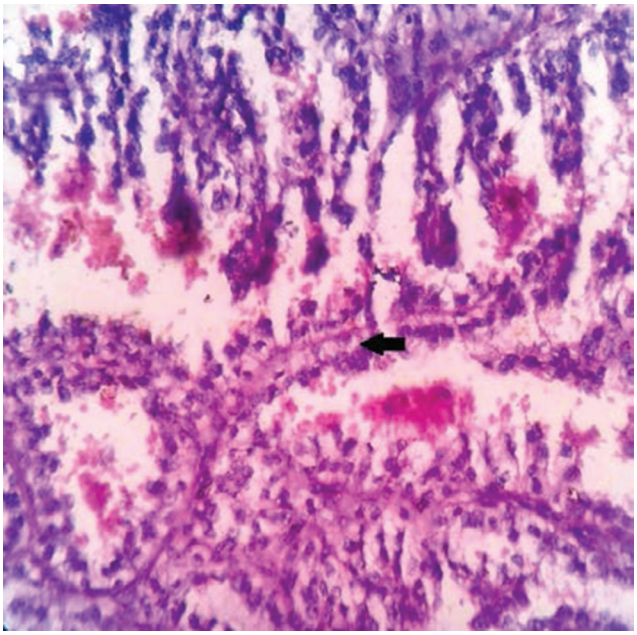

Fig. 7 Show clear cells arranged in a papillary core with the nucleus situated away from the basement membrane with sub nuclear vacuoles [Arrow]- clear cell papillary renal cell carcinoma [H&E, 40x].

The incidence of renal cell carcinoma was 80–85% according to Motzer et al.[27] Clear cell papillary renal cell carcinoma had the highest incidence among the adult renal tumors during our study period. It is a recently characterized tumor initially reported in patients with end stage renal disease[28]. Histologically, this tumor consists of papillary structures lined by clear cells with the nucleus oriented away from the basement membrane. Clear cell renal cell carcinoma areas are also seen (Fig. 7). Low nuclear Fuhrman grading is noted. It runs an indolent course. 3p deletion seen in clear cell RCC, trisomy7/17 seen in papillary RCC and VHL mutation

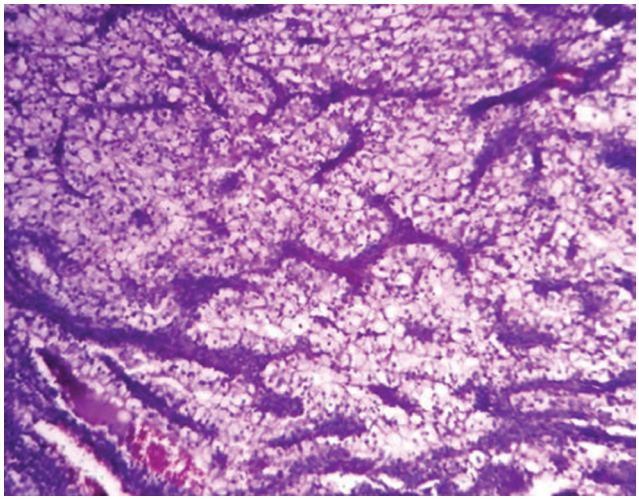

Fig. 8 Show clear cells arranged in nests separated by a fibrovascular septa – Clear cell renal cell carcinoma [H&E, 40x].

are all absent in clear cell papillary renal cell carcinoma[29]. HIF pathway is activated by VHL independent pathway in clear cell papillary renal cell carcinoma. Liddell et al. in their case study had reported it in a forty two-year-old female[30]. In contrast, in our study group there was an equal sex incidence. Immuno histochemically, these tumors are positive for CK7 [Papillary RCC marker], CA 1X [Clear cell RCC marker] and negative for CD10 [Clear cell RCC marker] and AMACR [Papillary RCC marker] thus exhibiting overlapping features of both clear cell RCC and papillary RCC.

Clear cell renal cell carcinoma constituted 11% of all the malignant tumors reported during our study period. In contrast, its incidence was 97% Rafique M' study, it was 51% in Lopez et al., 80% in Aiman et al. and 76% in Eggener et al.[5,6,31,32] Microscopically, tumor cells are arranged in sheets, nests, alveolar, acinar and microcystic or macrocystic structures, separated by thin-walled blood vessels. Individual cells have distinct cell membranes and clear cytoplasm (Fig. 8). Presence of tumor necrosis is a poor prognostic factor. Fuhrman's nuclear grade was grade I in our study in contrast to Aiman et al. and Popet et al.[5,7] This tumor is positive for EMA, RCC ma, CA IX and CD10 immunohistochemical markers.

Papillary renal cell carcinoma was seen in 11% of the cases in our study group. Papillary renal cell carcinoma was seen in 16% of the cases in Stîngă et al.[33] Microscopically, papillary renal cell carcinoma is composed of papillary and tubular structures lined by a single layer of tumor cells. The stalks contain fibrovascular cores, infiltrated by foamy macrophages–Type I tumor (Fig. 9). Type II tumors have thick papillary core lined by cells with eosinophilic cytoplasm. Type I tumors have a better prognosis than Type II tumors. Fuhrman's nuclear grade of this tumor was grade one in our study in contrast to Popat et al.[7] Immunohistochemical markers that are positive in this tumor include AMACR, CK7 and CD15.

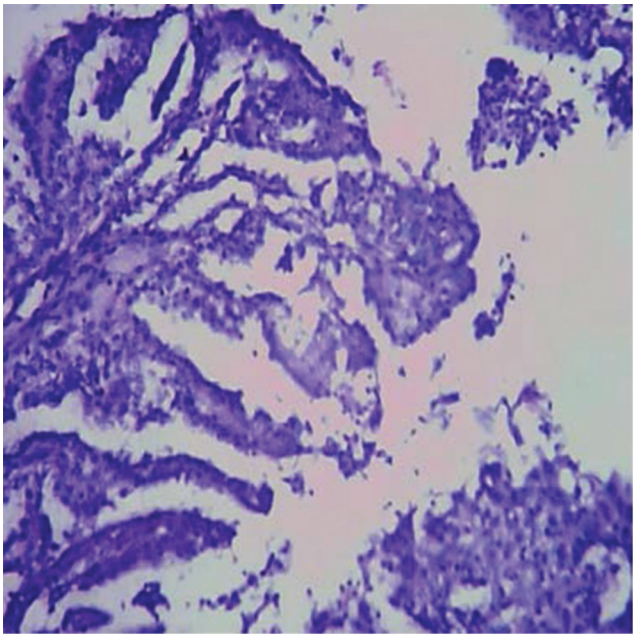

Fig. 9 Show tumor cells arranged in a papillary pattern with a thin fibrovascular core [H&E,10x].

CONCLUSION

Both benign and malignant tumors were seen in the received nephrectomy specimens during our study period. Chronic pyelonephritis was the commonest benign lesion. Wilms' tumor was the commonest pediatric tumor and renal cell carcinoma was the commonest adult tumor encountered in our study. This histopathological spectrum correlated well with the available literature studies except the fact that the incidence of chronic pyelonephritis had declined in the developed countries.

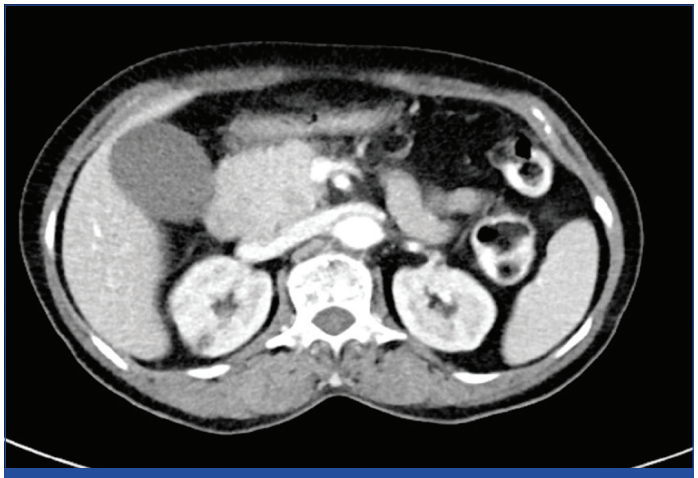
Pancreatic Plasmacytoma Misdiagnosed as Neuroendocrine Tumour: A Pathologist's Dilemma

SAKTHISANKARI SHANMUGASUNDARAM[1], UMAMAHESWARI GURUSAMY[2], PRASANNA N KUMAR[3], BIKU JOSEPH JOHN[4]

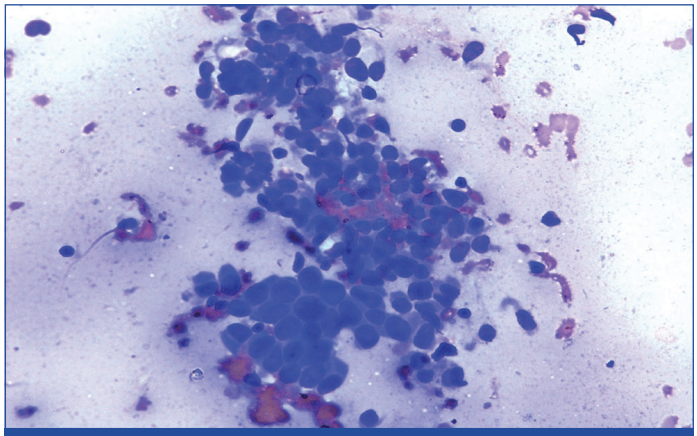
BY-NC-ND

ABSTRACT



Extramedullary plasmacytomas are rare, constituting to about 5% of plasma cell neoplasms. Pancreatic involvement is uncommon constituting to about 2.3%. Localised solitary plasmacytomas has a good response to radiation. When they are associated with pre-existing multiple myeloma, their prognosis is poor. A case of plasmacytoma of pancreas presenting with obstructive jaundice preceding plasma cell leukaemia is presented here. The lesion was misdiagnosed by fine needle aspiration cytology as neuroendocrine neoplasm. The patient did not present with symptoms of myeloma initially. The present case highlights the significance of considering other causes of pancreatic mass than primary carcinomas.

Keywords: Extramedullary plasmacytoma, Pancreatic neoplasm, Plasma cell leukaemia

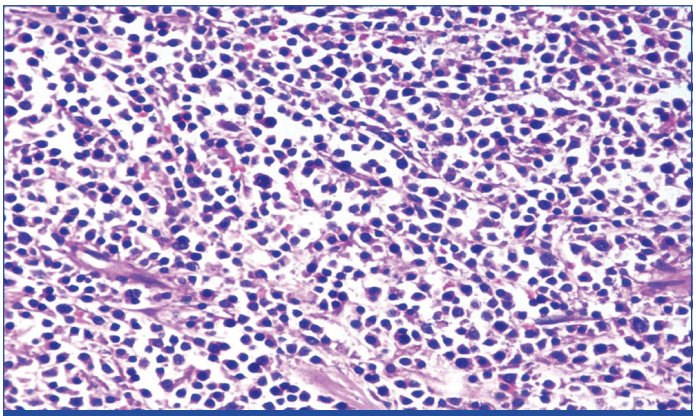


CASE REPORT

A 62-year-old female presented with complaints of fever on and off for 15 days, a vague, non-radiating, intermittent right upper quadrant, paraumbilical pain and vomiting for five days. There was no history of gastrointestinal bleed, loss of weight and loss of appetite. She was a known hypertensive and diabetic for five years and was on treatment with oral hypoglycemics and antihypertensives. Her vitals were within normal limits and there was no organomegaly.

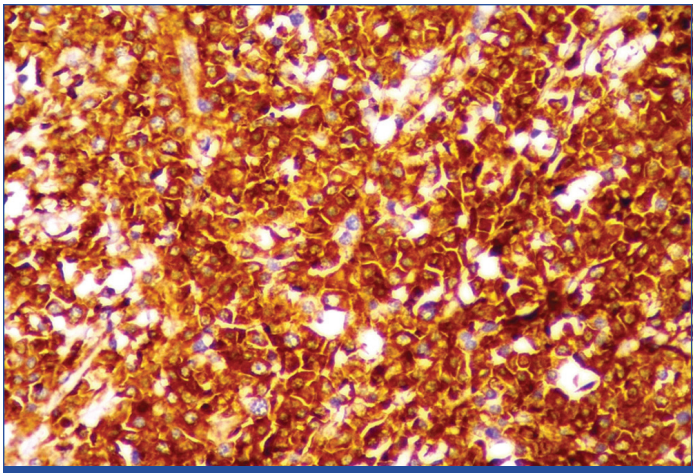
Ultrasound abdomen showed a hypoechoic mass in the pancreatic head dilating the main pancreatic duct. Computed Tomography (CT) revealed an isodense mass lesion with well defined borders in the head of pancreas measuring 4.8×5.5 cm [Table/Fig-1]. Acoustic Radiation Force Impulse (ARFI) elastography showed mean shear velocity of 3.6. The provisional diagnosis included primary pancreatic tumour. Endoscopic Ultrasound Guided Fine Needle Aspiration Cytology (EUS-FNAC) was planned for the evaluation of the pancreatic mass. EUS showed a 3×3.1 cm iso and hypoechoic mass in the head of pancreas with dilated common bile duct measuring 9 mm in the suprapancreatic portion. Dilated main pancreatic duct (6.5 mm) distal to the mass in the pancreas was identified. Visualised tail of pancreas and portal vein appeared normal. Cytological examination of the mass showed sheets and scattered plasmacytoid cells suspicious of a neuroendocrine neoplasm [Table/Fig-2].

[Table/Fig-1]: CT scan showing isodense lesion in head of pancreas.

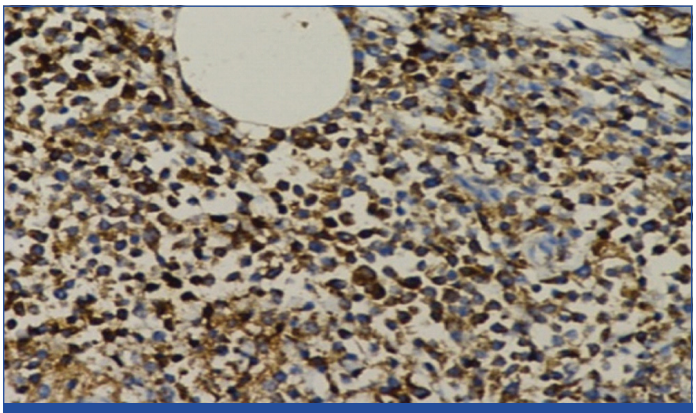


[Table/Fig-2]: Cytology smears showing plasmacytoid cells (40x).

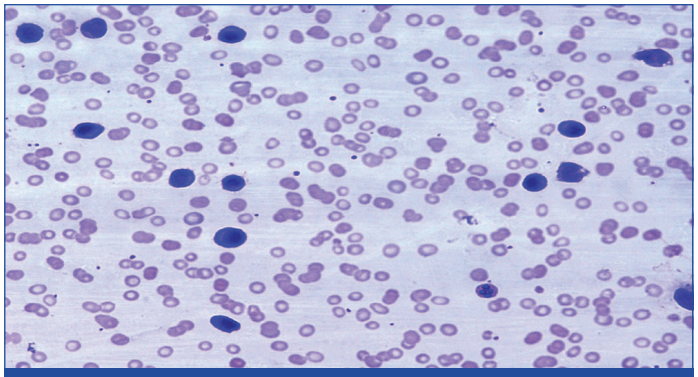
Whipple resection was done with a clinical and cytological diagnosis of a pancreatic neuroendocrine tumour. Pancreas showed an ill-defined mass occupying the head [Table/Fig-3]. Haematoxylin & Eosin (H&E) sections of the mass showed a diffusely infiltrating neoplasm composed of monotonous, plasmacytoid cells infiltrating the acini and ducts [Table/Fig-4]. Few binucleate and multinucleate plasma cells and lymphocytes were present. Morphological differential diagnosis included plasmacytoma and lymphoplasmacytic lymphoma. Immunohistochemical staining was done for confirmation of diagnosis. The tumour cells showed strong membranous positivity for CD138 [Table/Fig-5], CD45 and selective Kappa staining [Table/Fig-6]. They were negative for CD20 and Lambda immunostains. A diagnosis of Plasmacytoma was made and radiological and biochemical workup for multiple myeloma was suggested. Protein electrophoresis was normal. Urine for Bence Jones Protein was negative. Serum calcium and renal parameters were normal. CT spine survey did not reveal any osteolytic lesions. The case was treated as a solitary extramedullary plasmacytoma and suggested follow-up. A month later, the patient developed severe anaemia (Hb-6.8 g/dL). Total count was elevated and peripheral smear showed 40% plasma cells suggestive of plasma cell leukaemia [Table/Fig-7]. Reviewing the patient's peripheral smear and complete haemogram taken a month back, there was normocytic normochromic anaemia and no demonstrable plasma cells in peripheral smear. ESR was elevated (93 mm/hr). Bone marrow aspiration done showed infiltration by sheets of immature



and mature plasma cells. On immunohistochemistry, these cells showed kappa restriction. A diagnosis of plasma cell leukaemia was made. Investigations done at presentation and a month later are tabulated [Table/Fig-8]. The patient was referred to higher centre for further treatment.



[Table/Fig-3]: Whipple's specimen showing ill-defined lesion in pancreas.



[Table/Fig-4]: Diffuse infiltration by plasma cells (H&E, 40x).

[Table/Fig-5]: Strong membranous expression of CD138 by tumour cells (IHC, 40x).

[Table/Fig-6]: Neoplastic cells with kappa expression (IHC, 40x).

[Table/Fig-7]: Peripheral smear with plasma cell leukaemia (40X).

Parameters	At initial presentation	A month later
Serum urea	42 mg/dL	81 mg/dL
Serum creatinine	1.06 mg/dL	3.82 mg/dL
Direct bilirubin	3.3 mg/dL	1.8 mg/dL
Haemoglobin	9.5 g/dl	6.8 g/dL
Total WBC count	4.3×10^3/µL	30.5×10^3/µL
Peripheral smear	Normocytic anaemia	Plasma cell leukaemia
Serum calcium	1.116 mmol/L	1.178 mmol/L

[Table/Fig-1]: Biochemical and haematological investigations.

DISCUSSION

Plasma cell neoplasms include Plasma Cell Myeloma (PCM) which includes smouldering myeloma, non-secretory myeloma, plasma cell leukaemia and plasmacytoma which includes solitary bone and extraosseous plasmacytoma. In majority of the patients with PCM, features of end organ damage in the form of one or more of the following, hypercalcaemia, Renal insufficiency, Anaemia, and Bone lesions (CRAB) are present. The clonal proliferation usually begins in bone marrow. Renal failure occurs due to tubular damage caused by excessive synthesis of monoclonal immunoglobulins [1]. It constitutes 10 to 15% of haematological malignancies. Median age at diagnosis is 66 years [2]. The clinical spectrum varies from asymptomatic to highly aggressive.

Extramedullary Plasmacytomas (EMPs) are localised proliferation of monoclonal plasma cells forming solitary lesions outside the bone marrow. EMPs can be a manifestation of advanced multiple myeloma or can represent a solitary plasmacytoma without involving the bone marrow [3]. EMPs are uncommon and represent 5% of all plasma cell tumours. The most frequent site of involvement being upper respiratory tract followed by gastrointestinal tract and reticuloendothelial system [2].

Primary pancreatic plasmacytoma is rare constituting 2.3% of EMPs. Majority of the reported pancreatic plasmacytoma are secondary [3]. EMPs have the median age of presentation at 55 years (A decade younger than patients with multiple myeloma) and the majority (three-fourths) are males [4].

Most of these lesions are located in the pancreatic head. Diffuse enlargement and presenting as mass in body (4 cases) [5] and tail of the pancreas have also been reported. The typical presenting symptoms include abdominal pain and obstructive jaundice from bile duct compression when there is involvement of head. Diffuse lesions are picked up rather late as they tend to be asymptomatic [6]. The case presented here also had obstructive jaundice raising a concern for primary pancreatic carcinomas [7].

Radiologically plasmacytoma is characterised by a homogenously enhancing multilobular, solid mass on CT, which is non-specific and resemble that of neuroendocrine tumours or carcinoma [6]. The case described presented as an isodense lesion in the pancreatic head. Differentiating plasmacytomas radiologically from other pancreatic tumours is challenging.

Endoscopic Ultrasound (EUS) is a well recognised technique for confirmation of pancreatic masses by histology. EUS- FNAs are reported to have an accuracy of 78-95% in the diagnosis of pancreatic masses. Neuroendocrine tumour presents as a, homogeneous, isoechoic or hypoechoic mass on EUS while plasmacytoma shows heterogenecity with uneven margins. NETs are hypervascular [5,8].

When FNA was done, the lesion was morphologically misdiagnosed as neuroendocrine neoplasm since both share plasmacytoid morphology. In a rare site, one would be more likely to suspect a primary lesion with plasmacytoid features, particularly endocrine neoplasm. Islet cell tumours have been reported to be a great mimic of plasmacytoma with regards to clinical, cytological and radiological appearance [9]. EUS guided core biopsy from the lesion and immunophenotyping with cytokeratin for carcinoma and CD138, kappa and lambda for identifying monoclonality of plasma cells would have helped in arriving at the diagnosis. EUS guided FNA also serves as a platform for obtaining material for flow cytometry.

The patient described here did not present with any symptoms pertaining to myeloma prior to surgery. The patient progressed to plasma cell leukaemia within a short time (one month) which is evident from the investigations [Table/Fig-8]. Plasma cell leukaemias are primary in 60-70% of cases and secondary to multiple myeloma in 30-40 % cases [10,11].

To our knowledge, this is the first case of plasmacytoma of pancreas being the initial manifestation of a plasma cell leukaemia. Two other cases of plasma cell leukaemia have been reported in association with gastric plasmacytoma. One case reported also had a normal WBC and platelet count with normocytic normochromic anaemia three weeks prior to the diagnosis of gastric plasmacytoma. The authors had hypothesised that secondary plasma cell leukaemia would have occurred as a result of rapid transformation of possibly underdiagnosed light chain multiple myeloma. The present case could also represent a similar rapid transformation from a non-secretory myeloma presenting with an extramedullary plasmacytoma [12].

From the previous reports it is clear that in any mass lesion of a solid organ in a patient with multiple myeloma the possibility of secondary plasmacytoma is to be considered [3,4,7]. Present case in addition highlights the fact that plasmacytoma is to be considered when plasmacytoid cells are identified in EUS-FNAs even when previous diagnosis of myeloma or symptoms pertaining to myeloma is not there at presentation. Immunocytochemistry can be used as an ancillary technique to diagnose with certainty in such cases. Presurgical diagnosis is essential as the management varies between primary pancreatic carcinoma and plasmacytoma.

CONCLUSION(S)

This case highlights the importance of considering other causes of pancreatic head mass than a primary carcinoma in a patient with obstructive jaundice. It also emphasises the fact that pathologists must be aware of the existence of pancreatic plasmacytoma as initial manifestation of myeloma despite its rarity, a high index of suspicion being essential.

Abstract

Context: Peripheral T cell lymphomas (PTCLs) are uncommon subtypes of non Hodgkin lymphoma (NHL). The diagnosis is often challenging and not infrequently misdiagnosed. *Aims:* To analyse the morphological and immunohistochemical profile of Peripheral T cell lymphoma. *Settings and Design:* This study was carried out at the Department of Pathology, where cases were recruited using consecutive sampling method. *Methods and Material:* Immunohistochemical staining was performed in all cases of lymphoma and results were analysed. *Statistical Analysis Used:* Frequency distribution of the diagnoses was studied. *Results:* There were six casesof Peripheral T cell lymphoma – unspecified (CD3+, CD20-), two cases of Angioimmunoblastic T cell lymphoma (AITL)(CD3+, CD10+, CD23+), one case of Lennert's lymphoma(CD3+,CD20-) and a hepatosplenic T cell lymphoma(CD3+,CD2+). *Conclusions:* PTCLs constituted for 20% of NHLs. Immunohistochemistry was helpful in diagnosis when differentiation from Hodgkin lymphoma was difficult morphologically.

Keywords: Angioimmunoblastic T Cell Lymphoma; Lennert's Lymphoma; Lymphoma; Non Hodgkin Lymphoma; Peripheral T Cell Lymphoma.

Introduction

The World Health Organization (WHO), 2008 [1] classifies mature T cell / NK cell neoplasm into four categories (nodal, extranodal, cutaneous and leukemic). Nodal group includes peripheral T cell lymphoma unspecified, angioimmunoblastic T cell and anaplastic large cell lymphoma. PTCLs constitute 4 to 12% in western [2,3] and 12-26 % in eastern countries [4]. Indian studies have shown a frequency of 9 to 12% [5]. PTCLs show a higher morphological and immunological diversity than any other lymphoma. Hence the diagnosis of PTCL remains a challenge to the histopathologist.Thus, this study aims to analyze the morphological and immunohistochemical features of PTCL, for better understanding of this rare variant.

Key Messages

Immunohistochemistry (CD3, CD20, CD15, CD30, CD23, and CD5) is essential in differentiating peripheral T cell lymphoma from its mimics (Hodgkin lymphoma and reactive conditions) because of its varied morphological pattern on routine hematoxylin and eosin stained sections

Subjects and Methods

Between August 2011 and August 2013, 52 consecutive cases diagnosed as lymphoma in the histopathology department in a tertiary care hospital were included in the study.

Inclusion Criteria

Patients of all ages and both genders with both primary and/or extranodal lymphomas (treatment naïve) were included in the study.

Exclusion Criteria

Samples inadequate for light microscopy and

immunohistochemistry were excluded. Similarly, patients who were on treatment for lymphoma were excluded.

For histological and immunohistochemical studies, the samples were received in neutral buffered formalin. Routine Hematoxylin and eosin staining was done to study the pattern, cellular morphology and presence of key diagnostic features. A panel of immunohistochemical markers was chosen based on the histological differential diagnosis. For immunohistochemistry, 4μ sections were taken in specially coated slides. Slides were then deparaffinised and rehydrated in ethanol and xylene. Antigen retrieval was done by microwaving using two methods 1) by incubating sections with a Tris-EDTA solution, pH 9.0 for 20 minutes before staining with antibodies against CD3, CD15, CD30, CD2, TDT, CD23 and CD10 (mouse, monoclonal, biogenex), and 2) by incubating sections with 0.01 M citrate buffer solution, pH 6.0, for 20 min before staining with antibodies against CD45, CD20 (mouse, monoclonal, biogenex). The slides were then incubated under humid conditions at room temperature for 90 minutes.

The antibodies bound to antigens were detected by addition of secondary antibody conjugated with horse radish peroxidase polymer and diaminobenzidine substrate. The slides were counterstained with hematoxylin. Appropriate positive controls for the primary antibodies as per the manufacturer's instruction manual (biogenex) were used. The immunohistochemically stained slides were analyzed for the presence/absence of reaction and cellular localization. The positive reaction in the neoplastic cells was assessed. This study was conducted with approval of the Institutional ethical committee, in accordance with the ICMR guidelines for human research.

Statistical Analysis

Frequency distribution of gender and diagnoses were studied.

Results

Of the 52 cases of lymphoma, ten were peripheral T cell lymphomas. These ten cases included seven males and three females. The age of the patients ranged from four years to 90 years. All except one, presented with peripheral lymphadenopathy while the other presented with hepatosplenomegaly.

The diagnosis was made based on World Health Organization (WHO) 2008 classification. Six cases were diagnosed as Peripheral T cell lymphoma-unspecified (PTCL-U). These cases showed a heterogenous population of cells which were small to large with pleomorphic nuclei with irregular nuclear contours and variable amount of cytoplasm (Figure 1). Reactive population of cells included plasma cells, lymphocytes and eosinophils. Vascular channels were prominent in five cases. Occasional binucleated cells were seen in two cases (Table 1). The differential diagnosis included Hodgkin lymphoma as the reactive population of cells was seen in all the six cases and T cell rich B cell lymphoma in two cases as there were large neoplastic cells admixed with small lymphoid cells. Immunohistochemistry demonstrated absence of CD15, CD30 and CD20 staining in large cells. The neoplastic cells demonstrated membrane and cytoplasmic staining for CD3 (Figure 2) and CD2 (Table 2).

Two cases were diagnosed as angioimmunoblastic T cell lymphoma. Of the two cases one showed complete effacement of lymph node architecture by diffuse proliferation of small to medium sized lymphoid cells with scattered eosinophils and few histiocytes. The other showed partially preserved lymph node architecture with follicular hyperplasia and paracortical expansion by the polymorphic infiltrate of cells with few cells having clear cytoplasm (Figure 3 and 4). Pale eosinophilic areas comprising of cells with eosinophilic cytoplasm and indistinct cell membrane were observed in one case. Numerous branching and arborizing vascular channels lined by plump endothelial cells and few immunoblast like cells were noted in both the cases. Immunohistochemistry demonstrated CD 3 (Figure 5) and CD10 positivity. CD23 staining highlighted the extrafollicular dendritic cell network (Table 3) (Figure 6).

One case showed loss of nodal architecture by diffuse proliferation of small lymphoid cells and confluent clusters of epithelioid cells (microgranulomas). Scattered large atypical cells and few reactive cells composed of eosinophils and plasma cells were seen. There were no classical Reed Sternberg cells. This was diagnosed as Lennert's lymphoma. The differential diagnosis included reactive lymphadenitis and Hodgkin lymphoma. Immunohistochemistry showed absence of CD15 and CD30 in the large atypical cells, thus excluding Hodgkin lymphoma (Table 3).

In the single extranodal case, the site of biopsy was liver as the patient (four years old female) presented with hepatosplenomegaly without any lymphadenopathy. Histology showed sinusoidal

expansion by dense infiltration of monotonous small to medium sized lymphoid cells. Periportal involvement was also noted. Hepatocytes appeared normal. This was diagnosed as Hepatosplenic T Cell Lymphoma with a differential diagnosis of acute lymphoblastic leukemia. On immunohistochemistry, the lymphoid cells were positive for CD3, CD2 and negative for Terminal deoxynucleotidase(TdT) and thus Lymphoblastic leukemia was ruled out because of TdT negativity (Table 3).

Table 1: Morphological features of PTCL- U

Morphological Features	Distribution of the features (N = 6)
Effacement of architecture	6 (100%)
Heterogenous population of cells	6 (100%)
Reactive population of cells	5 (83%)
Reed Sternberg like cells	2 (33%)
Prominent vascular channels	2 (33%)

Table 2: Immunhistochemical profile of PTCL-U

IHC	Case 1	Case 2	Case 3	Case 4	Case 5	Case 6
CD45	+	+	+	+	+	+
CD3	+	+	+	+	+	+
CD2	ND	+	+	+	+	+
CD20	+ in reactive cells	-	-	-	Focally +	-
CD15	-	-	-	-	-	-
CD 30	-	-	-	-	-	-

ND – Not done, IHC- Immunohistochemistry

Table 3: Morphological and immunohistochemical features of other PTCLs

	Clinical features	Morphology	IHC	Diagnosis
1	70/M cervicalnode	Microgranulomas and small lymphoid infiltrates	Positive for CD45,CD3,CD2 and negative for CD20, CD15,CD30	Lennerts lymphoma
2	50/F cervical node	Arborizing vascular channels , polymorphic infiltrates and immunoblast like cells	Positive for CD3, CD10 AND CD23. Negative for CD20, CD15, CD30.	Angioimmunoblastic T cell lymphoma
3	50/M inguinal node			
4	4/F, liver biopsy	Sinusoidal expansion by atypical lymphoid cells	Positive for CD3, CD2. Negative for CD20, TdT.	Heptosplenic T cell lymphoma

Discussion

In the present study, PTCL constitutes 20 % of NHL. This is much higher when compared to other Indian studies [5]. In our study, Nodal PTCLs accounted for about 90% of PTCLs.

PTCL U is a heterogenous group of lesions which do not fit into any of the subtypes of peripheral T cell lymphoma and thus is a diagnosis of exclusion. It is the most common subtype of Mature T cell lymphoma, typically occurring in adults at sixth decade. Lymphadenopathy is the usual presentation. In this study PTCL- U accounts for about 60% of PTCLs which is comparable to other studies [5,6]. As found in other studies, there was a male predominance and 90% of cases had lymphadenopathy. The immuno-histochemistry demonstrated positivity for T cell markers CD3 and CD2 and also showed abberant loss of CD5 expression.

Lennert's lymphoma (lymphoepithelioid lymphoma) is a variant of PTCL-U. It is a rare entity displaying monomorphic small tumor cells, few scattered immunoblasts, epithelioid cells in clusters and absence of high endothelial venules and follicular dendritic cells (FDC) networks [7,8]. In our study, the patient presented with bilateral cervical lymphadenopathy and hepatosplenomegaly. The lymph node showed the unique histological features characterized by epithelioid cell clusters and infiltrates of small lymphoid cells. Immunoblastic cells were noted in this case. CD30 positive cells were not identified.

Angioimunoblastic T cell lymphoma forms approximately 15-20% of PTCLs [9,10]. In the present study, it constituted about 20 % of PTCLs. AITL is a systemic disease clinically characterized by lymphadenopathy, hepatosplenomegaly and skin rash. Polyclonal hypergammaglobulinemia and hemolytic anemias are other associations [10]. Both the patients in the present study presented with lymphadenopathy and hepatosplenomegaly while one patient also had skin rash. The presence of hemolytic anemia and hypergammaglobulinemia were not evaluated. However they showed the classical morphological findings which include arborizing high endothelial venules, polymorphic infiltrates and presence of clear cells. The vascularity was more pronounced in AITL when compared to other PTCLS. Extrafollicular follicular dendritic cell proliferation was evident in one case. CD 23 staining confirmed the presence of this follicular dendritic cell meshwork. In the other case, where extrafollicular dendritic cell network was not evident on H & E staining, immunostaining with CD23 showed the presence of these cells.

Hepatosplenic T cell lymphoma is a rare and aggressive subtype of extranodal peripheral T cell lymphoma. HSTL accounts for less than 1% of NHL and about 3% of T cell lymphoma [11]. It occurs more frequently in immunocompromised patients. It occurs predominantly in adolescents and young adults. However in this study, the patient was a 4 year old female who presented with abdominal distension and fever without any history of immunosuppression. The diagnosis was made based on morphology and immunohistochemistry (CD 3 positivity). TCR rearrangement analysis could have helped in analyzing the variant.

We acknowledge that the sample size was small to generalize our results, but in view of rarity of this Peripheral T Cell lymphoma, our study will help in differentiating PTCL from its mimics like Hodgkin lymphoma and thus by itself may guide further treatment modalities.

Conclusion

In our study, the frequency of Peripheral T cell lymphomas is higher when compared to other Indian studies. Knowledge about the various morphological patterns and cellular composition of PTCL is essential to select the panel of immunohistochemistry markers. In our study we found that morphology when combined with immunohistochemistry is more effective in differentiating PTCL from Hodgkin lymphoma and T cell rich B cell lymphoma and also to classify various PTCLs. We by this study, conclude that immunohistochemistry becomes essential in the diagnosis of PTCL.

Xeroderma Pigmentosum and Bone Marrow Aplasia: A Rare Association

Abstract

Xeroderma pigmentosum (XP) is a rare autosomal recessive disorder characterized by hypersensitivity to ultraviolet rays and predisposition to cutaneous malignancies. Hematological disorders associated with XP include myelodysplastic syndrome and acute leukemia. We report a 7-year-old child with XP along with squamous cell carcinoma and bone marrow aplasia.

Keywords: *Aplastic anemia, pancytopenia, squamous cell carcinoma, xeroderma pigmentosum*

Introduction

Xeroderma pigmentosum (XP) is a rare inherited autosomal recessive disorder characterized by extreme hypersensitivity to ultraviolet rays predisposing to early cutaneous malignancies. Other abnormalities include neurological and ocular diseases.[1,2]

The incidence of XP varies across geographic areas, one in one hundred thousand in Europe and the US to one in 22,000 in Japan. The incidence in India has not been studied so far but is believed to be less when compared to the Western countries.[2,3]

There is no sex predilection. Pathophysiology of this inherited disorder is the defect in the nucleotide excision repair mechanism, and hence, the DNA damage caused by ultraviolet (UV) rays is unrepaired resulting in genomic instability which leads to predisposition to oculo-cutaneous malignancies as well as other internal malignancies. The other manifestations of XP include hyperpigmentation, premature aging, and neurological dysfunction. Photosensitivity and burning sensation after exposure to the sun precede the dryness (xeroderma) and pigmentation of skin and ocular manifestations such as photophobia and keratitis.[4,5]

Hematological abnormalities reported include myelodysplastic syndrome, which is characterized by refractory anemia with excess blast cells and leukemias.[6] A single case of XP in association with bone marrow failure has also been reported.[7]

Bone marrow aplasia in XP is very rare when compared to its presence in other DNA repair mechanism defects such as Fanconi anemia, Bloom syndrome, and ataxia telangiectasia.

We present here an interesting case of XP associated with bone marrow aplasia.

Case Report

A 7-year-old male child, a known case of XP, presented with a swelling in the right infraorbital region of short duration associated with pain and discharge from the lesion.

The diagnosis of XP was made based on the clinical findings in the previous admission when the child presented with dermatological symptoms, photosensitivity, itching over the face, and hyperpigmentation. Pigmentation progressed with age. Erythematous scaly plaques with pigmented macules were seen over the areas exposed to the sun. The child was born of a nonconsanguinous marriage and attained normal developmental milestones. There were no neurological manifestations.

In the current admission, complete hemogram showed pancytopenia (white blood cell count - 3.5 × 10^3/μl, red blood cell count - 1.01 × 10^6/μl, and platelet count - 21 × 10^3/μl). Peripheral smear revealed a macrocytic blood picture. There were no atypical cells in the smear [Figure 1].

Bone marrow aspiration was done. The smears were paucicellular with adipocyte fragments and scant hematopoietic elements. There were no features of dyspoiesis in any lineage [Figure 2].

Bone marrow trephine was markedly hypocellular with fatty marrow and minimal hematopoietic tissue. There was no evidence of an infiltrative disease [Figure 3].

Wide-local excision of the infraorbital swelling showed a moderately differentiated squamous cell carcinoma [Figure 4].

Discussion

XP is a rare genodermatosis caused by defects in the normal repair of DNA damaged by exposure to sunlight. There are eight complementation groups of XP (XP-A to G) caused by defective nucleotide excision repair, corresponding to mutations in the genes encoding XPA, XPB, XPC, XPD, XPE, XPF, XPG, and XP dominant. The incidence and the age at presentation vary, ranging from early infancy to adulthood. XP has been reported to be common with consanguineous marriages.[8]

There are a 1000-fold increased risk of development of cutaneous malignancies, especially in those diagnosed under the age of 2 years and a 10-20-fold increased risk of developing noncutaneous malignancies.[9]

The commonly reported cutaneous malignancies include squamous cell carcinoma followed by melanoma and basal cell carcinoma.

Our patient had squamous cell carcinoma of the face.

In addition, the patient had pancytopenia which suggested the possibility of an infiltrative disorder of bone marrow. Bone marrow metastasis of malignant melanoma presenting as pancytopenia has already been reported in cases with XP.[10] In our patient, bone marrow aspirate and trephine were consistent with aplastic anemia.

Review of the literature revealed that the common hematological disorders associated with XP are myelodysplastic syndrome and acute myeloid leukemia.[6]

Marrow aplasia in XP is very rare and has been reported so far in only a single case of XP.[7] However, marrow

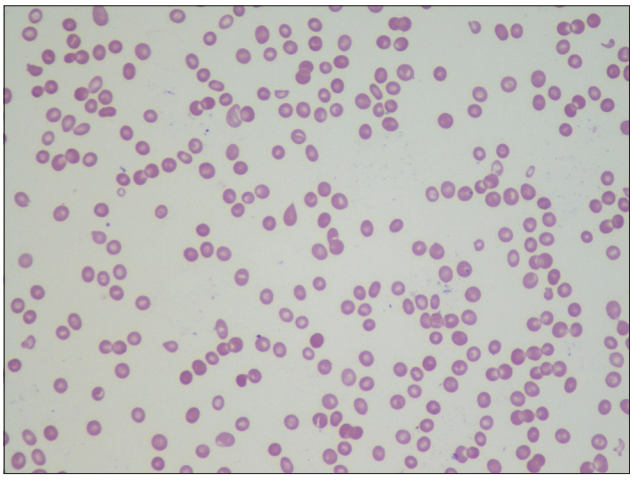

Figure 1: Peripheral smear showing pancytopenia (×40)

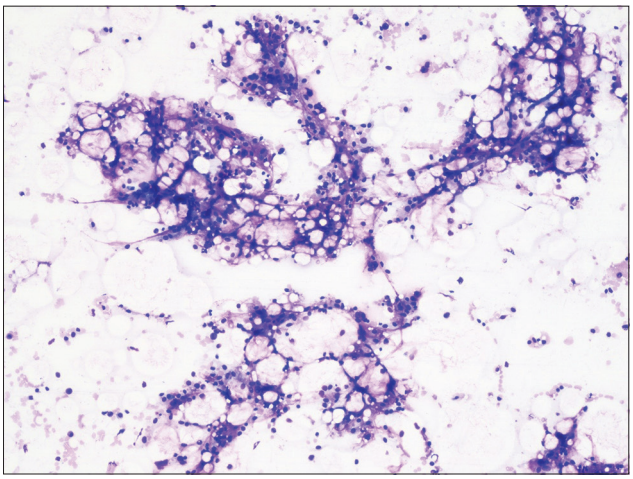

Figure 2: Bone marrow aspirate showing hypocellular marrow particles (×10)

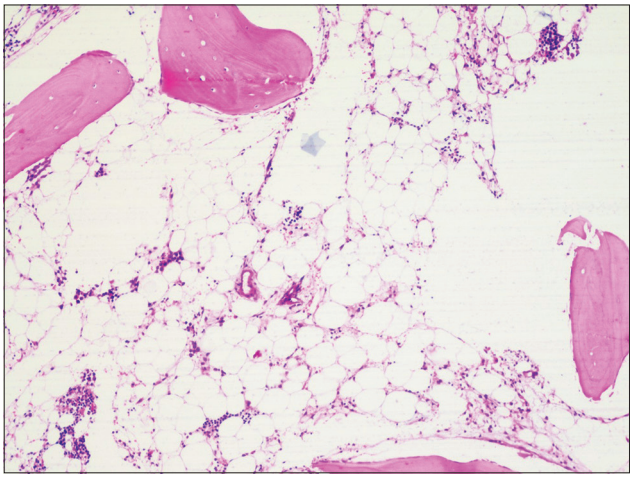

Figure 3: Bone marrow trephine showing fatty marrow (×10)

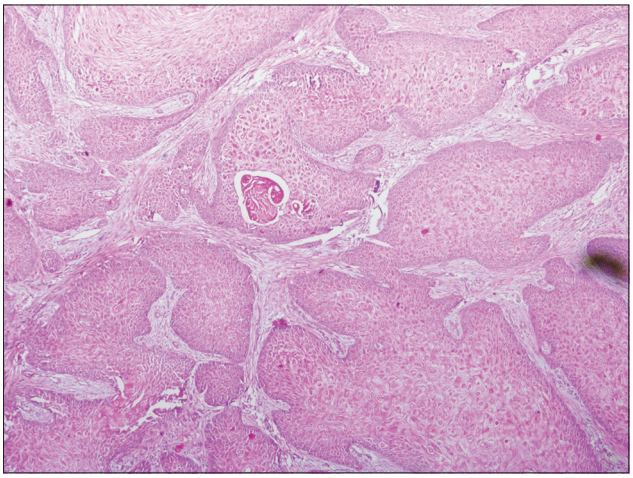

Figure 4: Biopsy showing squamous cell carcinoma (×10)

aplasia is quite common in other inherited DNA damage repair diseases such as Fanconi anemia. The patient did not have any features of Fanconi anemia. Even though skin hyperpigmentation has been reported in Fanconi anemia, it is not restricted to sun-exposed areas unlike in XP.

Aplastic anemia in children is generally attributed to drugs and viral infections. However, 90% of these cases are idiopathic in nature.[7]

The association of XP with leukemias and other internal malignancies shows that DNA damage repair mechanism is essential in repairing non-UV-mediated mutagenesis as well.

The association of aplastic anemia and XP as a new variant of this disease has not yet been proven.[7] The clonal evolution of aplastic anemia to leukemia has been reported.[7] Considering the foregoing discussion, it is tempting to suggest that this patient under reference can be considered to be at the increased risk of developing leukemia.

Abstract

Deep Angiomyxoma is very rare, slowly growing, and benign tumor of mesenchymal origin which affects women in perimenopausal age group and is associated with a high risk of local recurrence. A case of a 42-year-old female is presented, with a large firm gelatinous mass on the right labia majora, measuring 5.5 × 6 cm. The patient underwent wide local excision of the tumor. Histopathological examination showed a hypocellular neoplasm composed of uniformly distributed stellate cells in an abundant myxoid matrix and variably sized vessels suggestive of deep Angiomyxoma. 1 year followup showed no recurrance. Deep angiomyxoma of the vulva has to be distinguished from benign myxoid and malignant myxoid neoplasm. Wide local excision of the tumour is the treatment of choice. Long term follow up is indicated in view of local recurrence.

Key Words: Angiomyxoma, India, Rare, Vulva

Introduction

Deep angiomyxoma is a very rare, slowly growing, and benign tumor of mesenchymal origin, presenting in women of reproductive age, which has high risk for local relapse[1]. Deep Angiomyxoma was first described by Steeper and Rosai in 1983. It is a very rare local mesenchymal tumor of unknown etiology usually affecting vulva, labia major, buttocks, or pelvis of women in reproductive age[3]. Very few cases reports have also been described in men, which affect the scrotum [2]. Pathophysiology is unclear, but estrogen and progesterone influence may also play a role [4]. Women are affected predominantly in early reproductive years Adult men are less commonly affected. Female to male ratio is 6:1. It is Rare in children [4]. Controversy exists regarding management in view of local recurrence. It is a mesenchymal lesion, angiomyxoma mimics disorders which range from non neoplastic vulval hypertrophy and lymphedema to malignant tumours like myxoid liposarcoma.

Case Report

A 42-year-old female is presented, with a large firm gelatinous mass on the right labia majora, measuring about 5.5 × 6 cm with duration of 2 years and increased in size for 6 months.(Fig.1a) It was painless, soft, spongy in consistency, and non-tender. Menstrual cycles were regular with a normal flow. Examination of the cervix, external urethral meatus and vagina were unremarkable. Bilateral inguinal lymph nodes were not enlarged. Ultrasound of the abdomen and pelvis was normal. Cystoscopy was done in view of mass close to

the external urethral meatus, which showed normal urethral meatus, urethra and bladder. She underwent wide local excision of the lesion (Fig.1b). There was moderate bleeding during the procedure but the postoperative course was uneventful. Histopathologically, lesion showed a neoplasm covered by stratified squamous epithelium. The neoplasm was paucicellular (Fig.2a) composed of uniformly distributed spindle to stellate cells with ill-defined cell borders, moderate amount of eosinophilic cytoplasm and an elongated bland nucleus. Interspersed were thin fascicles of smooth muscle bundles and variably sized numerous thin and thick walled blood vessels (Fig.2b, 2c). These cells were set in an abundant myxoid and collagenous stroma(Fig.2d). Differential diagnosis at this stage included fibroepithelial polyp and, angiomyofibroblastoma both being commonly reported in Vulva. Because of the larger size, ill defined margins and absence of predominantly plump cells with perivascular accentuation, Angiomyofibroblastoma was ruled out. Angiomyofibroblastoma is usually a well circumscribed, smaller neoplasm with hypercellular and hypocellular areas with more plump cells with perivascular accentuation. Lack of bizarre stomal cells ruled out fibroepithelial polyp. There were no atypical cells or increased mitosis. With the above morphological features, it was diagnosed as Deep Angiomyxoma. 1 year follow-up revealed no recurrance.

□ □□□□□□□□□□

Deep angiomyxoma is the benign tumor commonly presents as an asymptomatic mass in the genital area of women in their reproductive life. The term “deep” denotes its propensity for local aggression and recurrence after excision. Approximately 70% - 80 % of the cases have recurrence after a period of 5 years postoperatively and it has been reported even 20 years after surgery. Local recurrences are treated with reoperation with wide local excision [1]. Some controversy exists with regard to need chemotheraphy. Some studies advocate that tumour cells are positive for estrogen and progesterone receptors[2,3]; hence hormonal therapy like tamoxifen and gonadotropin-releasing hormone analogue will reduce the tumor size and helps to make complete excision in large tumors and in the treatment of recurrence [5, 6]. Some studies also conclude that there is No role in Chemotherapy and radiotherapy in view of low grade mitotic figures. However most studies have consensus for Long term follow up with local examination and MRI pelvis for local recurrence [1]. Here we observed that wide local excision of the tumour even without chemotheraphy, with good follow- up can prevent local recurrence as observed in some of the studies. Angiomyxoma is a mesenchymal lesion. Immunohistochemically, these tumors stain for vimentin and desmin. The tumor cells also show some expression for muscle actin. Superficial angiomyxoma, angiomyofibroblastoma, and smooth muscle tumors like leiomyoma, hamartoma, liposarcoma also need to be considered in the differential diagnosis of a solid smooth mass in the perineum [2]. We observed that a wide range of vulvar mesenchymal lesions exist and angiomyxoma has to be differentiated from the mimics which range from non neoplastic vulval hypertrophy and lymphedema to malignant tumours like myxoid liposarcoma.

Deep Angiomyxoma is rare entity in the Vulva, especially when it is painless lesion, particularly in premenopausal women in their third to fourth decades of life. CT/MRI pelvis is advocated in this situation for the extent of the mass. A wide range of vulvar mesenchymal lesions exist and angiomyxoma has to be differentiated from the mimics which range from non neoplastic vulval hypertrophy and lymphedema to malignant tumours like myxoid liposarcoma. Wide local excision is the treatment of choice for deep angiomyxoma of vulva with low recurrence rate. Long term follow up is required with genital examination and imaging studies.

CD5 Positive Follicular Lymphomas- A Diagnostic Dilemma in a Resource Restricted Laboratory Setting

Sakthi Sankari S[1]*, Arjunan A[2], Bhuvaneswari M.G.[2], Sindhuja R[3], Rajeswari Thivya D[4]

[1]Department of Pathology, PSG Institute of Medical Sciences and Research, Coimbatore, Tamilnadu, India
[2]Department of Pathology, Coimbatore Medical college, Coimbatore, Tamilnadu, India
[3]Department of Pathology, Thirunelveli Medical college, Tamilnadu, India
[4]Department of Pathology, Karpaga Vinayaga Medical College, Kanchipuram, Tamilnadu, India

ABSTRACT

Background: Follicular lymphoma is an indolent B Non Hodgkin lymphoma which has a characteristic follicular growth pattern and immunohistochemical expression. The neoplastic cells express CD20, CD10, and BCL2 and are negative for CD5, CD23 and Cyclin D1. CD5 is a useful marker in the differentiation of various B cell lymphomas. Small cell lymphoma and mantle cell lymphoma express CD5. Some of the follicular lymphomas express CD5 which results in diagnostic confusion

Methods: 52 cases of lymphoma were diagnosed over a period of 2 years in a tertiary care centre in south India. Among these, 9 cases were diagnosed as follicular lymphoma based on the morphological and immunohistochemical study. A panel of antibodies was chosen based on the morphological diagnosis. The panel used for small cell lymphomas include CD20, CD3, CD5 CD23, Cyclin D1, CD10, BCL2 and Ki67.

Result: Of the nine cases of follicular lymphoma, three were CD5 positive. Two showed bone marrow involvement. There was no significant morphological difference between CD5 positive and CD5 negative follicular lymphoma.

Conclusion: The expression of CD5 by follicular lymphomas could be problematic when the follicular lymphoma as such lacks its characteristic follicular pattern andwhen there are no molecular studies available. Even though rare, follicular lymphoma is to be considered in the differential diagnosis of CD5 positive lymphomas.

Keywords: *Follicular Lymphoma, CD 5 Positive, Indolent Lymphomas, B Cell NHL, Immunohistochemistry*

Introduction

Follicular lymphoma (FL) is the second most common Non Hodgkin lymphoma (NHL) in India. It is an indolent lymphoma derived from germinal centre derived B cells. FL has a characteristic morphology with effaced nodal architecture, follicular growth pattern recapitulating germinal centres. Genetically, the hallmark of FL is t(14;18)q(32;q21) which has been detectable in a significant number of cases accounting to about 80%. This genetic alteration is responsible for the deregulated expression of BCL2 which can be detected using immunohistochemistry. FL has characteristic immunophenotypic expression, positive for pan B cell markers, CD20, CD19, germinal centre associated antigens CD10, BCL6 and BCL2. FL do not express CD5, a T cell marker that has a key role in the differential diagnosis of small B cell Non Hodglkin lymphomas. [4-6]

CD5 is a glycoprotein expressed on mature T cells and a small subset of B cells. CD5 positive cells in a lymph node are present in the follicular mantles. [7] Among the lymphomas, CD5 is considered a marker for small lymphocytic (SLL) and mantle cell lymphoma (MCL). However a small subset of diffuse Large B cell lymphoma, Burkitt lymphoma and extranodal marginal zone lymphoma are found to have expressed CD5.[8,9] And also, cases of CD5 positive follicular lymphomas have been reported in small numbers in the studies performed even before the advent of molecular studies. [10-12]

FL is basically a morphological diagnosis. Immunohistochemistry is used as an ancillary tool in the confirmation of diagnosis. CD5 expression however would result in diagnostic confusion when the morphology is not characteristic and flow cytometric and translocation studies cannot be done. In the present study, we describe morphologic and immune histochemical features of 3 such cases of CD5 positive FL.

Materials and Methods

Fifty two cases of lymphoma were diagnosed over a period of 2 years in a tertiary care centre in south India. The lymphomas were reported based on the WHO classification of tumours (2008 classification). Among these, 9 cases were diagnosed as follicular lymphoma

This work is licensed under the Creative Commons Attribution 4.0 License. Published by Pacific Group of e-Journals (PaGe)

based on the morphological and immunohistochemical study. Histology was evaluated in formalin-fixed, paraffin-embedded (FFPE) and H&E-stained sections. Grading of FLs was based on the number of centroblasts per high-power field. A panel of antibodies were chosen based on the morphological diagnosis. The panel used for small cell lymphomas include CD20, CD3, CD5 CD23, Cyclin D1, CD10, BCL2 and Ki67.

For immunohistochemistry, 4µ sections were taken in specially coated slides. Slides were then deparaffinised and rehydrated in ethanol and xylene. Antigen retrieval was done by microwaving using two methods 1) by incubating sections with a Tris-EDTA solution, pH 9.0 for 20 minutes before staining with antibodies against CD10, CD23, BCL2, CD5, CyclinD1, CD3 (mouse, monoclonal, biogenex), and 2) by incubating sections with 0.01 M citrate buffer solution, pH 6.0, for 20 min before staining with antibodies against CD45, CD20 (mouse, monoclonal, biogenex). The slides were then incubated under humid conditions at room temperature for 90 minutes.

The antibodies bound to antigens were detected by addition of secondary antibody conjugated with horse radish peroxidase polymer and diaminobenzidene substrate. The slides were counterstained with hematoxylin. Appropriate positive controls for the primary antibodies as per the manufacturer's instruction manual (biogenex) were used. The immunohistochemically stained slides were analyzed for the presence/absence of reaction and cellular localization. The positive reaction in the neoplastic cells was assessed. This study was conducted with approval of the Institutional ethical committee, in accordance with the ICMR guidelines for human research.

Result

Of the nine cases of FL, 3 were CD5 positive. All the three patients were males with the age range of 37 to 53 presenting with lymphadenopathy.

Histologically, all the three cases showed predominant follicular growth pattern, while one of them showed diffuse component accounting to less than 50 %.(fig 1 and 2). Histological grading was based on the number of centroblasts per high power field. On immunohistochemical study the cells were found to express CD20, CD10 and BCL2. (Fig 3 and 4) BCL2 was expressed in the follicular centres. Approximately 70% of the cells were CD5 positive. CD3 immunostaining was included in the panel to assess the proportion of T cells in follicles. As the T cells in the follicular centre usually express BCL2, CD3 immunostaining was compared with BCL2 before interpreting BCL2 expression in order to avoid misinterpretation. The follicular centre also had CD3 positive T cells which also expressed CD5 (fig5). Cyclin D1 was negative in all the three cases ruling out mantle cell lymphoma. (Table 1)

In case 2 there was weak expression of CD20 and CD5. Bone marrow trephine biopsies were subsequently received for these three cases. Two of the three cases showed bone marrow involvement, one was paratrabecular while the other aws diffuse. There was no peripheral blood involvement. Extranodal involvement was not detected in any of the three cases.

The other six cases which have not been described here showed typical histological and immunohistochemical features of lymphoma.

Discussion

Follicular lymphoma is a mature B cell lymphoma which accounts for 20% of NHL.It is usually a disease of adults having a slight female preponderance. FL predominantly involves the lymph nodes, involvement of bone marrow and other extranodal sites can happen in the setting of widespread disease. Primary Extranodal FL can also occur. [1]

FL is a heterogenous neoplasm having a variable immunoarchitectural pattern. Typically the involved lymph nodes show complete effacement of nodal architecture by uniform sized follicles composed of centrocytes and centroblasts. These neoplastic follicles lack polarization and evidence of apoptotic activity (tangible body macrophages). The growth pattern can be follicular, follicular and diffuse and predominantly diffuse. CD23 immunostaining which highlights the follicular dendritic cells aids in assessing the extent of follicular component. [13, 14]

The varied architectural patterns and variants lead to confusion with other small B cell lymphomas which include small lymphocytic lymphoma (SLL) and marginal

zone lymphoma. The typical immunoprofile of FL includes expression of CD10, BCL6, BCL2 and CD20. The expression of these markers are stronger in the follicles when compared to the interfollicular cells. [15]

CD10 is a germinal centre marker expressed both in reactive and neoplastic follicles. IT is also expressed in Burkitt and Diffuse Large B cell lymphoma. [15] BCL2 is an antiapoptotic protein which is negative in reactive germinal centres and overexpressed in FL, the expression of which is strong in grade 1 and 2 FL. It is a reliable marker for differentiating follicular lymphoma from follicular hyperplasia. T cells present within the follicular centres also express BCL2. [13]

CD5 is involved in T- and B cell receptor signaling. CD5 is a valuable marker in the differentiation of non Hodgkin B cell lymphomas. However CD5 is a mature T cell marker, but is expressed in a subset of B cell lymphomas (SLL and MCL). CD5 along with CD23 helps in the differentiation of small lymphocytic and mantle cell lymphoma. It has also been found to be expressed in marginal zone and diffuse large B cell lymphoma. [1-6] CD5 is one of the negative markers for follicular lymphoma. But CD5 positive follicular lymphomas have been reported to be a rare phenomenon. In the present study, 3 out of 9 cases of FL were CD5 positive, which appears more frequent when compared to the previous published studies.

They have been found to be associated with younger age, male predominance and grade 3 morphology. [15, 16] It has also been found to be expressed in follow up biopsies of FL which initially did not express.

In the present study, the age ranged from 37 to 53. All the three cases were males. Morphologically, all the three cases had follicular growth pattern except for one which showed a predominant diffuse pattern. Two of the cases were grade 2, while the other was grade 3. CD5 positive FL has been reported to be associated with advanced disease and Extranodal involvement. One of the grade 2 and the grade 3 case showed bone marrow involvement. Bone marrow involvement was paratrabecular in grade 2 FL (figure 6) and diffuse in grade 3 case. None of them had any evidence of Extranodal disease at presentation.

In the case 2 there was >50% diffuse component and immunohistochemically, there was weak expression of CD20. This weak expression of CD20 is characteristic of small lymphocytic lymphoma. This weak expression of CD20 along with CD5 positivity made SLL a strong possibility. However CD23 was negative in that case. Hence it was diagnosed as follicular lymphoma. CD5 positive follicular lymphomas reported so far has been confirmed with translocation and flow cytometric studies. These investigations were not conducted in the present study.

All the three cases showed morphological features of classical FL. No specific variants were found to comment on the association between CD5 positivity and any particular variant subtype. The other six cases of FL had wide age range (13 to 68), varied morphology, (4 of them grade 2 and the remaining two cases corresponding to grade 3).

The final diagnosis obtained was based on morphological and immunohistochemical study. Flow cytometry and cytogenetics were not performed to identify the translocation t (14, 18) characteristic of FL. Follow up data was not available to understand the prognostic significance of CD5 expression in a follicular lymphoma.

Conclusion

CD5 positive FL can pose a diagnostic problem especially when the morphology is not characteristic including the presence of diffuse component and when genetic studies are not available. However the use of panel of markers can aid in the diagnosis.

In summary CD5 positive Follicular lymphomas had the same morphological and immunophenotypic expression as that of CD5 negative FL. Eventhough the frequency is very low, we need to consider the possibility of follicular lymphoma in the evaluation of CD5 positive B NHL.

COEXISTENCE OF STRUMA OVARII AND BRENNER - A CASE REPORT

SAKTHISANKARI S SHANMUGA SUNDARAM
Department of Pathology,
COIMBATORE MEDICAL COLLEGE

Abstract :
Struma ovarii is a rare ovarian tumour. It is a monodermal variant of teratoma which is characterized by presence of more than 50 thyroid tissue. It constitutes about 1percent of ovarian tumours and 2.7 percent of teratomas. It usually occurs in pure form and rarely in association with Brenner and dermoid cyst. Most of struma is benign. Only 5 to 10 percent are malignant. Herein presented is a report of 65 year old female with benign struma ovarii with Brenner tumour.

Keyword : Struma ovarii, Brenner, cystic struma, monodermal teratoma

Introduction:

Struma ovarii is a germ cell tumour. It is a monodermal variant of teratoma which usually occurs in pure form and in association with dermoid, very rarely with Brenner and mucinous tumour. Struma ovarii is usually seen in fourth to sixth decade of life. There is risk of malignancy and thyroid hyperactivity. Hyperthyroidism is seen in 8 % of cases. Preoperative diagnosis is very difficult. Histopathological examination is the confirmatory.

Case report: 65 year old female presented with abdominal distension. Gynecological examination and imaging techniques revealed a complex right ovarian cyst. Ultrasonogram diagnosis was a malignant ovarian cyst possibly serous cystadenocarcinoma. Patient underwent hysterectomy with removal of right ovarian mass and left salphingo oophorectomy.

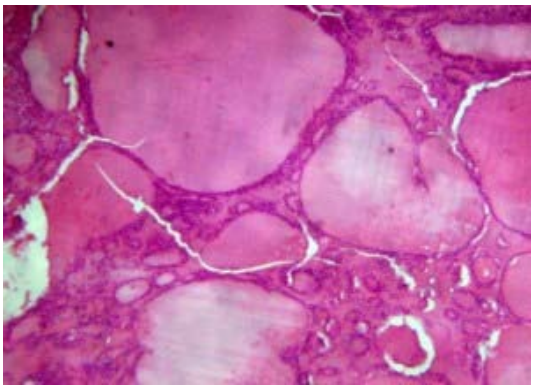
Gross findings:

Ovarian cyst measured 16 x 9 x 9 cm with smooth external surface (Figure 1). Ovarian cyst was unilocular filled with solidified light brown material (Figure 2). Few solid areas and few cystic spaces were seen. The solid areas were firm and yellow (Figure 3). Uterus, fallopian tubes and the left sided ovary were grossly normal.

Figure 1 gross picture of ovarian cyst
Figure 2 unilocular cyst with light brown material

Figure 3 showing solid yellow areas

Histopathological examination:
The cyst wall was composed of normofollicular and macrofollicular thyroid follicles filled with colloid representing struma ovarii (Figure 4 &5). Few areas of transitional epithelial nests representing Brenner component were also noted (Figure 6). Solid areas revealed features of mature teratoma. No atypia was seen in any of the components. No malignant transformation was noted. These components were present separately present and there was no merge among them. The left ovary and uterus showed no remarkable pathology.



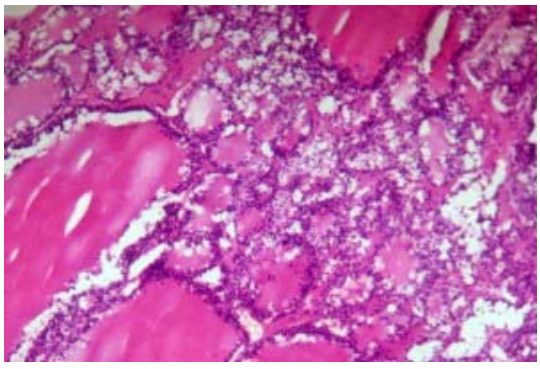


Figure 4 HPE showing thyroid follicles filled with colloid (10X) Figure5 HPE showing thyroid follicles filled with colloid (10X)

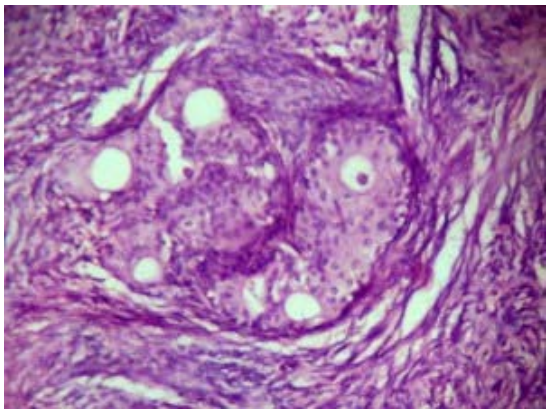

Figure 6 : HPE showing transitional cell nests in a fibrous stroma (40 X)

Discussion:

We hereby had presented a rare coexistence of Struma Ovarii & Brenner tumour. Struma ovarii was first recognized by Ludwig Pick to be composed of thyroid tissue and was labeled as ovarian goiter, which was actually teratoma with predominance of thyroid tissue.[1,2] Later, Plaut showed that the thyroid tissue in Struma ovarii was morphologically, biochemically, and pharmacologically identical to that of the normal thyroid gland. In the World Health Organization classification, Struma ovarii and malignant thyroid tumours arising within Struma ovarii are included in the thyroid tumour group under the category of monodermal teratomas (ICD 9090/ 0) [3,4] and somatic-type tumours associated with dermoid cysts.

As per the existing literature [1,3,5,6,7]. Struma ovarii is generally a unilateral tumour, usually occuring in pure form, less commonly with other germ cell tumours like dermoid, carcinoid and very rarely with epithelial tumours like Brenner, mucinous and serous neoplasms[5]. The tumour is usually solid, some may be cystic. Cut surface of the tumor is composed entirely of light tan, glistening thyroid tissue. Hemorrhage , necrosis, and foci of fibrosis may be present.In our case, struma ovarii was associated with Brenner component and was predominantly cystic**.** Struma ovarii usually shows normal thyroid tissue, but may represent thyroid adenoma and carcinomas[7,8]. In the present case, neither thyroid adenoma nor carcinoma were seen, rather thyroid tissue was normal.[1] Brenner is an epithelial tumour accounting less than 5% of ovarian neoplasms. They are small and mostly incidentally discovered and are 90% unilateral[9]. Brenner may be associated with mucinous tumour or dermoid cyst. Most tumors are well circumscribed, firm and rubbery with a grey white to yellow cut surface[10]. In the present case, the Brenner component exhibited the above typical morphological features. The pathogenesis of this type of ovarian tumor composed of Brenner's tumor and struma ovarii is uncertain. Brenner tumor is generally thought to be derived from surface epithelial cells while struma ovarii is a monodermal teratoma (germ cell tumor). In most cases where there is coexistence of Brenner and struma, both the components express thyroglobulin[11]. While there is strong evidence that pure Brenner tumors originate mostly from the ovarian surface, at least Brenner tumors associated with teratomatous elements may have a germ cell origin which could be confirmed by immunophenotyping.

Conclusion:

Coexistence of struma ovarii with Brenner is a rare entity which is highly unlikely to be diagnosed preoperatively. Struma ovarii has an overall better survival. Histopathology is the confirmatory. Histogenesis of Brenner associated with struma ovarii could be confirmed by further studies like immunophenotyping

and molecular studies.

KEYWORDS:
Fetal autopsy
Congenital cardiac anomalies
Complex cardiac defects

ABSTRACT

Aims: Major cardiac abnormalities can lead to miscarriages and is also an important indication of medical termination of pregnancy. The present study aims: (1) To determine the spectrum of cardiac anomalies in fetal autopsies, (2) To correlate the autopsy findings with prenatal imaging studies.

Methods: Fetal autopsies with cardiac anomalies were retrospectively analyzed over a period of five years. Autopsy diagnoses were correlated with prenatal ultrasound and echocardiogram findings.

Results: Of the 177 fetal autopsies, 40 (22.5%) cases with cardiac defects were identified. Among these cases, 11 (27.5%) showed only cardiac defects and associated extracardiac malformations were seen in 29 cases (72.5%). Septal defects (45%) were the most frequent cardiac defect followed by left ventricular outflow tract obstruction. Agreement with prenatal imaging and autopsy findings was seen in 65% of cases. There was 100% concordance between autopsy and echocardiogram wherever available.

Conclusion: Cardiac malformation forms a significant subset of fetal congenital anomalies. Meticulous examination and following sequential segmental analysis during autopsy are essential in identifying complex cardiac and additional extra cardiac defects in the fetuses. Fetal autopsy plays a vital role in confirming and/or refuting the imaging findings and could be the steppingstone in understanding the pathogenesis of cardiac abnormalities.

1. Introduction

Congenital malformations are a common cause of perinatal deaths and account for 10%-15% in India [1], the majority of which can be identified by fetal sonogram. Fetal medicine being emerging field, there is a rapid improvement in the detection rate of prenatal ultrasound screening for fetal abnormalities, which is further complemented by technological advancement in imaging [2]. But fetal autopsy remains the gold standard procedure to confirm the abnormalities and to detect additional findings if present, which can contribute to the final diagnosis. It also serves as a quality indicator for imaging evaluations and fetal medicine specialist [3]. While some authors recommend performing autopsy following termination of pregnancy (TOP) for fetal abnormalities, a few others recommend postmortem examination when an abnormal karyotype is detected [4].In either way, autopsy plays a pivotal role in diagnosing the anomalies and guide the clinicians in the effective management of subsequent pregnancies.

Among the congenital malformations, central nervous system defects are reported to be the most common, followed by cardiac defects accounting for 2.7%-8.8% [5]. The sophisticated imaging techniques to identify the cardiac abnormalities in- utero has allowed better understanding of pathology. But still there remain few unidentified or misdiagnosed lesions, which can be attributed to the pathology per se or the physician investigating it [6]. Decline in the autopsy rates fail to investigate the case completely. Cardiac abnormalities form a significant subset of malformation either as isolated lesions or as a component of syndrome. The present study aims to analyze the cardiac malformations in the present scenario in Indian subcontinent. The objective of the present study was to evaluate the spectrum of cardiac anomalies in routinely performed fetal autopsies and to correlate prenatal ultrasonogram (USG) with autopsy findings.

Abbreviations: TOP, termination of pregnancy; USG, ultrasonogram; IUD, intrauterine death; CNS, central nervous system; LVOTO, left ventricular outflow tract obstruction; RVOTO, right ventricular outflow tract obstruction; DORV, double outlet right ventricle; VSD, ventricular septal defect; TGA, transposition of great arteries; TOF, tetrology of Fallot; AVSD, atrioventricular septal defect; TAPVC, total anomalous pulmonary venous return; HLHS, hypoplastic left heart syndrome; HRHS, hypoplastic right heart syndrome; PLSVC, persistent left superior vena cava; ASD, atrial septal defect.

2. Materials and methods

All the fetal autopsies performed in the department of Pathology during the study period of January 2014 to December 2018 were retrospectively analyzed. The study was conducted after approval from Institutional Human ethics committee.

Fetuses of gestational age greater than 12 weeks were included in the study. Informed written consent was obtained from either of the parents before performing the autopsy. Detailed maternal history including parity, previous pregnancy outcome, consanguinity, medical illness, gestational age, sonographic findings, and mode of delivery was collected and recorded.

All the fetuses were examined using the protocol recommended by Royal college of Pathologists autopsy practice guidelines [7]. This includes whole body radiograph (anteroposterior and lateral view), photography (supine, prone, and lateral positions), external and internal examination.

After removing the chest plate, a systematic in situ examination of all organs, inclusive of heart was done, followed by evisceration with “en bloc” removal of organ systems.

External examination of pericardium, epicardium, cardiac situs [8], anterior interventricular groove, atrial appendages, relationship of great vessels and pulmonary venous connections.

Sequential segmental analysis was performed for internal examination using inflow outflow method. The first entry into the heart is through the caval veins by a lateral cut from inferior to superior vena cava. A perpendicular cut was made in the right atrium exposing the atrial septum. The patency of foramen ovale was assessed. The next cut was made posteriorly from atrium into the ventricle and extending the cut to the apex. The atrioventricular inflow connection was examined and documented. The next cut was from the apex through the outflow with the cutting angle maintained away from the heart and arterial valve. The great artery is cut across the arterial valve and the findings were documented. The left heart was examined by entering the left atrium through pulmonary veins and atrial appendage. The atrial morphology was assessed. Extending the cut posteriorly along the ventricular inflow tract and observation of atrioventricular connection was made. The outflow cut was made from apex to cut through the arterial appendage on the anterior aspect of heart. A spiraling cut around the base of artery was made. The morphology of valve, ventricle and infundibulum were studied and documented to assess the atrio ventricular concordance. The diameter of great arteries and ductus was measured and documented. Photographs were taken for documentation [9].

Rest of the organ systems were dissected, separated, and weighed individually. Representative sections were submitted for microscopic examination. Placenta if received was also examined and relevant tissue sections including cord and membrane roll were given. All the autopsies were performed by two trained Pathologists in the field of fetal and perinatal autopsies.

The cardiac defects were divided into two categories: isolated (single defect) and complex (two or more defects in the same heart). These defects were subcategorized based on the following terminologies: Malposition and isomerism, septal defects, left ventricular outflow tract obstruction (LVOTO), right ventricular outflow tract obstruction (RVOTO), conotruncal anomaly, connection anomaly, anomalous great vessels, and others [10]. These cases were further stratified based on the presence/ absence of extracardiac malformations involving single organ or more than one organ. The flow diagram for analysis is depicted in Fig. 1.

Prenatal ultrasound and fetal echocardiogram details were retrieved from the archives. The prenatal ultrasound examination was done by radiologists /obstetrician trained in fetal medicine. The autopsy findings were correlated with prenatal ultrasound findings. The cases were classified as having complete agreement, major agreement with additional findings and complete disagreement.

Data analysis was done using SPSS statistical software version 20. Comparison of variables was done using chi-square test.

3. Results

There were 177 fetal autopsies during the study period of which 40 (22.5%) cases showed cardiac anomalies inclusive of an intrauterine cardiac tumor, rhabdomyoma. The distribution of gestational age of fetuses when submitted for autopsy ranged from 12 to 37 weeks. Twenty-five (62.5%) were males and 14(37%) were females and one case had ambiguous genitalia. The indication for autopsy was TOP due to an abnormality detected in the sonogram in 32 cases and intrauterine death (IUD) in 8 cases. Considering the indication for TOP in 32 cases, 15 were due to cardiac anomaly, 6 cases due to hydrops, 5 each due to extracardiac anomaly and syndrome complex and a single case due to chromosomal abnormality (Turners syndrome).Of the eight cases of IUD, 5 could be attributable to cardiac defects identified on autopsy while 3 cases could not be directly attributed to cardiac anomalies.

3.1. Morphological findings

3.1.1. Isolated and complex cardiac defects

The distribution of cardiac defects included 20 cases each of isolated and complex defects, the details of which are summarized in Table 1 and the complex cardiac defects are described in Table 2. Eleven cases (27.5%) showed only cardiac defects and the rest of them were associated with extracardiac malformations.

Among all the cardiac defects regardless of being isolated or complex, septal defects were common, constituted 18 cases, followed by LVOTO (11), connection anomaly (8), conotruncal anomaly (4) and right ventricular outflow obstruction (RVOTO) in 5 cases. Of all these cases, coarctation of aorta, double outlet right ventricle, anomalous pulmonary venous return, and anomalous great vessels occurred only as a complex with other defects.

Of the 20 cases of isolated cardiac defects, LVOTO was the most frequent, accounted for 50% (n = 10) and this category occurring as an isolated defect rather than as part of a complex was found to be statistically significant ($P = .012$).

Septal defects occurring as part of a complex rather than isolated defect was statistically significant ($P= .003$). Ventricular septal defect (VSD) was the most common septal defect (n = 10). When considering the subtypes of VSD, there were 8 perimembranous, 1 muscular and 1 subaortic VSD. VSD occurring as a part of Tetrology of Fallot (TOF) (Fig. 2) was not categorized under septal defect and this included perimembranous type.

Two unusual cases of complex cardiac anomalies were observed. One case included atrioventricular septal defect, malposition of great arteries, total anomalous pulmonary venous connection (TAPVC), right atrial isomerism, pulmonary atresia, while the other showed atrioventricular septal defect, hypoplastic left heart, hypoplastic right heart, and right sided aortic arch.

Histological examination of heart in all the fetal autopsy cases did not reveal any nonstructural cardiac anomalies like myocarditis and cardiomyopathy.

3.1.2. Cardiac defects associated with extra cardiac/syndromic findings

These cases were categorized based on single or multiple organs involvement. Among the 29 cases, single organ and multiple organ involvement was found in 31% (n = 9) and 68.9% (n = 20) of cases, respectively (Fig. 3). When comparing the distribution of single organ and multiple organ involvement, there was no statistical significance ($P = .689$) between isolated and complex cardiac

ASD, atrial septal defect; AVSD, atrio ventricular septal defect; HLHS, hypoplastic left heart syndrome; HRHS, hypoplastic right heart syndrome; VSD, ventricular septal defect.
The occurrence of a cardiac defect to occur in isolation rather than in association with complex was compared using chi-square test. *P* value is significant only for septal defects.
* These defects occurred only as a complex and hence *P* value could not be obtained. ‡- p value obtained using chi square test.

defects. The most common extracardiac malformation was dysmorphism (46.2%) followed by genitourinary tract (41.3%), central nervous system (24%), musculoskeletal (20.6%), respiratory tract (20.6%) and gastrointestinal tract. The details are summarized in Supplementary Table 1 and illustrated in Fig. 4.

Overall, the fetal autopsy yielded additional cardiac defects in 40% of cases and extracardiac anomalies in 45% when compared with prenatal ultrasound.

3.2. Correlation between prenatal ultrasound and autopsy findings

The prenatal ultrasound details were available for all the 40 cases and fetal echocardiogram in 7 of them. Cardiac abnormalities were detected in 30 cases. There was complete agreement in 25% (n = 10) cases, major agreement with additional findings in 40% (n = 16) cases. Complete disagreement was seen in 10% (n = 4) cases.

Table 2
Description of cases classified in the category of complex cardiac defects (n = 20)

S. No	Complex cardiac anomalies
	AVSD, common atrium
	AVSD, PLSVC, hypoplasia of aortic arch
	AVSD, common atrium, PLSVC
	AVSD, TAPVC, right atrial isomerism, pulmonary atresia
	AVSD, common atrium
	AVSD, pulmonary stenosis, right heart hypoplasia, left heart hypoplasia, right aortic arch
	VSD, coarctation of aorta
	VSD, overriding of aorta
	VSD, TGA, pulmonary atresia
	VSD, truncus arteriosus, right aortic arch, vascular ring
	Dextrocardia, large ductus arteriosus
	HRHS, VSD, overriding of aorta
	HRHS, VSD
	HRHS, VSD
	TGA, DORV, pulmonary atresia
	TGA, common atrium
	TGA, VSD
	TGA, VSD, right aortic arch
	TOF, right aortic arch, patent ductus arteriosus
	TOF, right aortic arch, absent ductus, aberrant subclavian artery

AVSD, atrio ventricular septal defect; DORV, double outlet right ventricle; HRHS, hypoplastic right heart syndrome; PLSVC, persistent left superior vena cava; TAPVC, total anomalous pulmonary venous connection; TGA, transposition of great arteries; TOF, tetralogy of Fallot; VSD, ventricular septal defect.

In the remaining ten cases where, there were no cardiac anomaly detected prenatally the indication for autopsy was hydrops and IUD in 8 and 2 cases respectively. The cardiac defects identified in these cases were hypoplastic left heart syndrome (HLHS) (n = 5), followed by septal defects (n = 3) then by hypoplastic right heart syndrome and premature closure of ductus. The cases with major agreement and disagreement are described in Tables 3 and 4, respectively.

All the isolated cases had concordance with prenatal USG except for a single case of premature closure of ductus arteriosus in which no abnormality was detected. Fetal echocardiogram was available in seven cases and showed 100% concordance with autopsy.

4. Discussion

The rate of autopsy is declining in general. This is true with fetal autopsies as well, the main reason being the advancement in prenatal imaging techniques followed by declining interest in the field of autopsy pathology due to time consumption and the expertise required. In the current scenario, false positive diagnosis in prenatal USG resulting in TOP is extremely rare. However, associated malformations may be missed by USG and the detection of which might alter the diagnosis with varied recurrence risk. This was evident in the present study. The current study details the spectrum of cardiac abnormalities in prenatal autopsy and correlating these findings with prenatal imaging studies.

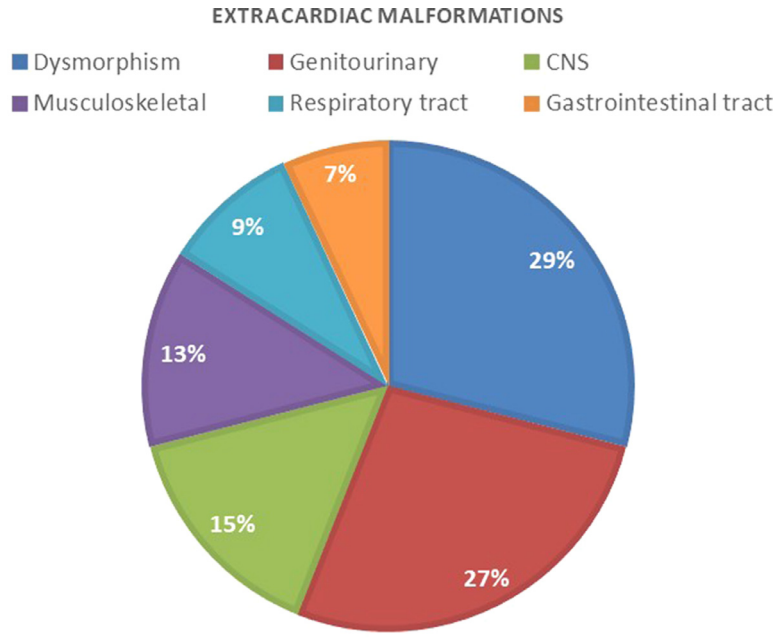

Fig. 3. . Distribution of associated extracardiac malformations.

Fig. 2. . Tetralogy of Fallot (A) Main pulmonary artery is stenosed with right ventricular hypertrophy (B) Perimembranous VSD with overriding of aorta (50%). (C) Right aortic arch.

Cardiac defects were the second most frequent congenital malformations in our institution following central nervous system malformations. The frequency of cardiac malformations (22.6%) was significantly higher in current study which is comparable to that of Taweevisit et al [11], while a few other studies report a lower frequency [12-14]. The higher frequency could be attributed either to increased rate of detection of cardiac anomalies on ultrasound thus leading to TOP or reflect a higher incidence in the given population. Male predominance (1.7:1) observed in this study was similar to majority of the other studies [14–17].

We found that 70% cases had an associated structural extra cardiac anomaly. Autopsy has enabled to identify additional cardiac defects in those fetuses terminated for other structural anomalies. This emphasizes the need for meticulous cardiac examination even in those fetuses.

Cardiac dissection in fetus is laborious and strenuous especially during the first and early second trimester, since the fetus itself is small in size. Usage of dissection microscope if available or loop glasses (in resource poor setting) will aid in qualitative analysis of cardiac defects in the tiny fetuses. A step by step approach by doing inspection, probing, assessing, documenting by taking pictures, dissecting and finally by cutting the heart is the best method.

Slight modifications in the dissection methods can be done in certain congenital heart diseases.

1) Cross-sectioning (transverse) of the heart starting from the apex, parallel to the atrioventricular groove up to the anterior papillary muscle (bread-loaf method) in a case of suspected rhabdomyoma is beneficial. It gives a better visualization for regional lesions confined to one or more walls. Hypoplasia and/or

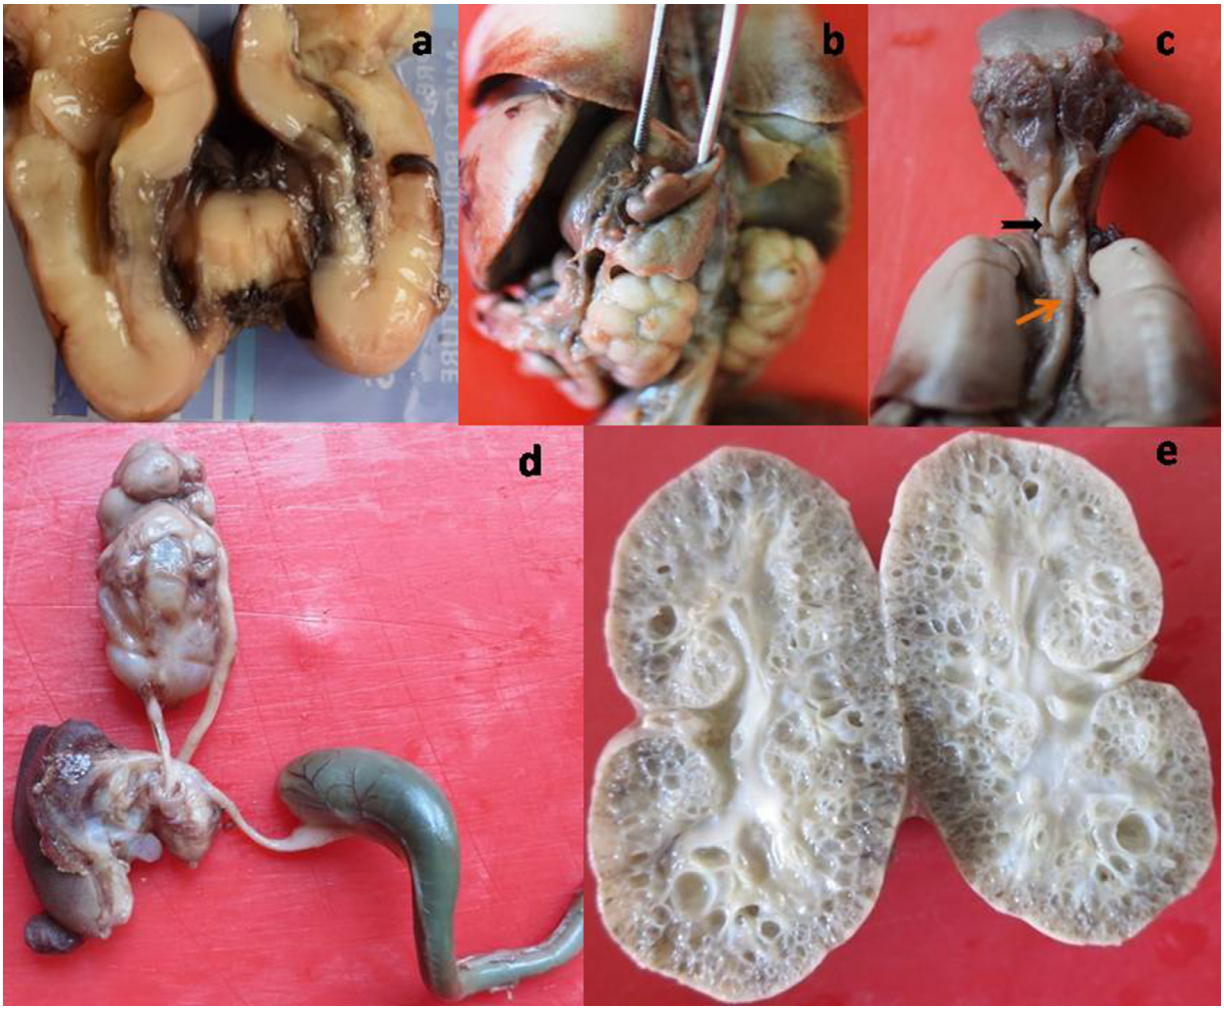

Fig. 4. . Extracardiac abnormalities (A) Coronal section of the brain shows absence of corpus callosum. (B) Splenenculi, there are small multiple brown nodules in peripancreatic region and gastrosplenic ligament. (C) Type C Tracheoesophageal fistula: atresia of proximal esophagus (⟶) with lower esophagus connected to tracheal carina (↗) (D) Urorectal septal malformation: atretic analcanal and ureters are draining into common pouch (cloaca) with crossed fused renal ectopia (E) Polycystic kidney disease.

Table 3
Cases with major agreement and additional findings in autopsy

S. No	Prenatal diagnosis	Additional autopsy findings
	TOF	Right aortic arch
	Cardiac outflow tract anomaly	TGA with pulmonary atresia, DORV
	TOF	TOF, aberrant subclavian artery right aortic arch, absent Ductus
	Dextrocardia	Dextrocardia, large ductus arteriosus
	Right atrial isomerism	Right atrial isomerism, AVSD, TAPVC, malposition of great arteries, pulmonary atresia
	AVSD	AVSD, common atrium
	VSD	VSD with coarctation of aorta
	Overriding of aorta and pulmonary atresia	TOF
	Multiple cardiac anomalies	Hypoplastic aortic arch, absent ductus
	Subaortic VSD, interrupted aortic arch	Hypoplastic left ventricle, Hypoplastic aortic arch, No VSD
	HRHS, pulmonary atresia	HRHS, Tricuspid atresia, muscular VSD
	VSD, overriding of aorta, tricuspid atresia	VSD, overriding of aorta, tricuspid atresia,Pulmonary atresia, hypoplastic right ventricle
	Dysplastic mitral valve, critical aortic stenosis	Mitral valve dysplasia, aortic stenosis Hypertrophied left ventricle
	TGA, VSD with hypoplastic right ventricle.	Congenitally corrected TGA, atrioventricular discordance
	Right atrial and ventricular dilatation with tricuspid regurgitation	Right atrial and ventricular dilatation with tricuspid regurgitation
	AVSD, DORV	VSD, hypoplastic right and left heart, right sided aortic arch

ASD, atrial-septal defect; AVSD, atrio-ventricular septal defect; DORV, double outlet right ventricle; HRHS, hypoplastic right heart syndrome; TGA, transposition of great arteries; TOF, tetralogy of Fallot; VSD, ventricular septal defect.

Table 4
Cases with complete disagreement with prenatal ultrasound

S. No	Prenatal diagnosis	Indication for autopsy	Autopsy finding
1	Atrioventricular septal defect	TOP due to the cardiac anomaly detected	Congenitally corrected Transposition of great arteries
2	Intracardiac echogenic focus	TOP due to other system anomalies	Secundum atrial septal defect
3	Tricuspid dysplasia, hypoplastic right ventricle and pulmonary artery	TOP due to the cardiac anomaly detected	Pulmonary valve atresia with intact ventricular septum
4	Hypoplastic left heart syndrome	Intrauterine fetal demise	Ventricular septal defect, overriding of aorta

asymmetry of ventricular chambers can also be assessed by this method.

2) Normally, we reach the aorta from the left ventricle by cutting through the anterior mitral leaflet. In case of doubtful mitral valve pathology, the aorta can be reached by cutting the left ventricular anterior papillary muscle without disturbing the valve.
3) The heart can be bissected longitudinally to visualize all the four chambers for asymmetry.

Septal defects were the commonest abnormality in the present series, dominated by VSD and seen as a part of other cardiac or extracardiac abnormalities similar to that of Ramalho et al some studies had observed VSD as the most commonly identified isolated defect [12,16,18–20]. This difference may be attributed to the sensitivity of prenatal ultrasound in identifying complex cases.

Atrial isomerism and persistent left superior vena cava (PLSVC) were only rarely encountered in the present series unlike the previous studies [12,21,22]. In identifying isomerism and atrio-ventricular and ventriculo-arterial concordance, the intricate knowledge of morphology of atrial appendages, ventricular trabeculations and outflow tracts is very crucial. Both the cases of PLSVC were found as part of a complex cardiac and extracardiac anomaly. The higher percentage of associated anomaly in PLSVC implies developmental abnormality rather than a variation. The findings also reemphasize the fact that PLSVC is a marker of cardiac and extracardiac anomaly as identified in previous studies [21,22] and when identified should prompt an extensive search for other associations. One of the indirect indicators of PLSVC is absence of left innominate vein on dissecting the thymus.

Hydrops fetalis resulting due to cardiac defect was identified in 20%, findings consistent with other studies that showed the frequency between 4 and 27.5% [23].

Autopsy helps to reach the diagnosis in majority of the cases either by confirming the prenatal diagnosis, or refine the diagnosis by means of identifying additional findings. Additional findings in the present series were identified in 45% of cases which altered the diagnosis in 30% of them. This was comparable to the previous studies [1,24]. Majority of these were syndrome complexes due to chromosomal abnormalities. Even though, karyotyping was not available for all these cases, autopsy has enabled to suggest the possibility of these syndromes by the presence of classic dysmorphic features and organ involvement in majority of the cases. Definitive diagnosis was possible in 95% of cases which is similar to that of other studies [24-26].

In two of these cases, the definitive diagnosis of syndrome complex was not possible. One fetus showed multiple anomalies including agenesis of the corpus callosum, Pierre Robin sequence and cardiac defects. Such association can be seen in multiple congenital malformation syndromes. In the present case, a diagnosis of Zellweger syndrome or Smith Lemli Opitz syndrome was offered in view of the presence of hemosiderosis of the liver and cerebral leukodystrophy. The second case showed heart defects with phenotypic features suggesting the possibility of aneuploidy which needs the help of karyotyping for a definitive diagnosis.

4.1. Extracardiac anomalies

Multiple organ involvement was more frequent than single organ involvement. Dysmorphism being the commonest is similar to some of the studies [11,14]. This was followed by genitourinary system malformations which are in contrast to the previous studies. This could be because of the technique of autopsy followed in our institution which includes meticulous dissection of external genitalia and lower urethra in all the cases. This has enabled us to identify majority of the lower urinary tract obstructions which otherwise could have been missed in both prenatal ultrasound and autopsy. Identification of these extracardiac anomalies is essential in arriving at a diagnosis of syndromes and/or association which has an impact in the management of subsequent pregnancies.

The organs which need attention are thymus, spleen (polysplenia, asplenia), gastrointestinal tract and excretory system. Polysplenia can present as very tiny nodules in gastrosplenic ligament and peripancreatic tissue which could be missed in prenatal imaging. Submission of suspected nodules for histological examination is essential.

In the present study, a high proportion of fetuses with HLHS predominantly had coexistent genitourinary, followed by central nervous system malformations. It is a well-known fact that HLHS fetuses experience in-utero hypoxia with dysregulated cerebrovascular hemodynamics [26]. But the exact mechanism of this association with genitourinary system defects is not known. It could also be related to early vascular insult with impaired autoregulation. The potential pathogenesis has to be explored.

4.2. Correlation of prenatal ultrasound and autopsy findings

The overall agreement found in the study was 65% which is slightly lower when compared to the majority of existing literature [25,27,28].

Complete disagreement was seen in 10% of cases and included lesions like Pulmonary valve atresia with intact ventricular septum, congenitally corrected transposition of great arteries and septal defects. Usage of five chambered view on ultrasound (the long axis view of heart highlighting the outflow tract in addition to four chamber view) could have been helpful in the accurate identification of some of these lesions [29]. 25% of cardiac lesions were missed on ultrasound, HLHS being the commonest followed by septal defects. These observations concur with that of Trivedi et al [27].

In spite of the improved accuracy of prenatal USG owing to the technical advancement in radiological techniques, some abnormalities can still be missed. These have been attributed to oligohydramnios, maternal obesity, position of fetus and expertise of the sonologists. In our series of autopsy, 32 cases were performed by expert sonologists experienced in fetal USG. However, some of the

previous studies had not found any statistically different detection rate of congenital heart disease between primary physician (77.9%) and pediatric cardiologist (85.0%) [29,30]. The other factors responsible for missed diagnosis in prenatal USG could not evaluated in the present study.

There was 100% correlation between fetal autopsy and echocardiogram wherever available. This imaging modality could be used as a supplement in fetuses with cardiac defects detected on ultrasound.

5. Strengths of the study

The study was done on all the fetal autopsies performed in our institution including a wider gestational age. Majority of the ultrasound diagnosis was made by expert radiologists and obstetrician trained in fetal medicine. All the autopsies were done by two pathologists with expertise in the field of perinatal and fetal autopsy using a standardized protocol and sequential segmental analysis of heart.

6. Limitations of the study

The exact detection rate of prenatal sonogram cannot be ascertained since the study is retrospective and includes only the cases with congenital heart defects identified in fetal autopsy. Hence the false positivity in prenatal imaging could not be analyzed. Secondly karyotyping was not available in majority of the cases.

7. Conclusion

A higher incidence of heart defects with significant proportion of associated extra cardiac malformations in our series highlights the importance of 1. Sequential segmental analysis of heart to identify even minor defects in all the cases irrespective of prenatal ultrasound findings and 2. modification of technique in certain conditions to demonstrate the lesion.

In the age of advanced imaging modalities with high sensitivity index, autopsy continues to be the gold standard in providing optimal diagnosis thereby guiding appropriate management in future pregnancies. Ensuring proper training of autopsy pathologists is essential to avoid the loss of valuable information in autopsy which could result from suboptimal approach. With a few centers performing routine fetal autopsies, more studies are anticipated to understand the epidemiology of heart malformations in the Asian subcontinent and pave new pathway in exploring the pathogenesis of rare associations.

Acknowledgments

The authors express their profound gratitude to Dr Ammu Sivaraman, emeritus professor, Department of Pathology, PSGIMSR, for her constant support and guidance. She is the main reason for rebirth of the perinatal autopsy in the department.

Abstract

Background: The Bethesda System for Reporting Thyroid Cytopathology (TBSRTC) is widely utilised by cytopathologists. The American College of Radiology (ACR) has also proposed a thyroid imaging reporting and data system (TIRADS) to classify thyroid nodules and guide their selection for fine needle aspiration (FNA). The current study aimed to analyse the usefulness of TBSRTC in thyroid cytology reporting, to examine its histological correlation with TIRADS, and to compare the management of lesions in each cytological category in our institute to the TBSRTC recommendations.

Materials and methods: A retrospective study was performed on all thyroid FNAs from a 2-year period at a tertiary care centre. Histological correlations of TBSRTC and ACR TIRADS were examined for cases with surgical follow-up, and the risk of malignancy in each TBSRTC category, and sensitivity and specificity of FNA and TIRADS, were calculated.

Results: A total of 337 thyroid FNAs were examined, with histological follow-up in 99 cases. Risk of malignancy in categories I-VI was 9.5%, 2.3%, 0.0, 8%, 87.5% and 100.0%, respectively. The sensitivity, specificity, positive predictive value, and negative predictive value of FNA were 60.0%, 99.0%, 85.7%, and 97.5%, respectively, while those values for thyroid ultrasound were 90.3%, 72.2%, 92.9% and 65%, respectively.

Conclusion: The study substantiates the usefulness of TBSRTC in arriving at a more precise diagnosis. Hurthle cell lesions with atypia were the common cause of misdiagnosis. The combination of TIRADS and TBSRTC aids in better stratification of thyroid nodules and in decision making for management of lesions.

1 | INTRODUCTION

Thyroid cancer is the most common endocrine malignancy and constitutes 0.1%-0.2% of all cancers in India. Fine needle aspiration (FNA) of the thyroid gland plays a vital role in the evaluation of thyroid lesions. It is a safe, cost-effective procedure to guide the management of thyroid lesions.[1] With the routine use of FNA, the number of surgeries being performed for benign lesions has been significantly reduced.[2] Most of the centres perform both palpation-guided and ultrasound-guided (USG) FNA.[3] Before the inception of The Bethesda System for Reporting Thyroid Cytopathology (TBSRTC), various terminologies were in use which often led to confusing risk assessments and unclear clinical management. TBSRTC has established a uniform, tiered reporting system for thyroid FNA specimens with an implied malignancy risk and recommendations for management, and is widely accepted by cytopathologists and clinicians.[4] But unfortunately, a significant subset of cytology interpretation yields indeterminate results (25%), as reported by Valderrabano et al.[5]

The use of ultrasound criteria in differentiating benign and malignant nodules of the thyroid gland has been the focus of research and much of the published literature has confirmed that ultrasound is highly sensitive but less specific in the detection of malignant thyroid nodules. A practical thyroid imaging reporting and data system (TIRADS) for thyroid nodules has been proposed by the American College of Radiology (ACR) to classify nodules of the thyroid gland and to solve the problem of nodule selection for FNAC.[6,7] Shen et al compared the effectiveness of the American Thyroid Association (ATA) classification, the ACR TIRADS, the TIRADS of the European Thyroid Association (EU-TIRADS), and a TIRADS developed by Kwak et al (Kwak-TIRADS) in a large cohort of patients, and concluded that all four risk-stratification systems had good diagnostic performance.[8] The combination of ultrasound imaging criteria using a TIRADS with TBSRTC in the risk stratification of thyroid nodules has not been explored extensively. The present study was carried out to establish the utility of such a combination of TIRADS with TBSRTC in the diagnostic and therapeutic approach to thyroid nodules.

The recent WHO classification has included new variants of thyroid carcinoma such as non-invasive follicular neoplasm with papillary-like nuclear features (NIFTP) and well differentiated thyroid tumour of uncertain malignant potential (WDT-UMP).[9] It is recommended that the risk of malignancy in each category be evaluated by every institution following TBSRTC for reporting as a tool for quality improvement. The current study aims (1) to analyse the diagnostic utility of TBSRTC in thyroid cytology reporting, (2) to establish the histological correlation of thyroid ultrasound using ACR TIRADS and (3) to analyse the adherence to TBSRTC recommendations of management for each category at our Institute.

2 | MATERIALS AND METHODS

This was a retrospective study which involved all patients who underwent FNAC of thyroid lesions over a period of two years (January 2018 to December 2019). The study was approved by the Institute's Human Ethics Committee (20/142). MGG- and PAP-stained smears and cytology reports of thyroid lesions were retrieved from the archives of the Department of Pathology at our Institute, a tertiary care centre. All of these cases were reviewed and diagnosed based on TBSRTC categories I to VI, as follows.

I. Non-diagnostic or unsatisfactory (ND/UNS)

II. Benign

III. Atypia of undetermined significance (AUS)/follicular lesion of undetermined significance (FLUS)

IV. Follicular neoplasm/suspicious for follicular neoplasm (FN/SFN)

V. Suspicious for malignancy

VI. Malignant

The probable diagnostic possibilities for categories V and VI were given wherever possible.

In cases with surgical excision, histopathology was considered the final diagnosis and correlated with cytology. Cases with histopathological diagnosis of follicular lesion, NIFTP, were reviewed for adherence to strict criteria for diagnosis. In cases where the cytology and histopathology were discordant, the cytology slides were reanalysed in a blindfolded technique to eliminate subjective bias. The sensitivity and specificity of FNAC in thyroid lesions and probable reasons for diagnostic errors in cytology were analysed.

A retrospective review of thyroid ultrasound features for those patients who underwent thyroidectomy in our institution was performed. The TIRADS score was given by an expert radiologist who was blinded to the histological diagnoses. The ACR TIRADS score was based on the evaluation of composition, echogenicity, shape, margin, and echogenic foci of the lesion, with each feature assigned 0-3 points. The total score is further stratified into categories ranging from 1 (benign) to 5 (highly suspicious). In cases with multiple nodules having different TIRADS scores, the highest score was considered for analysis. Risk of malignancy (ROM) for each TIRADS category was calculated based on the histological diagnosis. For calculating the sensitivity of the TIRADS in predicting malignancy, cross tabulation of the TIRADS score and the histological diagnosis was done. TIRADS categories 1, 2, and 3 were grouped as benign and 4, 5 as suspicious for malignancy.

For each category reported, the recommended management guidelines of TBSRTC and the management done for these cases were compared.

Microsoft Excel 2010 (Microsoft corporation) was used for data entry and statistical analysis was performed using SPSS version 20 (IBM Corporation).

3 | RESULTS

Three hundred and thirty-seven cases of thyroid FNAs were retrieved from the archives of the Department of Pathology. The distribution of the diagnostic categories as per TBSRTC is presented in Table 1.

TABLE 1 Distribution of diagnostic categories of The Bethesda System for Reporting Thyroid Cytopathology

Diagnostic categories	Subcategories	Number of cases (% per category)	Total number of cases (%) n = 337
I. ND/US	Cyst fluid	19	21 (6.2)
	Acellular specimen	2	
II. Benign	Benign follicular nodule	157 (60.6)	259 (76.9)
	Adenomatoid nodule	62 (24)	
	Lymphocytic (Hashimoto) thyroiditis in the proper clinical context	40 (15.4)	
III. AUS		9	9 (2.6)
IV. FN/SFN	Suspicious for follicular neoplasm	22 (88)	25 (7.4)
	Suspicious for Hurthle cell neoplasm	3 (22)	
V. Suspicious for malignancy	Suspicious for papillary thyroid carcinoma	11 (73.3)	15 (4.5)
	Suspicious for medullary carcinoma	2 (13.3)	
	Suspicious for malignancy, not otherwise specified	2 (13.3)	
VI. Malignant	Papillary thyroid carcinoma	3 (37.5)	8 (2.4)
	Anaplastic carcinoma	2 (25)	
	Medullary carcinoma	2 (25)	
	Non-Hodgkin lymphoma	1 (12.5)	

Abbreviations: AUS, atypia of undetermined significance; FN/SFN, follicular neoplasm/suspicious for follicular neoplasm; ND/US, non-diagnostic or unsatisfactory.

The most frequent interpretation was category II of TBSRTC, constituting 76.9% of the total. Among these, benign follicular nodule was the most common interpretation (60.6% of category II), followed by adenomatoid nodule (24%), and Hashimoto thyroiditis (15.4%). Among the category IV lesions, Hurthle cell lesions constituted 22.2% of the category. In both category V and VI lesions, papillary thyroid carcinoma (PTC) was the commonest. Subsequent histopathological examination was possible for 99 cases, and hence the rate of surgical excision constituted 29.4% of cases. The type of surgery depended on the cytological interpretation and radiology findings, and included 11 cases of lobectomy, 62 hemithyroidectomy, and 26 total thyroidectomies. The histological diagnoses for these cases are summarised in Table 2. There were 19 cases of malignancy (excluding three cases of NIFTP and a single case of well-differentiated follicular tumour of uncertain malignant potential), and 79 benign cases which included 10 cases of follicular adenoma. Partially or totally encapsulated nodules showing an admixture of micro- and macrofollicular growth pattern in the background of multiple nodules were interpreted as adenomatoid nodules. Solitary encapsulated nodules consisting of microfollicles were diagnosed as follicular adenoma. Papillary thyroid carcinoma was the commonest malignancy (78.9%). The surgical yield of malignancy in the study was 19.2%. There was a rare coexistence of papillary thyroid carcinoma and calcitonin negative neuroendocrine tumour of the thyroid. The preoperative cytological diagnosis of this case was category VI. The cytological and histological features of category III, IV, and V are shown in Figures 1 and 2. The risk of malignancy for each diagnostic category was calculated excluding NIFTP and WDT-UMP and summarised in Table 2. Risk of neoplasia (RON) was calculated including NIFTP, WDT-UMP and follicular adenoma.

Pre-FNA thyroid ultrasound was available for 90 cases that had histological follow-up. Most of the thyroid nodules belonged to TIRADS categories 2 and 3 on imaging, constituting 67.7% of the total. The distribution of TIRADS categories with the calculated ROM values is tabulated in Table 3. The sensitivity, specificity, positive and negative predictive values of thyroid ultrasound were 90.3%, 72.2%, 92.9% and 65.0% respectively.

The management recommendations as per TBSRTC for each category and the management of patients in the current study are outlined in Table 4. Repeat FNA under ultrasound guidance for ND/UNS category I lesions was done in 19% of cases, of which two showed cystic macrophages, while the remaining two were categorised as benign. Repeat FNA was not performed in any of the Category III lesions. Surgical resection was performed in 23.8%, 25.1%, 22.2%, 60.0%, 60.0%, and 37.5% of categories I, II, III, IV, V, and VI respectively. Molecular testing was not performed in any of these cases.

Of the cases with surgical excision, 3 (4.6%) excluding 2 cases of papillary microcarcinoma had a false-negative diagnosis (these cases were categorised as benign in FNAC but turned out to be PTC in histology), and 2 (22.2%) had a false-positive diagnosis (these two cases were categorised as suspicious for malignancy in FNAC and histology showed adenomatoid nodule). A review of the cytological smears of the 5 cases diagnosed as PTC in histopathology that had been assigned to category II in the cytology was performed. Two cases were papillary microcarcinoma, and no features of PTC were discernible cytologically. In the other three cases, the presence of nuclear grooves and pale nuclei were underdiagnosed as part of a cystic change in colloid goitre. There were no nuclear pseudoinclusions in any of these cases. On reviewing the

(B) Cells with nucleomegaly and occasional nuclear grooves (MGG, 40×). (C) Encapsulated nodule with no capsular invasion (H&E, 10×). (D) Closely packed follicles lined by cells exhibiting optically clear nuclei and grooves (MGG, 40×)

cytology smears of cases with a false-positive diagnosis on FNAC, in 1 case the presence of numerous aggregates of Hurthle cells exhibiting atypia was overestimated as features suspicious for malignancy. The cytological and histopathology images are shown in Figure 3. In the other case, hyperplastic changes with cells exhibiting occasional nuclear grooves, and follicular cells entrapped in blood clots with pale chromatin, were misinterpreted as features of malignancy.

The cytological features of WDT-UMP included repetitive microfollicular pattern, mild nuclear enlargement, occasional nuclear grooves, and no pseudoinclusions.

NIFTP constituted 3% of surgically resected thyroid lesions. The histopathology slides of the NIFTP cases were reviewed for the presence of the diagnostic criteria, which include complete encapsulation, follicular growth pattern, absence of invasion in extensive sampling, and optically clear nuclei as in Figure 4.

4 | DISCUSSION

The foremost advantage of TBSRTC is maintaining uniformity in the interpretation of thyroid FNA and guiding the clinicians to plan

appropriate therapy. The preoperative diagnosis of thyroid lesions in the present study using TBSRTC was comparable with other studies as summarised in Table 5.[10-14] The ND/UNS category still challenges accurate diagnosis. Despite the different expertise of cytologists in obtaining aspirates in a teaching hospital, the fraction of the ND/UNS category was well within the limits proposed by TBSRTC and other Indian[10,15] and Western studies.[13,16] This is in part due to the departmental protocol for rapid on-site evaluation (ROSE) in all cases of FNAC to assess for adequacy.

Benign lesions constituted the vast majority of FNA interpretation, which is similar to most other Asian studies[10,11] except a single study in the Chinese population,[8] where category VI was the most frequent interpretation. In Western studies, the reported proportion of the benign category ranges from 59% to 74.7%.[13,16] Regional variation may explain the difference in the distribution for this category.

The current study reports a lower rate of the AUS/FLUS category (2.6%), which is well within the preferred limit of 7% recommended by TBSRTC[4] and comparable to most Asian literature,[10,11,17,18] while some Western studies[9,12] have observed a higher percentage. The lower rate of this category could be attributed to the routine practice of obtaining an intradepartmental second opinion for all the indeterminate cases before assigning a category and hence the reasonable use of the AUS category.

As per the existing literature, the proportion of cases undergoing surgery varies among different institutions and ranges from 11.8% to 45.1%.[19,20] The malignancy rate of 19.2% in the present study was significantly lower when compared to the meta-analysis data by Bongiovanni et al (33.8%)[21] and Dawish et al (33.6%).[22,23] However, this malignancy rate does not reflect the true incidence in the population, because quite a few cases of thyroid malignancy were reported on histopathology and frozen section and did not have a cytological diagnosis before resection. Hence these cases were not included in the study. These resections were decided based on the clinical and sonographic findings.

4.1 | Risk of malignancy in each category

The risk of malignancy was comparable to that proposed by TBSRTC and other published literature for most of the categories except for ND/UNS and FN/SFN.[24] In the present study, the ROM in the ND/UNS category was 9.5%. Inadequate samples as the most common cause for false-negative diagnosis in FNA have been reported by Bakhos et al.[25] The risk of malignancy was calculated assuming that the unresected cases were benign. Hence the ROM across various studies ranges from 0% to 63%.[26,27] This increased risk of reported malignancy emphasises the importance of reaspirating all ND/UNS category lesions for cytology under guidance to rule out malignancy. Another pitfall that results in false-negative interpretation is the exclusive presence of cystic macrophages without cellular fragments, which could represent a cystic variant of PTC. In our study, there were two cases of PTC. The actual ROM in the AUS category is difficult to determine since only a subset of patients with clinical suspicion undergo surgical resection, thus resulting in selection bias. There were no malignancies in the AUS category with histological follow-up in the present data while other Asian studies report a higher ROM.[10-12,15] This could be explained by the fact that most of the cases showed architectural atypia rather than cytological atypia. Cytological atypia have been reported to be associated with a higher ROM as per the available evidence.[4] In cases of AUS, a repeat aspiration under guidance and correlation with clinical and radiological findings would lower the proportion of cases reported as AUS. The prevalence of NIFTP varies across the population and is reported to be between 5% and 13%.[28-30] In the present study, there was a much lower incidence at 3%. The cases of NIFTP showed a wide cytological spectrum spanning categories II to IV. However, the presence of diffuse cytological features of PTC and the absence of papillary fragments should prompt surgical resection to rule out the possibility of NIFTP.

In the recent years, various TIRADS systems have emerged and have been in use to stratify thyroid nodules as benign or malignant

based on ultrasound features and to decide on FNAC. The Kwak system is a simple classification based on suspicious ultrasound features. However, importance is not given to independent risk factors, for example extrathyroidal extension. Also, microcalcification, presence of solid area, and hypoechogenecity are given equal scores, whereas microcalcification generally has a higher malignancy risk.[31] ACR TIRADS is more complicated than other risk-stratification systems. Another drawback to this system is that malignant nodules exhibiting mixed echo patterns are given a lower score. Yet ACR TIRADS is an objective and comprehensive method for the evaluation of the thyroid nodules. The EU TIRADS is simpler than ACR TIRADS, and recommends FNA for mildly hypoechoeic nodules measuring greater than 1.5 cm.[8] However, it does not include solidity as an independent risk factor. The pitfall of the ATA guidelines is the classification of suspicious ultrasound features that have a variety of clinical significance into the same risk stratification with no independent categorisation.[8] In the present study ACR TIRADS was used for risk stratification. The sensitivity of ACR TIRADS observed in the current study is similar to that of other published studies.[6,32,33]

A similar study carried out by Fernandez et al has reported the percentage of malignancy as 77% in moderately and highly suspicious categories (TIRADS score ≥ 4) versus 65% in the current study.[32] ROM values for TIRADS scores except for score 2 are in consensus with most other published articles except for score 3, where a higher ROM (10%) was observed. Even though some malignant nodules were mislabelled as benign and some benign nodules were mistaken for malignant, the overall sensitivity was better.

While exploring the causes for a false-positive diagnosis in cytology, it was observed that cellular smears with a predominance of Hurthle cells exhibiting atypia, and the presence of focal nuclear features of PTC in the absence of nuclear inclusions, were overdiagnosed as features of malignancy. On the other hand, cases with diffuse cytological atypia even with focally observed pseudoinclusions are worth considering as suspicious for malignancy. Analysing the causes for the false negatives in FNA, papillary microcarcinoma being missed by sampling error in FNA has been reported previously. Under these circumstances, USG-guided FNA would have been useful.

4.2 | Adherence to TBSRTC recommendations for management

There exists a heterogeneity in approaches to the management of thyroid nodules despite the recently published guidelines for clinical management. TBSRTC recommends reaspiration under USG guidance as the preferred method for evaluation of ND aspirates unless the nodule is purely cystic. The majority of the ND/UNS lesions in the data consisted only of cystic macrophages, reflecting the lower rate of repeat aspiration in the present study.

The management decision for category II is determined predominantly by radiological findings, since there is a possibility of sampling error with FNA in larger nodules that can hinder detection of the underlying malignancy. However, a vast subset of patients undergo thyroidectomy for cosmetic reasons/pressure symptoms rather than for suspected malignancy.

The treatment for category III and IV lesions is controversial. While surgery is advised for category IV lesions, close follow-up with repeat FNA, and molecular analysis for BRAF and RAS gene mutations are recommended for the AUS category.[4] Chirayath et al[34] in their study in the Indian population have found, however, that mutational analysis for BRAF as an indicator of malignancy in AUS lesions has limited utility, in line with the results of many other studies.[35,36] Even though there was no ROM for the AUS category in the present study, in a country where molecular tests are not very feasible, a multidisciplinary approach based on clinical and radiological findings, together with patient preference, should guide the management.

Surgery as the treatment modality for category III and IV lesions was seen in 22% and 60% of cases, respectively. The resection rate in indeterminate categories is much lower than that reported by Western studies (22% in the current study vs 57.6%).[37] The lower rate could be explained by the loss of follow-up of these patients. Or et al[38] in their study have reported that for cases with indeterminate cytology, 77.4% of clinicians opted for repeat FNA and in case of repeat FNA being indeterminate, 50% opted for surgery.

The authors acknowledge the limitations of this study which include the retrospective design and a small proportion of cases with surgical follow up.

5 | HIGHLIGHTS

The reporting of AUS/FLUS lesions with a supplementary note describing the presence of architectural and/or cytological atypia may be helpful in treatment decisions, since cytological atypia could suggest the possibility of NIFTP or malignancy that would require surgical excision.

In the current study, it was found that there is higher interobserver variability in interpreting Hurthle cell atypia. There is a higher chance for misinterpretation as suspicious for malignancy . A further study analysing the various cytological parameters and cytohistological correlation of Hurthle cell lesions might help in achieving a more accurate cytological diagnosis and lower the rate of false positives in FNAC. The TIRADS score in conjunction with TBSRTC cytological diagnosis can aid in better stratification of thyroid nodules and aid in decision making.

6 | CONCLUSION

This study substantiates the usefulness of TBSRTC in thyroid cytology in arriving at a more precise diagnosis and guiding clinicians on management. The study reports a lower proportion of the AUS category. Hurthle cell lesions with atypia were the common cause

for misdiagnosis observed in the current study. The presence of nuclear features of papillary carcinoma with the presence of numerous microfollicles in the aspirate should prompt the diagnosis of NIFTP. Periodic cytohistological correlation and further studies on Hurthle cell lesions can aid in improving the sensitivity and specificity of FNA. In institutions where TBSRTC in reporting is practised, the clinicians should be aware of the implied risk of malignancy in each category. There was a good correlation between TIRADS, TBSRTC, and histology especially in benign nodules. However, further replication studies adapting a prospective design with a larger sample size are essential to validate the utility of thyroid ultrasound especially for indeterminate nodules.

ABSTRACT

Background and objective: Hirschsprung's disease is a disease that occurs in a newborn child with an incidence of one in 5000 live births with a male predominance. In our setup for the diagnosis of Hirshcsprung's disease, haematoxylin and eosin staining in a formalin fixed tissue was routinely practiced. As a novel diagnostic procedure, rapid on table acetylcholine esterase stain was tried. It is a diagnostic accuracy test done with the following objectives: 1.To perform acetylcholine esterase and rapid hematoxylin and eosin staining in the frozen section of rectal biopsy as a part of intra operative consultation. 2 To correlate routine formalin fixed, hematoxylin and eosin staining results with rapid methods. 3. Feasibility of these procedures in our setup.

Method: All infants who had not passed meconium since birth and who had symptoms of intestinal obstruction were screened by pediatric surgeons. As a part of intra-operative consultation, both frozen section and formalin fixation were done in the received specimen. In the frozen section, acetylcholine esterase staining and rapid haematoxylin and eosin staining was done. In the formalin fixed specimen routine haematoxylin and eosin was done.

Results: All the three stains- acetylcholine esterase, rapid hematoxylin and eosin and hematoxylin and eosin in a formalin fixed specimens gave equal results. When rapid methods were compared with the routine formalin fixed specimen haematoxylin and eosin staining method the turnaround time was very much reduced. By rapid staining, intra-operative consultation facilitated single stage Duhamel pull- through. Repeat surgery was avoided as both the diagnosis and the level of colon having ganglion cells were assessed simultaneously. As a result, hospital stay was reduced.

Conclusion: In this diagnostic study done on twenty cases of suspected Hirschsprung's disease, the diagnostic efficacy of rapid methods correlated with that of the routinely processed tissue sections stained with haematoxylin and eosin. The turnsaround time for the rapid tests were less. This facilitated on table diagnosis, reduced the need for repeat surgery, improved the outcome of surgery and, there by reduced the duration of hospital stay.

INTRODUCTION

Hirschsprung's disease (HSD) is a multi-genetic neurocrisopathic disorder of newborns and children. The incidence is estimated to be one in 5000 newborns, according to Badner *et al* and Parisi & Kapur (Badner *et al*., 1990; Kapur, 2001). But it varies between the racial groups. In Asians the incidence ratio is 2.8 per 10,000 live births (Torfs, 1998). There is a male predominance, male to female ratio being 4:1. This is less evident in patients with long segment aganglionosis and Down syndrome. Hirschsprung's disease has a sporadic occurrence. In about 20% of the sporadic cases, RET genetic mutation is present (Edery *et al*., 1994). The gold standard in the diagnosis of HSD is the demonstration of absent ganglion cells in the histopathological sections of rectal biopsy (Natarajan *et al*., 2002).

****Corresponding author: Shifa S. Ibrahim,***
Department of Pathology, Madurai Medical College, Madurai, India.

In 80% of the cases the aganglionosis involves the recto-sigmoid colon, in 11 to 26% the left colon, and in 5 to 15% the entire colon (Bax K. Duhamel, 2006). Usually, full thickness rectal biopsy specimen is examined for the evaluation of ganglion cells. The alternative is suction biopsy of the rectal mucosa, sectioning with cryostat and rapid acetylcholine esterase [ACHE] staining. ACHE stains on frozen sections had given best results in diagnosing HSD according to Coffin CM, *et al*. Meier-Ruge W *et al* and Qualman *et al*. (Coffin CM, *et al*., 2005 Meier-Ruge *et al.,*1972; Qualman *et al.,* 1999). Increase in acetylcholine esterase in the affected tissue is the pathophysiology of this disease (Schofield *et al*., 1990; Bagdzevicius *et al*., 2007; Ghosh and Griffiths, 1998). And acetylcholine esterases do not stain the normal nerve fiber. This concept is used in identifying this disease (Kleinhaus *et al*., 1979).

Before this study was attempted, the procedure followed in our hospital for patients suspected of Hirschsprung's disease were colostomy and formalin fixed full thickness rectal biopsy for ascertaining the diagnosis. Which of course takes time for the processing and later, after confirmation, Duhamel pull through was done. Frozen section and acetylcholine esterase staining was introduced in our histopathological lab in order to know the feasibility of this technique to diagnose accurately and to reduce the turnaround time of the rectal biopsy specimens received. Both confirmations of the diagnosis and the presence of ganglion cells from the cut ends were to be made at the same time. This study was done to evaluate the diagnostic accuracy of rapid on table staining method.

MATERIALS AND METHODS

During our study period (November2011-2013), twenty rectal mucosal biopsies were received from the Department of Paediatric surgery. Rectal biopsy from the children aged 4 days to 12 years suspected to have Hirschsprung's disease were received (Table 1).

Inclusion criteria

- All infants with symptoms suggestive of Hirschsprung's disease – Late passage of meconium, abdominal distension, bilious vomiting, and Hirschsprung's-associated entero-colitis were included.
- When investigated with contrast enema, they should reveal features of the narrow rectal segment, transition zone and proximal bowel dilation.
- Patients should be screened and selected by the Department of Pediatric surgery and their rectal biopsies sent to the Department of Pathology for evaluation
- Biopsy specimens should be taken 2-3cm proximal to dentate line.

Exclusion criteria

- If biopsy specimens contain epithelium of the anal canal.
- Inadequate specimen.
- Specimens that were not received in saline.

We were pre- informed and the biopsy specimens were transported to the laboratory in a saline soaked gauze or in saline. Specimens from the rectal mucosa 2-3 cm above the dentate line and specimens from various levels of the intestinal segment for assessment of ganglion cells were sent. They were labeled accordingly. Specimens were accompanied by a requisition form with detailed history, investigation and levels from where the biopsies were taken. The specimen was then washed to remove the blood, as red cells would take up the ACHE stain and cause background staining. Frozen sections of 10 µm thickness were taken after labeling the slides. Slides were stained with acetylcholine esterase and with rapid haematoxylin and eosin (H&E) method. Only part of the tissues were used for frozen section. The rest of the tissues were fixed in formalin and it was processed routinely and stained with haematoxylin and eosin. Acetylcholine esterase gives dark green color to the nerves when seen under light microscopy.

The principle behind the ACH stain

The thiocholine product produced react with ferricyanide and reduces it to ferrocyanide.It precipitates with copper to form copper ferrocyanide. This produces the dark green color according to Karnowsky and Roots (Karnowsky and Roots, 1964).

Interpretation of the ACHE stains

Presence of hypertrophic nerve bundles and absent ganglion cells are the criteria used for the diagnosis.

- Nerve fibers are stained greenish black
- Ganglion cells are negatively stained, (Fig 1)

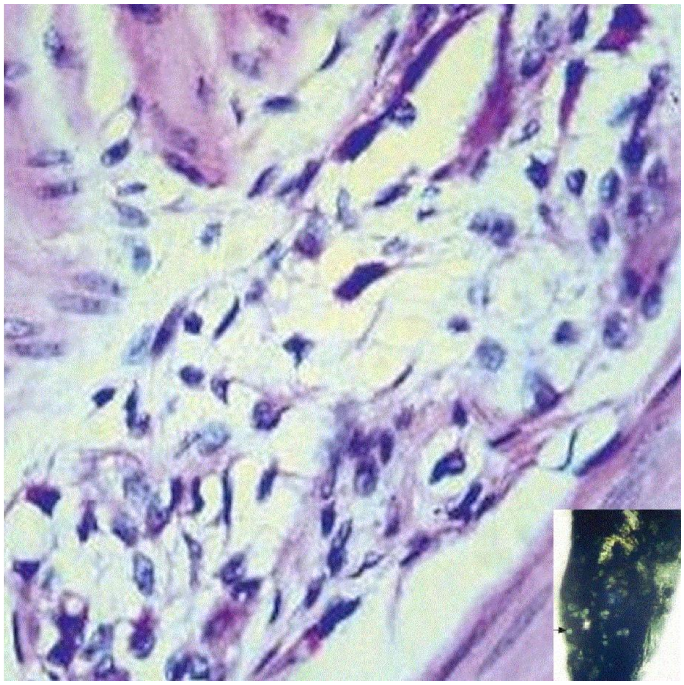

Fig. 1. Shows ganglion cells [H&E,40x].Inset shows ganglion cells are negatively stained with acetylcholine esterase[40x]

Four patterns are observed with ACHE staining based on level of stained nerve fibers. Nerve fibers and red blood cells provide the positive internal control.

Pattern A: Nerve plexus between the crypts in lamina propria, submucosa and muscularis mucosa stain positive with acetylcholine esterase, (Fig 2 & 3).

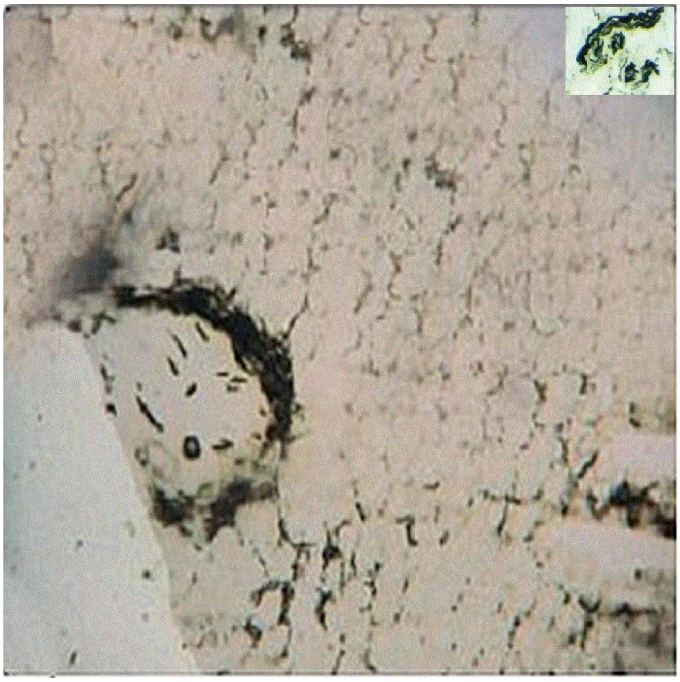

Fig. 2. Shows nerve plexus between the crypts in lamina propria, submucosa and muscularis mucosa stained positive with acetylcholine esterase- Pattern A.[4x].Inset shows hypertrophic nerve bundle [ACH,40x]

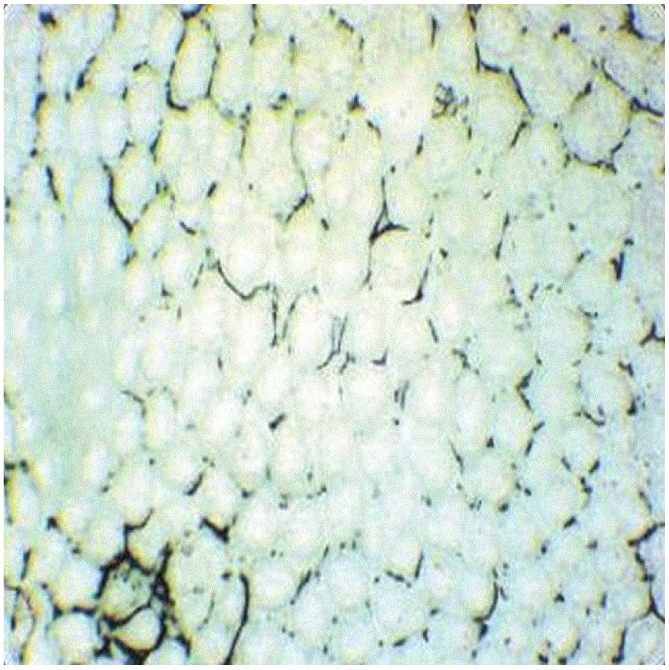

Fig. 3. Shows nerve plexus between the crypts in lamina propria, submucosa and muscularis mucosa stained positive with acetylcholine esterase- Pattern A[40x]

Pattern B: Nerve plexus at the base of the crypts, submucosa and muscularis mucosa stain positive with acetylcholine esterase, (Fig 4).

Equivocal pattern: Nerve fibers in the submucosa alone stained by acetylcholine esterase and absent ganglion cells.

Negative pattern: No staining identified

Interpretation of results of H & E stained sections

Positive for Hirschsprung's disease: Presence of hypertrophic nerve bundles in the submucosa and muscularis propria and absent ganglion cells, (Fig 5 & 6- Rapid H & E and Routine H&E respectively).

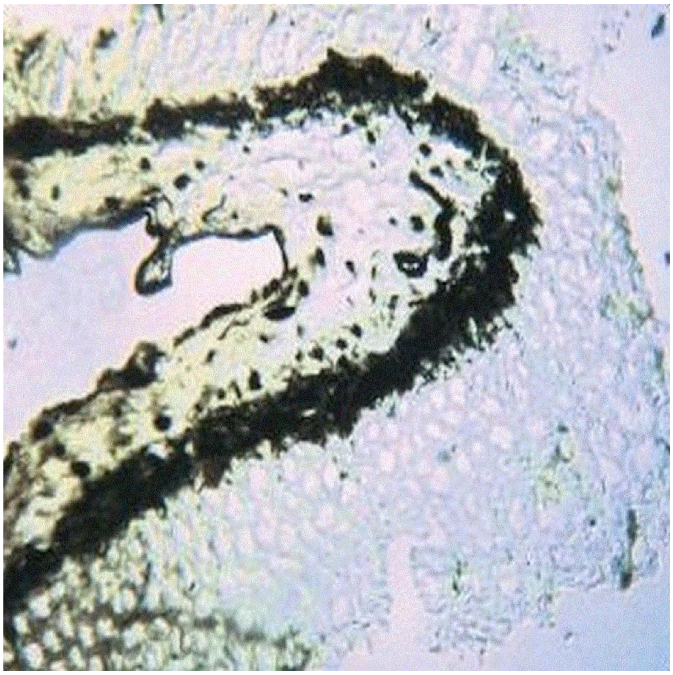

Fig. 4. Shows nerve plexus at the base of the crypts, submucosa and muscularis mucosa stained Positive with acetylcholine esterase- Pattern B[4x]

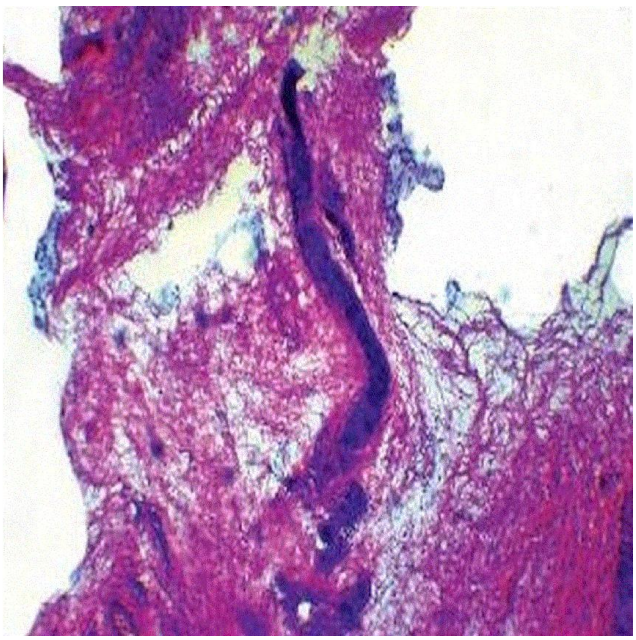

Fig. 5. Shows presence of hypertrophic nerve bundles in the muscularis propria and absent ganglion cells,[Rapid H&E, 40x]

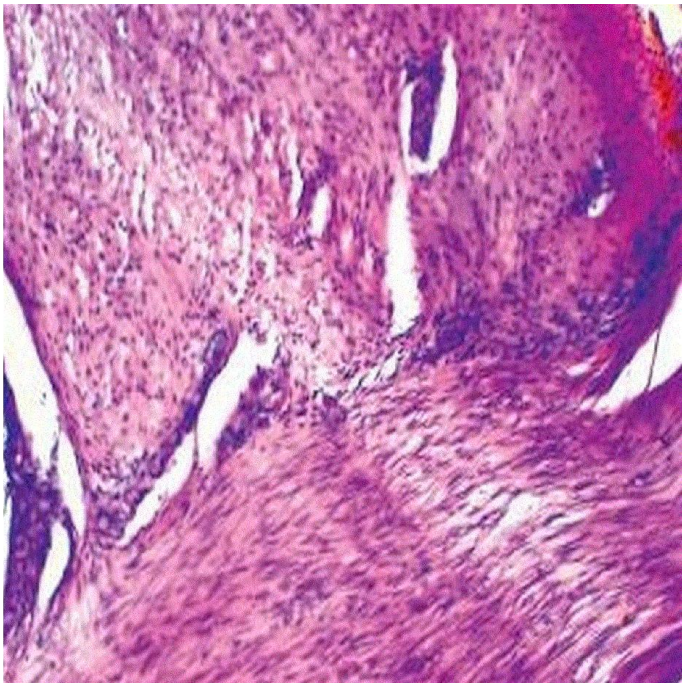

Fig. 6. Shows Presence of hypertrophic nerve bundles in the muscularis propria and absent ganglion cells,[Routine H&E,40x]

Transition zone: Ganglion cells are distributed unevenly along the circumference with hypertrophic nerve bundles. Negative for Hirschsprung's disease: Ganglion cells are present.

RESULTS

Over a two-year study period(November 2011-2013), twenty rectal mucosal biopsies from the children aged 4 days to 12 years suspected of Hirschsprung's disease were received from the Department of Pediatric surgery (Table 1).

Table 1. Age and sex distribution of patients suspected with Hirschsprung's disease

Age group(Years)	Male	Female
0-1	10(50%)	2(10%)
1-5	6(30%)	1(5%)
6-12	1(5%)	Nil

Positive results were obtained in all the three methods, namely, acetylcholine esterase stained sections, rapid haematoxylin and eosin stained sections and in those sections that were formalin fixed, routinely processed and stained with haematoxylin and eosin stain (Table2).

Table 2. Cases positive with ACH, rapid H&E and routine H&E stains

Positive with ACH stain	Positive with rapid H&E	Positive with routine H&E
16	16	16

There was no difference in the diagnostic sensitivity within these three methods used. Ghosh and Griffithshad used both haematoxylin and eosin and acetylcholine esterase to diagnose Hirschsprung's disease (Ghosh and Griffiths, 1998). When analyzing the results of their sensitivity, all the stains were 100% sensitive with 95% confidence interval being 79.41% to 100.00%. Specificity was 100%, 95% confidence interval being 39.76% to 100.00%. Disease prevalence was 80%, 95% confidence interval being 56.34% to 94.27%. Positive predictive value was 100% and negative predictive value was also 100%. When Cohens Kappa value was calculated to analyze the agreement between the observed values of ACHE stain and H&E stains, the number of observed agreements between them were 32 (80.00% of the observations). The Kappa= 0.600 SE of kappa value was 0.126 95% with confidence interval 0.352 to 0.848.The strength of agreement was good according this calculation.

Although the routine H & E and rapid staining methods had an equal sensitivity and specificity, rapid methods score over the routine method with reduced turnaround time The turnaround time was compared between routinely fixed and haematoxylin and eosin stained sections with acetylcholine esterase stain and rapid haematoxylin and eosin stain. The time taken for rapid haematoxylin and eosin was ten minutes. The time taken for acetylcholine esterase stain was about fifty minutes and for routinely stained sections it took about 48 hours (Table 3).

Table 3. Turnaround time noted with ACHE, rapid H&E and routine H&E

Acetylcholine esterase	Rapid H&E	Routine H&E
50 minutes	10 minutes	48 hours

All though rapid haematoxylin and eosin took lesser time than ACH stain, certain patterns that were recognized with the acetylcholine esterase stain were not appreciated with rapid haematoxylin and eosin stain. Two different patterns were observed according to Moore *et al*. (Moore and Johnson, 2005). Different patterns of stained nerve fibers observed with acetylcholine esterase stain with age wise stratification were analyzed. Acetylcholine esterase staining in the nerve plexus between the crypts in lamina propria, submucosa and muscularis mucosa was diagnosed as having pattern A-positive Hirschsprung's disease.

Acetylcholine esterase staining the nerve plexus in the base of the crypts, submucosa and muscularis mucosa was considered as pattern B positive -Hirschsprung's disease. Only one case with equivocal pattern and the hypertrophic nerve bundle was observed, which was also a positive Hirschsprung's disease pattern. Pattern A (9 cases) was more commonly observed than pattern B (6 cases) (Table 4). Aganglionosis could not be assessed perfectly using haematoxylin and eosin stain as ganglion cells normally were scattered and were difficult to find when present in the submucosa.

Table 4. Different patterns observed in ACH stain with age wise stratification

Age	Pattern A	Pattern B	Equivocal with hypertrophic nerves	Negative
1-6months	5	4	1	-
7months – 1 year	-	-	-	1
1-5 years	4	2	-	2
6-12 years	-	-	-	1

And when the hypertrophic nerve twigs formed were very sparse, especially in early infancy, diagnostic difficulty was ensued when H&E was used. Hypertrophic nerve bundles even if it was minimal were highlighted using the acetylcholine esterase, which was difficult when rapid haematoxylin and eosin was used. False positive results were rare, according to the study of Blisard, *et al*. (Blisard and Kleinman, 1986). Particularly, difficulty was encountered in the case of young infants. But H & E clearly complimented the acetylcholine esterase stain. Layer *et al*. in their study had questioned the role of acetylcholine esterase staining if there are clear cut evidence of hypertrophic nerves and ganglion cells (Layer and Kaulich, 1991). But in young infants when hypertrophic nerves are less developed and when the ganglion cells are immature ACH stain clearly compliments.Because the rapid technique diagnoses cases as efficiently as routine stain, the rapid diagnostic method was used as an intra -operative consultation method, thereby waiting period was reduced. As ACHE staining was an on table procedure the results were relayed immediately to the waiting surgeons, facilitating single stage pull through surgery.

DISCUSSION

There are four forms of Hirschsprung's disease.

1. Short segment disease (Classic) - Only a small segment of the rectum and sigmoid colon are involved. Distal sigmoid colon and rectum are affected in 75% to 80% of short segment disease.
2. Ultra short segment disease - Very short segment (<2cm) is involved.
3. Long segment disease - The disease extends beyond the splenic flexure. In 10% of the cases, the disease involves bowel segment proximal to the splenic flexure.
4. Total bowel aganglionosis – In total colonic aganglionosis the disease extends from the anal canal to at least the ileocaecal valve, but does not extend more than 50 cm beyond the ileocaecal valve. The incidence of this form is 5%.Total colonic aganglionosis presents outside the neonatal period, even in the adolescent age and early adulthood.

In Hirschsprung's disease, the main finding is the lack of ganglion cells in the narrow segment of the colon. The aganglionic segment starts distally at the anal ring and extends proximally to a variable length. The internal sphincter has a natural scarcity of ganglion cell close to the anus for a length about 10mm above the dentate line. This is the reason for the general rule to perform biopsies 2-3 cm proximal to the dentate line, according to Teitelbaum *et al*. (Teitelbaum and Coran, 2006)**.**

The affected segment has three zones which include the narrow segment, transition zone and a dilated proximal bowel segment. Histologically, in the narrowed segment there are aganglionosis and hypertrophic nerve bundles. The narrowed segment continues as a transition zone. Transitional zone can be few millimeters to varying centimeters in length. Ganglion cells begin to appear in this zone. Both the presence of hypertrophic nerves and presence of ganglion cells is seen in the transition zone. This continues as a dilated ganglionic segment.

Meier-Ruge did extensive research on the histopathological diagnosis of Hirschsprung's disease and other congenital neuronal intestinal malformations (Meier-Ruge *et al*., 1972). The following criteria for the diagnosis of HSD were formulated by him: Hirschsprung's disease is characterized by aganglionosis in both the Meissner and myenteric plexus. Acetylcholine esterase staining activity is increased in the coarse parasympathetic neurofibrils present in the lamina propria mucosae.

Absence of ganglion cells and the hypertrophic nerve bundles that are present in high numbers is the hallmark of HSD. This is always associated with an increase in acetylcholine esterase in the affected tissue (Qualman *et al*., 1999; Gath *et al*., 2001). Acetylcholine esterase does not stain normally innervated intestinal mucosa (Kamijo *et al*., 1953; Niemi *et al*., 19611 Ariel *et al*., 1983). Histological presence of coarse refractile acetylcholine esterase staining nerve fibrils and the absence of ganglion cells of the inter plexuses should be used in the diagnosis of Hirschsprung's disease according to Meier *et al* (Rouzrokh *et al*., 2010; Barr *et al*., 1985).Garrett *et al* demonstrated that severity with which the case presents and degree of obstruction in Hirschsprung's disease correlated with the acetylcholine esterase stained nerves in the aganglionic zone (Garrett and Howard 1969). The reason behind why acetylcholine esterase levels are raised in Hirschsprung's disease is complex. RET gene, which is the predominant gene identified in Hirschsprung's disease is considered as a potential candidate.

The differential diagnosis includes intestinal neuronal dysplasia. It is a clinical differential for HSD which is diagnosed histologically by the presence of giant submucosal ganglia, containing more than eight nerve cells. Segmental dilatation of the colon, a rare motility disorder affecting children is also a differential for HSD. It can be differentiated from HSD by normally distributed ganglion cells in the colon. Other differentials include internal anal sphincter achalasia in which absence of the rectosphincteric reflex on rectal balloon inflation and the clinical presentation is same as that of Hirschsprung's disease. Histopathologically the presence of ganglion cells on rectal suction biopsy helps to rule out HSD. Hypoganglionosis also a differential is characterized by decreased number of ganglion cells and reduced size of ganglia and wider distances between myenteric ganglia. According to the criteria of Meier-Ruge *et al*, less than 10 ganglion cells/mm (normal -14±3.3) and /or less than 2 ganglions/mm (normal:3.3±1.1) is used to diagnose hypoganglionosis. In contrast to the Hirschsprung's disease, hypoganglionosis do not have nerve plexus hyperplasia. Chronic idiopathic intestinal pseudo-obstruction, slow transit constipation and megacolon are also the mimickers, but can be differentiated histopathologically.

When routine haematoxylin and eosin (H&E) stains are used in rectal suction mucosal biopsies, there are many disadvantages. Submucosa should be equal in thickness to the mucosa in the biopsy specimens. But practically this is not possible. Ganglion

cells are fewer and it is scattered in the submucosa. Hence, evaluation of ganglion cells in the submucosal biopsy using H&E is difficult. This was not in a case when acetylcholine esterase staining was used. The turnaround time was also reduced. This study proved that acetylcholine esterase can be used as a rapid diagnostic tool and it has an advantage over H&E.

Conclusion

Acetylcholine esterase staining, rapid haematoxylin and eosin, and routine formalin fixed sections all had the same diagnostic efficacy. But the turnaround time was very much reduced when rapid diagnostic methods were used when compared with routine formalin fixed sections stained with H&E. Although rapid haematoxylin and eosin method took less time and was less expensive when compared with acetylcholine esterase, certain patterns like aganglionosis and hypertrophic nerve bundles seen using the acetylcholine esterase were not highlighted when rapid haematoxylin and eosin alone was used. Particularly, difficulty was encountered in the case of young infants. Immature ganglion cells are difficult to recognize in frozen sections stained with H&E. But rapid H&E clearly complimented the acetylcholine esterase stain. Intra operative consultation was possible in our setup. This reduced the need for a second surgery, improved the outcome of the surgery and reduced the duration of hospital stay.

Caught by Fingerprint: Dermoscopy of Solitary Neurofibroma

C. Shanmugasekar, N.M. Vinitha, S. Sakthisankari[1]

Department of Dermatology, PSG Institute of Medical Sciences and Research, Coimbatore, [1]Department of Pathology, PSG Institute of Medical Sciences and Research, Coimbatore, Tamil Nadu, India

A 61-year-old female presented to our outpatient department with an asymptomatic nodular lesion on the ventral aspect of the right forearm. She gives a history of a slow-growing nodule for the past 10 years. There were no similar lesions elsewhere in her body. On examination, a small 1 × 2 cm nodular lesion was seen on her right forearm [Figure 1]. The lesion was skin colored, firm, nonmobile, and non-tender on palpation. Button-hole sign was positive. Clinical differential diagnosis of Dermatofibroma and Solitary Neurofibroma were made.

Dermoscopy (Dermlite DL4; 10×) of the lesion revealed a round circumscribed lesion with a central white scar-like area and peripheral halo of pigmentation [Figure 2a]. Fingerprint-like pigmentary lines and peripheral pigment network [Figure 2b] were also observed. Histopathology confirmed the diagnosis of Neurofibroma [Figures 3a and b].

Figure 1: A small, firm, non-tender, 1 × 2 cm nodular lesion on right forearm

Slow growing nodular lesions are difficult to diagnose clinically and histopathology usually aids in the diagnosis. In our patient, the dermoscopy features are suggestive of neurofibroma. Zaballos *et al*.[1] described multiple dermoscopic patterns for Dermatofibroma. The central scar-like area and peripheral pigment network can be seen in both conditions, but the fingerprint pattern along with above-mentioned findings is more suggestive of Neurofibroma. In another study, Duman *et al*.[2] described the above-mentioned findings in a series of cases of neurofibromas and defined the fingerprint pattern as brown parallel cord-like structures within the lesions. Fingerprint pattern can occur in other conditions like seborrheic keratosis, but in the background of other dermoscopic findings, it can help in identifying neurofibroma. This case is presented to highlight the dermoscopy findings in Solitary Neurofibroma and its role in differentiating from Dermatofibroma.

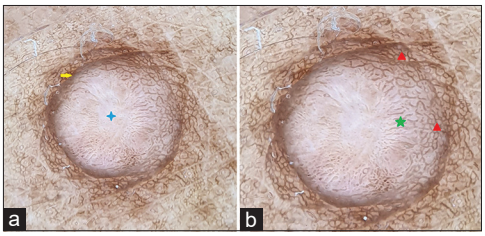

Figure 2: (a): Dermoscopic image showing central white scar like area (blue star) and peripheral halo of hyperpigmentation (yellow arrow) (b): Fingerprint-like pigmentary lines (green star) and peripheral pigment network (red triangle). (Contact polarised light dermoscopy; Dermlite DL4; 10×)

ABSTRACT

Context: Immunofluorescence (IF) is an immunological technique which is used for identifying antibodies against antigens that are bound to tissues or those circulating in body fluids. This study is an attempt to evaluate the dermatological lesions such as noninfectious vesiculobullous lesions, connective tissue disorders, vasculitis, and lichen planus using histopathology techniques and direct IF (DIF) studies. Furthermore, an attempt was made to evaluate the diagnostic utility of the IF technique in our hospital. **Aims:** (1) To determine the utility of IF in the diagnosis of skin lesions. (2) To correlate IF with histopathological findings. **Settings and Design:** A cross-sectional, observational study. **Subjects and Methods:** The present study was conducted in the Pathology Department, Coimbatore Medical College, Coimbatore, from August 2012 to August 2013. Fifty cases received during the period were included in our study. Two skin biopsies for each case - one in formalin for routine histopathological examination and other in phosphate buffer solution for IF studies - were received. **Statistical Analysis Used:** Fisher's exact value, mean, and coefficient of mean were calculated. **Results:** The lesions were diagnosed by both light microscopy and IF study. Out of fifty cases, 42 cases were positive with the IF technique and the overall sensitivity of IF was 84% in our study. When histopathological and IF findings were correlated, statistically significant two-tailed $P = 0.0130$ was obtained. Both light microscopic findings and IF findings complemented each other in our study. IF proved to be a necessary supplementary technique to both clinical and histopathological examinations, especially in cases of diagnostic dilemmas. **Conclusions:** IF is a rapid diagnostic procedure. IF was useful in early diagnosis, treatment, and monitoring of various disorders in our study. Positive and negative DIF had prognostic significance in certain cases. Clinicopathological correlation along with DIF studies proved to be a powerful tool in definite diagnosis of the skin lesions.

Key words: Autoimmune, connective tissue disorders, direct immunofluorescence, lichen planus, vasculitis, vesiculobullous

to one's well-being.[1] Skin is also an easily accessible site for biopsy. Not only well-defined *de novo* skin lesions but also many systemic autoimmune diseases such as systemic lupus erythematosus (SLE) and vasculitis can also be easily diagnosed by skin biopsy.[2]

Although histopathology is the gold standard diagnosis for most dermatological lesions, all lesions cannot be diagnosed by histopathology alone. Ancillary techniques such as Tzanck smear, immunofluorescence (IF), serology, and recent advancements such as immunoelectron microscopy and immunoblotting have refined the diagnosis. This study was an attempt to evaluate the dermatological lesions such as vesiculobullous lesions, connective tissue disorders, vasculitis, and lichen planus (LP) using both histopathology and direct IF (DIF) studies and to assess the diagnostic potential of the IF studies.

SUBJECTS AND METHODS

The present study was conducted in the Department of Pathology, Coimbatore Medical College, Coimbatore, from August 2012 to August 2013. All newly diagnosed cases of immunobullous disorders, connective diseases, vasculitis, and LP irrespective of age, sex, and associated disorders were included in the study. Patients treated with steroids in the past 3 weeks and specimens devoid of clinical details and histopathological specimens that were not fixed with formalin were excluded from our study.

Fifty cases with skin lesions were included in our study. The clinical details were collected from the patients. Two punch biopsies of early skin lesions were collected for each case. In case of autoimmune blistering disease (AIBD), perilesional biopsies were taken. In case of connective tissue disorders, LP and vasculitis, lesional biopsies were taken. One was sent in formalin for routine histopathological examination. These specimens were processed routinely and sections were cut and stained routinely using hematoxylin and eosin. The other was sent in phosphate buffer for IF studies. Four-micron-sized sections were cut using cryostat and tissues were transferred to six slides. One slide was used for rapid hematoxylin and eosin staining. The remaining slides were stained with fluorescein isothiocyanate-labeled immunoglobulin G (IgG), IgA, IgM, C3, and fibrinogen (in 1:25 dilution) for an hour and then viewed under a fluorescent microscope. The site (whether dermoepidermal junction [DEJ] or the intercellular spaces [ICSs] of epidermis), nature (IgG, IgA, IgM, C3, fibrinogen), and pattern (linear or granular) of staining were noted.

RESULTS

Our study was an observational one for a period of 1 year from August 2012 to August 2013. During the study period, 8576 specimens were received, of which 264 were skin biopsies. Our study group comprised fifty patients with clinically suspected and newly diagnosed noninfectious vesiculobullous lesions, connective tissue disorders and vasculitis.

In our study group of 50, 26 were men and 24 were women with a sex ratio of 1.08:1 [Table 1]. Most cases were in the age group 41–50 years in both the sexes [Table 1].

Vesiculobullous disorders constituted 0.45% of the total specimens and 14% of all skin specimens [Table 2].

PV: Pemphigus vulgaris, PF: Pemphigus foliaceus, IgAP: IgA pemphigus, PNP: Paraneoplastic pemphigus, SCPD: Subcorneal pustular dermatosis, BP: Bullous pemphigoid, DH: Dermatitis herpetiformis, LIBD: Linear IgA bullous disease, SLE: Systemic lupus erythematosus, DLE: Discoid lupus erythematosus, PSS: Progressive systemic sclerosis, LCV: Leukocytoclastic vasculitis, EED: Erythema elevatum diutinum, LP: Lichen planus

Among the vesiculobullous disorders, bullous pemphigoid (BP) was most frequently diagnosed in our study (18 cases) [Figures 1 and 2]. Histopathological examination confirmed the diagnosis of pemphigus in only 14 cases [Figure 3]. A case each of pemphigus vulgaris (PV) and pemphigus foliaceus (PF) did not show acantholytic cells.[3] Out of the 39 AIBD cases, DIF positivity was seen in 34 cases [Table 3]. PV, PF, and IgA pemphigus showed lace-like pattern in the ICS of the epidermis [Figure 4 and Table 4]. The sensitivity of DIF in diagnosing AIBD was calculated as 89.74% in our study.

Among the connective tissue disorders, three cases of discoid lupus erythematosus (DLE) [Figure 5], two of SLE [Figure 6], and one case of progressive systemic sclerosis (PSS) were diagnosed. However, DIF positivity was seen in five cases and one case was DIF negative (PSS) [Table 3]. The sensitivity of DIF in diagnosing connective tissue disorder was 83.33% in our study.

In the vasculitis category, leukocytoclastic vasculitis (LCV) was diagnosed in three cases and erythema elevatum diutinum in one case. DIF positivity was seen in only two of four histopathologically confirmed cases [Figures 7, 8 and Table 3]. The sensitivity of DIF in diagnosing vasculitis was 50% in our study.

One case of LP was included in our study. DIF was positive and the sensitivity was 100% [Table 3].

The discordant results observed between clinical, histopathological, and IF findings are tabulated in Table 5. In all the discordant cases, IF findings were taken to arrive at the final diagnosis in case of positive IF results.

Statistics

When histopathological and IF findings were correlated, the two-tailed $P = 0.0130$ which was statistically significant [Table 6]. The mean value calculated was 0.50 and the 95% confidence interval of this difference ranged from 0.12 to 0.88. Hence complementary nature of histopathology and IF was proved.

DISCUSSION

Autoimmune vesiculobullous disorders

Vesiculobullous disorders include a wide range of dermatoses, which are characterized by protean manifestations.[1] These disorders have varying etiology, prognostic factors, but united by the formation of blisters either within or beneath the epidermis. These lesions have a striking impact not only on the affected individuals but also for their family members. Histopathological evaluation of vesiculobullous lesions involves the systematic analysis, including the plane of separation of blisters and also the nature of inflammatory infiltrates. These have many differentials which can be sorted out using IF.

Pemphigus is a fatal disease affecting skin and mucosa. Pemphigus was first used by Hippocrates to describe pemphigoid fever as pemphigoides pyertoi. In 1760, De-Sauvages coined the term pemphigus from *pemphix* meaning pustule in Greek.[4] Lever in 1953 described BP and differentiated it from pemphigus.[5-7] This is of great historical significance as BP has a much better prognosis than pemphigus which is commonly fatal.

The most common age group in our study was fourth to fifth decades. This finding was in accordance with

PV: Pemphigus vulgaris, PF: Pemphigus foliaceus, IgAP: IgA pemphigus, PNP: Paraneoplastic pemphigus, SCPD: Subcorneal pustular dermatosis, BP: Bullous pemphigoid, DH: Dermatitis herpetiformis, LIBD: Linear IgA bullous disease, SLE: Systemic lupus erythematosus, DLE: Discoid lupus erythematosus, PSS: Progressive systemic sclerosis, LCV: Leukocytoclastic vasculitis, EED: Erythema elevatum diutinum, LP: Lichen planus

Kabir *et al*., Kambi *et al*., and Rizvi and Sadiq studies.[8-10] Male:female ratio [1.08:1] was approximately equal in this study, which was similar to Kabir *et al*. and Kambi *et al*. studies.[8,9] However, Anuradha *et al*. and Rizvi and Sadiq's studies showed a male predominance.[10,11]

From Table 1, BP (46.5%) constituted the majority followed by PV (20.5%) in the present study. This was in accordance with Kabir *et al*. and Monsef *et al*. studies.[8,12] Most of the other studies had PV as the predominant disorder. This discordance could be due to variation in the geographical distribution of vesiculobullous lesions. In BP, subepidermal bulla was seen in 77% patients. Other BP cases revealed only numerous eosinophils

Table 6: Clinical, histopathological and direct immunofluorescence correlation

Diagnostic mode	PV	PF	IgAP	PNP	SCPD	BP	DH	LIBD	SLE	DLE	PSS	LCV	EED	LP	Total
Clinical	9	3	1	1	2	17	3	3	2	3	1	3	1	1	50

Total case diagnosed	8	5	2	1	1	18	2	2	2	3	1	3	1	1	50

DIF: Direct immunofluorescence, HP: Histopathological, PV: Pemphigus vulgaris, PF: Pemphigus foliaceus, IgAP: IgA pemphigus, PNP: Paraneoplastic pemphigus, SCPD: Subcorneal pustular dermatosis, BP: Bullous pemphigoid, DH: Dermatitis herpetiformis, LIBD: Linear IgA bullous disease, SLE: Systemic lupus erythematosus, DLE: Discoid lupus erythematosus, PSS: Progressive systemic sclerosis, LCV: Leukocytoclastic vasculitis, EED: Erythema elevatum diutinum, LP: Lichen planus

in the papillary dermis. This could be due to biopsy of early lesions as prodromal stage shows nonspecific changes such as edematous dermis with abundant eosinophilic infiltration.[13]

The most common intraepidermal disorder in our study was PV. This finding was similar to Kabir *et al.* studies.[8] Suprabasal bulla was seen in 100% of cases and this was in accordance with Kambi *et al*. and Leena *et al*.'s studies.[9,14] In our study, the incidence of PF was 12.82%, which was similar as that of Kambi *et al*. study.[9] All pemphigus lesions show staining in the ICS of epidermis in a fish net-like pattern; hence, they should be interpreted along with histological findings. IgA pemphigus and linear IgA bullous dermatoses can be diagnosed confidently only by immunofluorescent studies. Two cases of dermatitis herpetiformis were seen in this study. Shave biopsy is preferred in dermatitis herpetiformis as IgA is only focally positive in this case. Due to this, DIF should be done at least twice in shave biopsy specimens before awarding a negative DIF diagnosis in DH according to Sontheimer *et al*.s study.[15]

In the present study, lesions such as subcorneal pustular dermatoses (SCPDs) and paraneoplastic pemphigus (PNP) which was not seen in other studies were seen. The five cases were DIF negative in our study which includes two cases of BP, a case of PNP, a case of PV, and a case of SCPD. Grolleau-Rochiccioli *et al*. in their study had mentioned three BP cases that showed negative DIF results.[16] This could be due to subthreshold immunoreactants. DIF negativity or delayed detection with IF technique had been observed in PNP.[17] Mysorekar *et al*. and Buch *et al*. in their study had mentioned about DIF negative PV cases.[18,19] Buch *et al*. in their study had mentioned that IF negative PV meant disease remission.[19] DIF is normally negative in SCPD as it is a nonimmune bullous lesion associated with IgA gammopathy.[20] Our DIF findings in vesiculobullous lesions were in accordance with the Wallach D's study.[20]

Connective tissue disorders

Connective tissue disorders have multisystemic involvement. They have a remarkable diversity, but at the same time, they are clinically similar in many aspects.[20] Cutaneous involvement is an important feature in these diseases. Therefore, skin biopsies play an important role in the classification of these diseases.[20] DIF is helpful in confirming the diagnosis of LE when suspected histologically, clinically, or both. It also helps in classifying the various types of LE as the morphology, site and frequency of immunoreactants deposition vary with various subtypes of LE.

DIF positivity in SLE usually varies with biopsy site, morphology of lesions, treatment profile, and disease activity. In our study, all LE cases were IF positive. Anuradha *et al*. studied four LE cases, of which two belonged to SLE and both showed DIF negativity.[11] In Kabir *et al*. study, seven cases of SLE were included and all were DIF positive which coincides with our study.[21] According to Mutasim and Adams, DIF was more commonly seen in the sun unexposed, oldest, and untreated DLE lesion. Moreover, positivity of combined IgM and IgG deposit was in favor of DLE.[22] In Kabir *et al*. study, of the 3 DLE cases, two showed DIF positivity.[21] Sandra *et al*. study which included 16 LE cases (13 females and 3 males), they had concluded that if DIF was positive in nonlesional skin, there was a greater chance of developing SLE. Hence, those patients required close follow-up.[23] One case of PSS was included in our study. Histopathological examination revealed findings consistent with scleroderma. However, DIF studies were negative. According to Mutasim and Adams, DIF was negative or nonspecific in PSS cases. PSS patients having positive DIF finding seem to have more often overlapping features of SLE, vasculitis, or dermatomyositis.[22] Winkelmann *et al*. had reported ten PSS cases that were DIF negative.[4] Kulthanan *et al*. have mentioned about the inconsistent IF results in PSS cases.[5] Hence, in PSS, clinical examination and histopathology play a more important role than DIF. From this, we conclude that a combination of histopathology, serology and immunology with the background of clinical examination is essential for definite diagnosis of connective tissue disorders.

Vasculitis

Vasculitis refers to necrosis and inflammation of arteries, veins, or both.[1] For confirmation of LCV and Henoch–Schonlein purpura, IF is very useful. In our study, four cases of vasculitis were noted. In Khetan *et al*. study of 61 cases, female predominance was noted unlike our study.[24] In Nandeesh and Tirumalae's study of 198 patients also, a female predominance was noted unlike our study.[25] In vasculitis, the immunoreactants are commonly deposited in the postcapillary venules in the papillary dermis. The pattern could be either fibrillary or granular. It could also be deposited either in the intravascular or extravascular space.[17] In this study, staining was seen in intravascular space of vessels. Henoch–Schonlein purpura was common in other studies, but it was not seen in our study. In Gupta *et al*. study, of fifty cases, LCV was the predominant lesion akin to our study, histopathology gave a conclusive diagnosis in 42 cases (84%) and DIF was positive in 74% cases,.[26] However, similar to this study, in Nandeesh and Tirumalae's study, LCV was the predominant lesion and it had DIF positivity of 54%. However, the overall DIF positivity was 62% in their study.[25] Like our study, LCV was the predominant lesion in Khetan *et al*.'s study (66%). But DIF positivity was seen in 39% and this was lower than our study.[24] Leelavathi *et al*. (85 cases) revealed DIF positivity in 13% cases.[27] DIF provides only supporting evidence in vasculitis. A definite diagnosis of vasculitis should be given after considering clinical, histopathological, laboratory investigations and IF studies. According to Mutasim and Adams, the sensitivity of DIF in vasculitis is limited by both duration and site. Lower limb lesions give false positive DIF results and lesions aged more than a day tend to give false negative test.[22]

Lichen planus

In Kabir *et al*. study, 7 of 12 LP cases were DIF positive showing irregular immunoreactant deposit along the DEJ, constituting 58% positivity.[21]

In Anuradha *et al*. study, all six LP cases showed fibrinogen positivity along the DEJ (100%). The pattern was linear, granular, or shaggy.[11] Sandra *et al*. showed fibrinogen positivity in all their 18 LP cases.[23] According to Mutasim and Adams, DIF was essential only when histopathological and clinical findings were inconclusive and was not necessary in LP as most cases were diagnosed by clinical examination alone.[22]

CONCLUSIONS

IF plays an ancillary role in the definite diagnosis of vesiculobullous disorders, connective tissue disorders and vasculitis and should be interpreted along with clinical features, laboratory workup and histopathology findings.

Abstract

Introduction Megaloblastic anemia is one of the common causes of anemia in India. Duodenal biopsies are routinely performed in the investigation of megaloblastic anemia. The present study was undertaken to analyze the value of duodenal biopsy in megaloblastic anemia and to correlate endoscopic findings with biopsy. As a secondary aim, the study has also analyzed the hematological profile and vitamin B_{12} and folate status of these patients.

Materials and methods All the cases of megaloblastic anemia with bone marrow studies diagnosed at PSG Institute of Medical Sciences and Research during the two year period from January 2016 to December 2017 were retrieved. Clinical and laboratory findings (serum vitamin B_{12} and folate levels) and endoscopic findings were retrieved from hospital records of the patients. Duodenal biopsies of these patients reported in the histopathology department were retrieved and reviewed. Statistical analysis was done using SPSS software 20.0.

Results There were 93 cases of megaloblastic anemia diagnosed on bone marrow biopsies. Tropical sprue was diagnosed in 49.5% of cases, followed by intraepithelial lymphocytosis (17.2%), peptic duodenitis (17.2%), and no significant pathology in 16% of cases. Pancytopenia was present in 54.8% of cases. Isolated vitamin B_{12} deficiency including low levels was present in 48.38% and folate deficiency was seen in 4.3% cases; 34.48% cases had both vitamin B_{12} and folate deficiency.

Conclusion The incidence of tropical sprue in megaloblastic anemia is 49.5% in the study. Duodenal biopsy is valuable in the work up of megaloblastic anemia, irrespective of the endoscopic changes in identifying the etiology.

Keywords
- megaloblastic anemia
- tropical sprue
- vitamin B_{12}

- pancytopenia
- intraepithelial lymphocytosis

Introduction

Megaloblastic anemia is characterized by the distinctive morphological appearance of developing hematopoietic cells in the bone marrow, resulting from nuclear cytoplasmic asynchrony, occurring as a result of defective deoxyribonucleic acid (DNA) synthesis.[1] The cause is usually nutritional deficiency or malabsorption of either cobalamin (vitamin B_{12}) and/or folate. Malabsorption can result from gastrectomy, tropical and nontropical sprue, intestinal resection, and drugs. It can also occur in defects of metabolism of these vitamins.[2] While pernicious anemia is reported to be the

common cause for megaloblastic anemia in Western countries, dietary deficiency and malabsorption are the common causes in India.[3,4] Duodenal biopsies are routinely performed in patients with megaloblastic anemia to look for any evidence of malabsorption since tropical sprue (TS) is reported to be more prevalent in India. These biopsies are performed irrespective of the macroscopic endoscopic findings. The present study was undertaken to study the value of duodenal biopsy in patients of megaloblastic anemia and correlate the biopsy findings with endoscopy. As a secondary aim, the study also analyzed the hematological profile of patients with megaloblastic anemia.

Materials and Methods

Approval was obtained from the institutional human ethics committee before the onset of the study. All the cases of megaloblastic anemia with bone marrow studies diagnosed at PSG Institute of Medical Sciences and Research during the period of 2 years from January 2016 to December 2017 were retrieved. Cases with nonmegaloblastic macrocytic anemia, those with other associated neoplastic conditions like myelodysplastic syndrome, and leukemia were excluded from the study. Hematology assays were performed on a LH 780 hematology analyzer (Beckman Coulter, Inc., United States) using volume conductivity and scatter technology. Clinical and laboratory findings (serum vitamin B_{12} and folate levels) were retrieved from hospital records of the patients. Duodenal biopsies of these patients reported in the histopathology department were retrieved. Endoscopic findings of these cases were retrieved from hospital information system and tabulated. Histopathological examination was performed after standard processing and hematoxylin and eosin staining procedures. All the biopsy slides were reviewed and only those that had well-oriented villi were included. Histomorphological features like villous and crypt architecture, intraepithelial lymphocyte (IEL) count per hundred enterocytes, and 20 villous tip enterocytes in 5 villi were studied. Up to 20 IELs per 100 enterocytes was considered normal; 21 to 30 IELs per 100 enterocytes and more than 30 per 100 enterocytes were graded as borderline and severe increase, respectively. Inflammatory cell component in lamina propria—lymphocytes, plasma cells, neutrophils, eosinophils, and epithelioid histiocytes were also analyzed and the severity was graded as mild, moderate, and severe.

Only those with unequivocal partial or complete villous atrophy, intraepithelial lymphocytosis, and increase in inflammatory cell content were diagnosed as TS. Patients with increase in IELs and no abnormality of villous architecture (Marsh I, lesion) were categorized as intraepithelial lymphocytosis. Data were analyzed using SPSS software for windows, version 20.0, IBM Corporation, NY, United States.

Results

There were 93 cases of megaloblastic anemia diagnosed on bone marrow biopsies during the study period. There were 68 (73.2%) males and 25 (26.8%) females. Age ranged from 16 to 85 years, the median age being 42 years. Out of 93 cases, vitamin B_{12} assay was done in all whereas folate levels were available in 73.

According to the World Health Organization (WHO), vitamin B_{12} status in adults is defined by the serum levels of the micronutrient with the following cutoffs and definitions: greater than 221 pmol/L (> 163 pg/mL) is vitamin "B_{12} adequacy"; between 148 and 221 pmol/L (109–163 pg/mL) is "low B_{12}"; and lower than 148 pmol/L (< 109 pg/mL) is "B_{12} deficiency."[5]

In our series we found 59 (63.4%) out of 93 patients to be vitamin B_{12} deficient. 18 (19.3%) had low vitamin B_{12} levels and 16 (17.2%) were categorized as to have adequate B_{12}. Out of the 16 patients with adequate B_{12}, 4 had folate deficiency. Five cases had vitamin B_{12} levels more than 2,000 pg/mL.

Isolated vitamin B_{12} deficiency including low levels was present in 45 (48.38%) patients and folate deficiency (4 ng/mL, reference range being 4.6–34.8 ng/mL) was seen in 4 (4.3%) patients; 32 (34.48%) patients had both vitamin B_{12} and folate deficiency. Twelve (12.9%) patients had normal serum vitamin B_{12} and folate levels.

Considering the hematological parameters, mean hemoglobin and mean corpuscular volume (MCV) of the patients were 6.68 g/dL and 103.9 fL, respectively. MCV was less than 90 fL in five patients (5%). These five patients had coexisting iron deficiency anemia (►**Table 1**).

Fifty-one patients (54.8%) had pancytopenia at presentation (defined by hemoglobin less than 11 g/dL, total WBC count less than 4×10^9/L and platelet count less than 150×10^9/L), 48 of whom had vitamin B_{12} levels < 30 pg/mL. Forty patients had bicytopenia and two had anemia. Peripheral smear and bone marrow morphology are highlighted in ►**Figs. 1** and **2**.

Duodenal biopsies were available for all 93 patients. Out of these, 46 (49.46%) patients who had villous blunting of any degree (mild, moderate, or severe) and intraepithelial lymphocytosis in a decrescendo pattern (more IELs in the crypts) and nucleomegaly were diagnosed as TS (►**Figs. 3** and **4**). Five other cases of TS diagnosed previously did not show unequivocal villous blunting and hence were categorized as intraepithelial lymphocytosis. Sixteen (17.2%) patients had only intraepithelial lymphocytosis, 16 (17.2%) had peptic duodenitis, and 15 (16.12%) had no significant pathology (►**Fig. 5**).

TS was found to be more frequent in the three groups (isolated vitamin B_{12} deficiency, isolated folate deficiency, and combined B_{12} and folate deficiency). TS was less frequent in the patients who had normal vitamin B_{12} and folate levels (►**Table 2**).

Table 1 Hematological profile of patients with megaloblastic anemia

Hematological parameters	Mean	Range
Hemoglobin (g/dL)	6.2 + 2.37	3.0–11.9
Mean corpuscular volume (fL)	103.9 + 15.49	51.8–144.4
Red cell distribution width (%)	19.2	16–28
Platelets ($\times 10^9$/L)	83.8	9–315
Total leucocyte count ($\times 10^9$/L)	3.1	1–18.1

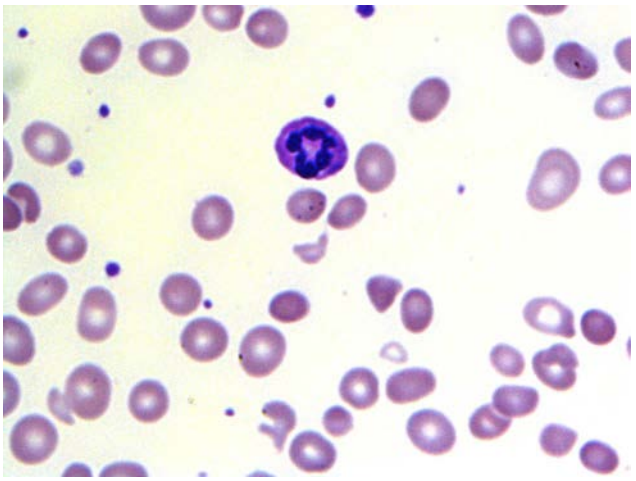

Fig. 1 Peripheral smear with hypersegmented neutrophil and macro-ovalocyte (100×)

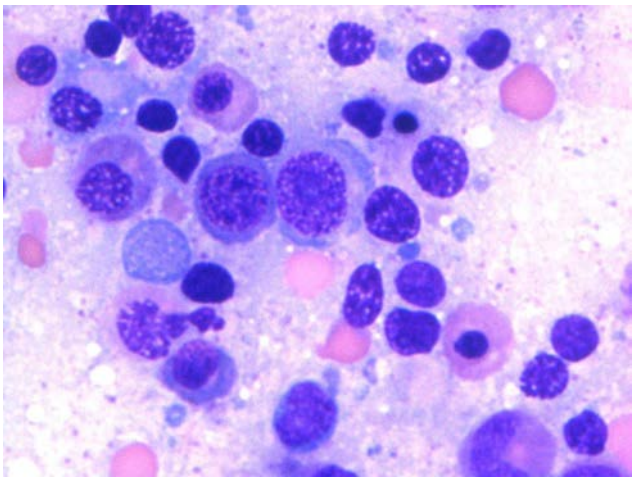

Fig. 2 Bone marrow aspirate showing megaloblastic erythroid hyperplasia (100×)

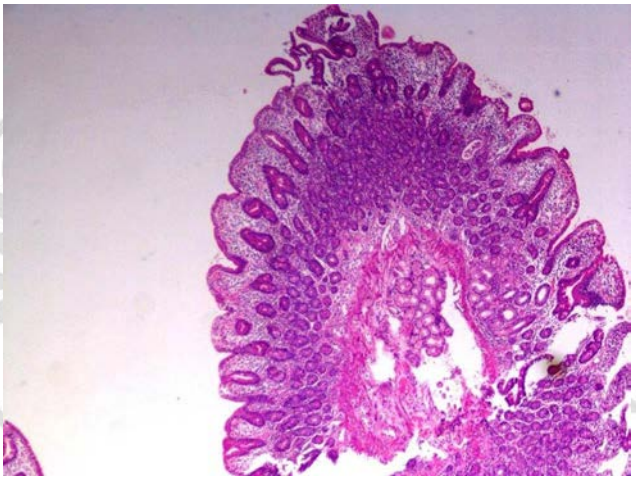

Fig. 3 Duodenal biopsy with villous blunting (4×, Hematoxylin and Eosin)

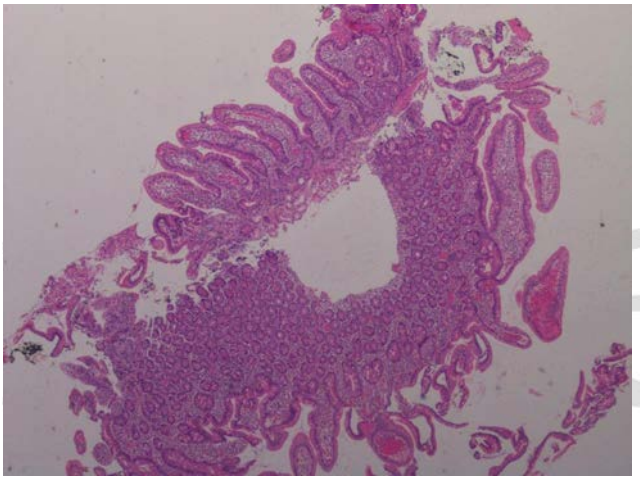

Fig. 4 Duodenal biopsy with variable villous blunting (Hematoxylin and Eosin, 4×)

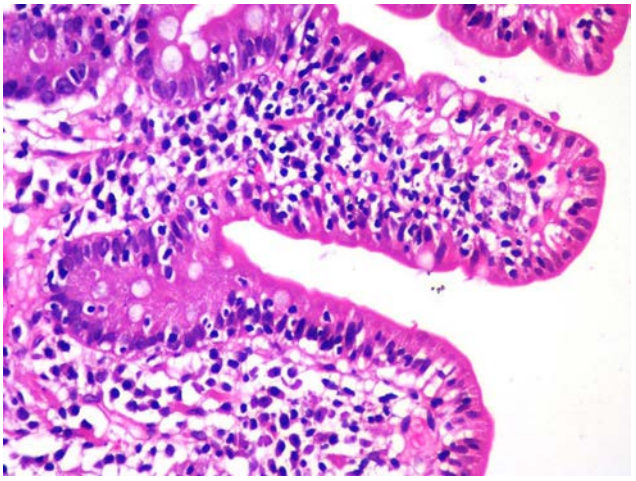

Fig. 5 Duodenal biopsy with marked intraepithelial lymphocytosis (Hematoxylin and Eosin, 40×)

Endoscopic macroscopic changes pertaining to malabsorption like scalloped duodenal and attenuated duodenal folds were identified in 26.8% ($n = 25$) of patients. Of these, the biopsy diagnosis of TS was made in 15 patients (60%). The remaining cases of TS diagnosed on biopsy showed either normal endoscopic appearance or other features like nodularity (►**Table 3**).

Discussion

Megaloblastic anemia is one of the commonest causes for pancytopenia in India. It has a characteristic peripheral smear picture (macrocytosis, ovalocytes, and hypersegmented neutrophils) and low reticulocyte count.[2] Bone marrow examination is done to rule out other neoplastic disorders which can have megaloblastosis, like myelodysplastic syndrome and leukemia. Serum vitamin B_{12} and folate levels will point toward the cause for megaloblastic anemia.[6,7] Duodenal biopsies are performed to identify if there is any evidence of malabsorption. The study reports a male predominance with a ratio of 2.7:1 which is considerably higher when compared with a vast majority of other studies.[8,9] The possible explanation could be the higher population of elderly men in the

Table 2 Duodenal biopsy findings in patients with vitamin B_{12} and folate deficiency

Number of cases (*N* = 93)	Tropical sprue	Intraepithelial lymphocytosis	Peptic duodenitis	No significant pathology
Vitamin B_{12} deficiency *n* = 45	24 (53.3%)	8 (17.7%)	5 (11.1%)	8 (17.7%)
Folate deficiency *n* = 4	3 (75%)	–	1 (25%)	–
Both *n* = 32	17 (53.1%)	6 (18.75%)	6 (18.75%)	4 (12.5%)
Normal *n* = 12	2 (16.6%)	2 (16.6%)	4 (33.36%)	3 (25%)

Table 3 Endoscopic findings with histological diagnosis

N = 93	Tropical sprue *n* = 46	Intraepithelial lymphocytosis *n* = 16	Peptic duodenitis *n* = 16	No significant pathology *n* = 15
Scalloped duodenal folds *n* = 25	15 (60%)	2 (8%)	3 (12%)	5 (20%)
Nodularity *n* = 25	10 (40%)	6 (24%)	3 (12%)	6 (24%)
Gastroduodenitis *n* = 12	6 (50%)	2 (16.6%)	1 (8.33%)	3 (25%)
No macroscopic abnormality *n* = 31	15 (48.5%)	6 (19.3%)	8 (25.8%)	2 (6.45%)

series in whom vitamin B_{12} deficiency due to intestinal malabsorption are reported to be common.[10]

Cobalamin and folate deficiency are predominantly due to decreased dietary intake or malabsorption in Indian population while pernicious anemia has been reported to be the common etiology in Western population.[11,12] Vitamin B_{12} deficiency has been reported to be the common cause for megaloblastic anemia in our population constituting to 63%, similar to that of Khandhuri et al (68%)[8] and Sarode et al (76%).[9] Combined vitamin B_{12} and folate deficiency was seen in 34% of cases which is slightly higher when compared with 8.8% and 12% reported by Sarode et al and Khandhuri et al, respectively. This is probably because of higher percentage of people with malabsorption in this series where combined micronutrient deficiencies are common. Folate deficiency was seen in 4.3% of patients which is similar to other studies. The cases with vitamin B_{12} levels greater than 2,000 pg/mL could represent cases treated inadvertently with vitamin B_{12} injections prior to investigation.

Pancytopenia and bicytopenia were observed in 54.8% and 43% of the patients, respectively. There are wide variations reported for the frequency of pancytopenia ranging from 17.2 to 43.8%.[13,14] Another study done in South India has reported pancytopenia in 40% of the patients.[15] The higher incidence of pancytopenia in our population can be attributed to severe vitamin B_{12} deficiency in these patients (48 out of 51 had vitamin B_{12} levels < 30 pg/mL). Mean MCV observed in the current study was 103.9 + 15.49 fL, which is lower when compared with that reported by Chidambaram et al (110 fL).[15] MCV was found to be normal in 5.3% of the patients which is lower than another study.[14]

TS was the commonest biopsy diagnosis in the study accounting for 49.5% of patients diagnosed as having megaloblastic anemia, which is similar to most other studies.[16,17] Endoscopic finding of scalloped duodenal folds was identified in 32.6% of TS. In the remaining cases, the diagnosis was possible only with the help of biopsy.

The diagnostic yield of gastrointestinal endoscopy is low in our study. This could be because subtle endoscopic changes were not documented since duodenal biopsies were routinely done in all the patients with megaloblastic anemia. However, Sharma et al[18] in their systematic review had found normal duodenal folds to be more common in TS.

Intraepithelial lymphocytosis without villous abnormality was the second commonest biopsy finding identified in 34.7% of patients. IEL without villous abnormality had been reported in various conditions such as gluten-sensitive enteropathy, infections, autoimmune conditions, drugs, and idiopathic etiology.[19] It has also been reported to be an early morphological feature of sprue.[19,20]

TS and IEL without villous abnormality together constituted 66.6% of cases, indicating malabsorption as the etiology for vitamin B_{12} and folate deficiency in these cases. Hence, biopsy contributes in identifying the etiology in 66.6% of cases.

In the remaining cases, the etiology of megaloblastic anemia could have been dietary deficiency or intrinsic factor deficiency.

Although the guidelines for investigation of megaloblastic anemia recommends serological assays of anti-intrinsic factor antibodies (anti-IFAB)[5] the incidence of pernicious anemia is very low in India. Duodenal biopsies have become a

 © 2021. The Indian Association of Laboratory Physicians.

routine practice in the workup more based on the evidence of high number of cases of TS being reported. Anti-IFAB levels were not done in the patients in the study.

It was found in the present study that routine duodenal biopsy in cases of megaloblastic anemia yields etiologic information in majority of the cases, irrespective of endoscopy. Hence it is recommended even in the absence of macroscopic endoscopic changes.

Current spectrum of malabsorption in India has found celiac sprue to be increasing in incidence.[19] Since the clinical, endoscopic, and histologic difference between celiac and tropical sprue are not well defined, serum antibodies against tissue transglutaminase and endomysial antibodies are needed in cases where there is no response to therapy for TS.

Limitations

Since this is a retrospective study, follow-up of patients to look for response to therapy for TS is not available. Since the study was conducted in a teaching hospital, endoscopy being done by different endoscopists would have influenced the results. Serological tests for celiac sprue and anti-IFAB antibodies were not done in the study.

Conclusion

Pancytopenia was the commonest presentation of megaloblastic anemia; vitamin B_{12} deficiency and folate deficiency constituted 82% and 4.3%, respectively. The incidence of TS in megaloblastic anemia is as high as 49.5% in the study population. Duodenal biopsy is valuable in the workup of megaloblastic anemia, irrespective of the endoscopic changes in identifying the etiology.

Abstract

Background: The Bethesda System for Reporting Thyroid Cytopathology (TBSRTC) is widely utilised by cytopathologists. The American College of Radiology (ACR) has also proposed a thyroid imaging reporting and data system (TIRADS) to classify thyroid nodules and guide their selection for fine needle aspiration (FNA). The current study aimed to analyse the usefulness of TBSRTC in thyroid cytology reporting, to examine its histological correlation with TIRADS, and to compare the management of lesions in each cytological category in our institute to the TBSRTC recommendations.

Materials and methods: A retrospective study was performed on all thyroid FNAs from a 2-year period at a tertiary care centre. Histological correlations of TBSRTC and ACR TIRADS were examined for cases with surgical follow-up, and the risk of malignancy in each TBSRTC category, and sensitivity and specificity of FNA and TIRADS, were calculated.

Results: A total of 337 thyroid FNAs were examined, with histological follow-up in 99 cases. Risk of malignancy in categories I-VI was 9.5%, 2.3%, 0.0, 8%, 87.5% and 100.0%, respectively. The sensitivity, specificity, positive predictive value, and negative predictive value of FNA were 60.0%, 99.0%, 85.7%, and 97.5%, respectively, while those values for thyroid ultrasound were 90.3%, 72.2%, 92.9% and 65%, respectively.

Conclusion: The study substantiates the usefulness of TBSRTC in arriving at a more precise diagnosis. Hurthle cell lesions with atypia were the common cause of misdiagnosis. The combination of TIRADS and TBSRTC aids in better stratification of thyroid nodules and in decision making for management of lesions.

1 | INTRODUCTION

Thyroid cancer is the most common endocrine malignancy and constitutes 0.1%-0.2% of all cancers in India. Fine needle aspiration (FNA) of the thyroid gland plays a vital role in the evaluation of thyroid lesions. It is a safe, cost-effective procedure to guide the management of thyroid lesions.[1] With the routine use of FNA, the number of surgeries being performed for benign lesions has been significantly reduced.[2] Most of the centres perform both palpation-guided and ultrasound-guided (USG) FNA.[3] Before the inception of The Bethesda System for Reporting Thyroid Cytopathology (TBSRTC), various terminologies were in use which often led to confusing risk assessments and unclear clinical management. TBSRTC has established a uniform, tiered reporting system for thyroid FNA specimens with an implied malignancy risk and recommendations for management, and is widely accepted by cytopathologists and clinicians.[4] But unfortunately, a significant subset of cytology interpretation yields indeterminate results (25%), as reported by Valderrabano et al.[5]

The use of ultrasound criteria in differentiating benign and malignant nodules of the thyroid gland has been the focus of research and much of the published literature has confirmed that ultrasound is highly sensitive but less specific in the detection of malignant thyroid nodules. A practical thyroid imaging reporting and data system (TIRADS) for thyroid nodules has been proposed by the American College of Radiology (ACR) to classify nodules of the thyroid gland and to solve the problem of nodule selection for FNAC.[6,7] Shen et al compared the effectiveness of the American Thyroid Association (ATA) classification, the ACR TIRADS, the TIRADS of the European Thyroid Association (EU-TIRADS), and a TIRADS developed by Kwak et al (Kwak-TIRADS) in a large cohort of patients, and concluded that all four risk-stratification systems had good diagnostic performance.[8] The combination of ultrasound imaging criteria using a TIRADS with TBSRTC in the risk stratification of thyroid nodules has not been explored extensively. The present study was carried out to establish the utility of such a combination of TIRADS with TBSRTC in the diagnostic and therapeutic approach to thyroid nodules.

The recent WHO classification has included new variants of thyroid carcinoma such as non-invasive follicular neoplasm with papillary-like nuclear features (NIFTP) and well differentiated thyroid tumour of uncertain malignant potential (WDT-UMP).[9] It is recommended that the risk of malignancy in each category be evaluated by every institution following TBSRTC for reporting as a tool for quality improvement. The current study aims (1) to analyse the diagnostic utility of TBSRTC in thyroid cytology reporting, (2) to establish the histological correlation of thyroid ultrasound using ACR TIRADS and (3) to analyse the adherence to TBSRTC recommendations of management for each category at our Institute.

2 | MATERIALS AND METHODS

This was a retrospective study which involved all patients who underwent FNAC of thyroid lesions over a period of two years (January 2018 to December 2019). The study was approved by the Institute's Human Ethics Committee (20/142). MGG- and PAP-stained smears and cytology reports of thyroid lesions were retrieved from the archives of the Department of Pathology at our Institute, a tertiary care centre. All of these cases were reviewed and diagnosed based on TBSRTC categories I to VI, as follows.

I. Non-diagnostic or unsatisfactory (ND/UNS)

II. Benign

III. Atypia of undetermined significance (AUS)/follicular lesion of undetermined significance (FLUS)

IV. Follicular neoplasm/suspicious for follicular neoplasm (FN/SFN)

V. Suspicious for malignancy

VI. Malignant

The probable diagnostic possibilities for categories V and VI were given wherever possible.

In cases with surgical excision, histopathology was considered the final diagnosis and correlated with cytology. Cases with histopathological diagnosis of follicular lesion, NIFTP, were reviewed for adherence to strict criteria for diagnosis. In cases where the cytology and histopathology were discordant, the cytology slides were reanalysed in a blindfolded technique to eliminate subjective bias. The sensitivity and specificity of FNAC in thyroid lesions and probable reasons for diagnostic errors in cytology were analysed.

A retrospective review of thyroid ultrasound features for those patients who underwent thyroidectomy in our institution was performed. The TIRADS score was given by an expert radiologist who was blinded to the histological diagnoses. The ACR TIRADS score was based on the evaluation of composition, echogenicity, shape, margin, and echogenic foci of the lesion, with each feature assigned 0-3 points. The total score is further stratified into categories ranging from 1 (benign) to 5 (highly suspicious). In cases with multiple nodules having different TIRADS scores, the highest score was considered for analysis. Risk of malignancy (ROM) for each TIRADS category was calculated based on the histological diagnosis. For calculating the sensitivity of the TIRADS in predicting malignancy, cross tabulation of the TIRADS score and the histological diagnosis was done. TIRADS categories 1, 2, and 3 were grouped as benign and 4, 5 as suspicious for malignancy.

For each category reported, the recommended management guidelines of TBSRTC and the management done for these cases were compared.

Microsoft Excel 2010 (Microsoft corporation) was used for data entry and statistical analysis was performed using SPSS version 20 (IBM Corporation).

3 | RESULTS

Three hundred and thirty-seven cases of thyroid FNAs were retrieved from the archives of the Department of Pathology. The distribution of the diagnostic categories as per TBSRTC is presented in Table 1.

TABLE 1 Distribution of diagnostic categories of The Bethesda System for Reporting Thyroid Cytopathology

Diagnostic categories	Subcategories	Number of cases (% per category)	Total number of cases (%) n = 337
I. ND/US	Cyst fluid	19	21 (6.2)
	Acellular specimen	2	
II. Benign	Benign follicular nodule	157 (60.6)	259 (76.9)
	Adenomatoid nodule	62 (24)	
	Lymphocytic (Hashimoto) thyroiditis in the proper clinical context	40 (15.4)	
III. AUS		9	9 (2.6)
IV. FN/SFN	Suspicious for follicular neoplasm	22 (88)	25 (7.4)
	Suspicious for Hurthle cell neoplasm	3 (22)	
V. Suspicious for malignancy	Suspicious for papillary thyroid carcinoma	11 (73.3)	15 (4.5)
	Suspicious for medullary carcinoma	2 (13.3)	
	Suspicious for malignancy, not otherwise specified	2 (13.3)	
VI. Malignant	Papillary thyroid carcinoma	3 (37.5)	8 (2.4)
	Anaplastic carcinoma	2 (25)	
	Medullary carcinoma	2 (25)	
	Non-Hodgkin lymphoma	1 (12.5)	

Abbreviations: AUS, atypia of undetermined significance; FN/SFN, follicular neoplasm/suspicious for follicular neoplasm; ND/US, non-diagnostic or unsatisfactory.

The most frequent interpretation was category II of TBSRTC, constituting 76.9% of the total. Among these, benign follicular nodule was the most common interpretation (60.6% of category II), followed by adenomatoid nodule (24%), and Hashimoto thyroiditis (15.4%). Among the category IV lesions, Hurthle cell lesions constituted 22.2% of the category. In both category V and VI lesions, papillary thyroid carcinoma (PTC) was the commonest. Subsequent histopathological examination was possible for 99 cases, and hence the rate of surgical excision constituted 29.4% of cases. The type of surgery depended on the cytological interpretation and radiology findings, and included 11 cases of lobectomy, 62 hemithyroidectomy, and 26 total thyroidectomies. The histological diagnoses for these cases are summarised in Table 2. There were 19 cases of malignancy (excluding three cases of NIFTP and a single case of well-differentiated follicular tumour of uncertain malignant potential), and 79 benign cases which included 10 cases of follicular adenoma. Partially or totally encapsulated nodules showing an admixture of micro- and macrofollicular growth pattern in the background of multiple nodules were interpreted as adenomatoid nodules. Solitary encapsulated nodules consisting of microfollicles were diagnosed as follicular adenoma. Papillary thyroid carcinoma was the commonest malignancy (78.9%). The surgical yield of malignancy in the study was 19.2%. There was a rare coexistence of papillary thyroid carcinoma and calcitonin negative neuroendocrine tumour of the thyroid. The preoperative cytological diagnosis of this case was category VI. The cytological and histological features of category III, IV, and V are shown in Figures 1 and 2. The risk of malignancy for each diagnostic category was calculated excluding NIFTP and WDT-UMP and summarised in Table 2. Risk of neoplasia (RON) was calculated including NIFTP, WDT-UMP and follicular adenoma.

Pre-FNA thyroid ultrasound was available for 90 cases that had histological follow-up. Most of the thyroid nodules belonged to TIRADS categories 2 and 3 on imaging, constituting 67.7% of the total. The distribution of TIRADS categories with the calculated ROM values is tabulated in Table 3. The sensitivity, specificity, positive and negative predictive values of thyroid ultrasound were 90.3%, 72.2%, 92.9% and 65.0% respectively.

The management recommendations as per TBSRTC for each category and the management of patients in the current study are outlined in Table 4. Repeat FNA under ultrasound guidance for ND/UNS category I lesions was done in 19% of cases, of which two showed cystic macrophages, while the remaining two were categorised as benign. Repeat FNA was not performed in any of the Category III lesions. Surgical resection was performed in 23.8%, 25.1%, 22.2%, 60.0%, 60.0%, and 37.5% of categories I, II, III, IV, V, and VI respectively. Molecular testing was not performed in any of these cases.

Of the cases with surgical excision, 3 (4.6%) excluding 2 cases of papillary microcarcinoma had a false-negative diagnosis (these cases were categorised as benign in FNAC but turned out to be PTC in histology), and 2 (22.2%) had a false-positive diagnosis (these two cases were categorised as suspicious for malignancy in FNAC and histology showed adenomatoid nodule). A review of the cytological smears of the 5 cases diagnosed as PTC in histopathology that had been assigned to category II in the cytology was performed. Two cases were papillary microcarcinoma, and no features of PTC were discernible cytologically. In the other three cases, the presence of nuclear grooves and pale nuclei were underdiagnosed as part of a cystic change in colloid goitre. There were no nuclear pseudoinclusions in any of these cases. On reviewing the

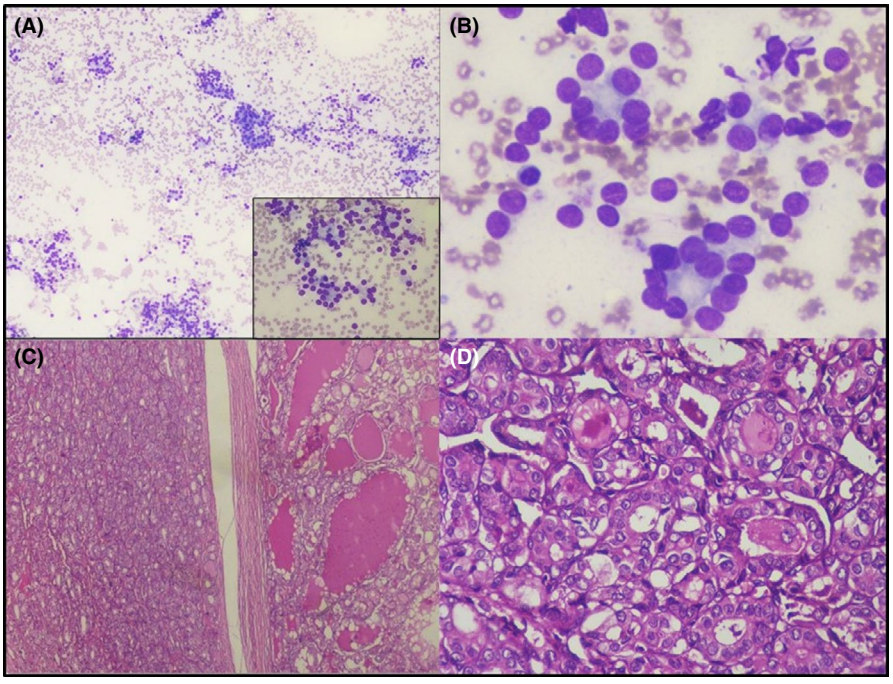

FIGURE 4 Non-invasive follicular neoplasm with papillary like nuclear features. (A) Cells arranged in repetitive microfollicular pattern (MGG, 10×). (B) Cells with nucleomegaly and occasional nuclear grooves (MGG, 40×). (C) Encapsulated nodule with no capsular invasion (H&E, 10×). (D) Closely packed follicles lined by cells exhibiting optically clear nuclei and grooves (MGG, 40×)

cytology smears of cases with a false-positive diagnosis on FNAC, in 1 case the presence of numerous aggregates of Hurthle cells exhibiting atypia was overestimated as features suspicious for malignancy. The cytological and histopathology images are shown in Figure 3. In the other case, hyperplastic changes with cells exhibiting occasional nuclear grooves, and follicular cells entrapped in blood clots with pale chromatin, were misinterpreted as features of malignancy.

The cytological features of WDT-UMP included repetitive microfollicular pattern, mild nuclear enlargement, occasional nuclear grooves, and no pseudoinclusions.

NIFTP constituted 3% of surgically resected thyroid lesions. The histopathology slides of the NIFTP cases were reviewed for the presence of the diagnostic criteria, which include complete encapsulation, follicular growth pattern, absence of invasion in extensive sampling, and optically clear nuclei as in Figure 4.

4 | DISCUSSION

The foremost advantage of TBSRTC is maintaining uniformity in the interpretation of thyroid FNA and guiding the clinicians to plan

TABLE 5 Comparison of the distribution of the diagnostic categories of the present report with other studies

appropriate therapy. The preoperative diagnosis of thyroid lesions in the present study using TBSRTC was comparable with other studies as summarised in Table 5.[10-14] The ND/UNS category still challenges accurate diagnosis. Despite the different expertise of cytologists in obtaining aspirates in a teaching hospital, the fraction of the ND/UNS category was well within the limits proposed by TBSRTC and other Indian[10,15] and Western studies.[13,16] This is in part due to the departmental protocol for rapid on-site evaluation (ROSE) in all cases of FNAC to assess for adequacy.

Benign lesions constituted the vast majority of FNA interpretation, which is similar to most other Asian studies[10,11] except a single study in the Chinese population,[8] where category VI was the most frequent interpretation. In Western studies, the reported proportion of the benign category ranges from 59% to 74.7%.[13,16] Regional variation may explain the difference in the distribution for this category.

The current study reports a lower rate of the AUS/FLUS category (2.6%), which is well within the preferred limit of 7% recommended by TBSRTC[4] and comparable to most Asian literature,[10,11,17,18] while some Western studies[9,12] have observed a higher percentage. The lower rate of this category could be attributed to the routine practice of obtaining an intradepartmental second opinion for all the indeterminate cases before assigning a category and hence the reasonable use of the AUS category.

As per the existing literature, the proportion of cases undergoing surgery varies among different institutions and ranges from 11.8% to 45.1%.[19,20] The malignancy rate of 19.2% in the present study was significantly lower when compared to the meta-analysis data by Bongiovanni et al (33.8%)[21] and Dawish et al (33.6%).[22,23] However, this malignancy rate does not reflect the true incidence in the population, because quite a few cases of thyroid malignancy were reported on histopathology and frozen section and did not have a cytological diagnosis before resection. Hence these cases were not included in the study. These resections were decided based on the clinical and sonographic findings.

4.1 | Risk of malignancy in each category

The risk of malignancy was comparable to that proposed by TBSRTC and other published literature for most of the categories except for ND/UNS and FN/SFN.[24] In the present study, the ROM in the ND/UNS category was 9.5%. Inadequate samples as the most common cause for false-negative diagnosis in FNA have been reported by Bakhos et al.[25] The risk of malignancy was calculated assuming that the unresected cases were benign. Hence the ROM across various studies ranges from 0% to 63%.[26,27] This increased risk of reported malignancy emphasises the importance of reaspirating all ND/UNS category lesions for cytology under guidance to rule out malignancy. Another pitfall that results in false-negative interpretation is the exclusive presence of cystic macrophages without cellular fragments, which could represent a cystic variant of PTC. In our study, there were two cases of PTC. The actual ROM in the AUS category is difficult to determine since only a subset of patients with clinical suspicion undergo surgical resection, thus resulting in selection bias. There were no malignancies in the AUS category with histological follow-up in the present data while other Asian studies report a higher ROM.[10-12,15] This could be explained by the fact that most of the cases showed architectural atypia rather than cytological atypia. Cytological atypia have been reported to be associated with a higher ROM as per the available evidence.[4] In cases of AUS, a repeat aspiration under guidance and correlation with clinical and radiological findings would lower the proportion of cases reported as AUS. The prevalence of NIFTP varies across the population and is reported to be between 5% and 13%.[28-30] In the present study, there was a much lower incidence at 3%. The cases of NIFTP showed a wide cytological spectrum spanning categories II to IV. However, the presence of diffuse cytological features of PTC and the absence of papillary fragments should prompt surgical resection to rule out the possibility of NIFTP.

In the recent years, various TIRADS systems have emerged and have been in use to stratify thyroid nodules as benign or malignant

based on ultrasound features and to decide on FNAC. The Kwak system is a simple classification based on suspicious ultrasound features. However, importance is not given to independent risk factors, for example extrathyroidal extension. Also, microcalcification, presence of solid area, and hypoechogenecity are given equal scores, whereas microcalcification generally has a higher malignancy risk.[31] ACR TIRADS is more complicated than other risk-stratification systems. Another drawback to this system is that malignant nodules exhibiting mixed echo patterns are given a lower score. Yet ACR TIRADS is an objective and comprehensive method for the evaluation of the thyroid nodules. The EU TIRADS is simpler than ACR TIRADS, and recommends FNA for mildly hypoechoeic nodules measuring greater than 1.5 cm.[8] However, it does not include solidity as an independent risk factor. The pitfall of the ATA guidelines is the classification of suspicious ultrasound features that have a variety of clinical significance into the same risk stratification with no independent categorisation.[8] In the present study ACR TIRADS was used for risk stratification. The sensitivity of ACR TIRADS observed in the current study is similar to that of other published studies.[6,32,33]

A similar study carried out by Fernandez et al has reported the percentage of malignancy as 77% in moderately and highly suspicious categories (TIRADS score ≥ 4) versus 65% in the current study.[32] ROM values for TIRADS scores except for score 2 are in consensus with most other published articles except for score 3, where a higher ROM (10%) was observed. Even though some malignant nodules were mislabelled as benign and some benign nodules were mistaken for malignant, the overall sensitivity was better.

While exploring the causes for a false-positive diagnosis in cytology, it was observed that cellular smears with a predominance of Hurthle cells exhibiting atypia, and the presence of focal nuclear features of PTC in the absence of nuclear inclusions, were overdiagnosed as features of malignancy. On the other hand, cases with diffuse cytological atypia even with focally observed pseudoinclusions are worth considering as suspicious for malignancy. Analysing the causes for the false negatives in FNA, papillary microcarcinoma being missed by sampling error in FNA has been reported previously. Under these circumstances, USG-guided FNA would have been useful.

4.2 | Adherence to TBSRTC recommendations for management

There exists a heterogeneity in approaches to the management of thyroid nodules despite the recently published guidelines for clinical management. TBSRTC recommends reaspiration under USG guidance as the preferred method for evaluation of ND aspirates unless the nodule is purely cystic. The majority of the ND/UNS lesions in the data consisted only of cystic macrophages, reflecting the lower rate of repeat aspiration in the present study.

The management decision for category II is determined predominantly by radiological findings, since there is a possibility of sampling error with FNA in larger nodules that can hinder detection of the underlying malignancy. However, a vast subset of patients undergo thyroidectomy for cosmetic reasons/pressure symptoms rather than for suspected malignancy.

The treatment for category III and IV lesions is controversial. While surgery is advised for category IV lesions, close follow-up with repeat FNA, and molecular analysis for BRAF and RAS gene mutations are recommended for the AUS category.[4] Chirayath et al[34] in their study in the Indian population have found, however, that mutational analysis for BRAF as an indicator of malignancy in AUS lesions has limited utility, in line with the results of many other studies.[35,36] Even though there was no ROM for the AUS category in the present study, in a country where molecular tests are not very feasible, a multidisciplinary approach based on clinical and radiological findings, together with patient preference, should guide the management.

Surgery as the treatment modality for category III and IV lesions was seen in 22% and 60% of cases, respectively. The resection rate in indeterminate categories is much lower than that reported by Western studies (22% in the current study vs 57.6%).[37] The lower rate could be explained by the loss of follow-up of these patients. Or et al[38] in their study have reported that for cases with indeterminate cytology, 77.4% of clinicians opted for repeat FNA and in case of repeat FNA being indeterminate, 50% opted for surgery.

The authors acknowledge the limitations of this study which include the retrospective design and a small proportion of cases with surgical follow up.

5 | HIGHLIGHTS

The reporting of AUS/FLUS lesions with a supplementary note describing the presence of architectural and/or cytological atypia may be helpful in treatment decisions, since cytological atypia could suggest the possibility of NIFTP or malignancy that would require surgical excision.

In the current study, it was found that there is higher interobserver variability in interpreting Hurthle cell atypia. There is a higher chance for misinterpretation as suspicious for malignancy . A further study analysing the various cytological parameters and cytohistological correlation of Hurthle cell lesions might help in achieving a more accurate cytological diagnosis and lower the rate of false positives in FNAC. The TIRADS score in conjunction with TBSRTC cytological diagnosis can aid in better stratification of thyroid nodules and aid in decision making.

6 | CONCLUSION

This study substantiates the usefulness of TBSRTC in thyroid cytology in arriving at a more precise diagnosis and guiding clinicians on management. The study reports a lower proportion of the AUS category. Hurthle cell lesions with atypia were the common cause

for misdiagnosis observed in the current study. The presence of nuclear features of papillary carcinoma with the presence of numerous microfollicles in the aspirate should prompt the diagnosis of NIFTP. Periodic cytohistological correlation and further studies on Hurthle cell lesions can aid in improving the sensitivity and specificity of FNA. In institutions where TBSRTC in reporting is practised, the clinicians should be aware of the implied risk of malignancy in each category. There was a good correlation between TIRADS, TBSRTC, and histology especially in benign nodules. However, further replication studies adapting a prospective design with a larger sample size are essential to validate the utility of thyroid ultrasound especially for indeterminate nodules.

Abstract

Objective: To study the suitability of the developed polyamide/hydroxyapatite (PA/HA) composite orthopaedic scaffold in *vitro* and *in vivo*.

Methods: The fabricated scaffolds were seeded with human osteoblast-like cell line (MG 63) and tested for its viability & cytotoxicity, proliferation and calcium mineralization through MTT assay, ALP assay and Alizarin red S staining respectively. Finally, the scaffolds were implanted in non-immunocompromised male wistar rats subcutaneously and pathological tests were carried out.

Results: The results of *in vitro* studies indicate that PA/HA (90:10) composite was non-cytotoxic and supported calcium mineralization relatively better than the other compositions of PA/HA. From the Hematoxylin & Eosin staining, inflammation was observed in the tissues surrounding the scaffold 7 weeks post implantation in rats. However, the scaffolds were found to be incorporated into the subcutaneous tissue at the end of one year without any rejection.

Conclusion: PA/HA (90:10) composite scaffold fabricated using SLS is biocompatible when tested in rats, and could more likely be used for orthopedic applications.

Keywords: Scaffold, orthopedic, biocompatibility, MG 63, rat model.

1. Introduction

Recent reports suggest that among the total injuries due to accidents, 11.5% are bone fractures [18]. Besides fractures, bone replacement is also essential for patients with congenital disorders, tumor resection, and those in a revision surgery to replace the infected implant. This signifies the need for a material that is mechanically strong and biologically compatible to be a good orthopedic scaffold.

Pure HA is a bioactive ceramic known for its osteoinductive property. However, its brittle nature makes it unsuitable to repair the bone defect by itself. Hence, HA is used along with PA. This polymer/ceramic composite yields greater strength [14].

PA and HA are being used as bone scaffolds for many years. Conventional techniques such as freeze-drying and cross-linking [15], thermally induced phase separation [16] and injection-molding technique [17] were used to develop PA/HA scaffolds.

However, Selective laser sintering, a rapid prototyping technique helps in customized development of 3D porous PA/HA composite scaffolds with 100% pore interconnectivity. Here we present the *in vitro* and *in vivo* performance of the 3D porous scaffold of different compositions of PA and HA fabricated using SLS.

PA 66 was used by many researchers [7,8,11,14] for developing the bone scaffold. But in this study, PA 12 is employed. Though PA12 is cost ineffective compared to

PA66, it has the advantage of resistance to corrosion, cracking and chemical degradation [19, 20].

PA/HA scaffolds fabricated using Selective Laser Sintering, an additive manufacturing technique described elsewhere [5] is used in this study.

The aim of this work is to analyze the *in vitro* and *in vivo* performance of the 3D porous scaffold fabricated with different compositions of PA and HA fabricated using SLS, for its use as an orthopedic scaffold.

2. Methods

2.1. Polyamide/hydroxyapatite scaffold

PA 12 was purchased from Duraform 3D systems, and HA was synthesized chemically as per the protocol specified by Sneha *et al* [9]. PA and PA/HA composite scaffolds were fabricated in Selective Laser Sintering machine (Sinterstation DTM 2500 *plus*). The scaffolds have cubical pores of size 800 µm contributing for 70% porosity. 3D porous scaffolds of cubical shape (0.9 x 0.9 x 0.4 cu.mm.) and cylindrical shape (0.9 mm diameter and 0.4 mm thickness) were used for *in vitro* and *in vivo* studies respectively. The images of the fabricated scaffolds are presented in Figure 1.

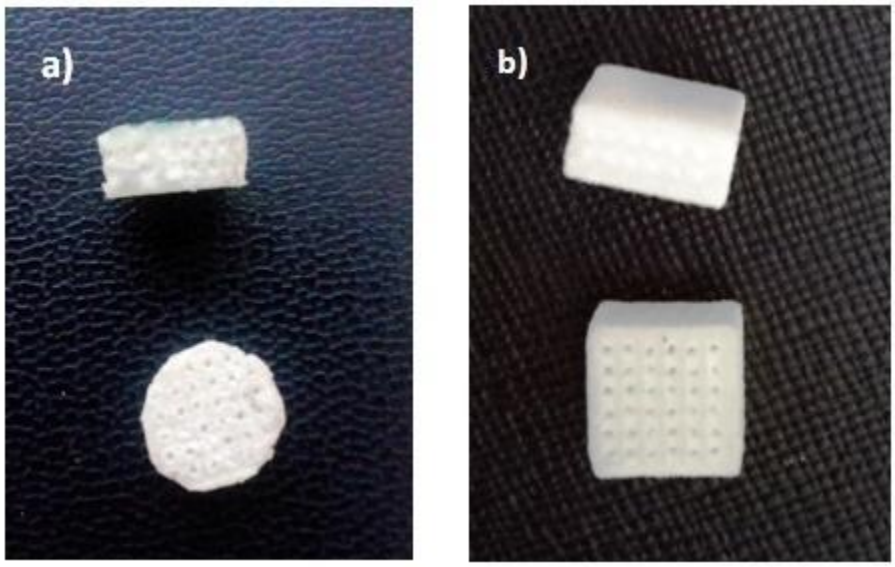

Figure 1: Three dimensional porous scaffolds a) cylindrical shape with 0.9 mm diameter and 0.4 mm height used for *in vivo* testing; b) cubical shape with dimensions 0.9x0.9x0.4 cu.mm used for *in vitro* testing

2.2. Cell culture

The human osteosarcoma cell line, MG-63, (NCCS Pune, India) was cultured in DMEM medium (AL007S, HiMedia, India) supplemented with 200mM L-glutamine, 10% Fetal bovine serum, and 1X of Antibiotic Antimycotic Solution (A002, Himedia, India). The cells were incubated with 5% CO_2 at 37°C. On attaining 80-90% confluency, the cells were trypsinized with trypsin-EDTA. Unless specified, the chemicals were procured from HiMedia, India.

2.3. Cell viability and proliferation studies

MTT assay was employed to assess the cell viability and proliferation of the cells on interacting with the scaffold material. This is a colorimetric assay measuring the reduction of yellow 3-(4, 5-dimethythiazol- 2-yl)-2, 5-diphenyl tetrazolium bromide (MTT) substrate to an insoluble purple formazan product by mitochondrial succinate dehydrogenase enzyme. The MTT enters the cells and passes into the mitochondria where it gets reduced to an insoluble, dark purple colored formazan product. The intensity of the purple color is proportional to the number of live cells.

Each well containing the UV sterilized scaffold was seeded with 1000 µL of medium containing approximately $1x10^4$ cells. The plates were incubated at 37^oC with 5% CO_2. MG 63 cells cultured without any scaffold was used as the control. After 1, 3 and 5 days of incubation, 5mg per ml of freshly prepared MTT (HiMedia, India) solution was added to each well and incubated for 3.5 h at 37^oC with 5% CO_2. After the incubation time, the above solution was discarded and the scaffolds were air dried. The insoluble purple colored formazan crystals formed were solubilized by adding 200 µl of Dimethyl sulphoxide (SD Fine Chemicals). The plate was left in shaking condition for 10-15 min in dark. The solutions from 48-well plate were then transferred to 96-well plate and, the absorbance was read at 570 nm in a multiwell plate reader (Thermo Multiscan Labsystems, Model 352). The absorbance values were plotted in graph using MS Excel.

2.4. Alkaline Phosphatase assay

Alkaline phosphatase (ALP) is a hydrolase enzyme responsible for removing phosphate groups from nucleotides, proteins, and alkaloids. Higher levels of ALP activity is observed during the active bone formation, as it is a by-product of the osteoblast activity and, also observed in elevated levels in the cell membrane of undifferentiated pluripotent cells. The alkaline phosphatase assay was carried out using the p-nitrophenol pyrophosphate (N7653 Sigma Aldrich) as the substrate according to the protocol specified by the manufacturer. ALP catalyses the hydrolysis of the colorless ρ-Nitrophenyl phosphate (pNPP) to a colored ρ-Nitrophenol, that has a strong absorbance at 407 nm. The absorbance is a measure of the level of the enzyme activity.

Each well containing a UV sterilized scaffold was seeded with 1000 µL of medium containing approximately $1x10^4$ cells in a 48 well plate, and incubated for 4, 7 and 10 days at 37^{o}C with 5% CO_2. After the incubation, 200µL of p-nitrophenol pyrophosphate solution was added to each well. The plates were then incubated in dark for 30 minutes at room temperature. After 30 minutes, 50µL of 3M NaOH solution was added per 200 µL of the reaction mixture to stop the reaction. The absorbance was then read at 407 nm in a multiwell plate reader (Thermo Multiscan Labsystems, Model 352). Statistical analyses for MTT and ALP assays were carried out using paired t-test using MINITAB 15.0 software. $P<0.005$ were considered to be statistically significant.

2.5. Alizarin Red S staining

Alizarin Red S, an anthraquinone derivative, is used to identify calcium in tissue sections. The reaction is not strictly specific for calcium, since magnesium, manganese, barium, strontium, and iron may interfere. But as these elements usually do not occur in sufficient concentration in this experiment to interfere, the scaffolds were tested for calcium mineralization using Alizarin red S staining. Alizarin Red S powder (A5533 Sigma Aldrich) was used to prepare a fresh solution (pH 4.1-4.2) each time as per the protocol specified by Gregory *et al*, 2004 [3].

Each well containing a UV sterilized scaffold was seeded with 1000 µL of medium containing approximately $1x10^4$ cells in a 48 well plate, and was incubated for 25 and 28 days at 37^{o}C with 5% CO_2. After the incubation period, the media was discarded, and the wells were rinsed gently with 1 mL PBS. The cells were then fixed with 1.0 mL of 10% formalin in each well for 15 minutes at room temperature. Formalin solution was then removed and the wells were washed twice gently with double distilled water. To each well, 500 µL of 40 mM Alizarin red S solution was added and left at room temperature for 20 minutes with gentle shaking. After 20 minutes, the dye solution was removed and the wells were washed four times with 1.0 mL distilled water, replacing the water at each 5 minutes interval. The specimens were then air dried, and images were taken. Mineralized areas appear red in color.

2.6. In vivo Rat model studies

Eight male Wistar rats (*Rattus norvegicus*) each weighing 200-250 g were obtained from the Animal house, PSG Institute of Medical Sciences and Research, Coimbatore. The surgical procedure in the rats was approved by the Institutional Animal Ethics Committee, PSG Institute for Medical Sciences & Research, Registration No. 158/PO/ReBi/SL/99/ CPCSEA. The rats were randomly divided into two groups, each containing two rats as given in Table 1. Two rats per cage were housed in a temperature-controlled facility.

Table 1: Biocompatibility test by subcutaneous implantation of the scaffold in rats

Period/ scaffold material	Polyamide (PA 12)	PA/HA (90:10) composite
7 weeks	2 rats	2 rats
One year	2 rats	2 rats

2.7. Rat Surgical Procedure

Non-immuno compromised eight male Wistar rats were used for this study. Intraperitonial injections of Aneket ® Ketamine (30 mg/kg) and Astra Zeneca ® 2% xylocaine (13 mg/kg) were administered to anesthetize the animals (Figure 2a). The lateral aspect of the abdomen was shaved under aseptic precaution. Using a sterile surgical blade no. 15, an incision of about 3 cm was made (Figure 2b). Skin and subcutaneous tissue was dissected (Figure 2c) and the autoclaved scaffold of dimensions 0.9 mm diameter x 0.4 mm thickness was implanted in the subcutaneous plane (Figure 2d), as given in table 1. Upon implantation of the scaffold in the subcutaneous pouch, the skin was sutured using an Ethicon (5-0) Non-absorbable surgical suture NW 3316 (Jhonson & Jhonson) (Figure 2e). After four days the sutures were found to be eaten off by the rats exposing the scaffolds to outside. The closure was then made using the Glue, N-butyl-2-cyanoacrylate. The animals were fed with rat feed pellets, and the cages were changed every fortnight. Rat surgical procedure was performed according to Subramanian *et al* [12].

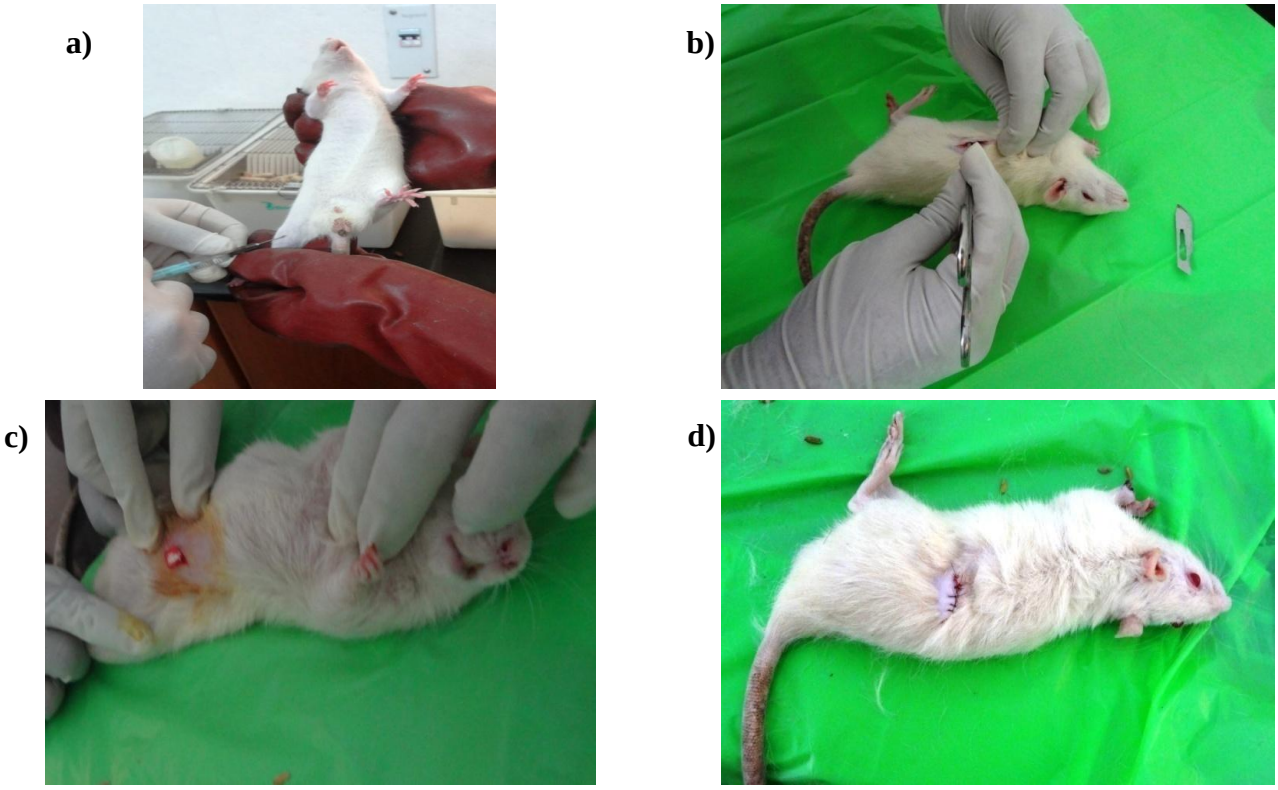

Figure 2. Rat surgical procedure. (a)administration of general anesthesia; (b) creating a subcutaneous pouch; (c)implanting the autoclaved scaffold; (d)sutured using Ethilon 5-0

2.8. Pathological testing

Post-implantation of the scaffold in the rat model, four rats (two in each group) after 7 weeks, and remaining four rats after one year were euthanized with over dose of diethyl ether. Using the previous scar site, incision was made and the scaffold along with the surrounding tissue was removed. The tissues were stored separately in 10% formalin for histopathological analysis.

2.9. Hematoxylin & eosin staining

The samples, with soft tissue cleaned, were stored in 10% formalin for 10 days. The samples were then rinsed in tap water, followed by fixing and dehydration in successive alcohol concentration. The samples were then cleared with xylene and embedded in paraffin wax. After hardening, the sample were cut into 4 µm sections perpendicular to the implants, under cooling water with microtome (Leica RM2255, Germany). The sections were glued onto a plastic support and finally stained with Harris Hematoxylin and Eosin.

3. Results and Discussion

Increasing trauma and injuries in day-to-day life demands orthopedic scaffolds with desirable and reproducible design, adequate strength and biocompatibility. Rapid prototyping is one such fabrication technique that facilitates development of customized scaffolds rather than standardized scaffolds, in a short time. Advantages of custom-made scaffolds of satisfactory size matching the defect area could easily be implanted at the defect site. Besides reducing the time for surgery, custom-made scaffold contributes to the rapid healing of the defects [6]. Selective Laser Sintering uses a high temperature of around 1100^{o}C for fabricating the components. However, the chemical composition of HA and PA were known to remain unmodified even at higher temperatures. Hence, variation in the scaffold properties due to the sintering stays ineffective.

Pores in the bone scaffold aids cellular infiltration and also facilitate the exchange of nutrients and wastes across the bone. The scaffold material becomes more desirable if it supports/enhances cell attachment, proliferation and calcium mineralization in addition to possessing adequate mechanical properties. HA/PA66 composite developed with 75-85% porosity and 500 micron pores yielded the compression strength of 10-20 MPa [14]. Bone screws fabricated using PA/HA without pores yielded bending strength of 200- 300MPa [11]. Porosity is directly proportional to the biological functions of the scaffold, and inversely proportional to the mechanical strength of the scaffold. Hence, fine tailoring of the porosity and pore size without compromising the mechanical property of the scaffold is crucial. The HA/PA12 composite scaffold used in the present study was fabricated with 70% porosity and 800 micron pores using Selective Laser Sintering, discussed

elsewhere [5], yielded a mechanical strength of 25 MPa, which was identified to be adequate to support a person weighing 75 kg.

3.1 In vitro tests

From the MTT assay result shown in Figure 3, it can be observed that there is a gradual increase in the cellular proliferation from day 1 to day 5 in all the scaffold types tested including the control. Incorporation of HA in the composite facilitated better cell attachment and proliferation compared to the polyamide as seen on day 1 and day 5, which could be due to the bioactive nature of the HA. However, it can also be observed that there is no significant difference between the PA/HA (95:5) and PA/HA (90:10) as the percentage increase in minimal. A similar trend was reported by Tang *et al* [13].

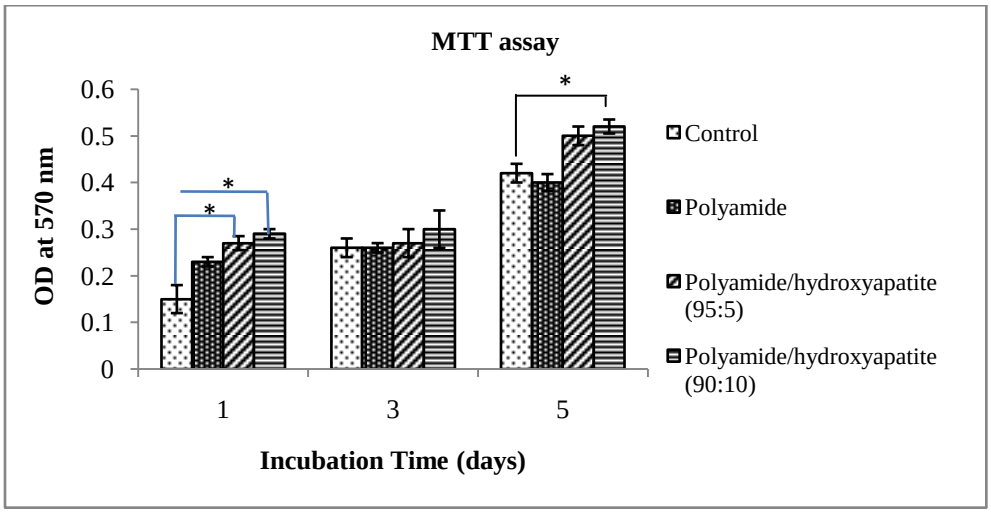

Figure 3: MTT assay results for MG 63 cells cultured on the scaffolds made of polyamide and various compositions of polyamide/Hydroxyapatite

ALP is an early differentiation marker for the osteoblasts. A general increase in the ALP activity is observed from day 4 through day 7 in all the scaffolds tested (Figure 4). ALP level in PA/HA (90:10) was observed to be lower than the control on day 4. However on day 10, the ALP levels of the cells cultured on the PA/HA (90:10) scaffolds were found to be on par with that of the control (cells cultured without scaffold).

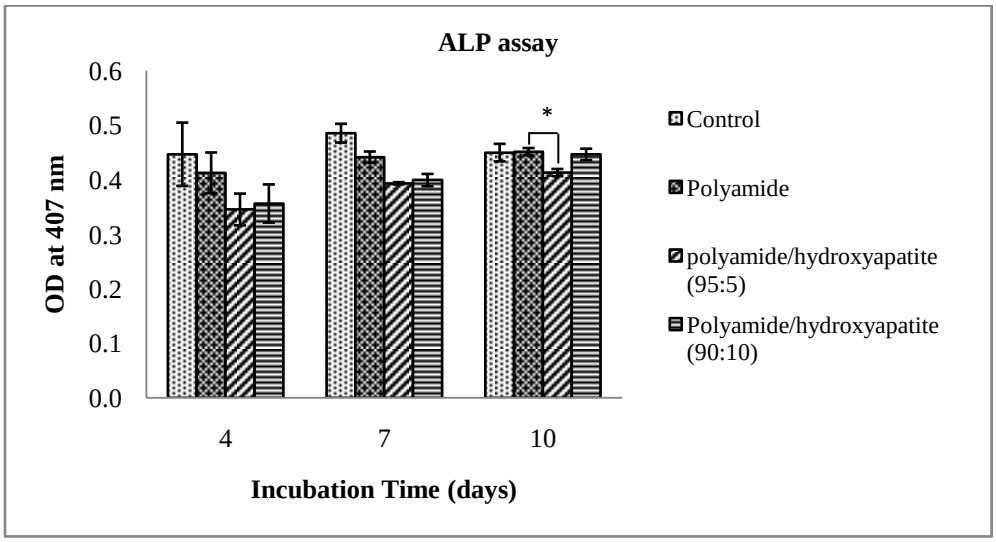

Figure 4: ALP assay results of MG 63 cells cultured on the scaffolds made of polyamide and different compositions of polyamide/hydroxyapatite

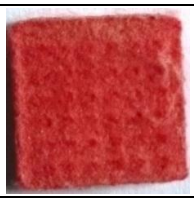
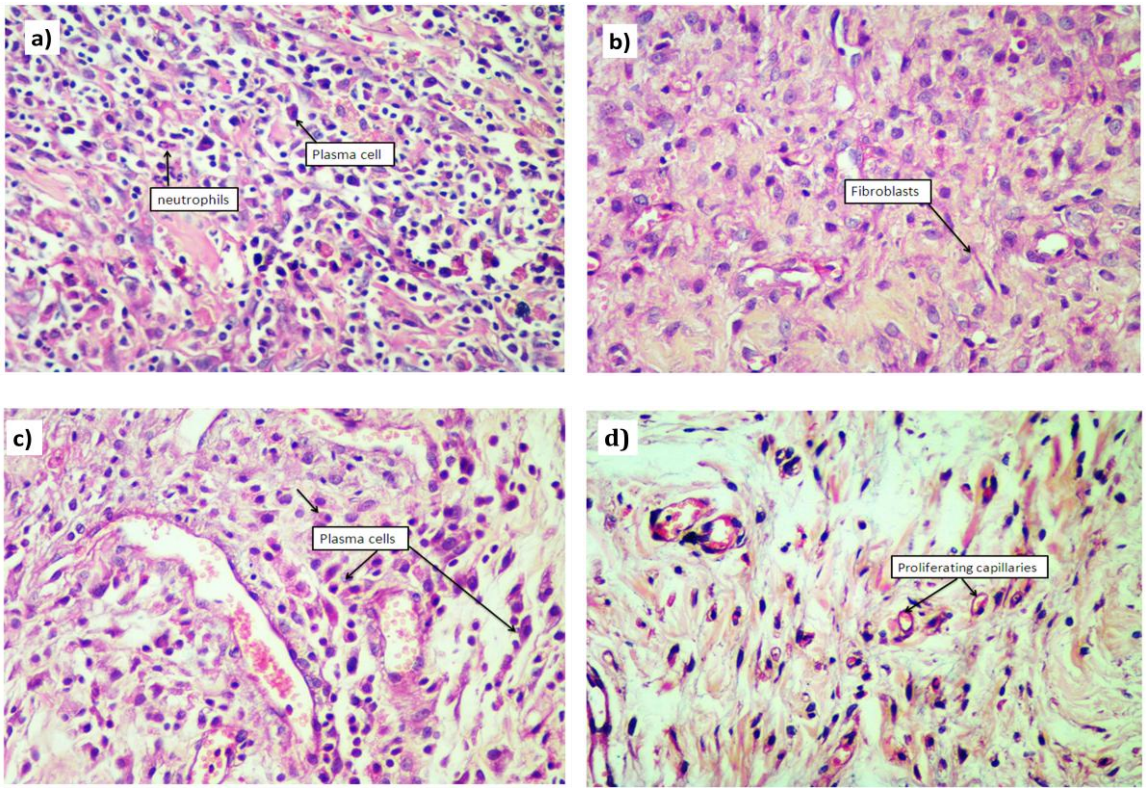
Alizarin Red S staining results (Figure 5) shows that the polyamide scaffolds were stained less intense than the scaffolds containing HA. These results suggest that though the polyamide was found to be non-cytotoxic and supporting ALP activity, it lacked the property to support calcium mineralization, which is the desirable criterion for a material to act as a bone scaffold.





Component	Polyamide	Polyamide/Hydroxyapatite (95:5) composite	Polyamide/Hydroxyapatite (90:10) composite
Day 25			
Day 28			

Figure 5: Images of PA/HA (90:10), PA/HA (95:5) and polyamide scaffolds stained with Alizarin red S stain to identify the mineralized regions

3.2 In vivo study

There was significant difference in the *in vitro* assays observed between PA and PA/HA composite. However, the difference observed between PA/HA (95:5) and PA/HA (90:10) *in vitro* is minimal, as the percentage variation is lesser. Hence, PA and PA/HA (90:10) scaffolds were implanted subcutaneously in the rat models to analyze their performance *in vivo*. Immunological responses were observed after seven weeks and one year post-implantation in the rat models. Scaffold samples implanted in the rat models were stained with H&E after 7 weeks of implantation. Rat implanted with polyamide showed inflammatory response, whilst the H&E staining results of PA/HA (90:10) composite suggests that there is no inflammatory response, and the tissues were in the process of healing (Figure 6). Figure 6a and b are replicates for PA scaffold and, 6c and d are the replicates for the PA/HA (90:10) scaffold seven weeks post-implantation in rat. H&E staining of polyamide scaffold (Figure 6a and b) shows plasma cells, neutrophils, fibroblasts and scattered inflammatory infiltrate, while staining of polyamide/hydroxyapatite (90:10) scaffold. Figure 6c and 6d shows fibroblasts, scattered macrophages, plasma cells and occassional neutrophils. Proliferating vascular channels are also seen.

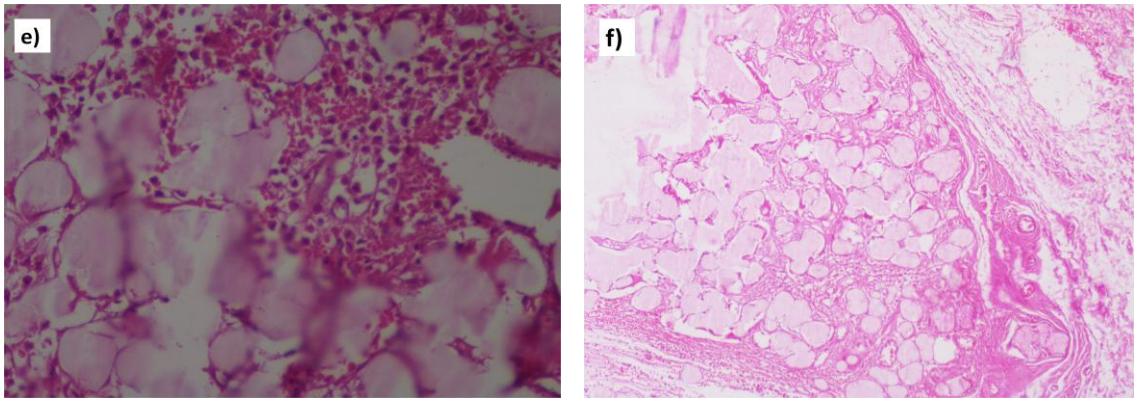


Figure 6: Representative images of Hematoxylin & eosin staining of polyamide (a and b), and PA/HA(90:10) (c and d) scaffolds after 7 weeks of subcutaneous implantation in rats. And Hematoxylin & eosin staining of polyamide (e), and PA/HA(90:10) (f) scaffolds after one year of subcutaneous implantation in rats.

During this course of one year observation post-implantation, of four rats (two with PA and two with PA/HA), a rat with polyamide scaffold was deceased on the 11th month post-implantation due to its age. Meanwhile complete scaffold disintegration was observed in the rat with PA/HA (90:10) scaffold at the end of one year. Consequently, one in each scaffold type were obtained and subjected to pathological analysis, the images of which are presented in Figure 6e & f.

H&E staining of one year old PA scaffold section (Figure 6e) shows fibroblastic reaction, collagenisation and scant inflammatory infiltrate, while PA/HA (90:10) composite scaffold section (Figure 6f) shows sclerosis, mixed inflammatory infiltrate and focal hyalinization. These results suggest that both the scaffold types were biocompatible.

Post-implantation, follow-up for longer durations of one-year was carried out to identify the scaffold failures due to infection, failure of osseintegration or implant loss by mechanical loading [6]. Staffa *et al* suggests a two year follow-up of porous HA cranial prosthesis as per the protocol of Neurosurgicals. This would facilitate the monitoring of osseointeggration. A perfect fit between the implant and the bone allows in-growth of capillaries, perivascular mesenchymal tissue and osteoprogenitor cells from the living bone into the graft. This is crucial to validate the success of the bone implant [10]. Xiong *et al* performed a longer follow-up of rabbit tibial defects fixed with PA/HA composite for internal fixation loosening and joint collapse till 5.3 years [14]. In our study, analysis after one year of implantation was carried out. However, neither any infection nor any inflammation was observed.

Burnett *et al* assessed the safety of using Polyamide and reported to be used in cosmetics and personal care products. And the acute oral LD_{50} for polyamide 12 was reported to be 1g per kg of body weight in rat, mice, guinea pigs and rabbits [2]. Recently, Polyamide is used with nano-hydroxyapatite for developing bone screws [11] and vertebral plates [14]. PA/HA composite has entered the clinical trials for testing in the proximal and distal regions of femur, tibia and humerus in humans [14].

4. Conclusion

3D porous PA and PA/HA scaffolds were tested *in vitro* and *in vivo*. *In vitro* tests such as MTT assay, ALP assay and Alizarin Red S staining carried out using MG 63 cell line reveals that all the three types of scaffolds (PA, PA/HA (95:5) and PA/HA (90:10)) were non-cytotoxic. However, PA/HA (90:10) outperformed the three scaffold types tested. Hence, pure PA and PA/HA (90:10) scaffolds were implanted subcutaneously in the rat models. Pathological tests of 7 week old scaffolds showed that polyamide scaffold showed presence of inflammatory cells, whilst the PA/HA (90:10) composite scaffold showed presence of proliferating capillaries and were in the process of healing. However, pathological testing of scaffolds one year post-implantation showed that both scaffold types were biocompatible and neither showed immune rejection nor infection. The PA/HA (90:10) composite having performed consistently better under *in vitro* and *in vivo* conditions, we conclude that the above composite could more likely be used in orthopedic applications.

ABSTRACT: In this study, silk filaments are coated with different concentrations (5, 7.5, and 10% w/w) of carbon nanofibers (CNFs) dispersed in poly-ε-caprolactone. The nanocomposite-coated silk filaments are subjected to knitting, braiding, and twisting. The tubular structures are covered with a silk fibroin/polyvinyl film for the nerve conduit application. Physical characterization of the developed nerve conduits demonstrates suitable mechanical properties comparable to native nerve tissue. Cell proliferation is confirmed through in vitro cell culture studies using Neuro 2a and rat primary cortical neural progenitor cells, which show that the proliferation happens along the interconnected macrochannels of the internal structure of the nerve conduit. The knitted structure presents better biological properties than the nerve conduits with other internal structures. The in vivo sciatic nerve implantation is performed in a rabbit model using the best conduit, i.e., 10% CNF-based nanocomposite-coated silk with a knitted inner structure without any biomolecules or tube filling gels. Regeneration of a 2 cm gap excised sciatic nerve is investigated by immunohistochemistry and histology of implanted nerve conduits removed after 30 days. Results suggest that the CNF-based conducting nanocomposite coating in this well-defined architecture of the conduit helps in signal transmission and neural growth during the regeneration of the transected nerve.

KEYWORDS: *Knitted, braided, twisted, artificial nerve conduit, nanocomposite coating*

1. INTRODUCTION

There are a large number of incidences of peripheral nerve injury reports each year with a lack of feasible nerve regeneration techniques. Compared to the central nervous system, the peripheral nervous system has an intrinsic ability to regenerate. However, peripheral nerve regeneration is a slow regeneration process and leads to neural and muscle atrophy at the site of denervated area. The present practice of using autografts for peripheral nerve injury repair has limitations like availability, multiple surgeries, sensory loss, and immune suppression.[1] Therefore, the development of bioengineered artificial nerve conduits (ANCs), which mimic the physical and biological characteristics of the native nerve tissue, would be beneficial for suffering patients.[2] Several synthetic and natural-polymer-based ANCs have been successfully developed for short nerve gaps up to 5−10 mm. However, development of the ANC more than 10 mm in length still remains a challenge due to the risk of breakage, lack of continuity, and directional growth.[3] These issues can be overcome by selection of a suitable biomaterial combination as well as structure to enhance the biomechanical property of the ANC and to provide a suitable microenvironment for the cells to proliferate.

Researchers have been using various approaches to develop nerve conduits using different biomaterials[4−6] such as collagen, hyaluronic acid, silk fibroin (SF), polyhydroxybutyrate, poly-D,L-lactide-*co*-glycolic acid (PLGA), poly-ε-caprolactone (PCL), poly-L-lactate (PLA), polyvinyl alcohol (PVA), etc.[7] Among these polymers, SF, PCL, and PVA can be potential polymers for nerve tissue engineering. SF is widely used for peripheral nerve regeneration due to its unique biological and physical properties. SF has the ability to preserve the neuronal physiology, which in turn can promote peripheral nerve regeneration.[8] ANCs based on SF fibers were developed by Xue et al.[7] and successfully bridged the sciatic nerve gap of 30 mm length in a study period of 12 months. Similarly, PCL, a synthetic polymer, also possesses excellent properties such as biocompatibility, slow degradation, and required mechanical properties for nerve tissue engineering application. Panahi-Joo et al.[9] developed 3D tubular aligned PCL nanofibrous scaffolds for peripheral nerve tissue engineering. These scaffolds were found to be promising for PC12, SH-SY5Y, and C6 cell elongation, migration, and proliferation. PCL nanofibrous scaffolds for spinal cord regeneration were developed, and in vitro studies showed the efficacy in Schwann cells and induced pluripotent stem cells.[10] Furthermore, they studied the

scaffolds' regeneration ability in a rabbit model, and they observed axonal regeneration and re-myelination in the implanted cell-seeded scaffolds. PVA is another biocompatible polymer and possesses prominent features such as nontoxicity and biodegradability, which makes it suitable for nerve tissue engineering. Due to its poor cell affinity and weak antigenicity,[11] PVA is preferably mixed with other polymers such as silk,[12] fibronectin,[13] etc. for enhancing the physical and biological properties of scaffolds.

Regardless of promising results achieved by using non-conducting scaffolds, incorporation of conductive nanoparticles in the scaffolds has been widely investigated to further enhance the electrical and mechanical properties of the scaffold. Nanoparticles such as carbon nanofibers (CNFs),[14,15] graphene,[16] nanosilver,[17] gold,[18] etc. were supplemented within the polymer matrix to enhance the biomaterial−nerve cell interaction followed by regeneration of damaged nerve tissue. Among these nanoparticles, CNF is easy to process and offers very good electrical conductivity with limited toxicity.[2,15]

For the development of ANCs, researchers have been using different techniques such as electrospun nanofibers,[19] multilayer molding,[20] and integration molding.[21] Shrestha et al.[19] developed a nanofibrous nerve conduit using polyurethane/silk fibroin functionalized with multiwalled carbon nanotubes. The developed ANC was found to be efficient for in vitro axonal regeneration and cell proliferation. Qian and his group developed nerve conduits using multilayer molding[20] and integration molding[21] techniques. In the multilayer molding technique, they used a 3D pointed rolling tube mold to coat polydopamine onto the PCL-gold nanocomposite. The in vivo nerve regeneration results were promising for angiogenesis and peripheral nerve repair. In the integration molding technique, they developed tubular molds with concentric rings, and the empty spaces were filled with PCL-graphene oxide combination, and finally, pores were developed using a 3D printer and showed in vivo nerve regeneration potential.[21]

Peripheral nerve conduits are made up of bundles of nerve fibers and surrounding connective tissue with blood vessels. Each bundle of nerve fibers is held together by collagen fibrils.[22] Thus, the natural structure of the peripheral nerve is an intercalated fibrous structure covered with a sheath (epineurium). To mimic these structures rather than a hollow cylinder-based structure, fibrous structures may show a higher biomechanical property as well as regeneration ability. Thus, textile fabrication techniques are used to develop promising scaffolds for nerves, tendons, and ligaments. Recently, knitted, twisted, and braided structures have widely been used for tissue engineering applications due to their excellent mechanical strength, flexibility, precise structure and surface topography, controllable geometry, porosity, and viscoelastic behavior.[2,23] Lu et al.[24] developed microbraided PLA nerve conduits that were found to be promising in regeneration of the rat sciatic nerve (10 mm gap). In another study, Wang et al.[25] developed a braided PLGA catheter with high-density PLGA yarn with chitosan outside and PLGA of low density treated with hydrogen peroxide inside. The developed nerve conduit was found to be efficient in in vitro Schwann cell proliferation. Wang et al.[23] fabricated porous knitted scaffolds using chitosan yarns that exhibited promising results for Neuro 2a cell proliferation along with desirable mechanical properties. A similar study was performed on the efficiency of the twisted (wire-rope) structure for tissue tendon, nerve, and ligament tissue engineering applications.[26]

In this study, different textile structures including knitted (KS), twisted (TS), and braided (BS) were developed using CNF-PCL-based nanocomposite-coated silk fibroin (SF) filaments and analyzed for their potential application in nerve regeneration. Degummed (after removal of surface sericin) SF filaments were subjected to PCL-CNF nanocomposite coatings (5, 7.5, and 10% w/w). The CNF concentrations were selected based on our previous studies.[14,15,27] In our pervious study, we developed a braided conduit structure using degummed silk fibroin coated with PCL and different concentrations of CNF.[28] These conduits' performance in in vitro cell proliferation was satisfactory, which motivated us to study the impact of a defined architecture in the nerve regeneration efficiency. For this, degummed silk fibroin threads were converted to conduit scaffolds using knitting, braiding, or twisting techniques. The final scaffold consists of a knitted, braided, or twisted scaffold as a core structure and SF:PVA (3:1) as an outer layer. The polymer combination selected as the outer layer was based on our previous studies[12,29] to protect the inner core from muscle cell infiltration as well as allow the nutrients to pass inside the inner region. The sample abbreviations are given in Table 1.

Table 1. Different SF-Based Nanocomposite ANCs Developed and Their Abbreviations[a]

		coating		
inner core structure	silk filament	PCL (w/v)	CNF (w/w)	sample code
knitted (KS)	S			S
	S	10%		SP

silk-PVA film (outer wall)				SF-PVA

[a]KS: knitted structure, TS: twisted structure, BS: braided structure; S:SF, SP:SF coated with PCL, SPC:SF coated with different concentrations of CNF (5, 7.5, and 10% w/w)-dispersed PCL solution (10% w/v in DMF).

Based on the in vitro cell culture studies using Neuro 2a and rat primary cortical neural progenitor cells, the conduit with a knitted core structure was selected for in vivo sciatic nerve implantation in a rabbit model.

2. EXPERIMENTAL METHODS

2.1. Fabrication of Silk-Fibroin-Based Conducting Nanocomposite ANCs. ANCs developed using silk-based nanocomposites consist of two parts: (i) an inner matrix composed of different inner core structures (KS, TS, and BS) made of silk fibroin (SF) coated with PCL and various concentrations of CNF (5, 7.5, and 10% w/w) and (ii) an outer cover to prevent invasion of unwanted cells into the ANC, consisting of SF:PVA (3:1) thin films.

https://dx.doi.org/10.1021/acsabm.0c00430
ACS Appl. Bio Mater. XXXX, XXX, XXX−XXX

For the inner core structure, raw silk threads were purchased from handloom dealers of Mettupalayam, Tamilnadu. The silk threads were degummed to remove sericin by boiling in 0.5 M sodium carbonate solution for 1 h at 60 °C. The degummed silk fibroin threads were coated with PCL and CNF solutions of various concentrations (5, 7.5, and 10% w/w).[15] PCL (10% w/v) was dissolved in *N*′,*N*′-dimethylformamide (DMF) solution, and CNF (diameter: 60−150 nm; length: 30−100 μm, Pyrograf Inc., USA) was added to this solution followed by 2 h of stirring and then 30 min of sonication (Elmasonic S30H, Germany) to form a uniform dispersion of CNF in solution. The PCL-CNF dispersions were used to coat single SF threads using an in-house built coating setup.[30] Finally, the coated SF threads were subjected to knitting, twisting, and braiding. Pure degummed silk threads (S) were used as control for further studies.

For the outer cover, the outer matrix consisted of isolated silk from the *Bombyx mori* cocoon, per our previous protocol.[12] Briefly, SF was dissolved in Ajisawa's reagent and was dialyzed against distilled water followed by concentrating in polyethylene glycol solution (4% v/v). The total weight after degumming was considered as protein weight, and dialyzed SF solution was taken according to the required percentage followed by dissolving PVA in the SF solution in a ratio of 3:1 (v/v) and made up to the final concentration by addition of distilled water. The SF:PVA (3:1 v/v) film was prepared in deionized water, and the solvent casting method was employed to develop a thin film of SF-PVA, and then the film was cross-linked with glutaraldehyde (25%). These films were washed several times to remove unreacted glutaraldehyde and used for fabrication of ANCs by wrapping the inner core and the sides of films by applying a thin layer of SF-PVA solution, cross-linking, and leaving under lab conditions to dry.

Thus, in a complete nerve conduit, the outer cover SF-PVA film is wrapped around the inner tubular textile structures (made of degummed silk threads coated with PCL and CNF) to create a nonporous protective layer for preventing other cellular (mostly muscle cells) migration into the inner core to facilitate nerve cells in their regeneration process.

2.2. Characterization. SF, SP, and SPC10 threads were subjected to Raman spectra and X-ray diffraction analysis (XRD). Raman spectra of samples were recorded using a PerkinElmer Raman Station 400 with a 784 nm laser as the excitation source. XRD patterns of samples were analyzed by using a Bruker D4 Endeavor X-ray diffractometer with copper Kα1 radiation. Surface topography of the ANC was analyzed using a scanning electron microscope (SEM, Carl Zeiss, model EVO18, Germany) at 10 kV after gold coating of the SF filaments. Percentage of porosity of the ANC was calculated using the liquid displacement method with hexane as solvent. Impedance analysis of the ANCs was performed using an impedance analyzer (E4990A, Keysight Technologies, USA) with a Kelvin clip at a distance of 20 mm in a frequency range of 20 Hz to 20 MHz. Normally, the nerve undergoes cyclic expansion and compression for a number of times inside the body. To simulate this condition, dynamic mechanical (DMA) properties of the developed scaffolds were evaluated with a modulated compact rheometer (MCR102, Anton Paar, USA). Universal extension fixture (UXF) mode was used for DMA analysis at 1% initial constant strain with 20 mm length and 37 °C (body temperature).Tensile testing was performed using a universal testing machine (model 3366, Instron, USA) with a 20 mm sample, 100 N load cell, 2 mm/min speed rate, and at room temperature.

2.3. In Vitro Cytotoxicity and Cell Proliferation Studies Using the Neuro 2a Cell Line. To analyze the cell proliferation rate, total DNA estimation was performed using fluorescent DNA binding stain Hoechst as per our previous protocol. Briefly, each scaffold was seeded with 1×10^4 cells and incubated for 10 days. At different time intervals (days 2, 4, 6, 8, and 10), the cell-seeded scaffolds were trypsinized, and the isolated cells were stained with Hoechst, which specifically binds to live cellular DNA. The absorbance was read at wavelengths of 358 (excitation) and 461 nm (emission) using a Fluoroskan Ascent microplate fluorimeter (Thermo Scientific). The evaluation of Neuro 2a cell attachment was performed by SEM and confocal imaging. For SEM, samples were dried using different concentrations of ethanol (70−100%) followed by overnight hexamethyldisilazane (HMDS) treatment. They were placed in a stub with carbon tape followed by sputter coating for 60 s and visualized under SEM. For fluorescence staining, phalloidin and Hoechst were used. For staining, cell-seeded ANCs were removed from the medium and were fixed using 4% glutaraldehyde solution. After that, 10 μL of phalloidin stain was added and incubated for 10 min followed by addition of the Hoechst stain and incubation for 10 min. Further, HMDS was added for complete drying of scaffolds, which is a chemical drying agent and does not alter the ultrastructure of cells. After complete drying, scaffolds were visualized under a confocal microscope.

2.4. In Vitro Live/Dead Microscopic Analysis Using Primary Cortical Neural Progenitor Cells Seeded on Developed Conduits. Primary cortical neural progenitor cells (cortical neurospheres) were isolated from E18 Sprague Dawley rat pups (ethical committee approval: AEC St. Vincent's Hospital Melbourne, Australia Project 015/14r1) and were passaged in neurosphere media (Neurocult NSA, StemCell Technologies), 20 ng/mL EGF (Peprotec), 20 ng/mL basic FGF (Peprotec), 100 units/mL penicillin, and 100 μg/mL streptomycin. Cytocompatibility analysis was performed on KS (SP, SPC5, SPC7.5, and SPC10). Cortical neurospheres were cultured, seeded on the KS scaffolds, and allowed to attach and migrate for 7 days with half medium changes every day. At the end of day 7, KS conduits were stained with calcein AM (Thermo) and ethidium homodimer (Thermo), according to the manufacturer's instruction for the live/dead assay. Images of live, stained cells on developed samples were obtained using an EVOS FL cell imaging system.

2.5. In Vivo Studies. KS, SPC10 was selected for animal studies. Healthy rabbits were selected for this study after getting animal ethical committee approval (approval no. 405/2018/IAEC). Animals were grouped into test and sham animals (three animals per group) and were maintained according to CPCSEA (Committee for the Purpose of Control and Supervision of Experiments on Animals) guidelines. For nerve regeneration studies, animals were anesthetized using drugs such as ketamine and xylazine. Entire surgery was performed under aseptic conditions. The right thigh sciatic nerve of 2 cm was exposed, clipped on both sides, and excised using microscissors. Further, the distal and proximal nerve stumps were sutured with the SPC10% KS, artificial nerve conduit. After surgery, the wound was closed and rehabilitated under standard conditions. At the end of day 30, the implant was removed, and the nerve stumps were joined together by end-to-end sutures. Similarly, for the control animal, the sciatic nerve was also excised and was used for comparative studies. All animals were observed for recovery of gastrocnemius muscle contraction.

The implanted artificial nerve conduit was subjected to histological and immunohistochemical (IHC) analysis. Histological analysis was performed using hematoxylin and eosin (H&E) and toluidine blue staining (Thermo Fischer kit). The expression levels of S-100, CD 34, and CD 31 were analyzed in the excised regenerated nerve and control nerve tissue (healthy nerve excised from sham). For IHC, Thermo Fischer kits were used, and the experiment was performed according to the manufacturer's instruction. The artificial nerve conduit (SPC10 KS) was further subjected to confocal microscopic imaging to visualize the primary nerve cells attached using Hoechst and phalloidin stains.

All the tests were performed in triplicate, and data are expressed as mean ± standard deviation. Statistical analysis was carried out using one-way ANOVA (Tukey's test) in Origin Pro8.0 software.

3. RESULTS AND DISCUSSION

The main prerequisite for an ideal ANC fabrication is oriented topography with unidirectional fiber arrangement and pore distribution to enhance neurite proliferation and tissue repair.[2,31] In this study, the ANC was assembled with two different components: an inner core wrapped with an outer layer. The outer wall consists of an SF-PVA film wrapped over

https://dx.doi.org/10.1021/acsabm.0c00430

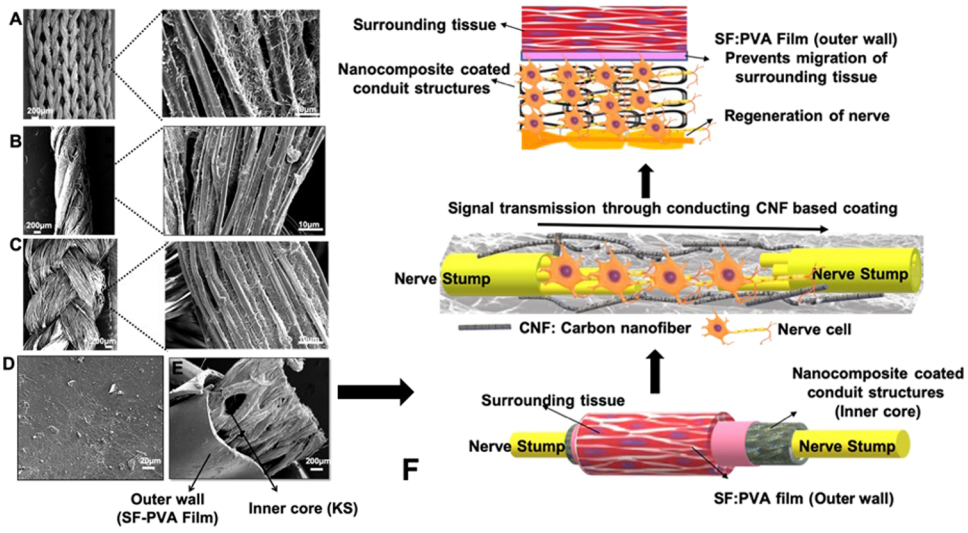

Figure 1. Scanning electron microscopic images of different inner core structures of the (A) KS (magnified image of SPC10), (B) TS (magnified image of SPC10), and (C) BS (magnified image of SPC10). SEM image of the outer wall (D) SF-PVA film and (E) complete nerve conduit with the inner core (knitted structure (KS)) and outer wall SF-PVA film. (F) Combined effect of the CNF and well-defined architecture of the conduit to enhance nerve regeneration.

the inner core; i.e., three different inner core structures were used to investigate the effect of the inner core structure on the mechanical and biological properties of the ANC. The inner core structures included knitted, braided, and twisted scaffolds, which are great options for nerve tissue engineering due to their well-defined architectures, mechanical properties, and controllable porosities (Table1).

3.1. Characterization of Developed ANCs. Figure 1 shows the macroscopic appearance of representative images of the developed ANCs. The KS-ANC with a diameter of 573 ± 19 μm showed well-aligned macrochannels with pores (Figure 1A). A magnified image in Figure 1A reveals the distribution of CNF in the coating layer. The SEM images show very detailed structures with axially oriented fibers and interconnected micropores. Similarly, Figure 1B shows the topographic details of TS. Compared to the KS, the TS is a well-packed wire-rope structure with mere pores that are visible. The average diameter of the TS was 159 ± 13 μm. The fibers in the TS were radially twisted to provide a guided channel for nerve regeneration. A magnified version of the TS shows the dispersed CNF in the PCL coating on silk fiber (right side of Figure 1B). The average thickness of BS is about 273 ± 14 μm (Figure 1C). In the BS-ANC, the fibers were radially arranged with sufficient pores in between the intercalated fibers (Figure 1C). The right side of Figure 1C shows the distribution of PCL-CNF (10%) in the matrix. All the structures exhibited uniform coating of PCL-CNF (5−10%) throughout the matrix. Figure 1D shows the surface topography of the outer wall of the ANC consisting of the SF-PVA film. The average thickness of the film is about 54.2 ± 11 μm with a very small number of pores. The structure of the complete ANC with the inner core (KS) and outer wall (SF-PVA film) is shown in Figure 1E. Figure 1F shows the hypothesis of this study; we hypothesize that (i) addition of conducting CNF in the inner core of the ANC can enhance the nerve cellular signaling and proliferation, (ii) the outer wall of the ANC can prevent invasion of the surrounding cells into the ANC (in vivo) so that undisturbed nerve cell proliferation and regeneration occur, and (iii) effective nerve regeneration depends on the nerve conduit structure and its composition.

SEM images of the developed inner core of the ANC with a well-defined fiber architecture and surface topography are shown in Figure 1. PCL coating with different concentrations of CNF was found to be uniform throughout the matrix. Porosity of the matrix is an important factor to be considered as it has a vital role in passing nutrients and cell percolation. The developed inner core of the ANC in this study showed sufficient porosity to facilitate nutrient transport and cellular migration within the ANC. Further, the outer wall of the ANC, SF-PVA film, showed the least porosity to help in gas and nutrient exchange while preventing migration of tissue cells from outside to inside the conduit.

The Raman spectra and XRD patterns of pure and coated SF threads are given in Figure S1A,B. Raman spectral analysis of the coated and pure SF threads confirmed the presence of SF, PCL, and CNF in the developed threads. The characteristic peaks of SF were at 1665, 1249, and 1334 cm^{-1}, which correspond to amide I, amide III, and CH_2, respectively.[32] SF threads coated with PCL showed the characteristic peaks of SF and PCL. The peaks of different functional groups such as C−COO (826 cm^{-1}), CH_2 (1282 and 1452 cm^{-1}), and C=O (1668 cm^{-1}) confirmed the presence of PCL on SF threads.[33] The presence of G and D bands in the SF threads coated with PCL-CNF confirmed the presence of CNF in the sample (Figure S1A). Diffractograms of coated and uncoated SF filaments showed the characteristic peak of SF at 20°.[34] Two distinct peaks for PCL-coated SF samples were visible at 21.6 and 23.7°, which correspond to the (110) and (200) planes of the PCL orthorhombic crystalline structure, respectively.[35] Similarly, SF filaments coated with PCL and 10% CNF showed a diffraction pattern at 26.5° (002), which reveals the presence of CNF in the coating layer (Figure S1B).[36]

Porosity is an important factor that affects the cellular ingrowth and proliferation. Textile-based scaffolds generally provide adequate porosity for this purpose due to their loose structure. Figure S2A shows the percentages of porosity for developed ANCs in this study. All the developed inner cores

https://dx.doi.org/10.1021/acsabm.0c00430
ACS Appl. Bio Mater. XXXX, XXX, XXX−XXX

for ANCs were found to be highly porous, around >90% porosity (Table 2), and this value is 42.3 ± 2.3% for the outer wall. The outer layer with low porosity prevents invasion of outer cells to the inside of the ANC. The electrical impedance profile of the inner cores of ANCs with varying concentrations of CNF showed a significant decrease in the impedance value with increasing CNF concentration (Figure S2B–D). The impedance values at a frequency of 20 MHz for the KS, TS, and BS were 10 ± 5.2, 8.36 ± 3.4, and 171 ± 4.3 Ω, respectively. These values demonstrate the superior electrical properties of ANCs at high CNF concentration irrespective of structural variations (Table 2). The objective of the impedance measurement over a length of 20 mm was to assess the electrical conducting network formation from one end to another end of the conduit. This is expected to help in nerve cell proliferation and repair.[28]

3.2. Mechanical Properties of Developed ANCs.

Biomimetic scaffolds can provide a good microenvironment for cell proliferation and tissue repair.[37] As reported in the literature, biologically inspired nanoscale topography can be developed in scaffolds by adding nanometer-scale particles such as CNF to enhance the surface area and electrical, mechanical, and biological properties.[37] By incorporation of CNF into the developed inner core of the ANC, the electrical property improved significantly due to its porous nature. As the concentration of CNF was increased, the electrical property was also found to increase with significantly lower impedance. The porous structure of the scaffold with high surface area provided lower impedance, which further enhances the ion penetrating ability into the conducting network of the polymer.

Neural tissue has an anisotropic mechanical behavior due to the epineurium that covers the perineurium and endoneurium.[38] Under normal physiological conditions, nerves are exposed to different mechanical stresses such as compressive, tensile, or combination of stresses.[38] Therefore, understanding the mechanical behavior of the ANC is essential as it has to meet the mechanical requirements in the in vivo environments.

The dynamic mechanical property of the developed inner core of the ANC was studied using a dynamic mechanical analyzer (Figure 2A–C). As the concentration of CNF increased in the inner core of the ANC, the storage modulus increased; the storage modulus values are 42.4 ± 3.2 (KS), 995.8 ± 9.6 (TS), and 29.4 ± 4.5 MPa (BS) at a frequency of 7 Hz. The highest storage modulus was achieved by the TS compared to the KS and BS (Table 2). This proves that the structure has an effect on the mechanical property even using the same material composition. This similar trend was observed in tensile properties of these developed ANCs. The samples showed strains of 112, 172, and 63.3% for the KS, TS,

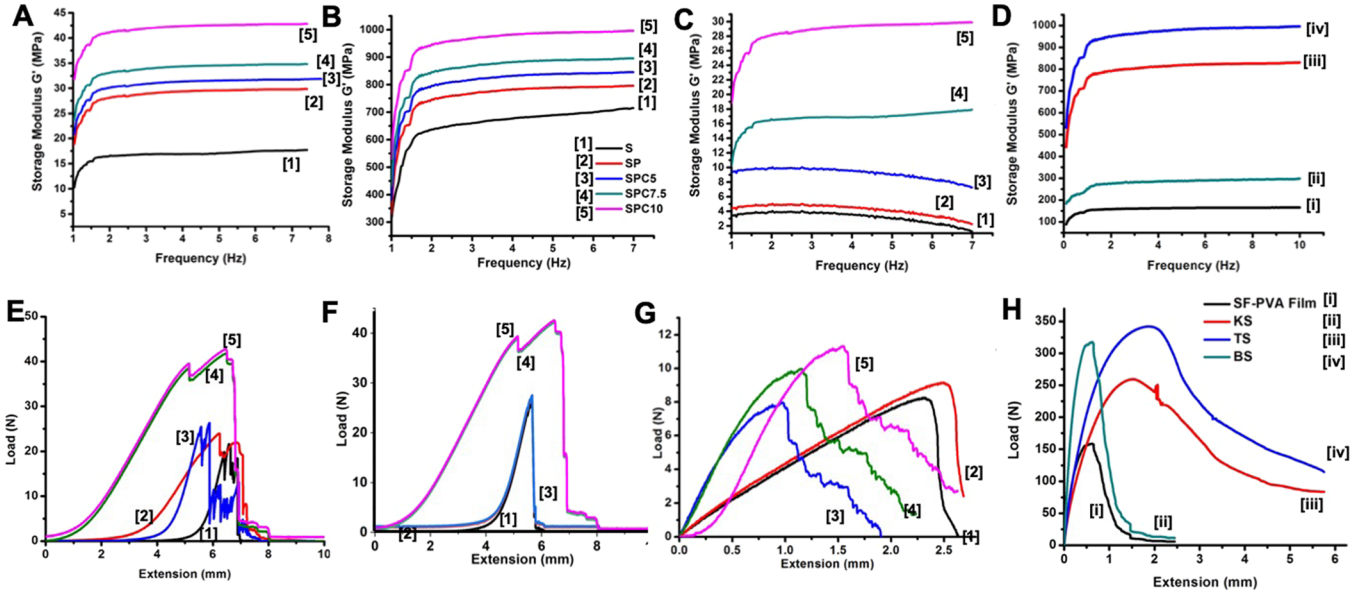

Figure 2. Mechanical characterization of the ANC. Storage moduli of the (A) KS, (B) TS, (C) BS, and (D) assembled nerve conduits (outer coating and 10% CNF-based coated inner structures) and tensile properties of the (E) KS, (F) TS, (G) BS, and (H) assembled nerve conduits (outer coating and 10% CNF-based coated inner structures).

https://dx.doi.org/10.1021/acsabm.0c00430
ACS Appl. Bio Mater. XXXX, XXX, XXX−XXX

and BS, respectively, with 10% CNF-based samples (Figure 2D−F).

The mechanical properties of the assembled ANCs including the outer wall and inner cores (10% CNF-based coated structures) are shown in Figure 2D,H. The storage modulus of the outer wall of the ANC was 165 ± 0.4 MPa at a frequency of 10 Hz. The storage modulus was improved significantly compared with inner core structures when assembling ANCs with KS, TS, and BS inner cores and SF-PVA film as an outer layer. The highest storage modulus of the assembled ANC was achieved by TS and KS, 995 ± 0.8 and 885 ± 0.6 MPa, respectively (Figure 2D). The same trend was observed in tensile properties of assembled ANCs (Figure 2H).

The storage modulus was found to be varying in ANCs with various inner core structures. This proves that structural changes in the inner structure of the ANC affect the final properties of the ANC even if they are all made of the same polymer combinations. All the developed ANCs showed comparable mechanical properties to native tissue. However, it is evident from the results that the TS has the highest storage modulus compared to the KS and BS due to the more flexible structure and less interlock between the filaments, which helps in moving filaments without deformation. It means that the strength of the TS is the strength provided by the twisted filaments. Addition of CNF has an effect on storage moduli in the samples. As the concentration of CNF increased, the mechanical properties of samples increased significantly. Figure 2D shows the storage moduli of assembled SF-PVA-wrapped KS, TS, and BS. The impact of SF-PVA wrapping in the different inner core structures on the mechanical property is significant. The storage moduli of TS and KS were found to be highest compared with that of the BS. In summary, this high mechanical property of the assembled ANC can resist muscular contractions and withstand its original shape for a long period after implantation in the body.

Tensile strength is another important mechanical property of the nerve conduit as nerve tissue experiences tensile stress during joint movement, and it was reported that the nerve elongates 1 mm per day, which shows remarkable changes in electro-physiochemical properties of nerve tissue.[38] Femoral lengthening in the range of 0.5−1.5 mm per day reduced the signal transduction ability in sciatic nerves of a rat up to 22−47%.[39] In this scenario, it is very crucial to consider the tensile properties of the inner core in fabricating the assembled ANC. In this study, all ANCs developed with various inner core structures showed remarkable tensile properties. The impact of CNF and structure on the tensile property of the developed ANC is shown in Table 2. The samples with 10% CNF showed the highest tensile property compared to other concentrations irrespective of the inner core structure. Among the different inner core structures studied, the TS showed maximum tensile strength. TS, KS and BS samples with 10% CNF showed maximum loads of 52.4 ± 3.9 (6.7 mm), 40.5 ± 3.2 (6.6 mm), and 12 ± 1.7 N (1.5 mm), respectively, while the tensile property of the human cadaver median nerve was reported to be around 2 N with 7.5 mm extension.[40] Therefore, TS and KS showed superior tensile properties to native tissue. Furthermore, the maximum tearing load is about 343 ± 2.8 N for the TS wrapped with the SF-PVA film compared to all other samples. Thus, the assembled ANC with the TS inner core showed superior mechanical properties.

3.3. In Vitro Cell Culture Studies. In vitro cell culture studies on the developed ANC (inner core) showed promising results. The ANC topography, fiber arrangement, and its microarchitecture had an impact on cell proliferation and growth. The viability of Neuro 2a cells was quantitatively estimated using the MTT assay (Figure S3A). From this study, the nontoxicity of the developed ANC was confirmed. All the developed assembled ANCs showed a viability of >80%, which demonstrates the suitability of SF-PCL-CNF-based ANCs as nerve conduits. The rate of cell proliferation was measured using the DNA estimation method by means of Hoechst staining. To study how Neuro 2a cells proliferate in the developed ANC, cells were allowed to grow on the developed ANC, and at different time intervals, DNA was estimated (Figure S3B−D). The Neuro 2a cellular proliferation profile in the developed ANC increased as the days increased. The effect of CNF on the cellular proliferation was clear in this study: as the concentration of CNF was increased, the cell proliferation rate was also found to be in an increasing trend. At the end of day 10, the SPC10 KS structure showed the highest viability of 115.2 ± 0.3% (Figure S3B). This result was found to be statistically significant for the cell proliferation rate ($p < 0.05$) compared to other structures. In the case of TS and BS, cell viability percentages were around 90.8 ± 0.5 and 105.23 ± 0.6%, respectively. Thus, the results show that the structure of the ANC has an influence on cellular proliferation. Day 10 samples were processed for SEM and confocal microscopic imaging. From the SEM images, it was clear that Neuro 2a cells were able to attach and proliferate on the surface of the developed ANC (Figure S4). The ANC with the KS inner core, arrangement of microchannels, and pores in its architecture can help in guiding the cells to spread in a better way than those with TS and BS structures. KS and TS structures showed promising results in SEM imaging (Figure S4C) compared to SP, SPC, and SPC10 BS. Neuro 2a cells flourished in the interconnected walls of the KS structure giving a thin layer on its surface. Figure S4F shows the morphology of Neuro 2a cells attached on the SPC10 KS structure. From the figure, nerve cell axonal projections are clearly visible. Developed structures were found to be efficient enough for nerve cell differentiation factors or growth factors. These results were in line with phalloidin- and Hoechst-stained confocal images of cells seeded on TS and BS artificial nerve conduits for day 10 samples (Figures S5 and S6, respectively). On day 10, the Neuro 2a cells covered the surface of the ANC with the KS inner core with a thin layer (Figure 3). The SPC10 KS showed interconnected nerve cell proliferation. This provides support for the efficiency of microchanneled structures with sufficient porosity for cell attachment and proliferation. The TS showed the highest mechanical property compared to the KS and BS. However, the cell attachment and proliferation were found to be the best for the KS inner core structure. The sample with 10% CNF showed the highest cell proliferation rate compared to other concentrations.

Primary cortical neural progenitor cells were successfully isolated from the rat and cultured on the KS SPC10 artificial nerve conduit (Figure S7). At the end of day 7, the samples were stained with calcein to stain live cells. Cells were found to attach and proliferate on the artificial nerve conduits, which confirm the cytocompatibility of the ANC with primary neural progenitor cells. Therefore, the KS SPC10 artificial nerve conduit was found to be a potential structure for nerve tissue engineering applications and further studied in vivo.

3.4. In Vivo Animal Studies. Figure 4 shows the total procedure of ANC implantation in a rabbit model and the

ACS Appl. Bio Mater. XXXX, XXX, XXX−XXX

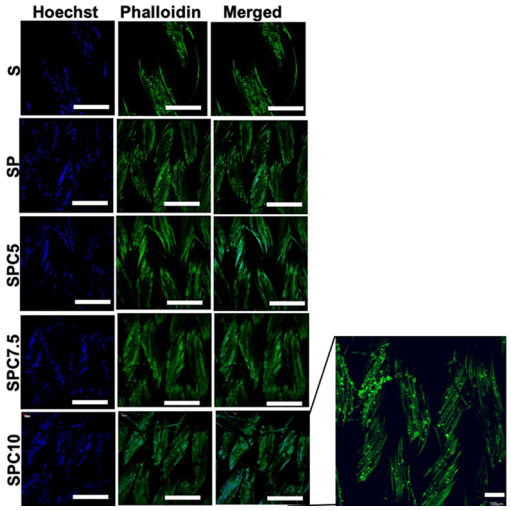

Figure 3. Confocal microscopic images of Hoechst- and phalloidin-stained cells seeded on knitted conduit structures (KS) on day 10 (scale bar − 100 μm).

confocal and SEM images. After implantation, the rabbit's limb movement was gradually improved, and at the end of day 30, the implanted ANC along with regenerated tissue was removed and subjected to microscopic studies, histology, and IHC. After 30 days of implantation, the ANC was found to be intact, and a thin layer of fibrous tissue was covered around the ANC (Figure 4). During removal of the ANC, the gap was found to be bridged by the regenerated nerve. The results from in vivo animal studies confirmed that the KS inner core with 10% CNF (SPC10) nanocomposite-coated silk can be a potential artificial nerve conduit with good nerve regeneration and can bridge the gap.

Confocal microscopic imaging and SEM were performed on the surgically removed implanted conduits to study the in vivo cellular proliferation on the implanted ANC and compared with the healthy control sciatic nerve (Figure 4). Primary nerve cells of the rabbit were found to migrate and proliferate on the inner core of the artificial nerve conduit as shown in Figure 4. The neural continuity was achieved in the neonerve within 30 days compared to the control nerve as seen in the confocal

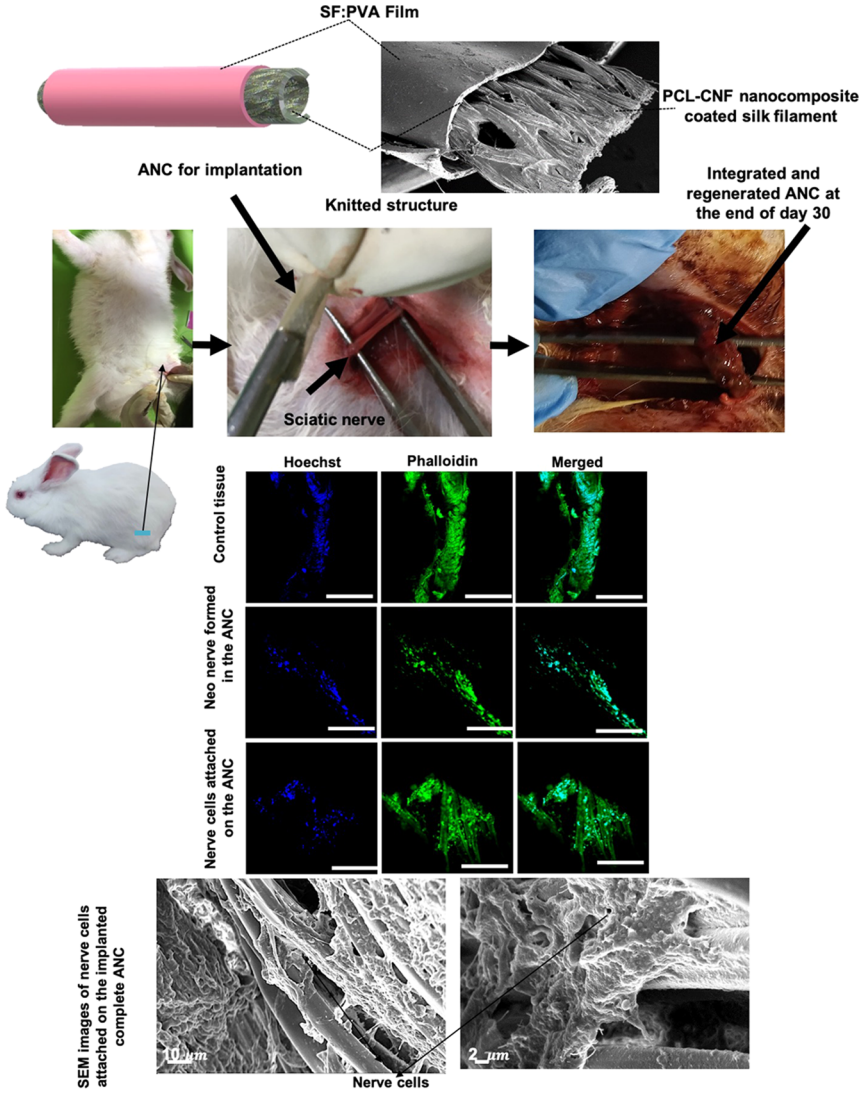

Figure 4. Depicting in vivo rabbit model studies. ANC before implantation in the sciatic nerve and at the end of day 30 of implantation. Confocal images of control tissue, regenerated neotissue from the implanted ANC, and primary cells adhered on the ANC (scale bar − 100 μm). SEM images depict the primary rabbit cells adhered on the ANC.

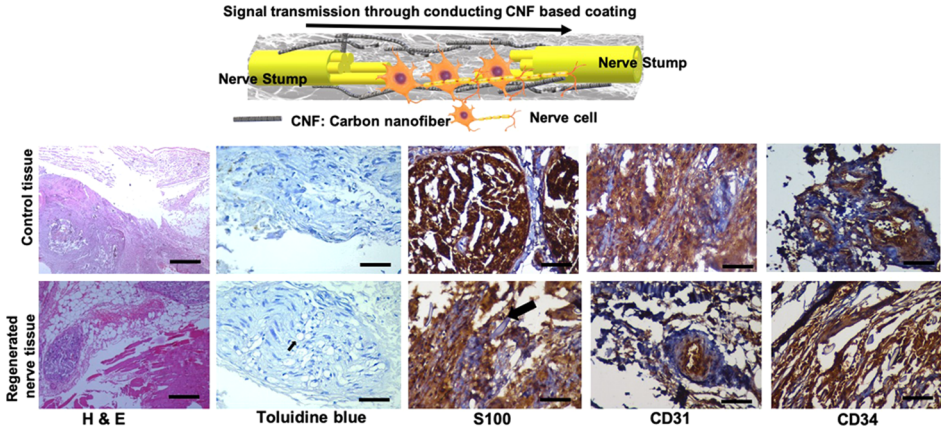

Figure 5. Neural regeneration in the presence of conducting CNF coating. Microscopic images of histology IHC to compare nerve regeneration in control tissue and regenerated nerve using H&E, toluidine blue, S-100, CD 31, and CD34 staining (scale bar − 100 μm).

images. The inside surface of the excised ANC was also subjected to confocal and SEM imaging (Figure 4) that proves the efficiency of developed scaffolds for in vivo nerve regeneration. The cells attach, grow, and proliferate on the inner core of the nerve conduit. The cell attachment and elongated cellular morphology with an extended axon-like structure are clearly visible. CNF plays a major role in signal transmission and helps the subject to move his limb during the regeneration period. The regenerated nerve shows directional growth comparable to the control nerve. Nerve ends are connected at a distance of 2 cm, and almost full diameter of the neonerve was achieved in 30 days.

Further, the histological assessment of removed tissue from the ANC using H&E staining showed the regenerated nerve along with adjacent connective tissue and blood vessels (Figure 5). This was confirmed using toluidine blue staining, which showed the myelinated axons in the regenerated nerve bundle. S-100 staining confirmed the peripheral nerve regeneration with Schwann cell expression. CD 31 and CD 34 depicted the angiogenesis in the regenerated nerve tissue. Histological assessment using H&E and toluidine blue staining of the excised ANC along with regenerated nerve tissue (ANC-implanted nerve) showed promising results as the H&E staining showed the regenerated nerve bundles along with the surrounding tissues. This depicts that the developed ANC was compact enough, outer layer with low porosity, to prevent invasion of connective tissues, which can interfere with the nerve regeneration. The outer wall (SF-PVA film) of the ANC provided an important barrier for the nerve regeneration as well as preventing the surrounding cells to invade the ANC. In toluidine blue staining, myelinated nerve bundles were detected, which confirms the nerve regeneration in the implanted KS-ANC. The toluidine blue stain is a metachromatic stain especially for myelinated nerve bundles. Toluidine blue staining gives clear visuals of the myelinated sheath established by the presence of a circular ring, which is clear in Figure 5 (toluidine blue staining). The circular nerve bundles in the regenerated nerve sample are a remarkable result in a short period of time. In the case of control, it showed mature tissue with collagen bundles. Similar observation was also reported by Iijima et al.[41] and Zhao et al.[42] S-100 is a reliable marker to identify nerve fragments and plays an important role in regeneration of defective nerves as an emergency response to proliferate Schwann cells.[43] In Figure 5, for S-100 staining, closed nerve fragments were visible (labeled with an arrow), which shows the regenerated nerve. Such a fragmented nerve is absent in the control tissue as it is a mature tissue. Thus, the IHC result of S-100 depicts functional recovery of the nerve tissue via bridging the gap by proliferation of Schwann cells. CD 31 and CD 34 positive expression reveals the angiogenesis in the regenerated nerve tissue.[44,45] In CD 31 and CD 34 staining in the case of the regenerated nerve, neovascularization was detected with the appearance of small vessel-like structures. However, in the case of control tissue, such neovascularization was absent. Thus, CD 31 and CD 34 expression proves that the developed ANC is robust enough for angiogenesis.

The KS structure showed good cytocompatibility after seeding with primary cortical neurosphere cells (Figure S7). This confirms that primary mice neurosphere cells were able to proliferate and attach without any additional growth factors, which is a good confirmation for the cytocompatibility of primary cells.

Cytocompatibility studies proved that the developed ANC was nontoxic to Neuro 2a cells (Figure S2A). Furthermore, the biocompatibility of SF:PVA (3:1) nanofibers and cryogels was studied by Pillai et al. and Wang et al.[12,25] and was found to be safe for primary cell attachment and proliferation. From the DNA estimation study, it was observed that CNF has an impact on enhancing cell proliferation rates. It was observed that, as the concentration of CNF increased, the cell proliferation was also found to be in an increasing profile irrespective of the inner core structure (Figure S2B−D). This proves the efficiency of CNF in enhancing the nerve cell communication and signaling process, which may lead to faster cell proliferation. Generally, the nerve has electric potentials of 60 to −100 mV in the resting stage, and during signal transmission, it has potentials of 70 to −55 mV (action potential),[35] which is used to communicate with other cells. Thus, the addition of a conducting material like CNF can enhance electric impulse transmission and can further help in cellular communication, which ultimately leads to cell proliferation. CNF also possesses biomimetic properties that gives nanotopography similar to native tissue and mimics the structure of collagen.[31] Therefore, it can provide an appropriate microenvironment for the cells to proliferate. The cell proliferation in the KS is better than those in other inner core structures in this study. Despite having a high mechanical property, the TS showed comparatively less proliferation ability, which may be due to its compact wire-

https://dx.doi.org/10.1021/acsabm.0c00430
ACS Appl. Bio Mater. XXXX, XXX, XXX−XXX

rope structure and reduced cell migration and penetration at the inner region of the developed ANC.

4. CONCLUSIONS

The main aim of this study was to analyze the structural effect of the inner core of the nerve conduit on physical and biological properties of assembled ANCs. The SF-based nanocomposites with various inner structures, including KS, TS, and BS, were developed by wrapping the inner cores with the SF-PVA film to assemble the ANC. Among the three structures, the knitted structured ANC showed excellent properties comparable to native tissue such as low swelling, good porosity, mechanical property, and in vitro cytocompatibility. In vivo studies in New Zealand white rabbits in the transected sciatic nerve demonstrated good rehabilitation with almost normal limb movements within 30 days. The regenerated neonerve was found to be comparable to the control. Thus, without any additional growth factors and tube filling gels, the developed KS structure was found to be promising for regeneration of nerve tissues.

Abstract

Aims

We aimed to assess the incidence of the BRAF V600E mutation in thyroid neoplasms at a tertiary care center and its association with various phenotypic features.

Methods and material

We included all cases diagnosed as thyroid neoplasm in the past decade at the Department of Pathology of our institute and obtained their clinical details from the medical records department of the institute after obtaining permission from the authorities and due International Human Epigenome Consortium clearance. We included data on age, sex, clinical presentation, hormone status, and T and N status of the malignant neoplasms. Hematoxylin and eosin (H&E) slides of all cases were evaluated for the type of neoplasm, nuclear features, invasion into the capsule and vascular spaces, extrathyroidal extension, lymph node metastases, mitoses, necrosis, and presence/absence of amyloid. Paraffin blocks of sections with high tumor density and less normal tissue were chosen for evaluation after H&E staining. The slides showing tumors with large areas of hemorrhage, cystic change, or necrosis were excluded. Two primers were used to amplify a 339-bp fragment containing the V600E mutation in exon 15 of BRAF. Tissues were prepared from formalin-fixed paraffin-embedded (FFPE) blocks, and DNA was isolated using a standard protocol BRAF NF and BRAF NR Primer Standardized Protocol For FFPE Tissue DNA. Percentages and tables have been used for data presentation.

Results

Among 47 identified cases, 14 were positive for the BRAF V600E mutation and had papillary carcinoma (n = 9) or follicular neoplasms (n = 5; follicular adenoma, n = 3; follicular carcinoma, n = 2). In the BRAF-positive papillary carcinomas, five cases were aged 20-30 years, eight were female, eight (88.88%) were euthyroid, and one was hypothyroid. Furthermore, 55.55% (5/9 cases) of BRAF-positive cases were stage I, 33.3% (3/9 cases) were stage II, and 0.02% (1/9 cases) were stage III.

Conclusions

In our cohort, 31% of cases of papillary thyroid carcinoma (PTC) and 18.72% of follicular neoplasms expressed the BRAF V600E mutation.

BRAF V600E mutation-positive papillary thyroid carcinomas consistently showed all characteristic nuclear features, such as nuclear crowding, overlapping, and grooves.

Considering the greater prevalence in the younger age group, the importance of mutation surveillance in PTCs for a total thyroidectomy may be warranted in mutation-positive patients.

Introduction

Thyroid cancers account for approximately 1% of all malignancies and are one of the most common malignancies of the endocrine system [1,2]. The development of malignancy in the thyroid is influenced by both environmental factors as well as genetic factors. Specifically, the thyroid is vulnerable to genotoxic effects of radioactive iodine and nongenotoxic effects (thyroid-stimulating hormone stimulation) of iodine

deficiency both of which can lead to neoplastic lesions in the thyroid [3].

Most thyroid tumors can be diagnosed based on morphological assessment and immunohistochemical findings [4,5] As altered gene expression can be discovered before morphological changes, knowledge regarding the genetic background helps in understanding thyroid carcinogenesis and facilitates the planning of appropriate therapeutic strategies and development of drugs that target specific molecules.

Thyroid tumors are classified based on the 2004 World Health Organization guidelines [3]. Recently, the RAS-RAF-MAP kinase signaling pathway has been implicated in many cancers, particularly more frequently in thyroid carcinomas, with the BRAF V600E mutation playing a vital role in papillary thyroid carcinoma. Furthermore, the BRAF mutation is specific for papillary carcinoma, is associated with poorer outcomes, and is frequently noted in high-grade tumors [6-8]

BRAF: an overview

BRAF is a serine-threonine kinase belonging to the family of RAF proteins. It acts upstream of MEK1/2 kinases in response to RAS signals. BRAF mutations are involved in early thyroid carcinogenesis and are somatic genetic alterations rather than germline mutations [9,10]. BRAF mutations occur early and play an important role in the pathogenesis of papillary thyroid carcinoma (PTC). Point mutations of BRAF are the most common types of mutations and occur in approximately 40%-45% of cases [11,12]. Other studies have reported [13,14] BRAF mutation rates of 35%-69% in PTC. The most common BRAF mutation is V600E, which is from missense thymine (T) to adenine (A) transversion at nucleotide 1799 in exon 15. This results in the substitution of valine by glutamate at residue 600. A less common mutation is the K601E mutation found in thyroid cancer [15,16]. Structurally, the RAF protein is divided into two functional domains, namely, the N-terminal and C-terminal regulatory domains, with three conserved regions (CR 1,2, and 3). CR1 and CR2 are present in the N-terminal domain and CR3 in the C-terminal domain [17].

Normally, RAS proteins are attached to the plasma membrane on the cytoplasmic side of the cell, endoplasmic reticulum, and Golgi membrane and are activated by growth factors binding to receptors at the plasma membrane. In an inactive state, RAS proteins bind to guanosine diphosphate (GDP), and upon activation, exchange GDP with guanosine triphosphate (GTP), leading to a conformational change that produces active RAS [2]. This activated RAS binds to the RAS-binding domain in CR1 of RAF, recruits RAF to the membrane, and activates a downstream signaling cascade wherein RAF phosphorylates mitogen-activated protein kinase (MAPK) [17]. Extracellular signal-regulated kinases 1 and 2 (MEK 1 and 2) become activated, which consecutively phosphorylate and activate extracellular signal-regulated kinases 1 and 2 (ERK 1 and 2). Activated ERK migrates to the nucleus where it activates various transcription factors that trigger cell cycle progression and result in cell proliferation and differentiation [8]. The RAF protein has three isoforms, ARAF, BRAF, and CRAF. Among these, BRAF is the most common isoform and most commonly mutated isoform because it has higher basal kinase activity [17] Additionally, BRAF protein expression is higher in hematopoietic cells, neurons, and testicles; is the predominant isoform [18,19] in thyroid follicular cells; and is the most potent activator of the MAPK pathway. Gain-of-function BRAF mutations function as an alternate pathway for aberrant activation of ERK signaling, resulting in constitutive activation of BRAF kinase, i.e., it can phosphorylate MEK as monomers in a RAS-independent manner. Such chronic stimulation of the MAPK pathway results in increased proliferation but reduced survival and differentiation of cells [11]. This signaling cascade is implicated in the etiology of several human cancers including malignant melanoma; thyroid, colorectal, and ovarian carcinomas; and carcinomas of the biliary tract, ovary, and cervix [9,20]

BRAF expression in thyroid carcinomas

Thyroid malignancies are predominantly diagnosed based on morphological assessment alone, and an immunohistochemical study is beneficial in confirming the diagnosis and establishing prognosis if tumor(s) exhibits unusual patterns. A significant improvement has been noted in the knowledge of molecular alterations over the past two decades in all tumors, including thyroid malignancies, and oncogenic BRAF activation represents one of the most prevalent molecular alterations. Reportedly, BRAF mutations are associated with poorer clinicopathological outcomes [21,22]. Among its various subtypes, BRAF most commonly occurred in the tall cell variant of PTC, followed by conventional PTC, and less commonly in the follicular variant of PTC. The tall cell variant is the most aggressive tumor, indicating that BRAF mutations are associated with poorer outcomes [9,23]. Other factors associated with the mutation and aggressive tumor phenotype include older age, extrathyroidal tumor invasion, lymph node, and distant metastasis, higher tumor stage, and poorly differentiated cancer [21,22,24-26].

Frasca et al [27] found that the presence of the BRAF V600E mutation in PTC is associated with aggressive tumor behavior and that tumor aggressiveness is independent of tumor size, suggesting that even small BRAF-positive tumors carry a higher risk of progression and invasiveness than BRAF-negative tumors.

BRAF mutations can be readily tested on thyroid tissue samples obtained by fine-needle aspiration with high preoperative clinicopathological prognostic capabilities in PTC. However, they have limited diagnostic value because [28-30] of low sensitivity in cytologically indeterminate specimens that are mostly non-PTC

and therefore do not harbor the BRAF mutation. Nonetheless, controversies regarding BRAF mutations with poorer clinicopathological outcomes in papillary thyroid cancers have been reported in some studies [31,32]. In the thyroid, apart from papillary carcinomas, BRAF mutations are expressed in anaplastic carcinoma and poorly differentiated carcinoma (prevalence, 20%-30%, and 10%-15%, respectively).

BRAF-mutated, poorly differentiated, anaplastic carcinoma will have a papillary component, suggesting that these tumors progress from BRAF-positive papillary carcinoma [33-36]. The BRAF V600E mutation is not found in follicular thyroid cancers and benign thyroid nodules [23]. However, the other BRAF mutation, K601E, has been detected in follicular adenoma, carcinoma, and follicular variants of PTC. However, Kebebew et al reported a BRAF V600E mutation in one case of follicular carcinoma [22]. Newly developed mitogen extracellular kinase (MEK) inhibitors are particularly promising therapeutic agents for thyroid cancer. With these advances, it has become clearer that BRAF mutation will likely have a significant impact on the clinical management of PTC. Thus, this study aimed to assess the incidence of the BRAF V600E mutation in thyroid neoplasms at a tertiary care center and its association with various phenotypic features.

Materials And Methods

We included all cases diagnosed as thyroid neoplasm in the past decade at the Department of Pathology of our institute and obtained their clinical details from the medical records department of the institute after obtaining permission from the authorities and due International Human Epigenome Consortium clearance (IRB number/Proposal number: 10/098). We included data on age, sex, clinical presentation, hormone status, and T and N status of the malignant neoplasms. Hematoxylin and eosin (H&E) slides of all cases were evaluated for the type of neoplasm, nuclear features, invasion into the capsule and vascular spaces, extrathyroidal extension, lymph node metastases, mitoses, necrosis, and presence/absence of amyloid. Paraffin blocks of sections with high tumor density and less normal tissue were chosen for evaluation after H&E staining. The slides showing tumors with large areas of hemorrhage, cystic change, or necrosis were excluded. Two primers were used to amplify a 339-bp fragment containing the V600E mutation in exon 15 of BRAF. Tissues were prepared from formalin-fixed paraffin-embedded (FFPE) blocks, and DNA was isolated using a standard protocol BRAF NF & BRAF NR Primer Standardized Protocol For FFPE Tissue DNA (Figures *1*-*4*). Percentages and tables have been used for data presentation.

Results

Of the 50 identified cases, DNA could only be extracted from 47 because extraction proved futile in the remaining three cases (Table *1*).

TABLE 1: Master chart showing demographic variables, morphologic subtype of thyroid neoplasms, stage, and mutant status.

PTC: papillary thyroid carcinoma; FN-LMP: follicular neoplasm - low malignant potential

Only 14 cases were positive for the BRAF mutation; of these, nine were of papillary carcinoma (Figure *5*).

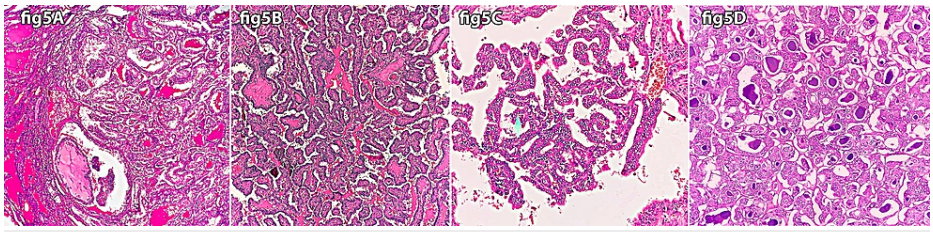

FIGURE 5: Papillary thyroid carcinoma H&E stain (A x10, B x20, C x20, D x20).

A, B, C: Papillary thyroid carcinoma - Showing characteristic papillary architecture, characteristic nuclear features with ground class chromatin, nuclear grooving, nuclear crowding, nuclear overlapping, and intranuclear cytoplasmic pseudo-inclusions.

D: Papillary thyroid carcinoma (follicular variant) - Showing prominent follicular architecture with characteristic nuclear features with ground class chromatin, nuclear grooving, nuclear crowding, nuclear overlapping, and intranuclear cytoplasmic pseudo-inclusions.

Out of the 14 BRAF-positive cases, five were follicular neoplasms, with the latter category comprising three cases of follicular adenomas and two of follicular carcinomas (Tables *1*, *2*) (Figure *6*).

Types of neoplasms	BRAF V600E positive - mutant type (%)	Wild type (%)	Total
Papillary carcinoma: (Conventional papillary thyroid carcinoma - 8 cases) (Encapsulated follicular variant of papillary thyroid carcinoma - 1 case)	9 (31%)	20 (69%)	29
Follicular neoplasm: (Follicular adenoma - 3 cases) (Follicular carcinoma - 2 cases)	5 (31.25%)	22 (68.75%)	16
Medullary carcinoma	0	1 (100%)	1
Anaplastic carcinoma	0	1 (100%)	1
Total	14 (29.8%)	33 (70.2%)	47

TABLE 2: Break up of BRAF V600E-positive cases (n = 47).

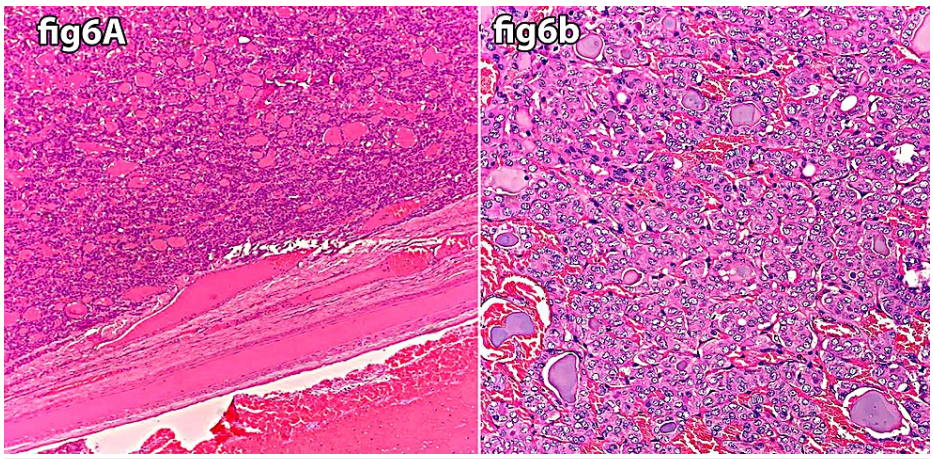

FIGURE 6: Follicular adenoma H&E stain (A x20, B x40).

A: Follicular adenoma showing marked circumscription and encapsulation.

B: Follicular adenoma showing a prominent repetitive microfollicular pattern.

The nine cases of BRAF-positive papillary carcinomas predominantly comprised individuals aged 20-30 years (Tables *1*, *3*), were almost all female (8/9) (Tables *1*, *4*), and were euthyroid (8/9, 88.88%) (Tables *1*, *5*).

Age group	Number of cases
20–30 years	5
31–40 years	1
41–50 years	1
51–60 years	1
61–70 years	1

TABLE 3: Number of BRAF-positive papillary thyroid carcinoma and age distribution.

Male	Female
One case	Eight cases

TABLE 4: BRAF-positive carcinomas and sex distribution.

Number of BRAF-positive cases	Hormonal status
8	Euthyroid
1	Hypothyroid

TABLE 5: BRAF-positive papillary thyroid carcinoma and hormonal status.

Next, eight of the nine cases were euthyroid (88.88%), whereas one was hypothyroid (Tables *1*, *5*). Additionally, 55.55% of BRAF V600E-positive cases were found to be stage I (5/9 cases), 33.33% to be stage II (3/9 cases), and 11.11% to be stage III (1/9 cases) (Tables *1*, *6*).

BRAF-positive papillary thyroid carcinoma staging	Number of cases
Stage I	5
Stage II	3
Stage III	1
Stage IV	0

TABLE 6: BRAF-positive papillary thyroid carcinoma stage at presentation.

Scoring for nuclear and other microscopic features revealed characteristic features compared with other features observed for BRAF-positive papillary carcinomas (Tables *7*, *8*). The scoring was done on a relative qualitative double consensus scale based on mild (Score 1), moderate (Score 2), and severe (Score 3) appearance of the nuclear features.

Histologic nuclear feature	Mild	Moderate	Severe
Nuclear enlargement (NE)	1	2	3
Nuclear irregularity (NI)	1	2	3
Chromatin clearing (CC)	1	2	3
Nuclear crowding (NC)	1	2	3
Nuclear grooves (NG)	1	2	3
Nuclear pseudoinclusions (PI)	1	2	3
Fibrosis (Fib)	1	2	3
Psammoma bodies (PB)	1	2	3

Discussion

The BRAF V600E mutation is most often expressed in stage III (30%). Importantly, its expression, particularly in the early stages, indicates an aggressive course and warrants a total thyroidectomy, whereas its expression in the later stages is associated with poor outcomes.

In our group of 30 papillary carcinoma cases, DNA could be extracted from 29 and only nine expressed the BRAF V600E mutation. Its prevalence is lower than that reported in the literature, i.e., 40%-45% of PTCs harbor the mutation.

We found that five of the nine cases of BRAF V600E-positive papillary carcinoma were in the 20-30-year age group. Rossella et al found that V600E was expressed more in an older age group [6]. Given the greater prevalence in the younger age group, the importance of mutation surveillance in PTCs for a total thyroidectomy may be warranted in mutation-positive patients.

We found five cases of stage I (55.55%) and three cases of stage II (33.33%) showing BRAF positivity, indicating a significantly higher expression in stages I and II lesions. Therefore, we reanalyzed the reports of PTC.

This high incidence of V600E mutation can be explained by the fact that at a tertiary care hospital, the radiologist and cytopathologist could probably detect PTC at an early stage. Furthermore, the strongest argument against using BRAF mutation as an independent prognostic and predictive factor in PTC is its high prevalence (30%-80%). As the V600E mutation is associated with poor outcomes, these patients require very close follow-up. We found no correlation between nuclear features and BRAF V600E mutations; however, the characteristic nuclear crowding, overlapping, and grooves were consistently observed (Tables *6*, *7*).

The incidence of the BRAF V600E mutation in follicular neoplasms was 31% (five out of 16 cases). In contrast, the literature shows that the V600E mutation is rarely seen in follicular neoplasms, with very few reports that have identified this mutation in follicular neoplasms with minimal incidence [37]. Therefore, a reanalysis of routine H&E slides identified two cases of focal papillary architecture with nuclear features, which might have been overlooked during the morphological assessment. Despite their exclusion, the percentage incidence of the V600E mutation in follicular neoplasm was 18.72% (three out of 16 cases). Nonetheless, papillary carcinoma, particularly the microfollicular type, was possibly missed on routine evaluation as specimens were not extensively sampled, rather were only drawn from the most representative areas of the lesion.

Overall, we show that a significant number of cases of papillary carcinoma (31%; 9/29) and follicular neoplasms (18.7%; 3/16) express the V600E mutation. A larger prospective study, including preoperative cytology specimen and surgically resected specimens of the same patients, is needed to establish the utility of the V600E mutation as a routine diagnostic tool. After development, the primers would be cost-effective

to patients.

An increase in the incidence of papillary carcinoma in areas where there is high iodine intake has been reported [3,38,39] and there is high iodine supplementation to correct iodine deficiency, particularly in the population with an existing V600E mutation. This raises the question of establishing dietary iodine supplementation levels to prevent the incidence of non-neoplastic conditions including multinodular goiter. Furthermore, papillary carcinoma usually remains intra-thyroid and few cases may present with rapid onset of clinical manifestations with enlargement of multiple cervical lymph nodes [40]. Therefore, a larger, multicenter, prospective study that includes cytology specimens collected preoperatively and following surgical resection is essential to establish the relationship between the incidence of papillary carcinoma and V600E mutation in the background of iodine supplementation and deficiency and to prove the utility of BRAF in routine diagnosis. However, the most recent American Thyroid Association (ATA) recommendations do not indicate a routine application of BRAF status for initial risk stratification in differentiated thyroid cancer due to a lack of evident confirmation of a direct influence of mutation on the increase in relapse risk.

Further, considering the increase in the prevalence of the BRAF V600E mutation in follicular neoplasms, a larger study of the V600E mutation in follicular neoplasms is vital to observe changes in the expression patterns of mutations in the Indian population.

Conclusions

In our cohort, 31% of cases of PTC and 18.72% of follicular neoplasms expressed the BRAF V600E mutation.

BRAF V600E mutation-positive PTCs consistently showed all characteristic nuclear features, such as nuclear crowding, overlapping, and grooves.

Considering the greater prevalence in the younger age group, the importance of mutation surveillance in PTCs for a total thyroidectomy may be warranted in mutation-positive patients.

Basidiobolomycosis - Miss Me; It Hurts You

Murali Alagesan[1], Joel Franklin[2], J Jayalakshmi[3], TM Subba Rao[4], V Chaithra[5]

Abstract

Basidiobolomycosis is a subcutaneous infection of the limbs and trunk caused by *Basidiobolus ranarum*. It is one of the under diagnosed infection which usually occurs in tropical areas. High index of clinical suspicion is needed to diagnose this condition. We hereby report a case of basidiobolomycosis in a 25 year old male who presented to us with a non healing ulcer in left thigh. Biopsy showed granulomatous inflammation with fungal infection suggestive of phycomycosis. Fungal culture grew *Basidiobolus ranarum*. Patient was treated with oral itraconazole. The ulcer resolved completely after 3 months of treatment.

Introduction

Zygomycosis is an infection caused by fungal agents belonging to the phylum Zygomycota. These are saprophytic fungi and are found ubiquitously in the environment. The class Zygomycetes includes two fungal orders: Mucorales and Entomophthorales. They have different pathogenic potentials; the order Mucorales primarily affects the immunocompromised patients causing invasive diseases like rhino cerebral or pulmonary mucormycosis with high mortality, where as the order entomophthorales, which include *Basidiobolus* and *Conidiobolus* genera, cause chronic infection in the subcutaneous tissue in the immune competent individual.[1] Basidiobolomycosis is caused by the fungus *Basidiobolus ranarum*. Here we present a case of subcutaneous basidiobolomycosis which was misdiagnosed as mucormycosis by histopathological examination.

Case Details

A 25 year old male software engineer from Coimbatore was referred to us for intravenous amphotericin B, for the treatment of his non healing ulcer over the anterior aspect of left thigh as biopsy of the lesion was reported as mucormycosis. He had this lesion for the past 3 months which started as a painless nodular swelling (Figure 1A). He had consulted many clinicians earlier and was on multiple antibiotics, but his skin lesion progressively increased in size. He had no co-morbid illness and was apparently normal 3 month back. Ultra sonogram of the thigh was suggestive of abscess in subcutaneous plane. He underwent incision and drainage (I and D) of the abscess which resulted in a deep cavitatory lesion. Culture from the material during I and D was sterile. As the lesion was worsening (Figure 1B) he underwent another debridement. Gram's stain, AFB stain of the tissue didn't reveal any organisms and bacterial culture of the pus was sterile. Biopsy of the ulcer was performed and sent for histopathological examination (HPE). The HPE was reported as extensive ulceration and dense inflammation of dermis and subcutaneous area with fat necrosis and abscess formation composed of neutrophils and eosinophils along with thin walled broad aseptate fungal hyphae branching at right angles and surrounded by fibrosis and dense inflammation with giant cells. PAS stain was positive. Final report was foreign body granuloma with many fungal hyphae resembling mucormycosis. At this point we decided to re-evaluate the patient. On examination, he had a 3×1 cm linear non tender ulcer with surrounding induration on the left thigh (Figure 1C). His complete blood count showed total leukocyte count – 7400 (Neutrophils -50 %, Lymphocytes-34%, Eosinophils-4%, Monocytes-7%), ESR – 24 mm in 1 hour. His blood glucose, renal function test and liver function test were within normal limits. Human Immunodeficiency virus 1 and 2 were non-reactive. Since the history and clinical picture didn't fit with a diagnosis of mucormycosis (the morphology of the lesion, duration of the ulcer), a second opinion of the slide was sought. The histopathology description (Figure 2A, 2B, 2C) included the presence of granulomas in dermis and subcutis associated with the presence of numerous eosinophils. There were also scattered abscesses and eosinophilic material surrounding the fungal hyphae resembling Splendore–Hoeppli phenomenon. A probable diagnosis of subcutaneous phycomycosis was suggested with a comment that fungal culture was required for confirmation. Additional biopsy specimen was collected aseptically for fungal culture from the edge of the lesion. On Sabouraud's Dextrose Agar, furrowed creamy brown, heaped up, radially folded colonies grew after 3 days of incubation (Figure 3). Lactophenol cotton blue wet mount showed aseptate hyphae and smooth walled zygospores with characteristic conjugation beaks which confirmed the fungus to be *Basidiobolus ranarum* (Figure 4). After the diagnosis of basidiobolomycosis was confirmed, the patient was started on oral Itraconazole 200 mg once daily for 3 months. The ulcer healed slowly and complete resolution of the lesion (Figure 1D) was seen after 3 months.

Discussion

Basidiobolomycosis is caused by *Basidiobolus ranarum*, a saprophytic fungus present in soil, decaying fruit and vegetable matter as well as in the gut of amphibians and reptiles.[2] It can cause a variety of clinical manifestations including subcutaneous zygomycosis, gastrointestinal zygomycosis and occasionally an acute systemic illness. The subcutaneous form is a granulomatous infection of the skin and subcutaneous tissues characterized by the formation of firm, painless, disciform nodule generally on the

thighs and buttocks in a "bathing suit" distribution.[1] It mainly affects young, male and immunocompetent persons. It is usually transmitted by minor trauma which may be through insect bite, intravenous catheter, or even intramuscular injection. Clinically it starts as small hardened swelling over the extremities and progressively increases in size to form a painless, non tender swelling. Macroscopically it closely mimics a soft tissue tumor, synovial sarcoma, Burkitt's lymphoma or histopathologically mimics mucormycosis. The other differential diagnosis would be atypical mycobacterial infections, sporotrichosis and parasitic infections like oncocerciais.[3]

In our patient also it started as a small painless swelling and progressively increased in size. Even though the histopathology was reported as mucormycosis, the possibility of mucormycosis could be ruled out by the absence of features such as angio/tissue invasion and necrosis; and slow growing nature of the lesion. Laboratory diagnosis is mainly based on histopathological features and culture of the organism which is the "gold standard". Histologically, basidiobolomycosis is associated with eosinophilic infiltration; with short broad aseptate hyphae.[4] Some may be surrounded by an eosinophilic material which is called as 'Splendore – Hoeppli' phenomenon.[5]

Most patients with basidiobolomycosis respond well to oral itraconazole. The other treatment options are potassium iodide, trimethoprim-sulfamethoxazole. Some strains do not respond to amphotericin B. In the present case also the patient responded well to itraconazole and the ulcer got completely resolved after three months of treatment.

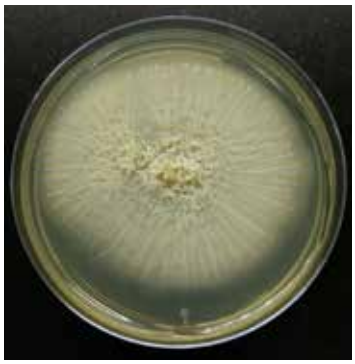

Fig. 3: Growth of basidiobolus ranarum on Sabouraud's dextrose agar appearing yellowish grey rugose and smooth colonies with a waxy texture on the obverse end

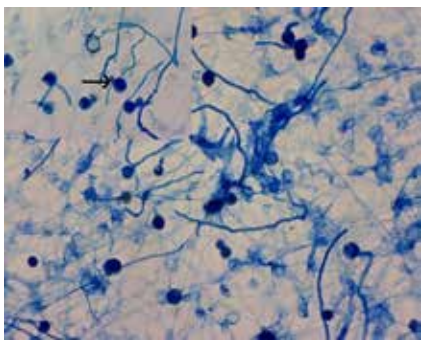

Fig. 4: Lacto phenol cotton blue staining of basidiobolus ranarum. Non septate broad hyphae and zygospores with conjugation beaks seen (Insert - arrow) X 400 magnification

Conclusion

This case is presented to insist on the importance of clinical correlation of histopathology reports along with proper sampling and appropriate microbiological test while treating rare infections.

Case Report

Erythrokeratoderma En Cocardes – A Rare Phenotype

P Arunprasath, Reena Rai, G Umamaheswari[1]

Departments of Dermatology and [1]Pathology, PSG Institute of Medical Sciences and Research, Coimbatore, Tamil Nadu, India

Abstract

Erythrokeratodermas are disorders of keratinization with two major types, namely erythrokeratodermia variabilis and symmetrical progressive erythrokeratoderma. Apart from the two main types, rare variants include erythrokeratoderma en cocardes (EEC), erythokeratoderma with erythema gyratum repens-like lesions, erythema annulare centrifugum-like lesions, and reticulate erythrokeratoderma. Herein, we report a rare case of EEC with associated palmoplantar keratoderma, the association which has not been described in previous reports.

Keywords: *En cocardes, erythrokeratoderma, palmoplantar keratoderma*

Introduction

Erythrokeratodermas are disorders of keratinization which encompass two main subtypes, namely erythrokeratodermia variabilis (EKV) and symmetric progressive erythrokeratoderma (SPEK) and other atypical rare variants.[1] Erythrokeratoderma en cocardes (EEC) is a rare variant characterized by polycyclic, concentric, and targetoid lesions along with erythematous plaques.[2]

Case Report

A 4-year-old boy born out of third-degree consanguineous marriage presented with multiple hyperpigmented scaly lesions involving the arms, forearms, back, gluteal region, thighs, and legs since 6 months of his age. There was a history of aggravation of lesions during cold season and improvement during summer. There was no history of atopy and other systemic symptoms. Milestones were achieved normally. There was no history of similar skin lesions in siblings or other family members.

Cutaneous examination revealed multiple scaly plaques with polycyclic borders involving the arms, forearms, thighs, and legs [Figures 1a,b and 2]. In the posterior aspect of the thigh, there were scaly plaques with polycyclic borders sparing of the popliteal fossa [Figure 3]. There were multiple discrete annular scaly plaques with concentric rings involving the forearms and thighs. Anterior aspect of legs showed diffuse ichthyosis extending to the dorsum of the feet [Figure 4]. Palms and soles revealed diffuse keratoderma with fissuring and scaling [Figure 5]. Examination of hair, nails, and teeth was normal. Systemic examination was essentially normal. Hematological examination did not reveal any abnormality. Scrapings of skin for potassium hydroxide mount were negative for fungal elements.

Histopathology revealed hyperkeratosis, focal mild parakeratosis, conspicuous granular layer, and irregular acanthosis. There were mild spongiosis and lymphocytic exocytosis. The papillary and upper dermis showed pigment incontinence, prominent capillaries, and a mild perivascular lymphohistiocytic infiltrate, a picture compatible with erythokeratoderma [Figure 6].

Owing to the distinct clinical morphology with annular lesions, polycyclic borders, and histopathological features, a diagnosis of EEC was entertained.

Discussion

Erythrokeratoderma has two variants: SPEK and EKV. SPEK is characterized by well-demarcated, hyperkeratotic plaques distributed symmetrically over the elbows, knees, dorsal aspect of the hands, feet, and buttocks, sparing the trunk. SPEK has its onset in infancy or early childhood.[3] EKV, on the other hand, manifests as two distinct clinical pictures: with generalized, erythematous, hyperkeratotic plaques in one and localized sharply demarcated

hyperkeratotic plaques in the other. EKV has its onset in birth or in neonatal period in 50% of patients and within 1st year of life in 90% of patients.[4]

Rare variants of EKV described include EEC, EKV with erythema gyratum repens-like lesions, EKV with

[Downloaded free from http://www.ijpd.in on Wednesday, July 1, 2020, IP: 103.196.30.49]

erythema annulare centrifugum-like lesions, and reticulate erythrokeratoderma.[4,5] Degos *et al*., in 1947, described EEC in a 13-year-old girl, a rare and atypical variant of EKV with polycyclic plaques, with concentric layers of scaling and erythema giving a targetoid, or "en cocardes" appearance.[6]

The index case described by Degos had an onset at birth, remissions and recurrences, desquamation of palm, similar skin lesions in father and paternal uncle pointing to autosomal-dominant inheritance, and improvement of skin lesions during summer.[7] The present case had onset during 6 months of age, without any family history and improvement during summer. Unlike the index case, the cases reported by Rajagopalan *et al*. and López-Ferrer *et al*. did not show improvement of lesions during the summer.[1,2] Furthermore, the present case showed prominent palmoplantar keratoderma, which has not been described in previous reports.[1,2,8]

Apart from EEC, differential diagnoses considered include annular type of epidermolytic ichthyosis, X-linked recessive ichthyosis, and SPEK. Unlike, in annular epidermolytic ichthyosis, there was no history of blisters and erosions at birth, and histopathology did not revealed any epidermolytic hyperkeratosis. X-linked recessive ichthyosis presents with dark brown ichthyotic scales with sparing of popliteal and antecubital fossa with associated cryptorchidism, autism, and deep stromal corneal opacity.[4] Although the present case had ichthyosis of legs with sparing of popliteal fossa, there were no associated systemic abnormalities. Tinea imbricata can be a morphological differential diagnosis, but the presence of skin lesions since 6 months of age and negative test for skin scrapings for fungus preclude the condition.

Histopathology cannot distinguish between the variants of erythrokeratodermas. Genetic studies show mutation in connexin genes in cases of EKV. Connexins are a family of transmembrane proteins that form gap junctions in the cells. These intercellular channels play an important role in cell growth, homeostasis, and epidermal differentiation.[4] Mutations in genes, namely GJB3, GJB4, and rarely GJA1 encoding the connexins, have been identified as the underlying pathogenesis in EKV.[3,9] In SPEK apart from GJB4 mutation, mutations reported include a frameshift mutation in loricrin gene, homozygous loss of function mutation in KRT83 gene, and mutation in KDSR gene which codes for an enzyme involved in ceramide synthesis.[3] López-Ferrer *et al*. have reported a case of EEC with missense mutation R32W in GJB3 gene.[1] Similar mutation in GJB3 gene had been reported in patients with palmoplantar involvement and deafness.[10] The present case had clinical lesions analogous to EEC and palmoplantar involvement but without any hearing impairment. However, genetic study for mutation analysis was not done due to resource constraints.

Treatment options include topical emollients, retinoids, salicylic acid, and corticosteroids. Systemic retinoid such as acitretin and isotretinoin shows good improvement, but with recurrence of lesions once the treatment is stopped.[8] Improvement with retinoids with psoralen and ultraviolet A therapy has been reported.[11] Since the disease is a genodermatoses, parents should be counseled regarding the chronic nature of the disease and the need for long-term follow-up. Treatment plan with acitretin was considered, but the patient did not report for follow-up.

The present case is highlighted for its distinct clinical picture and its association with palmoplantar keratoderma.

Declaration of patient consent

Author certify that they have obtained all appropriate patient consent forms. In the form the patients/parents have given their images and other clinical informations to be reported in the journal. The patients & parents understand that their/their children's names and initials will not be published and due efforts will be made to conceal their identity.

Abstract

Hemophagocytic syndrome or hemophagocytic lymphohistiocytosis (HLH) is a rare but potentially fatal disease caused by dysregulated activation of macrophages against one's blood cells. Major pathologic feature of HLH is hemophagocytosis. We present a case of HLH complicating methotrexate toxicity in a 65-year-old psoriatic patient with history of renal disease. Diagnosis of HLH was established as he fulfilled five out of eight HLH diagnostic criteria. This case report is presented to enlighten clinicians about the clinical entity of HLH and to suspect and recognize this rare and generally fatal disease at the earliest.

Keywords: *Cytopenias*, *hemophagocytic lymphohistiocytosis*, *hemophagocytic syndrome*

Introduction

Hemophagocytic syndrome or hemophagocytic lymphohistiocytosis is a clinical syndrome of hyperinflammation resulting in uncontrolled and ineffective immune response.[1,2] It may be primary or secondary. Primary HLH is a genetic entity. Secondary HLH is associated with infections, malignancies, immune disorders, or drugs.[2,3,4,5] In both types, activated macrophages engulf erythrocytes, leukocytes, platelets, and precursor cells in bone marrow, liver, and lymph nodes.[6] Most severe forms of the disease lead to a sepsis like picture and multiorgan dysfunction. HLH is a disease of rapid progression and has high mortality despite treatment.[3,7,8,9] We report a case of secondary HLH complicating methotrexate toxicity and sepsis.

Case History

A 65-year-old male, a case of chronic plaque psoriasis on intermittent therapy with methotrexate since 15 years and chronic kidney disease since 5 years presented with fever, severe body ache, and ulcerative lesions over lips and trunk. He developed these symptoms 5 days after inadvertent intake of tablet methotrexate 5 mg for 5 consecutive days. Examination showed tender inguinal and axillary lymphadenopathy, hemorrhagic crusting of lips, and necrotic ulcers over psoriatic plaques and as well as normal skin with severe skin tenderness and positive Nikolsky's sign. Since ulcers were present over

psoriatic plaques, methotrexate-induced skin necrosis was suspected. Histopathology findings were skin with detached stratum corneum, large subcorneal pustule [Figure 1a], mild spongiosis, marked regenerative atypia, basal vacuolar degeneration, pigment incontinence, and apoptotic keratinocytes [Figure 1b]. Routine investigations showed bicytopenia with hemoglobin of 9.6 g/dl, WBC of 600 cells/mm^3 with normal platelet count of 120,000 cells/mm^3. His renal function tests were altered with elevated urea (106 mg/dl) and creatinine levels (3.16 mg/dl). The patient was started on antibiotics, leucovorin rescue therapy (folinic acid 10 mg every 6^{th} hourly), and injection Filgrastim (Granulocyte colony-stimulating factor) 300 mg subcutaneously daily. There was worsening pancytopenia and renal function and further developed splenomegaly, features of sepsis. Blood culture was positive for Group B streptococci and methicillin sensitive *staphylococcus aureus* and procalcitonin levels were elevated (24.5 ng/ml). His antibiotics were upgraded and platelet transfusion given in spite of which patient developed fever, tachycardia, hypotension with further decrease in platelet count to 6,000 cells/mm^3 on 5^{th} day. Secondary HLH was suspected and a workup was rapidly initiated based on HLH 2004 diagnostic criteria. Peripheral smear revealed pancytopenia [Figure 2]. Bone marrow aspiration was done which showed megaloblastic erythroid maturation, maturation arrest in the myeloid series, and hemophagocytosis [Figure 3a and b]. Patient had hyperferritinemia (>500 mcg/L) with normal fibrinogen (522 mg/dl) and triglycerides (50 mg/dl) levels. He thus fulfilled 5 out of 8 diagnostic criteria of HLH and was treated as per HLH 2004 protocol with systemic antifungals and injection dexamethasone 10 mg/m^2. Despite all supportive measures, patient developed multiorgan dysfunction and succumbed.

Discussion

HLH is a rare disease characterized by cytokine overproduction and tissue infiltration with cytotoxic lymphocytes and activated macrophages resulting in fever, hepatosplenomegaly, and cytopenias.[1,2,9] A strict diagnostic criteria of HLH was given in 2004 by Histiocyte Society and is as follows.[9,10] Molecular diagnosis consistent with HLH that is the identification of mutations of PRF1, UNC13D, or STX11 or patient should fulfill five out of the eight criteria: fever (>100.4°F), splenomegaly, cytopenia affecting at least two of three lineages: Hb <9 g/dl (in infants <4 weeks: Hb <10 g/100 ml, platelets <100 × 10^9/L, Neutrophils <1 × 10^9/L), hypertriglyceridemia (fasting >265 mg/dl) and or hypofibrinogenemia (≤150 mg/dl), ferritin >500 ng/ml, hemophagocytosis in bone marrow, spleen, or lymph nodes, low or absent NK cell activity, soluble CD25 (soluble IL-2 receptor) >2400 U/ml and in the case of familial HLH there should be no evidence of malignancy.

This patient presented with features of methotrexate toxicity with skin necrosis, bone marrow suppression, and renal failure. His progressive pancytopenia was initially thought to be due to high dose methotrexate. He did not respond to leucovorin rescue therapy or injection Filgrastim and worsened clinically with features suggestive of sepsis due to which antibiotics were upgraded. He was evaluated for HLH as he had progressive pancytopenia unresponsive to treatment and decreased counts in spite of platelet transfusions. The major pathologic feature of HLH is hemophagocytosis as seen in our patient. It is also seen in conditions like sepsis and multiorgan failure.[3] There is considerable clinical and laboratory overlap between sepsis and HLH.[8,9] Diagnosis of HLH was established in our patient as he fulfilled five out of eight diagnostic criteria of HLH. This is a rare presentation of HLH complicating methotrexate toxicity. This case report is presented to enlighten clinicians about HLH inorder to reduce the mortality associated with the disease.

Declaration of patient consent The authors certify that they have obtained all appropriate patient consent forms. In the form the patient(s) has/have given his/her/their consent for his/her/their images and other clinical information to be reported in the journal. The patients understand that their names and initials will not be published and due efforts will be made to conceal their identity, but anonymity cannot be guaranteed.

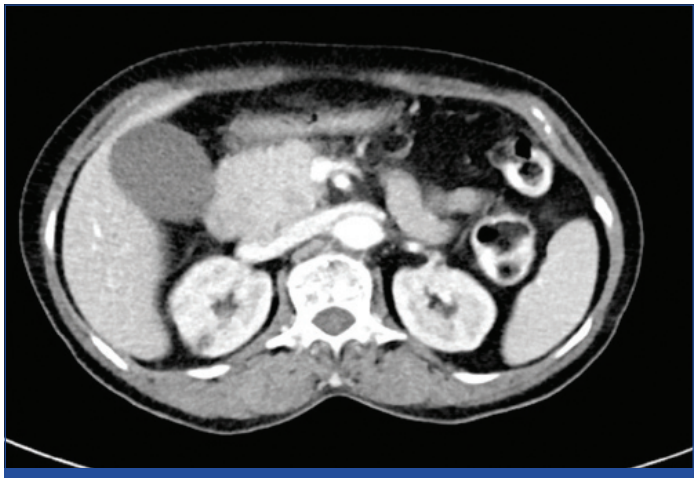
Pancreatic Plasmacytoma Misdiagnosed as Neuroendocrine Tumour: A Pathologist's Dilemma

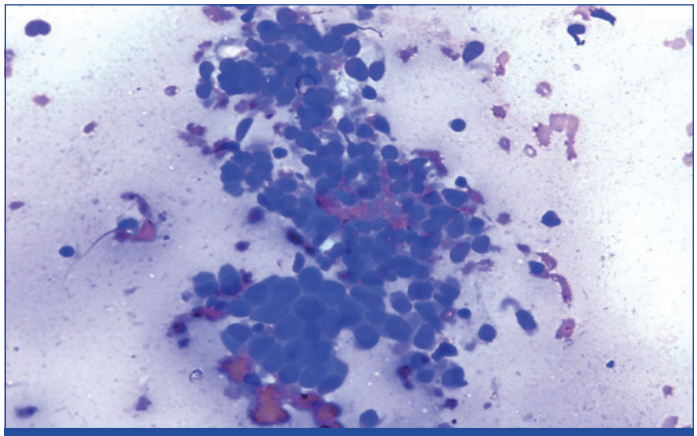
SAKTHISANKARI SHANMUGASUNDARAM[1], UMAMAHESWARI GURUSAMY[2], PRASANNA N KUMAR[3], BIKU JOSEPH JOHN[4]

ABSTRACT



Extramedullary plasmacytomas are rare, constituting to about 5% of plasma cell neoplasms. Pancreatic involvement is uncommon constituting to about 2.3%. Localised solitary plasmacytomas has a good response to radiation. When they are associated with pre-existing multiple myeloma, their prognosis is poor. A case of plasmacytoma of pancreas presenting with obstructive jaundice preceding plasma cell leukaemia is presented here. The lesion was misdiagnosed by fine needle aspiration cytology as neuroendocrine neoplasm. The patient did not present with symptoms of myeloma initially. The present case highlights the significance of considering other causes of pancreatic mass than primary carcinomas.

Keywords: Extramedullary plasmacytoma, Pancreatic neoplasm, Plasma cell leukaemia

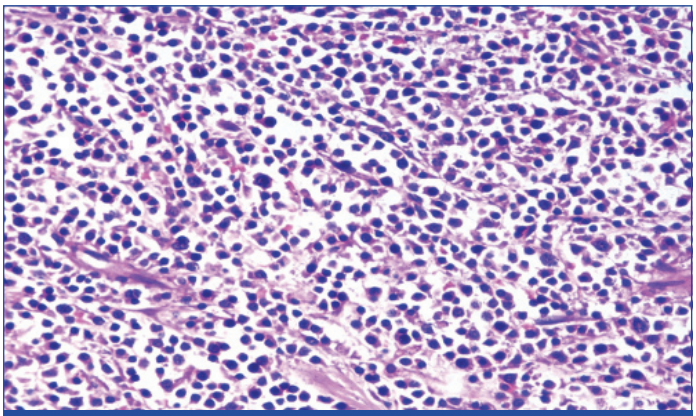


CASE REPORT

A 62-year-old female patient presented with complaints on and off fever from past 15 days. A vague, non-radiating, intermittent paraumbilical pain in right upper quadrant, and vomiting from past five days. There was no history of gastrointestinal bleed, loss of weight and loss of appetite. She was a known hypertensive and diabetic for five years and was on treatment with oral hypoglycemics and antihypertensives. Her vitals were within normal limits and there was no organomegaly.

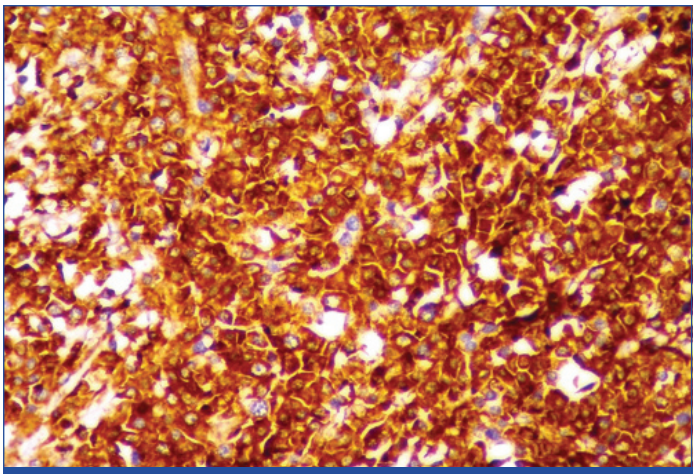
Ultrasound abdomen showed a hypoechoic mass in the pancreatic head dilating the main pancreatic duct. Computed Tomography (CT) revealed an isodense mass lesion with well defined borders in the head of pancreas measuring 4.8×5.5 cm [Table/Fig-1]. Acoustic Radiation Force Impulse (ARFI) elastography showed mean shear velocity of 3.6. The provisional diagnosis included primary pancreatic tumour. Endoscopic Ultrasound Guided Fine Needle Aspiration Cytology (EUS-FNAC) was planned for the evaluation of the pancreatic mass. EUS showed a 3×3.1 cm iso and hypoechoic mass in the head of pancreas with dilated common bile duct measuring 9 mm in the suprapancreatic portion. Dilated main pancreatic duct (6.5 mm) distal to the mass in the pancreas was identified. Visualised tail of pancreas and portal vein appeared normal. Cytological examination of the mass showed sheets and scattered plasmacytoid cells suspicious of a neuroendocrine neoplasm [Table/Fig-2].

[Table/Fig-1]: CT scan showing isodense lesion in head of pancreas.

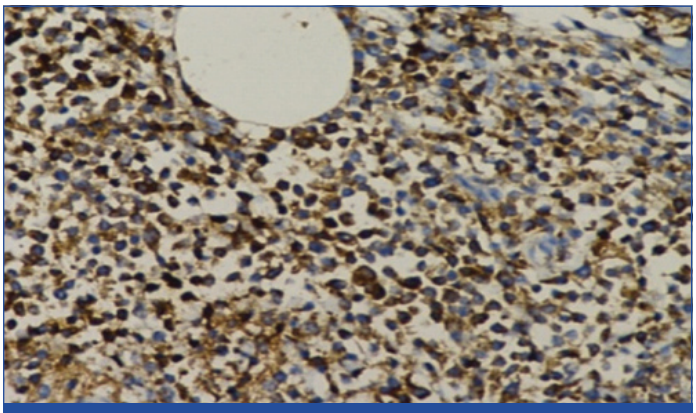


[Table/Fig-2]: Cytology smears showing plasmacytoid cells (40x).

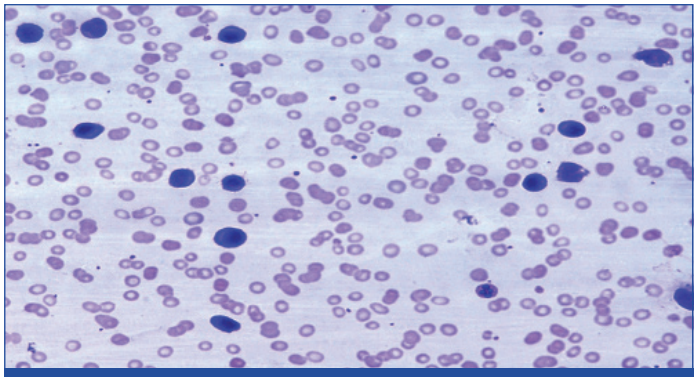
Whipple resection was done with a clinical and cytological diagnosis of a pancreatic neuroendocrine tumour. Pancreas showed an ill-defined mass occupying the head [Table/Fig-3]. Haematoxylin & Eosin (H&E) sections of the mass showed a diffusely infiltrating neoplasm composed of monotonous, plasmacytoid cells infiltrating the acini and ducts [Table/Fig-4]. Few binucleate and multinucleate plasma cells and lymphocytes were present. Morphological differential diagnosis included plasmacytoma and lymphoplasmacytic lymphoma. Immunohistochemical staining was done for confirmation of diagnosis. The tumour cells showed strong membranous positivity for CD138 [Table/Fig-5], CD45 and selective Kappa staining [Table/Fig-6]. They were negative for CD20 and Lambda immunostains. A diagnosis of Plasmacytoma was made and radiological and biochemical workup for multiple myeloma was suggested. Protein electrophoresis was normal. Urine was negative for Bence Jones Protein. Serum calcium and renal parameters were normal. CT spine survey did not reveal any osteolytic lesions. The case was treated as a solitary extramedullary plasmacytoma and follow-up was suggested. A month later, the patient developed severe anaemia (Hb-6.8 g/dL). Total count was elevated and peripheral smear showed 40% plasma cells suggestive of plasma cell leukaemia [Table/Fig-7]. Reviewing the patient's peripheral smear and complete haemogram taken a month back, there was normocytic normochromic anaemia and no demonstrable plasma cells in peripheral smear. ESR was elevated (93 mm/hr). Bone marrow aspiration done showed infiltration by sheets of immature



and mature plasma cells. On immunohistochemistry, these cells showed kappa restriction. A diagnosis of plasma cell leukaemia was made. Investigations done at presentation and a month later are tabulated [Table/Fig-8]. The patient was referred to higher centre for further treatment.



[Table/Fig-3]: Whipple's specimen showing ill-defined lesion in pancreas.



[Table/Fig-4]: Diffuse infiltration by plasma cells (H&E, 40x).

[Table/Fig-5]: Strong membranous expression of CD138 by tumour cells (IHC, 40x).

[Table/Fig-6]: Neoplastic cells with kappa expression (IHC, 40x).

[Table/Fig-7]: Peripheral smear with plasma cell leukaemia (40X).

Parameters	At initial presentation	A month later
Serum urea	42 mg/dL	81 mg/dL
Serum creatinine	1.06 mg/dL	3.82 mg/dL
Direct bilirubin	3.3 mg/dL	1.8 mg/dL
Haemoglobin	9.5 g/dl	6.8 g/dL
Total WBC count	4.3×10^3/µL	30.5×10^3/µL
Peripheral smear	Normocytic anaemia	Plasma cell leukaemia
Serum calcium	1.116 mmol/L	1.178 mmol/L

[Table/Fig-8]: Biochemical and haematological investigations.

DISCUSSION

Plasma cell neoplasms include Plasma Cell Myeloma (PCM) which includes smouldering myeloma, non-secretory myeloma, plasma cell leukaemia and plasmacytoma which includes solitary bone and extraosseous plasmacytoma. In majority of the patients with PCM, features of end organ damage in the form of one or more of the following, hypercalcaemia, Renal insufficiency, Anaemia, and Bone lesions (CRAB) are present. The clonal proliferation usually begins in bone marrow. Renal failure occurs due to tubular damage caused by excessive synthesis of monoclonal immunoglobulins [1]. It constitutes 10 to 15% of haematological malignancies. Median age at diagnosis is 66 years [2]. The clinical spectrum varies from asymptomatic to highly aggressive.

Extramedullary Plasmacytomas (EMPs) are localised proliferation of monoclonal plasma cells forming solitary lesions outside the bone marrow. EMPs can be a manifestation of advanced multiple myeloma or can represent a solitary plasmacytoma without involving the bone marrow [3]. EMPs are uncommon and represent 5% of all plasma cell tumours. The most frequent site of involvement being upper respiratory tract followed by gastrointestinal tract and reticuloendothelial system [2].

Primary pancreatic plasmacytoma is rare constituting 2.3% of EMPs. Majority of the reported pancreatic plasmacytoma are secondary [3]. EMPs have the median age of presentation at 55 years (A decade younger than patients with multiple myeloma) and the majority (three-fourths) are males [4].

Most of these lesions are located in the pancreatic head. Diffuse enlargement and presenting as mass in body (4 cases) [5] and tail of the pancreas have also been reported. The typical presenting symptoms include abdominal pain and obstructive jaundice from bile duct compression when there is involvement of head. Diffuse lesions are picked up rather late as they tend to be asymptomatic [6]. The case presented here also had obstructive jaundice raising a concern for primary pancreatic carcinomas [7].

Radiologically plasmacytoma is characterised by a homogenously enhancing multilobular, solid mass on CT, which is non-specific and resemble that of neuroendocrine tumours or carcinoma [6]. The case described presented as an isodense lesion in the pancreatic head. Differentiating plasmacytomas radiologically from other pancreatic tumours is challenging.

Endoscopic Ultrasound (EUS) is a well recognised technique for confirmation of pancreatic masses by histology. EUS- FNAs are reported to have an accuracy of 78-95% in the diagnosis of pancreatic masses. Neuroendocrine tumour presents as a, homogeneous, isoechoic or hypoechoic mass on EUS while plasmacytoma shows heterogenecity with uneven margins. NETs are hypervascular [5,8].

When FNA was done, the lesion was morphologically misdiagnosed as neuroendocrine neoplasm since both share plasmacytoid morphology. In a rare site, one would be more likely to suspect a primary lesion with plasmacytoid features, particularly endocrine neoplasm. Islet cell tumours have been reported to be a great mimic of plasmacytoma with regards to clinical, cytological and radiological appearance [9]. EUS guided core biopsy from the lesion and immunophenotyping with cytokeratin for carcinoma and CD138, kappa and lambda for identifying monoclonality of plasma cells would have helped in arriving at the diagnosis. EUS guided FNA also serves as a platform for obtaining material for flow cytometry.

The patient described here did not present with any symptoms pertaining to myeloma prior to surgery. The patient progressed to plasma cell leukaemia within a short time (one month) which is evident from the investigations [Table/Fig-8]. Plasma cell leukaemias are primary in 60-70% of cases and secondary to multiple myeloma in 30-40 % cases [10,11].

To our knowledge, this is the first case of plasmacytoma of pancreas being the initial manifestation of a plasma cell leukaemia. Two other cases of plasma cell leukaemia have been reported in association with gastric plasmacytoma. One case reported also had a normal WBC and platelet count with normocytic normochromic anaemia three weeks prior to the diagnosis of gastric plasmacytoma. The authors had hypothesised that secondary plasma cell leukaemia would have occurred as a result of rapid transformation of possibly underdiagnosed light chain multiple myeloma. The present case could also represent a similar rapid transformation from a non-secretory myeloma presenting with an extramedullary plasmacytoma [12].

From the previous reports it is clear that in any mass lesion of a solid organ in a patient with multiple myeloma the possibility of secondary plasmacytoma is to be considered [3,4,7]. Present case in addition highlights the fact that plasmacytoma is to be considered when plasmacytoid cells are identified in EUS-FNAs even when previous diagnosis of myeloma or symptoms pertaining to myeloma is not there at presentation. Immunocytochemistry can be used as an ancillary technique to diagnose with certainty in such cases. Presurgical diagnosis is essential as the management varies between primary pancreatic carcinoma and plasmacytoma.

CONCLUSION(S)

This case highlights the importance of considering other causes of pancreatic head mass than a primary carcinoma in a patient with obstructive jaundice. It also emphasises the fact that pathologists must be aware of the existence of pancreatic plasmacytoma as initial manifestation of myeloma despite its rarity, a high index of suspicion being essential.

Second-trimester fetal autopsy: A morphological study with prenatal USG correlations and clinical implications

Chaitra Venkataswamy, Umamaheswari Gurusamy, S. Vidhya Lakshmi

Abstract:

OBJECTIVES: The objective of this study is to analyze the second-trimester fetal autopsies and to reemphasize the role of autopsy by comparing autopsy findings with prenatal ultrasound observations.

MATERIALS AND METHODS: Retrospective analysis of second-trimester fetal autopsies over a period of 7.5 years (January 2009–June 2016). A standard protocol of autopsy procedure was followed, which included external examination with photography, X-ray, internal examination, and histopathological examination. In fetuses with congenital malformations (CMs), the findings of prenatal ultrasonogram and autopsy examination were compared.

RESULTS: We analyzed a total of 66 fetuses, which includes 17 intrauterine fetal death, 49 terminations for CM, and increased risk for chromosomal abnormality. In fetuses with CM, multiple anomalies were more common than a single anomaly. The most common anomalies were seen involving central nervous system (neural tube defect) followed by the genitourinary system. Autopsy confirmed prenatal ultrasound findings in all cases except three. Complete agreement between USG findings and autopsy were seen in 17 cases (39.7%). Additional findings on autopsy were noted in 25 cases (62.2%). Among these, 15 cases had a significant change of recurrence risk due to altered initial ultrasound diagnosis.

CONCLUSION: Fetal autopsy plays an important role in arriving at the final diagnosis and detecting the cause of death. This information is very essential for the clinicians, in genetic counseling of the parents, and management of future pregnancies.

Keywords:

Congenital malformations, fetal autopsy, multiple anomalies, prenatal ultrasound

Introduction

The common indications for second-trimester fetal autopsies are termination of pregnancy (TOP) for congenital anomalies, intrauterine fetal death (IUFD), and inevitable abortion.[1] TOP for congenital anomalies accounts for the majority of cases of second-trimester fetal autopsies as most of the anomalies are detected during 18–20 weeks of gestation by anomaly scan which is an integral part of antenatal screening. These remain the common cause of perinatal deaths both in developed and developing countries and account for 25%–30% and 10%–15%, respectively.[2] The occurrence of these anomalies in subsequent pregnancy varies from negligibly low to 25%, and it depends on the etiology of diagnosis. Hence, it is important to make an accurate diagnosis.

In the present era, Ultrasonographic (USG) examination can accurately diagnose many lesions but has its own limitation in detecting soft-tissue lesions such as malrotation

of intestines, asplenia/polysplenia, and pulmonary hypoplasia, and the success rates of ultrasound also depend on the equipment used and expertise of the sonologist. Perinatal autopsy either confirms or refute the ultrasound diagnosis and complements USG examination in making a precise diagnosis.

The objectives of the present study are to evaluate the reasons for second-trimester fetal autopsies, to categorize the congenital malformations (CMs) into various systems, syndromes, and complexes, and to compare the autopsy findings with prenatal USG examination.

Materials and Methods

The retrospective analysis of all second-trimester fetal autopsies from January 2009 to June 2016 (7.5 years) was done in the Department of Pathology. Fetuses with gestational age 14–28 weeks were included in the study. Fetuses with gestational age <14 weeks and >28 weeks were excluded from the study. Informed written consent for performing autopsy examination was obtained from either of the parents before the autopsy. All the fetuses were examined on preset protocol based on the recommendation given in guidelines in autopsy practice by Royal College Of the Pathologists,[3] which included photography, fetogram (whole body radiography), and external and internal examination.

Evisceration is performed by starting with a linear skin incision extending from symphysis menti to midline of chest, abdomen, passing to the left side of the umbilicus, and extending up to the symphysis pubis. *In situ* assessment of the intestines was done to rule out malrotation and they were removed from jejunum up to the rectum. Rest of the organs was taken out as "*en bloc*" by freeing the tongue from the floor of the mouth and releasing the attachments of the neck structures. The pelvic organs were cut as low as possible. External genitalia and urethra were dissected in case of suspected urorectal septum malformation. The individual system was thoroughly inspected and dissected for anomalies.

The brain is removed by incising the scalp behind one ear extending to vertex and to the other ear. Skin flaps are reflected anteriorly up to the eyebrows and posteriorly up to the nape of the neck. Skull bones are opened along the suture lines. The brain is delivered by placing the head at a lower level than the body, by releasing the nerve attachments, and falx cerebri, tentorium cerebelli and the upper cervical spinal cord is incised. The removed brain is then fixed by hanging in formalin using gauze.

All the organs are weighed. Histopathological examination of the brain, thyroid, thymus, heart, lung, liver, pancreas, spleen, kidney, adrenal, gonads, and placenta was carried out. Additional sections from the skin, muscle, bladder, pylorus, etc., were also studied when required.

In cases of fetuses terminated for CMs, the findings on autopsy and prenatal ultrasound examination were compared.

Approval was obtained from the institutional Ethical Clearance Committee.

Results

There were 87 fetal autopsies in 7.5 years of which 66 cases (75.8%) were second-trimester fetuses. Causes of second-trimester fetal autopsies are summarized in Figure 1.

In cases of IUFD and abortions, mean maternal age was 27 years (range19–35) and mean gestational age was 22 weeks (range 16–27). An autopsy provided a final diagnosis in 15 (88.2%) out of 17 cases. The causes are summarized in Table 1. In two cases, there was no detectable anomaly in the fetuses and the placental causes could not be excluded as placenta was not available for examination.

Cases terminated for increased risk for chromosomal abnormality include two cases of Down syndrome. One case presented with hydrops fetalis, cystic hygroma neck, common atrioventricular canal defect with persistent left superior vena cava, and hypoplasia of thymus. Other case showed nuchal edema, hydrocephalus, and abnormal left hand, feet, and legs. There was one case of Turner syndrome with partial deletion of short arm of X chromosome. This case showed telangiectatic vascular nevi, hypoplastic nails, widely spaced nipples, clitoromegaly, septate vagina, and aortic arch isthmus hypoplasia. In one case, amniocentesis and FISH showed deletion of short arm of chromosome

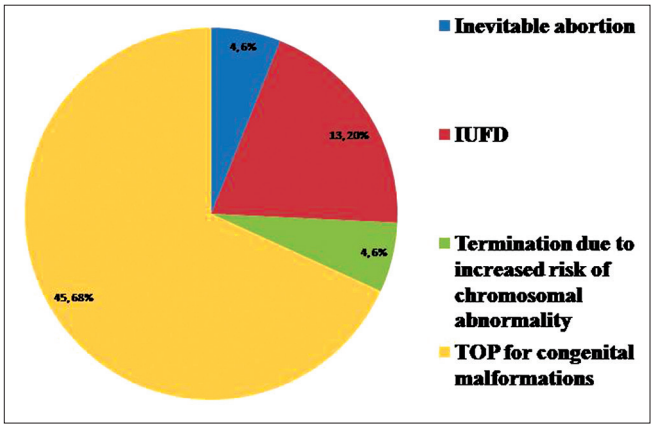

Figure 1: The pie diagram shows causes of fetal autopsies requested

Table 1: Causes of intrauterine fetal death in the second trimester

Causes	Number of cases (*n*=17)
1. Placental causes	10
Cord stricture	6
Hyper coiled cord with fetal vascular obstruction	1
Massive perivillous fibrin deposition	1
Infectious villitis with hydrops fetalis	1
Isolated hydrocephalous with central placenta previa in mother and cord stricture (spontaneous abortion)	1
2. Fetal causes	4
Hypoplastic left heart syndrome with visceral heterotaxy	1
Healed myocardial infarction	1
Hydrops fetalis due to premature ductus closure	1
Bladder outlet obstruction due to distal urethral stenosis (spontaneous abortion)	1
3. Maternal cause	
Maternal thrombophilia	1
4. Diagnosis not possible	2

15. USG examination of fetus showed bilateral mild ventriculomegaly, hypoplastic cerebellum, increased nuchal pad thickness, postaxial polydactyly in both feet, and multiple anomalies. An autopsy confirmed the USG findings and in addition showed focal cerebellar dysplasia. Parental karyotyping was suggested to confirm Prader–Willi/Angelman syndrome.

In fetuses terminated for congenital anomalies, the mean maternal age was 24 years (range: 18–32). The mean gestational age at the time of diagnosis was 21 weeks (13–27). A majority of them showed multiple malformations which are summarized in Tables 2 and 3. Central nervous system (CNS) anomalies were the most common followed by genitourinary malformations. The frequently encountered CNS anomaly was Arnold–Chiari II malformation with myelomeningocele. Two cases of rhombencephalosynapsis characterized by fusion of cerebellar hemisphere with absent cerebellar vermis were seen. There were four cases of hydrops fetalis and the underlying cause was detected in all. In a case of DiGeorge syndrome (DGS), there was hypoplastic thymus in the cervical region which was not detected on ultrasound [Figure 3]. A case of sirenomelia showed single median lower limb. Fetogram revealed single femur, two tibias, and no fibula [Figure 4].

Prenatal USG examination was available in all fetuses terminated due to prenatally diagnosed anomalies. There were a total of 121 anomalies in 45 cases. About 50 (41.3%) out of 121 anomalies were diagnosed only on autopsy. Three anomalies identified on USG were not confirmed on autopsy examination and includes two Dandy–Walker complex (DW) and aqueduct stenosis. One of the cases of DW complex showed additional findings on autopsy, and a diagnosis of Fryns syndrome was offered. Anomalies detected exclusively on autopsy examination include 13 (26%) gastrointestinal (malrotation of intestine), 13 (26%) genitourinary, 5 (10%) cardiovascular, 5 (10%) facial abnormality (cleft palate and micrognathia), four cases of CNS lesions, two cases each of polysplenia, skeletal abnormalities, and ductal plate malformation liver, and one case each of congenital diaphragmatic hernia, omphalocele, choanal atresia, microphthalmia, and nesidioblastosis.

Complete agreement between the USG findings and autopsy results were seen in 17 cases (39.7%). An additional finding in autopsy was noted in 25 (62.2%) out of 45 cases. In 15 cases (34.8%), the additional findings on autopsy changed the initial ultrasound diagnosis [Table 4]. In nine out of 15 cases, the revision of diagnosis led to significant change in recurrence risk (3%–25%) in subsequent pregnancy.

Discussion

With the advent of newer imaging techniques with higher resolution, the rate of autopsy is declining steadily. This is true even in cases of perinatal autopsies.[4] Perinatal autopsy still remains the gold standard in detecting the cause of death in IUFD and confirming the anomalies detected on ultrasound.[1] The present study focuses on second-trimester fetal autopsies and in reemphasizing its value in detecting congenital anomalies.

In the present study, major indication for second-trimester fetal autopsy was TOP for congenital anomalies. In cases of IUFD, fetal malformations were noted in 23.5% of cases, this is slightly higher as compared to the study done by Joó *et al*. where fetal malformation was seen in 13.05% in second-trimester miscarriages.[5] A study done by Peng *et al*. showed that 18.7% cases of IUFD were associated with umbilical cord stricture, hypercoiling or combination of both, most of these demises occurred in the second trimester.[6] The current study showed cord stricture and hypercoiling as a cause of IUFD in 41.1% of cases, significantly high. This highlights the importance of examination of the placenta and umbilical cord in cases with absence of congenital anomalies.

In fetus with deletion in chromosome 15, there were multiple anomalies including cerebellar hypoplasia. Deletion in chromosome 15 is known for phenotypic heterogeneity, with well documented, diverse clinical syndromes. The best known of these are Prader–Willi syndrome and Angelman syndrome, both of which are not associated with generalized cerebellar hypoplasia

Table 2: Postmortem diagnosis in fetuses terminated for congenital malformations (limited to 1 or 2 systems)

Congenital anomalies	Associated anomalies	Number of cases (*n*=27)
1. Central nervous system malformations		9
Arnold–Chiari malformation II with meningomyelocele	Agenesis of the right kidney and fused adrenals (1 case)	3
Hydrocephalous with aqueduct stenosis		1
Rhombencephalosynapsis	Lobar holoprosencephaly, aqueductal stenosis, interhemispheric cyst, TEV (1)	2
	Craniofacial dysmorphism (1)	
Hydrocephalus	Double aortic arch	1
Lumbar meningomyelocele	Kyphoscoliosis spine, ruptured omphalocele	1
Mild ventriculomegaly	Hypoxic ischemic encephalopathy	1
2. Urogenital malformations		8
AR polycystic kidney disease	Ductal plate malformation	2
Bladder outlet obstruction due to the posterior urethral valve	Hydrops fetalis (2 cases)	3
	TEV (1 case)	
Persistent cloaca with persistent Mullerian duct syndrome	Male pseudohermaphroditism (2), Occipital encephalocele, TEV, agenesis right kidney, imperforate anus, and malrotation intestine (1)	2
Persistent Mullerian duct syndrome	Ambiguous genitalia, male pseudohermaphroditism, anorectal atresia, bladder outlet obstruction with bilateral hydronephrosis, and renal obstructive dysplasia SUA	1
3. Cardiovascular system malformation		3
D-transposition of great arteries	Omphalocele (1 case)	2
Congenitally corrected transposition of great arteries		1
4. Respiratory system		2
Congenital high-airway obstruction syndrome	Hydrops fetalis	1
Alveolar capillary dysplasia with misalignment of pulmonary veins		1
5. Congenital diaphragmatic hernia [Figure 2]	Choroid plexus cyst (1 case)	3
	Meckel's diverticulum, bicuspid aortic and pulmonary valves, bicornuate uterus (1 case)	
6. Talipes equinovarus	Accessory tragi	1
7. Hydrops fetalis	Placental mesenchymal dysplasia	1

SUA = Single umbilical artery, TEV = Talipes equinovarus

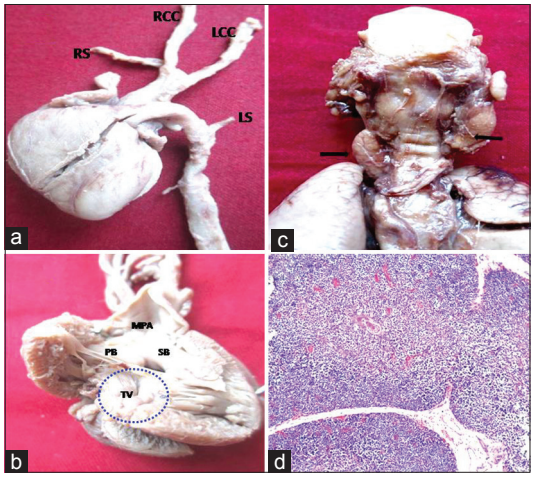

Figure 3: DiGeorge syndrome; (a) Interrupted aortic arch Type-B, (b) ventricular septal defect, perimembranous type, (c) cervical hypoplastic thymus, (d) lobules of thymic tissue composed cortex, medulla with Hassall's corpuscles (H and E, ×100)

as seen in present case. To the best of our knowledge, this association has not been described in literature. It is possible that this might belong to the expanding spectrum of chromosome 15q deletions.[7-9]

In 45 fetuses terminated for congenital anomalies, multiple malformations were seen in 75% of cases which is relatively high when compared to previous studies.[2,10]

CNS malformations were the most common followed by genitourinary anomalies. This is in concordance with the previous studies.[2,9-12] Arnold–Chiari malformation is characterized by downward displacement of cerebellum and brainstem into the spinal cord and is divided into three types. Type II is the most common form; this was true even in our series.[13]

Table 3: Postmortem diagnosis in fetuses terminated for congenital malformations (involving multisystem)

Diagnosis multiple malformations	Number of cases (*n*=17)
1. Syndromes/complexes/association	13
Fraser syndrome	1
Meckel–Gruber syndrome	2
Fryns syndrome	1
DiGeorge syndrome (SUA)	1
DiGeorge/velocardiofacial syndrome	1
Amniotic band syndrome	1
Charge syndrome	1
Zellweger syndrome/Smith–Lemli–Opitz syndrome	1
Sirenomelia with pseudo tail (SUA)	1
VACTERL or VATER Association (SUA)	2
Tuberous sclerosis complex	1
Multiple malformations – no definite syndrome	4
Renal hepatic pancreatic dysplasia with duodenal atresia	
Situs inverses with polysplenia and conotruncal malformation	
Meningocele, Arnold–Chiari malformation, tricuspid atresia, and double-outlet right ventricle	
Neural tube defect, Arnold–Chiari malformation, hydrocephalus with aqueductal stenosis, agenesis of corpus callosum, cerebellar hypoplasia, renal dysplasia, malrotation of small intestine, and polysplenia	

SUA = Single umbilical artery

Figure 4: Mermaid fetus; (a) single median lower limb with pseudo tail in the lumbosacral region, (b) fetogram shows fused pelvic bones, single femur, and absent fibula, (c) hypoplastic descending abdominal aorta continuing as single umbilical artery, (d) meconium filled, blind-ended colon

DGS also known as del22q11.2 is the most common microdeletion. Phenotypic features include heart defects, thymic hypoplasia/agenesis, facial dysmorphism, and developmental delay.[14] Two cases of DGS were diagnosed on prenatal ultrasound examination in view of congenital heart defects and absent thymus. Autopsy examination revealed hypoplastic cervical thymus in one case. Ectopic thymus was noted in 1% of children in a study of 3236 children at autopsy, of these 71% had features of DGS.[15] This might explain the variable immune status in the patients with DGS. Radiologist should be familiar with the locations of ectopic thymus and try to look for them when it is not found in the anterior mediastinum.

There was a case of sirenomelia with atypical skeletal framework. Sirenomelia is a rare CM characterized by varying degree of fusion of the lower limbs, single umbilical artery, and internal malformations related to genitourinary and gastrointestinal systems.[16] Stocker and Heifetz have classified sirenomelia into seven types based on skeletal framework in the lower limbs.[17] The bone pattern in the present case does not fit into any of the subtypes described in the literature. The exact etiological cause for sirenomelia remains unclear, but widely accepted hypothesis include defective blastogenesis and vascular steal hypothesis.[16]

In the present study, fetal autopsy provided definitive diagnosis in 95% of cases and confirmed ultrasound findings in 93% of cases, which is comparable to the previous studies.[2,12,18] An autopsy could not confirm DW complex in two cases. The previous studies have shown a poor correlation between ultrasound and autopsy findings in cases of DW complex with concordance being achieved in 55%, even after standardized reevaluation of sonographic and pathology images.[19] The poor correlation could be attributed either due to the membranous quality of the cyst wall with loss of fluid during anatomical dissection or due to the overdiagnosis of DW complex on ultrasound. Hence, the diagnosis should be reserved to cases which show all the classical findings on ultrasound. In doubtful cases, repeat ultrasound or magnetic resonance imaging (MRI) should be suggested to confirm the diagnosis.[19]

On comparing autopsy and ultrasound findings, our study showed complete agreement in 37.7% (17/45), partial agreement in 22.2% (10/45), and discordance in 33.3% (15/45). Thus, overall agreement was seen in 59.9%. This is in concordance with study done by Yeo *et al*.[20] Table 5 shows comparison of autopsy and ultrasound findings in various studies.[2,10,12,20,21]

Anomalies that were missed on USG examination were related to gastrointestinal, genitourinary, cardiovascular

Table 4: Comparison of ultrasound findings with autopsy findings in cases of discrepancy

Serial number	USG finding with diagnosis	Autopsy findings with diagnosis
1	Sacral meningomyelocele, bifid spine with the hypoplastic right ventricle of the heart	Arnold–Chiari malformation and tricuspid atresia with double-outlet right ventricle
2	Anhydramnios, B/L renal agenesis	Cryptophthalmos, ventriculomegaly, bifid nasal tip, clitoromegaly, B/L renal agenesis, absent vagina, uterus, and proximal fallopian tubes - Fraser syndrome
3	Anhydramnios, cystic dilatation of biliary radicles and common bile duct, a cyst in pancreas, bilateral multicystic dysplastic kidneys, microcephaly and shot bowed tibia - Ivemark syndrome	Bilateral cleft lip, cleft palate, lingual abnormalities and dysplastic epiglottis. Occipital encephalocele, Arnold–Chiari malformation Type III. Holoprosencephaly. Diffuse cystic renal dysplasia congenital hepatic fibrosis (ductal plate malformation), choledochal cyst Todani Type IV. Persistent left SVC, mild atrioventricular valve dysplasia. Ambiguous external genitalia, bilateral testes. Postaxial polydactyly, bow legs Meckel–Gruber syndrome
4	Situs ambiguous, isolated levocardia, VSD, and truncus arteriosus	Situs inversus, isolated levocardia with polysplenia, and conotruncal malformation
5	Cerebellum V-shaped with large cisterna magna. ? partial agenesis of inferior cerebellar vermis- possibility of DW complex	CDH, malrotation of the intestine, B/L cleft palate, ankyloglossia, bifid tongue, and uterus didelphys-Fryns syndrome
6	Short femur, humerus, narrow chest- Possibly achondroplasia	Syndactyly, postaxial polydactyly of hands and feet, dysplasia of epiglottis, nonrotation of intestine, ductal plate malformation of liver, renal dysplasia, X-ray - B/L shortening of long bones of the upper and lower limbs - Meckel–Gruber syndrome-variant
7	Oligohydramnios, B/L echogenic kidneys to R/O CMV	AR PCKD with congenital hepatic fibrosis
8	Increased nuchal translucency, generalized subcutaneous edema, hypertelorism, midline facial cleft, small omphalocele, cardiac outflow tract anomaly. Suggested invasive test to rule out aneuploidy. Patient not willing for amniocentesis	Craniofacial defects with a membranous tag at the head - cranioschisis, absent ears, and nose, bilateral cleft lip and palate, Conotruncal cardiac anomaly? Transposition of great arteries with pulmonary atresia? Double outlet right ventricle with pulmonary atresia, abdominoschisis, renal cystic dysplasia - suggestive of amniotic band syndrome
9	Lumbosacral spina bifida and Arnold–Chiari malformation	Lumbar meningomyelocele, ruptured omphalocele
10	Bilateral presacral kidneys with bilateral hydronephrosis due to pelviureteric junction obstruction, parenchyma of left kidney is dysplastic	Ambiguous genitalia, male pseudohermaphroditism, persistent mullerian ducts Anorectal atresia, bladder outlet obstruction with bilateral hydronephrosis, and renal obstructive dysplasia. SUA
11	SUA, TOF, ectopic hydronephrotic left kidney, left clubfoot with absent 2nd to 5th digits	TOF with the right aortic arch and left-sided patent ductus arteriosus, atresia of distal sigmoid, rectum and anus, fused crossed renal ectopia with hydronephrosis, left clubfoot with a single digit Fetogram-hemivertebra, absent metatarsal l bones-vacterl association
12	Pierre syndrome, left hydronephrosis due to pelviureteric obstruction	Bilateral posterior choanal atresia, lop ears, Micrognathia, Microphthalmia, persistent cloaca, left hydronephrosis - CHARGE syndrome
13	Two echogenic masses suggestive of cardiac rhabdomyoma	Heart: Multiple rhabdomyomas Brain: Subependymal nodules of dystrophic neurons and astrocytes - tuberous sclerosis complex [Figure 5]
14	Complete AVSD Bilateral cleft lip and palate, echogenic focus left ventricle	Congenitally corrected transposition of great arteries Alveolar capillary dysplasia with misalignment of pulmonary veins, bilateral cleft lip and palate, mild pyloric stenosis, bladder outlet obstruction? Vascular dysplasia kidneys and brain

TOF = Tetralogy of Fallot, CDH = Congenital diaphragmatic hernia, SUA = Single umbilical artery, SVC = Superior vena cava, USG = Ultrasonography, CMV = Cytomegalovirus, B/L = Bilateral, DW = Dandy-walker complex, AVSD = Atrio ventricular septal defect, VSD = Ventricular septal defect, R/O = Rule out, AR PCKD= Autosomal recessive polycystic kidney disease

systems, and facial defects. Antenatal detection of these CMs depends on the expertise of sonologist, quality of equipment, maternal habitus, and reduction in liquor volume.[22] In addition, some cardiac, gastrointestinal, and renal abnormalities are not evident at 20 weeks. Few are histopathological diagnosis (e.g.: tuberous sclerosis, PCKD). Oligo- and anhydramnios were noted in some of our cases. All the above factors could explain the shortcomings of routine antenatal USG examination. Other prenatal diagnostic modalities such as three-dimensional ultrasound and MRI will provide better resolution for CNS and soft-tissue abnormalities. Detailed analysis of fetus using these advanced imaging modalities may help in achieving higher rates of complete agreement. Implementing them in routine antenatal screening may not be feasible due to higher cost, lack of expertise, and limited availability in developing countries.

When the parents are reluctant to give consent for full autopsy due to religious reasons, limited, or minimally invasive autopsy may be of value. Minimally

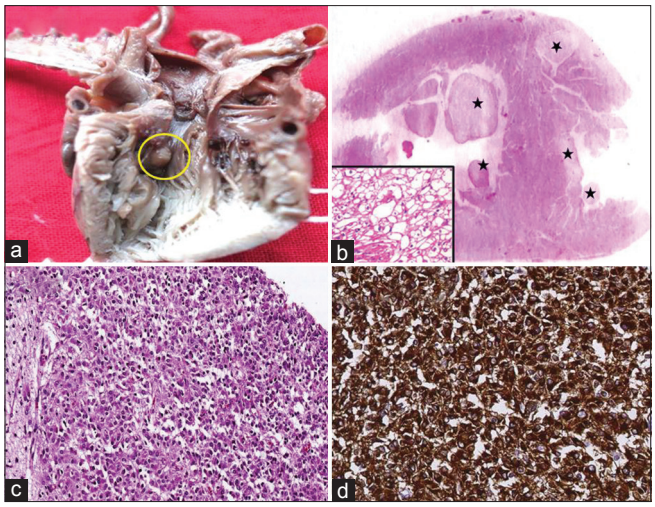

Figure 5: Tuberous sclerosis complex: (a) fleshy, pale brown mass in the left ventricular outflow tract, (b) transverse section of the heart shows multiple paler nodules(*) in subendocardial and intramural location. Inset shows high-power view of the nodule consisting of large vacuolated cells-rhabdomyoma (H and E, ×400), (c) section from medulla shows large subependymal plaque consisting of a cellular admixture of glial cells (H and E, ×100) and (d) these cells strongly express GFAP (IHC, ×400)

USG = Ultrasonography

invasive autopsy includes external examination with photography, placental examination, genetic analysis, and histopathological assessment of open or targeted biopsy of specific internal organs. Imaging studies, such as X-ray, postmortem MRI or micro-computed tomography, and assessment of body cavity fluids may be helpful to a certain extent.

Postmortem MRI can provide the details of structural malformation; however, it is not useful in cases of suspected infection, skeletal dysplasia, and in fetuses with severe maceration. It is not cost-effective and cannot provide details at histopathological levels.

Although minimally invasive autopsy can provide additional information in some cases, clinicians should explain to the concerned parents that complete perinatal autopsy remains the gold standard method for identifying the causes of fetal autopsy and its risk of recurrence.

Conclusions

The abnormalities detected by the fetal autopsy can be minor, major, or additional findings that modify the recurrence risk in subsequent pregnancy from 1%–3% to 25%. Thus, autopsy plays an essential role in accurate diagnosis and appropriate genetic counselling. The present study reemphasizes the need for fetal autopsy even in the era of advanced imaging techniques

Declaration of patient consent

The authors certify that they have obtained all appropriate patient consent forms. In the form the patient(s) has/have given his/her/their consent for his/her/their images and other clinical information to be reported in the journal. The patients understand that their names and initials will not be published and due efforts will be made to conceal their identity, but anonymity cannot be guaranteed.

Acknowledgment

The authors express their profound gratitude to Dr. Ammu Sivaraman, emeritus professor, Department of Pathology, PSGIMSR, under whose guidance all the autopsies were meticulously performed.

Financial support and sponsorship

Background: Authors sought to determine the possible factors in the causation of nonimmune hydrops foetalis by perinatal autopsy with placental examination and to reduce the number of cases in which the cause remains elusive.

Methods: Twenty five cases of nonimmune hydrops foetalis were identified in about 200 consecutive perinatal autopsies (including placental examination) performed during a 11 year period. The results were correlated with clinical, laboratory and imaging characteristics in an attempt to establish the aetiology.

Results: Perinatal autopsy and placental examination confirmed the following aetiologies: cardiovascular causes (8) [isolated (4), syndromic (3) and associated chromosomal (1)], placental causes (5), chromosomal (4) [isolated(3) and associated cardiovascular disease (1)], intrathoracic (3), genitourinary causes (3), infections(1),gastrointestinal lesions (1) and idiopathic causes (1). Placental mesenchymal dysplasia was a unique pathology identified among the placental lesions, which constituted the second most common cause of nonimmune hydrops foetalis. Despite careful examination no cause was identified in one case. In more than 50% of studied cases, autopsy examination either refuted or altered the ultrasound diagnosis completely.

Conclusions: The perinatal autopsy in combination with placental study and prenatal imaging represents the most promising tool in the evaluation of aetiology of nonimmune hydrops foetalis. The identification of a cause for nonimmune hydrops foetalis will provide a better correlation with recurrence risk and parental counselling.

Keywords: Aetiology, Nonimmune hydrops foetalis, Perinatal/foetal autopsy, Placental mesenchymal dysplasia, Prenatal imaging

Introduction

Foetal hydrops is a syndrome characterized by generalized skin oedema and abnormal accumulation of fluid in one or more serous cavities of foetuses. It has been broadly classified into immune mediated (materno - foetal blood group incompatibility) and non immune types. There is a steady fall in the incidence of immunologic hydrops foetalis due to the prevention of maternal isoimmunisation and treatment of affected foetuses in utero.[1] This has shifted the focus towards the non immunologic causes of hydrops which now constitutes up to 90% of cases of foetal hydrops.[2]

There are many impressive and ever growing causes of non immune hydrops foetalis (NIHF) and its development is known to be associated with maternal, foetal and placental diseases.[3] The foetal hydrops can be identified anytime throughout the pregnancy. The perinatal mortality rate is generally high. The spectrum of possible causative factors of NIHF include cardiovascular diseases, chromosomal aberrations, haematologic

abnormalities, infections, intrathoracic lesions, lymphatic dysplasias and placental causes including twin-twin transfusion syndrome. The other causes are syndromes, urinary tract malformations, inborn errors of metabolism, extra thoracic tumours, gastrointestinal disorders, miscellaneous and idiopathic.[4]

Improvements in obstetric ultrasound (USG) and foetal echocardiography enable the early and frequent detection of hydrops, resulting in foetal interventions / termination of pregnancy and have altered the incidence of hydrops.[5]

Given the multiple aetiologies of NIHF, we sought to determine the presence of possible factors in its causation by analysing the autopsy with placental material and to reduce the number of cases in which the cause remains elusive.

M□□□□□□□

Twenty five cases of NIHF were identified in about 200 consecutive perinatal autopsies (including placental examination) performed during a 11 year period from January 2007 to December 2017 at the department of pathology, PSG Institute of Medical Sciences and Research. The institutional ethical review board approval was obtained for the study.

Exclusion criteria

Hydrops foetalis of immunologic origin were excluded from the study on the basis of blood typing, direct and indirect coomb's tests.

The detailed maternal history, antenatal ultrasounds and genetic tests if any were collected. The autopsy was performed after getting informed consent. Photograph of the foetus was routinely taken with special attention to sites where abnormalities were suspected. A thorough systematic examination of foetuses and placenta was done, which included foetogram, foetal weight, anthropometric measurements (head circumference, chest circumference, abdominal circumference, crown rump length, crown heel length, foot length), external and internal examination.

After opening the body cavities, serous fluid collections were measured, and the thoracic and abdominal organs were removed en bloc. All the visceral organs were examined, and the bits were given for microscopic analysis. The brain was removed, inspected, weighed and suspended in a formalin fixative. After fixation, the brain was sliced; examined and relevant bits were taken. Examination of bone, including marrow and spinal cord were performed in selected cases. The placenta and cord were also examined thoroughly, photographed (maternal / foetal surfaces, parenchyma, umbilical cord), cut at 1cm intervals and the parenchyma was assessed for specific lesions. Relevant lesional sections were taken along with 2 sections of membrane roll, 2 sections from the umbilical cord and 3 full thickness sections of the normal parenchyma.

All the histologic sections were stained with haematoxylin and eosin. Special stains such as Grocott-Gomori's methenamine silver (GMS), Giemsa stains for toxoplasma gondii, warthin starry stain for spirochetes and reticulin stain for vascular network were done, when required. Immunohistochemical marker for cytomegalovirus was available, hence done for suspected infectious cases. After the microscopic study, the results were correlated with clinical, laboratory and imaging characteristics and the final results were drawn.

□□□□□□□□

Out of 200 perinatal autopsies performed during the 10-year period, 25 cases met the criteria for NIHF, representing 12.5%. The gestational age ranged from 13 weeks to 35 weeks. All were dead-born foetuses except two. The two liveborn foetuses were delivered at 35 weeks and survived only a few hours postnatally. There were no cases of multiple gestation.

Clinical findings

Maternal age ranged from 19 to 35 years, of whom 9 were primigravidas. Five cases each of polyhydramnios and oligohydramnios were present. Maternal medical diseases included 2 cases each of preeclampsia and autoimmune diseases and 1 case each of hypothyroidism and rheumatic heart disease. None of the mothers had diabetes. Recurrence of hydrops was found on 5 occasions. Previous history of hydrops was documented in 2 cases of cardiac (complete heart block and transposition of great arteries with ventricular septal defect), one case each of intra thoracic lesion (Congenital pulmonary airway malformation), chromosomal (Down syndrome) and placental mesenchymal dysplasia.

Ultrasound findings

Hydrops foetalis is diagnosed with typical findings during prenatal imaging. The sonographic features include subcutaneous / scalp oedema, fluid accumulation in different serous cavities (Figure 1), polyhydramnios and placentomegaly. Correlation between prenatal USG and autopsy findings in elucidating the causes of hydrops were studied (Table 1). Complete agreement between prenatal USG and autopsy findings were seen in 11 cases (44%), while in 6 cases autopsy examination revealed additional findings (24%). In 8 cases, autopsy findings changed the diagnosis (32%).

Autopsy findings

Foetus

There were 12 males and 13 females with an almost equal gender distribution. Hydrops was noted in <20 weeks (10

cases), 21-28 weeks (10 cases) and >28 weeks (5 cases) of gestation. Aetiological distribution of NIHF is listed in Table 2.

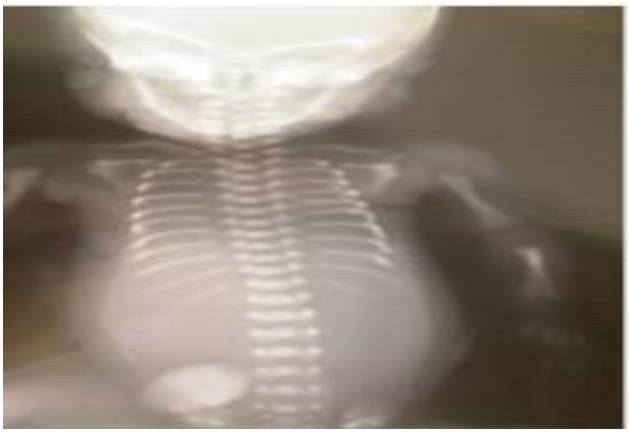
Parvo virus	1
Placental causes	5
[illegible]	
Ellis van creveld syndrome	1
Zellweger syndrome	1
Vacterl	1
Idiopathic	1

*Coexistent with congenital heart disease

Cardiovascular diseases (n=8)

Congenital cardiac defects represented the largest aetiological group and were seen in 8 foetuses (32.0%). Among these 8 cases, 7 foetuses had structural malformations and 1 had functional defect. 2 cases of isolated cardiac defects, 3 cases of syndromic association and one case of chromosomal abnormalities were identified (Table 3). Cystic hygroma was noted in 2 instances.



[illegible]

[illegible]	[illegible]
Premature closure of ductus	
Complete heart block secondary to fibrosis of cardiac conduction system, immune mediated	
TGA with hypoplastic pulmonary arterial trunk	
Subaortic VSD	
TOF with right aortic arch and left sided PDA	VACTERL association
Secundum ASD	Multiple congenital anomaly syndrome -? Zellweger syndrome-? Smith Lemli Opitz syndrome
Common atrium with complete common AVSD	Ellis- Van Creveld syndrome
Common AVSD with persistent left superior vena cava and mild tubular hypoplasia of aortic arch	Down syndrome
TGA and VSD	Partial urorectal septum malformation sequence (Cloacal dysgenesis sequence)

TGA-transposition of great arteries; VSD-ventricular septal defect; TOF-tetralogy of fallot; PDA-patent ductus arteriosus; VACTERL-vertebral defects, anal atresia, cardiac defects, tracheo-esophageal fistula, renal anomalies, and limb abnormalities; ASD-atrial septal defect; AVSD- atrioventricular septal defect.

The most common causes of NIHF in our series were cardiovascular diseases, of which structural anomalies predominate. The most frequently found structural heart lesion with hydrops is atrio ventricular septal defects, and transposition of great vessels. Less common structural cardiac abnormalities observed were premature closure of ductus, tetrology of Fallot and secundum atrial septal defect. There were 2 cases of isolated heart defects. One foetus had premature closure of ductus and the other was a neonate with complete heart block. In the second instance, an association with maternal connective tissue disease was identified. This newborn female with complete heart block also had a sibling delivered at same gestational age with similar hydropic features and died within a few hours of birth. Autopsy was not performed

for the sibling. Our newborn was delivered preterm at 34 weeks of gestational age due to severe bradyarrhythmia. The neonate was hydropic, hypertonic and had intractable bradycardia at birth. Pace maker insertion was not acceptable to the parents. Child expired within 3 hours of birth. Autopsy examination revealed biventricular hypertrophy, dysplasia of atrioventricular valves, fibrosis of sinoatrial and atrioventricular nodes and patchy endocardial fibroelastosis.

In present series, cardiac defects were also seen in association with Ellis-Van Creveld Syndrome (Figure 2), Multiple congenital anomaly syndrome and VACTERL association.

There were 3 cases of Down syndrome, all with typical phenotypic manifestations and one with atrioventricular septal defect (Figure 5). The other significant associated anomaly noted was partial urorectal septum malformation sequence (Cloacal dysgenesis sequence).

Other disorders associated with NIHF

Placental, intrathoracic and genitourinary lesions are summarized in (Table 4).

Placental lesions (n=5)

The placenta was examined in all the cases and showed villous edema, prominent Hofbauer cells and villous capillary erythropoiesis.

Placental causes of hydrops were found in 5 cases. Two cases each of maternal vascular malperfusion and placental mesenchymal dysplasia. The underlying pathology in the fifth case was foetal vascular malperfusion (organising and recanalizing thrombi with avascular villi), villitis of unknown aetiology and acute chorioamnionitis.

Histologically, the cases with maternal vascular malperfusion had multiple parenchymal infarcts, increased syncytial knotting and distal villous hypoplasia. Preeclampsia was noted in both the mothers.

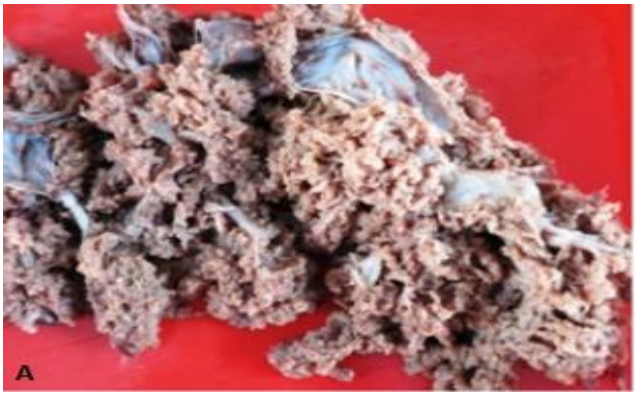


Figure 6: Gross photograph of placenta showing hypercoiled cord, parenchymal disruption with thick, oedematous villi and small vesicles

The placentas with mesenchymal dysplasia grossly showed hypercoiled cord, parenchymal disruption with thick, oedematous villi and small vesicles (Figure 6). Histologically, all villi showed collapsed vesicle with central cystic degeneration with absent trophoblastic proliferation and markedly dilated vascular channels (Figure 7).

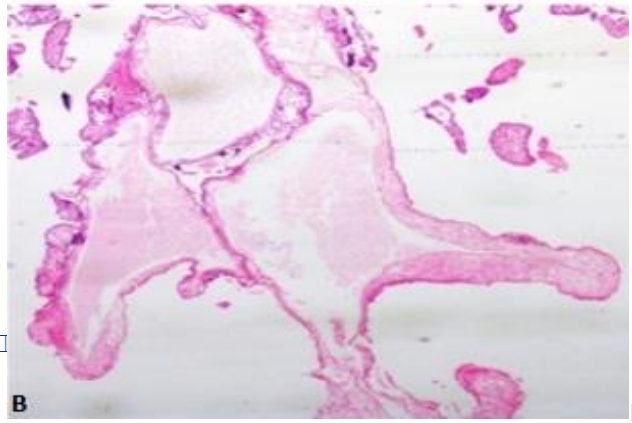

Figure 7: Histology showing collapsed vesicle with central cystic degeneration with absent trophoblastic proliferation and markedly dilated vascular channels

Table 2: Distribution of cases with non-immune hydrops fetalis and associated malformations

Placental causes (N=5)	Case 1: Preeclampsia, Multiple parenchymal infarcts, increased syncytial knotting: MVM
	Case 2: Preeclampsia, infarcts, Distal villous hypoplasia: MVM
	Case 3: The Placental parenchyma is disrupted, fleshy, pulled apart and the villi appear thick. The stem villi oedematous, hypercoiled cord : Placental mesenchymal dysplasia
	Case 4: Small vesicles in the parenchyma, thick stem villi: Placental mesenchymal dysplasia
	Case 5: placenta with FVM.VUE and A/C CAM
Intra thoracic lesions (n=3)	Case 1: Both lungs: dilated airways and lymphatics : CPAM
	Case 2: The right lung appears large and occupies almost the entire thoracic cavity: CPAM
	Case 3: Laryngeal (Glottic) atresia : CHAOS
Genitourinary abnormalities (n=3)	Case 1: BOO due to posterior urethral valve causing dilated posterior urethra, bladder, ureters and bilateral hydronephrosis. Ventriculomegaly, absent corpus callosum
	Case 2: Distal urethral stenosis with dilatation and hypertrophy of the urinary bladder: BOO. Pulmonary hypoplasia
	Case 3: BOO due to posterior urethral valves. Mild dilatation of both ureters and pelvis

CPAM- congenital pulmonary airway malformation; CHAOS- congenital high airway obstruction syndrome; BOO- bladder outlet obstruction; MVM-maternal vascular malperfusion; FVM- foetal vascular malperfusion; VUE- villitis of unknown aetiology; A/C CAM- acute chorioamnionitis

Authors did not find any chorangioma as a cause of NIHF.

Intrathoracic lesions (n=3)

There were 3 instances of intrathoracic lesions causing NIHF. Two cases of congenital pulmonary airway malformation (CPAM) (Figure 8) and one case of congenital high airway obstruction Syndrome (CHAOS) were identified in our series. Mediastinal deviation was noted in all foetuses.

Genitourinary abnormalities (n=3)

Three foetuses with NIHF were complicated by genitourinary causes. Two of them had bladder outlet obstruction (BOO) due to posterior urethral valves, and the third one had distal urethral stenosis with dilatation and hypertrophy of the urinary bladder. However, one

subject with posterior urethral valve also had ventriculomegaly, absent corpus callosum, deep posterior fossa, hypoplastic ductus and pulmonary arteries.

[illegible]

Chromosomal abnormalities (n=4)

Among cases with chromosomal abnormalities, we found one foetus with Turner syndrome, in which cytogenetic study revealed partial deletion of short arm of X chromosome. There were 3 cases of Down syndrome, all with typical phenotypic features and one foetus additionally had cardiac defect.

Miscellaneous causes

Congenital parvovirus B 19 infection was suspected in one instance. The foetus had marked subcutaneous oedema, serous effusions, enlarged liver and spleen. Lymphocytic infiltration of all viscera, predominantly myocardium with no identifiable inclusions were seen. The placenta had no lesion.

One of the foetus had hypertrophic pyloric stenosis which is a relatively uncommon cause of NIHF. The mother had polyhydramnios and autopsy revealed thickened and narrowed pylorus.

The cause of the hydrops foetalis could not be determined in only one case (4%) and it was classified as idiopathic. Subcutaneous oedema, serous effusions, micrognathia, high arched palate and dysmorphic villi were identified, and chromosomal abnormality was suspected. However, the karyotype was normal.

[illegible]

Nonimmune hydrops foetalis is a clinical sequel of wide range of pathology and is not a diagnosis in itself. It is known to be associated with maternal, foetal and placental diseases. In the past, the causes of hydrops were not identified in significant number of cases, even after extensive investigations. Postmortem examination including clinical assessments and targeted investigations can identify the underlying cause in majority of cases.

Cardiovascular diseases

Cardiovascular causes of NIHF accounts for about 20% of cases and includes both structural and functional defects.[6] In the present study cardiac defects represented the largest group and were found in 32% of foetuses.

Association of cardiac lesions with well-defined syndromes, chromosomal aberrations such as Down syndrome, cystic hygroma and additional major congenital anomalies were also noted in some of our cases.

The lone functional cardiac cause for hydrops identified in our study was complete heart block, which had serological evidence of maternal connective tissue disease. Even though sectioning is difficult, and time consuming, microscopic examination is critical in identifying fibrosis of the conduction system.

The cardiogenic hydrops would result from increase in right atrial pressure, reduced preload reserve and congestive cardiac failure.[7]

The immaturity of foetal myocardium (both structural and functional) with reduced relaxation is more vulnerable to any in utero insult leading to decrease in cardiac output.[1]

Hydrops associated with cardiac malformations generally have poor prognosis with high mortality. Recent developments in diagnostic capabilities of prenatal ultrasound along with in utero interventions will probably improve the outcome of foetuses with congenital cardiac lesions.[8]

Placental lesions

Interestingly, in present study group, placental lesions constituted the second most common cause of NIHF. Five of our patients demonstrated exclusive placental lesions significant enough to explain the aetiology of hydrops. Rodriguez et al, demonstrated placental pathology as the cause of hydrops in 10 patients (19.6%). In agreement with their study we too observed a similar incidence.[9]

Notwithstanding its rarity, we found placental mesenchymal dysplasia (PMD) as a unique pathology in two of our cases. PMD is an underreported and under recognized placental vascular anomaly causing hydrops.

It is characterized by placentomegaly (>90th percentile) with hydropic villi and absent trophoblastic proliferation.

The vascular changes observed in PMD might have led to heart failure with hydrops and ultimately resulting in intrauterine foetal demise.[10]

The other causes identified were maternal vascular malperfusion, foetal vascular malperfusion, villitis of unknown aetiology and acute chorioamnionitis.

Intrathoracic lesions

Among the intrathoracic causes (CPAM and CHAOS), an increase in intrathoracic pressure by enlarged lungs leading to impaired venous return could have contributed to foetal hydrops.[11]

Genitourinary abnormalities

Bladder outlet obstruction causing hydrops foetalis have been well documented in the literature. Mechanical obstruction of great vessels due to enlarged urinary bladder with resultant reduced venous return to heart is the underlying pathology.[12] Early onset oligohydramnios secondary to BOO leads to pulmonary hypoplasia, further reducing the survival chances.

Chromosomal abnormalities

In previously reported series of NIHF, chromosomal abnormalities were found in 10% of cases.[4,6,13] In the present study, there was 1 case of Turner syndrome and 3 instances of Down syndrome accounting for 16% of cases. Except for the Turner syndrome, none were confirmed by karyotyping. Among the 4 foetuses, 3 were identified in early gestation and one was associated with cardiac defect and cystic hygroma. Chromosomal analysis should be performed in all cases of NIHF, more so when identified in earlier gestation and when associated with structural anomalies.[14]

Miscellaneous causes

Intrauterine infections can cause foetal hydrops. There was one case of Parvovirus B19 infection in our study which showed hepatosplenomegaly with dense lymphocytic infiltration of myocardium. The underlying mechanisms include foetal anaemia, viral myocarditis and impaired hepatic function.[14,15] High index of suspicion and prenatal screening for intrauterine infections will make the interpretation easier. Incidence of "idiopathic" category varies among studies.[9,16,17] After detailed and systematic examination of foetuses including placenta, we found only one case (4%) of NIHF in which the cause was not identified. This highlights the value of autopsy with accompanying placental examination as the most complete procedure to establish the cause of NIHF.

Ultrasound correlation

Studies comparing the utilisation of foetal autopsy with prenatal USG findings have shown correlation in 98% of cases.[18,19] But these studies did not involve cases with hydrops foetalis. In more than 50% of studied cases, autopsy examination either refuted or altered the USG diagnosis completely. Though it is known that USG might miss some findings due to many reasons like equipment quality, sonographer expertise, maternal body habitus and liquor volume, this gross discrepancy is speculative. This might emphasis the need for autopsy, especially in cases of hydrops to arrive at a final aetiological diagnosis.

Also worthy of mention are the absence / rare diagnosis of inborn errors of metabolism and infective diseases in our series of cases. A better and complete laboratory work up with utilization of immunohistochemistry for lymphatic dysplasia/viral inclusions may be helpful to overcome this low diagnostic yield.

The causes of NIHF is heterogenous and the survival of the foetus depends on the underlying aetiology. The most promising tool in understanding the aetiology of NIHF is systematic evaluation of the foetuses including placenta. Multidisciplinary approach including foetal imaging, laboratory work up, postmortem bacterial / viral culture, genetic study, complete autopsy with utilization of immunohistochemistry (when necessary) will identify the potential causes in foetuses with suspected NIHF. This will determine new strategies for in utero therapy, and thus make a positive impact on perinatal outcome. Knowledge about the aetiology and pathogenesis will provide a better correlation with risk of recurrence. It may also improve parental counselling and prevent similar mishaps in subsequent pregnancies.

□□□□□□□□□□

In conclusion, the autopsy provides the final diagnosis and enables us to understand the disease process and its natural history. The decline in clinical autopsies is a matter of great concern to the clinicians and pathologists alike. State of the art imaging devices and molecular biology techniques can complement, but not replace a comprehensive autopsy.

Abstract

Background: Nonimmune hydrops foetalis (NIHF) is a terminal catastrophic event of pregnancy caused by numerous diverse etiology. The aim of this study was to assess the significance of foetal autopsy and to compare the prenatal ultrasound (USG) and foetal autopsy findings in cases of NIHF.

Methods: All perinatal autopsies performed at the department of pathology between March 2011-February 2018 were retrospectively reviewed. Of the received 130 autopsies, twenty cases of NIHF were identified, records of which were collected and correlated with maternal medical history, prenatal imaging and autopsy findings.

Results: The malformations with hydrops foetalis were classified according to the involved organ system. They were cardiothoracic (7/20 cases), genitourinary (3/20 cases), gastrointestinal lesions (1/20 cases), chromosomal (4/20 cases) and multisystem anomaly/syndromic association (5/20 cases). Complete agreement between USG and autopsy was seen in 8 (40%) cases. In 5 (25%) cases autopsy findings were in total disagreement with USG diagnosis. The rest of the 7 (35%) cases, autopsy revealed additional information and changed the recurrence risk in two cases.

Conclusions: Present study demonstrates the high rate of discordancy between USG and autopsy examination in cases complicated by NIHF. Foetal autopsy confirms the USG findings (quality control/audit), adds additional findings or changes the final diagnosis, which helps in redefining the recurrence risk and plausible genetic counselling for future pregnancies. Hence present study underscores the need for autopsy in all cases of NIHF.

Keywords: Nonimmune hydrops foetalis, Perinatal/ foetal autopsy, Prenatal imaging, Ultrasound

Introduction

Hydrops foetalis remains a distressing pregnancy complication with high perinatal mortality. It is characterized by generalized oedema and presence of fluid in pleural, peritoneal and pericardial cavities. Polyhydramnios and abnormally thickened placenta are often associated with hydrops.[1]

Traditionally, hydrops is classified into immune and nonimmune types. There is marked reduction in the incidence of immune hydrops due to effective immunologic prophylaxis for maternal isoimmunisation. Currently, the focus is on nonimmune hydrops foetalis (NIHF), which accounts for >90% of cases of hydrops.[2]

NIHF is associated with multiple aetiology. The various causes include cardiovascular, genitourinary, thoracic lesions, chromosomal aberrations, infections, haematological, genetic/metabolic, placental and idiopathic.[3]

Initial diagnosis of hydrops foetalis is usually made by ultrasound. In most of the cases, an accurate and complete antenatal imaging also points to the cause behind the development of hydrops. Despite having a

high diagnostic accuracy, foetal ultrasonography (USG) has some limitations, especially in cases with hydrops. Foetal autopsy in such instances can help to overcome the challenges.

The goals of this retrospective study were to compare the accuracy and completeness of prenatal ultrasonography with perinatal autopsy in cases of NIHF.

M□□□□□□

All perinatal autopsies performed at the department of pathology between March 2011-February 2018, were retrospectively reviewed. It included foetuses of all gestational ages. Causes of deaths were termination of pregnancy for foetal malformations, spontaneous abortions, stillbirths and early neonatal deaths. Of the 130 autopsies, twenty cases of NIHF were identified, records of which were collected and correlated with maternal medical history and prenatal imaging studies.

Immune hydrops foetalis were excluded from the study. Institutional ethical committee approval was obtained. Maternal data collection included maternal age, obstetric history, maternal medical diseases, gestational age of the foetus, and prenatal ultrasound findings.

Sonograms were predominantly performed by radiologists and some by obstetricians trained in obstetric ultrasound examination. The diagnostic criteria for hydrops foetalis were foetal skin oedema >5.0mm with one serous cavity effusion or fluid collection in at least two serous cavities (peritoneal, pleural or pericardial cavities).

The autopsies were performed by pathologists with perinatal experience. Informed written consent was obtained for all cases. A standard autopsy protocol was followed which included foetogram, photography, biometric measurements, external and internal examination. Microscopic examination of relevant organs such as thyroid, thymus, lungs, heart, liver, spleen, pancreas, adrenals, kidneys and ovary (in case of female), testis (in case of male) were done.

The brain was removed and fixed in formalin solution with the help of a gauze in a hanging position, then relevant sections were studied. Spinal cord, bone, muscle were also studied when necessary.

Special stains such as Periodic acid–Schiff (PAS) and Perls' Prussian blue were done if needed. Placental examination was done in all cases, but findings were not considered for the present study.

Placental causes of hydrops were also excluded from the study. Results of karyotype, if known was collected. The final autopsy diagnosis was correlated with prenatal ultrasound findings and results were drawn.

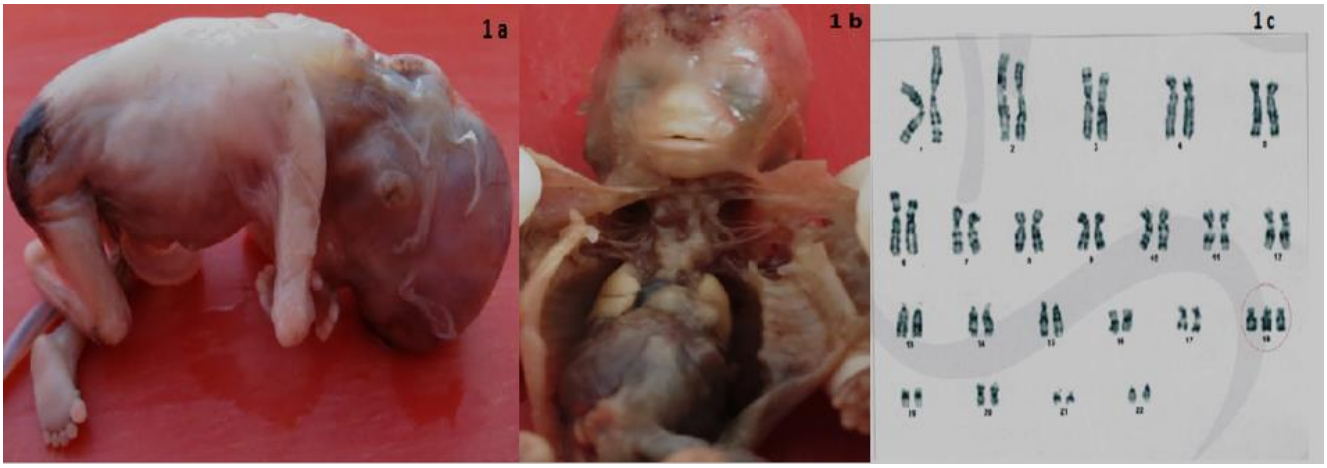
□□□□□□□

The maternal age ranged from 19 to 35 years with the mean age of 25.55years. Gestational age ranged from 13 to 35 weeks, with the mean gestational age of 21.45 weeks. There were 18 stillborn foetuses and 2 neonates with the Male: Female ratio of 3:2. Authors did not come across any multiple gestation. Four cases had recurrent hydrops.

Prenatal diagnosis of hydrops was noted in 14 cases and in the remaining 6, diagnosis was made at post-mortem. present data showed prenatal diagnosis of the presence of hydrops in only two-third of the cases.

Subcutaneous oedema and serous cavity effusions were identified in the rest one-third only during autopsy. All of these were second trimester foetuses. Cystic hygroma was identified in five cases.

The malformations with hydrops foetalis were classified according to the involved organ system. They were cardiothoracic (7/20 cases), genitourinary (3/20 cases), gastrointestinal lesions (1/20 cases), chromosomal (4/20 cases) and multisystem anomaly/syndromic association (5/20 cases).



Cardiac lesions (n=4): The cardiovascular malformations included premature closure of ductus (1case), complete heart block(1case), atrioventricular septal defect (AVSD) with persistent left superior vena cava (SVC) with other findings suggestive of Down syndrome(1case) and 1 case of transposition of great arteries (TGA), which also had an associated partial urorectal septum malformations.

Thoracic lesions (n=3): The thoracic lesions were congenital pulmonary adenomatoid malformations (CPAM, 2 cases) and congenital high airway obstruction syndrome (CHAOS, 1 case).

Genitourinary lesions (n=3): Three cases of bladder outlet obstruction (BOO) were included in the group of urogenital malformations, of which one had an associated ventriculomegaly, absent corpus callosum (ACC) with hypoplasia of ductus, right and left pulmonary arteries, distal aortic arch and left subclavian artery

Gastrointestinal lesions (n=1): The gastrointestinal lesions included, a 28weeks foetus with hypertrophic pyloric stenosis.

Chromosomal abnormalities (n=4): Of the 4 cases, two showed phenotypic features of Down syndrome, but karyotype confirmation was not available. Karyotyping was possible in the remaining 2 cases of which one showed partial deletion of short arm of X chromosome (Turner syndrome) and the other showed trisomy 18 (Edwards syndrome) (Figure 1).

[illegible] (Edward's [illegible]

Multisystem anomalies/ syndromic association (n=5): The autopsy findings suggested syndromic associations in five instances. They were one case each of Ellis- Van Creveld syndrome, Multiple congenital anomaly syndrome, VACTERL (vertebral defects, anal atresia, cardiac defects, tracheo-esophageal fistula, renal anomalies and limb abnormalities) association, FRYNS Syndrome and Cerebro-oculo-facio-skeletal syndrome. Karyotype analysis was done for the last two cases and were found to be normal.

Correlation between prenatal ultrasound and autopsy findings: Complete agreement between USG and autopsy was seen in 8 (40%) cases. In 5 (25%) cases, autopsy findings were in total disagreement with USG diagnosis. The rest of the 7 (35%) cases, autopsy revealed additional information.

[illegible]

[illegible]	[illegible]	[illegible]	[illegible]
1.	Cardiac	HF	Premature ductus closure.
2.	Thoracic	Large cystic hygroma	CPAM
3.	Chromosomal	HF, oesophageal atresia, absence of stomach	Phenotypic features of foetal trisomy No oesophageal atresia Karyotype-not done
4.	Urogenital	No anomaly	BOO-distal urethral stenosis
5.		HF	BOO-distal urethral stenosis Ventriculomegaly, ACC

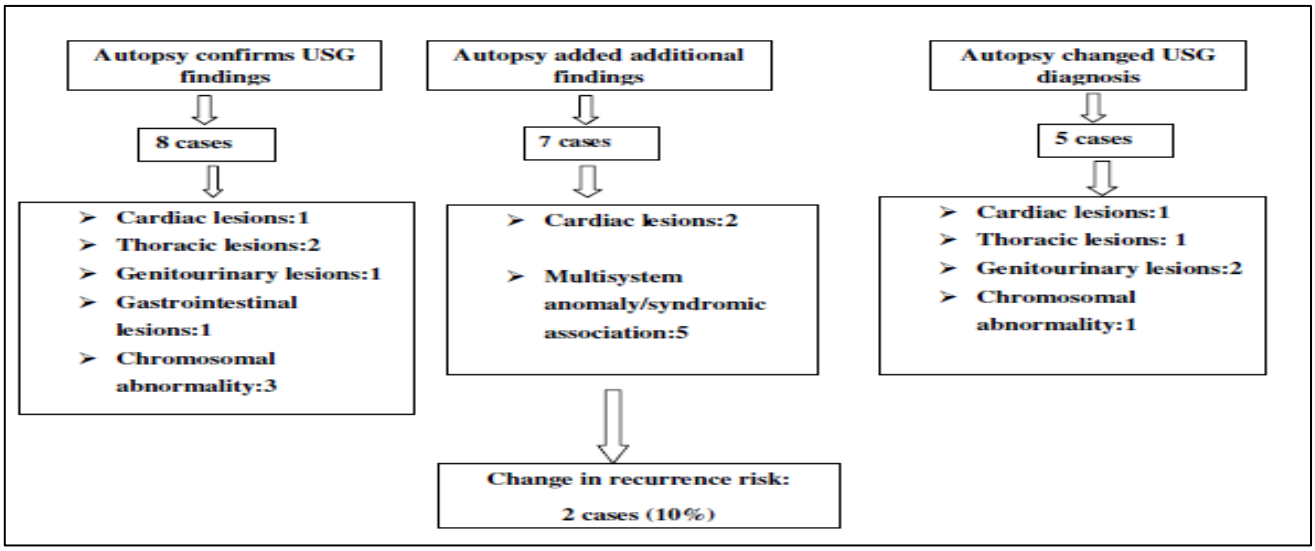
HF- hydrops foetalis; BOO- bladder outlet obstruction; CPAM- congenital pulmonary airway malformation; ACC –absent corpus callosum.

Cases with complete disagreement has been shown in Table 1.

Two had bladder outlet obstruction, one each had CPAM and premature closure of ductus.

In all the four cases, there was a complete change in the diagnosis after the autopsy.

The fifth case showed no oesophageal atresia, in contrast to prenatal imaging.

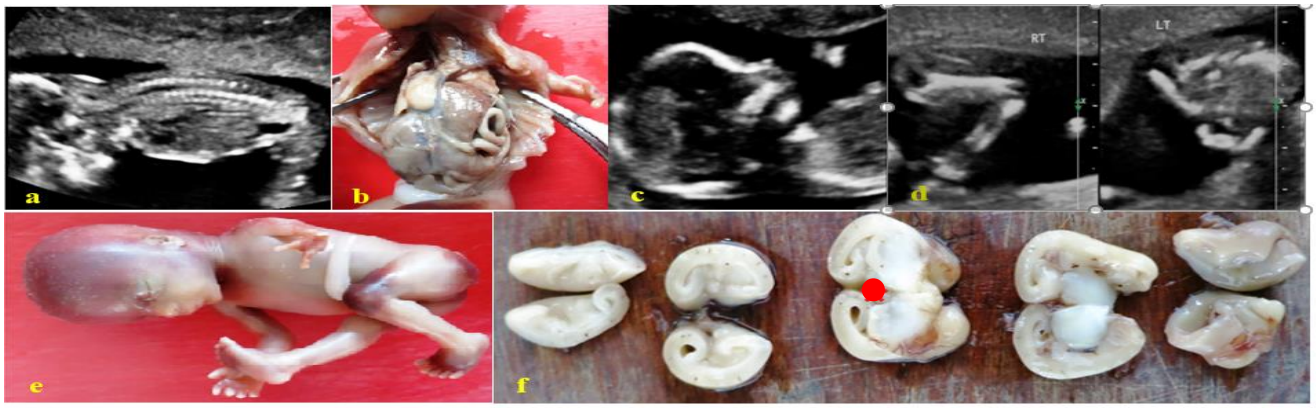


Though this was a significant disagreement, there was no major shift in the final diagnosis as both modalities suggested chromosomal aetiology.

[illegible]

[illegible]	[illegible]	[illegible]
1.	Short long bones, polydactyly, tricuspid atresia with VSD-probably Ellis Van Creveld syndrome	Common atrium with complete AVSD- Ellis-Van Creveld syndrome
2.	Polyhydramnios, HF, micrognathia, hypospadias, cleft soft palate, ACC, cardiomegaly, tricuspid regurgitation	Hypotelorism, depressed nasal bridge, low set ears, Heart – secundum ASD, Liver – haemosiderosis Pancreas – giant islets and nesidioblastosis Multiple congenital anomaly syndrome, Zellweger syndrome, Smith Lemli Opitz syndrome.
3.	SUA, TOF, ectopic hydronephrotic Left kidney, Left club foot with absent 2nd to 5th digits	Hemivertebra, fusion of ribs on the left side, Atresia of distal sigmoid, rectum with absent anal opening VACTERL association
4.	Left diaphragmatic hernia, hypoplastic left heart, short humerus on left side, absent forearm with claw hand on left side; dilated jugulolymphatic sacs: multiple anomalies and with SUA, could be VACTERL association.	Partial ACC, and hydrocephalus Karyotype was normal -Suggestive of FRYNS Syndrome
5.	HF, Foetal akinesia deformation sequence, sloppy forehead, micrognathia, gross bilateral lateral ventriculomegaly	Cerebro-oculo-facio-skeletal syndrome with persistent urogenital sinus
6.	Increased nuchal translucency, cystic hygroma, absent nasal bone	AVSD with persistent left SVC -Suggestive of Down syndrome
7.	Cystic hygroma with TGA and VSD	Partial urorectal septum malformation

VSD-ventricular septal defect; AVSD- atrioventricular septal defect; HF- hydrops foetalis; ACC-agenesis of corpus callosum; ASD-atrial septal defect; SUA-single umbilical artery; TOF-tetralogy of Fallot; VACTERL-vertebral defects, anal atresia, cardiac defects, tracheo-esophageal fistula, renal anomalies, and limb abnormalities; SVC-superior vena cava; TGA-transposition of great arteries



There were seven cases with additional autopsy findings which has been summarized in Table 2. Authors had two cases with cardiac lesions and the rest of the cases showed multisystem involvement. After autopsy, two out of seven cases had a change in recurrence risk (Figure 2).

[illegible]

In cases of multi system involvement, the autopsy finding of hemi vertebra, atresia of distal sigmoid, rectum, anal canal with absent anal opening, completed the diagnosis of VACTERL association (case 3, table 2).

In the same group (case 4, table 2), prenatal diagnosis of VACTERL association was changed to FRYNS syndrome after the identification of central nervous system anomaly (Figure 3).

[illegible]

Table 3 highlights the cases that showed full agreement between USG and autopsy findings. This included three cases of chromosomal abnormality, two cases of thoracic lesions (CPAM and CHAOS) and one case each from cardiovascular system (complete heart block), genitourinary (BOO) and gastrointestinal group (hypertrophic pyloric stenosis). There were none from the multiple anomaly group.

[illegible]

[illegible]	[illegible]	[illegible]	[illegible]
1.	Cardiac	Polyhydramnios, HF, complete heart block	Complete heart block secondary to fibrosis of cardiac conduction system
2.	Thoracic	CHAOS with HF.	Laryngeal atresia (CHAOS)
3.		Polyhydramnios, HF, CPAM with short long bones	CPAM, type 3
4.	Urogenital	Oligohydramnios, bilateral hydronephrosis, distended bladder	BOO - posterior urethral valves.
5.	Gastrointestinal	Polyhydramnios, HF. Hepatomegaly. Stomach visualized	Hypertrophic pyloric stenosis. Hirsutism.
6.	Chromosomal	NT: 3mm. Combined test – increased risk of trisomy 21	Phenotypic features of foetal trisomy Karyotype-not done
7.		NT: 1.75mm Combined test – increased risk of trisomy 21	Phenotypic features consistent with Turners syndrome Karyotyping shows partial deletion of short arm of X chromosome
8.		Cystic hygroma, HF Single outflow with peri membranous VSD, pulmonary atresia	TGA with hypoplastic pulmonary arterial trunk subaortic VSD Cystic hygroma Anteriorly placed anus Hypoplasia of thymus Karyotyping shows trisomy 18.

After extensive search of literature authors came across many studies comparing prenatal USG findings with post-mortem examination. Most of these studies dealt with cases of foetal malformations, stillbirth and neonatal death.[4-8] But, there were only few studies comparing the same in cases of NIHF.[9,10] Hence authors chose to address the accuracy of prenatal USG findings and compare it with perinatal autopsy in cases of NIHF.

Prenatal diagnosis of hydrops was missed in one third of present cases. Fluid collection is initially diagnosed by USG during the first or mid trimester. Significant fluid accumulation is recognized easily, but sometimes the effusions are limited and can escape diagnosis during imaging.

Present data showed complete agreement between USG and autopsy findings in 40% of cases. This was similar to a study by Antonella et al done in 2012.[11] In their study they have compared the USG and autopsy findings of 144 second trimester foetuses. In 49% of cases there were total agreement between the two. Additional information was provided by post-mortem in 34% of cases, while in present study it was 35%. Astonishingly in 13% of their cases, functional anomalies detected by ultrasound could not be confirmed by autopsy. This is due to the fact that ultrasound examination is a dynamic examination, optimum to reveal functional changes like valve insufficiencies, flow reversals and sometimes even cavity effusions. This should not be considered as false positive USG findings, but as an advantage of the imaging modality.

In 7 cases (35%), there were additional findings in autopsy not detected by USG. In two of these cases, the additional findings provided by autopsy redefined the recurrence risk. It seems that the higher proportion of additional findings in the present study might be due to critical identification of minor anomalies at autopsy such as anal atresia, partial agenesis of corpus callosum and urorectal septum malformation.[10]

The identification of these minor anomalies is significant as they might change the diagnosis from an isolated lesion to complex malformation.[4]

All cases in the multiple anomaly had additional findings in autopsy. The identification of partial agenesis of corpus callosum with hydrocephalus in a case with prenatal imaging diagnosis of VACTERL association changed the final diagnosis to be Fryns syndrome. The other anomalies were concordant. The foetus was 16 weeks at the time of diagnosis, and identification of the cranial anomaly at this gestational age is challenging.[12] Fryns syndrome (FS) is the commonest autosomal recessive syndrome in which congenital diaphragmatic hernia (CDH) is a cardinal feature.[13]The autosomal recessive inheritance in FS contrasts with the sporadic inheritance seen in cases of VACTERL anomaly.[14] This underscores the importance of the correct diagnosis for accurate genetic counselling.

Among the cases with cardiovascular lesions, prenatal ultrasound showed increased nuchal translucency, cystic hygroma and absent nasal bone which was all suggestive of trisomy 21. The presence of AVSD, the characteristic heart lesion in these foetuses was made out by post-mortem examination. This more or less confirmed the diagnosis of Down syndrome.

In addition to multiple anomaly, the histological presence of haemosiderosis of the liver with giant islets and nesidioblastosis of the pancreas led to the suggestive diagnosis of multiple congenital anomaly syndrome, Zellweger syndrome, Smith Lemli Opitz syndrome.

One of the study case showed USG findings of Foetal akinesia deformation sequence, with gross bilateral lateral ventriculomegaly. But post-mortem examination also revealed hydranencephaly, lens opacity along with facial and skeletal lesions which led to the diagnosis of cerebro-oculo-facio-skeletal syndrome. Persistent urogenital sinus was noted additionally.

There was total discordance between USG and autopsy in 5 cases of 20(25%). In all 5 cases, though hydrops was diagnosed prenatally, the causative lesion could not be detected by imaging. But autopsy revealed structural anomaly in 4/5 cases. Though all these four lesions (premature closure of ductus, CPAM, BOO) could be identified by antenatal imaging, they were missed. As hydrops foetalis carries a bad prognosis and once it is evident by ultrasound, further careful and complete imaging is overlooked. This could have led to the non-identification of structural abnormality by USG and the discordance with post-mortem examination.

USG as well as autopsy have unavoidable limitations in analysing cases of NIHF. So, they are considered complementary to one another. Both of these modalities depend on the expertise of the personnel, the technological advancement of the ultrasound equipment and the autopsy technique.

The causes for differences in prenatal USG include early gestational age (structures are too tiny to evaluate, respective organs not completed development structurally or functionally), abnormal amount of liquor (oligo/polyhydramnios) which makes visualization of organs difficult, altered maternal habitus (obese, thick abdominal wall) and foetal position. Authors found that additional findings were high in cases of multi system involvement, which was similar to the observation by Rossi et al.[5] This is attributed to the increased focus of the sonographer on severe and more interesting abnormalities, overlooking minor or less lethal abnormalities or not completing the examination once a major/lethal anomaly is detected .[4]

The main limitations of post-mortem examination are longer duration of reporting and the need for appropriate training and expertise in the field of perinatal pathology. There are a few other factors which may hinder the accurate post-mortem examination:

- intrauterine foetal death with long period of foetal retention and superimposed maceration may distort the foetal anatomy
- in foetuses with suspected CNS abnormality, the autopsy findings may be inconclusive due to extreme autolysis
- satisfactory dissection may not be possible in foetuses of very early gestation with small organs (can be overcome by dissecting microscope) and presence of post-mortem artefacts
- functional anomalies can be missed.[10,15-18]

Although present study is a retrospective analysis involving less number of cases, it is the only study to specifically correlate the prenatal USG findings and post-mortem examination of foetuses with nonimmune hydrops. This knowledge and further studies involving large number of cases of NIHF will contribute to improve parental counselling.

NIHF is a terminal catastrophic event of pregnancy caused by numerous diverse aetiology and is known for its low diagnostic yield. Initial recognition of hydrops is usually made by ultrasonographic examination. But the aetiology in many cases remains elusive even after a carefully performed imaging.

In such instances post-mortem study of the foetus including placental examination and other ancillary work up like genetic study, testing for infections and metabolic derangements help in identifying the cause. present study demonstrates a high rate of discordancy between USG and autopsy examination in cases complicated by NIHF.

Foetal autopsy confirms the USG findings (quality control/audit), adds additional findings or changes the final diagnosis. Although, foetuses with nonimmune hydrops carry worse prognosis, it is indispensable to identify the genesis of the hydrops to counsel the couple regarding prognosis, recurrence risk and future pregnancy outcomes. Hence present study underscores the need for autopsy in all cases of NIHF.
